

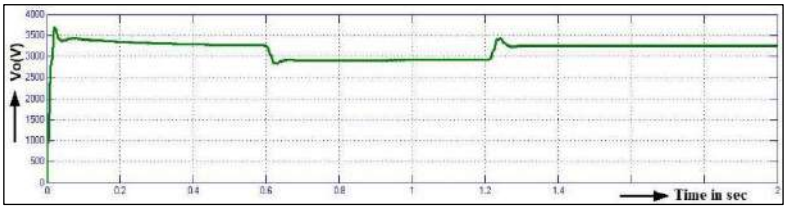

Figure 24: RMS Output Voltage.
Source: Authors, (2026).

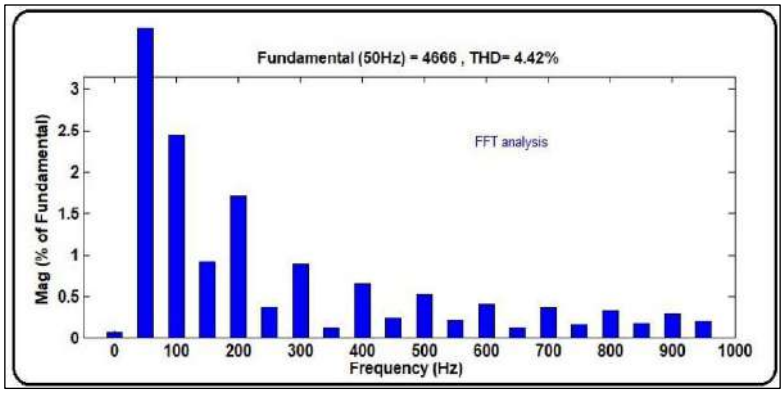

Figure 25: Output Voltage THD.
Source: Authors, (2026).

The output voltage THD, illustrated in Figure 25, is around 4.42%. The output current waveform, illustrated in Figure 26, indicates that the system supplies an average load current of approximately 13.2 A under FOPID-controlled operation.

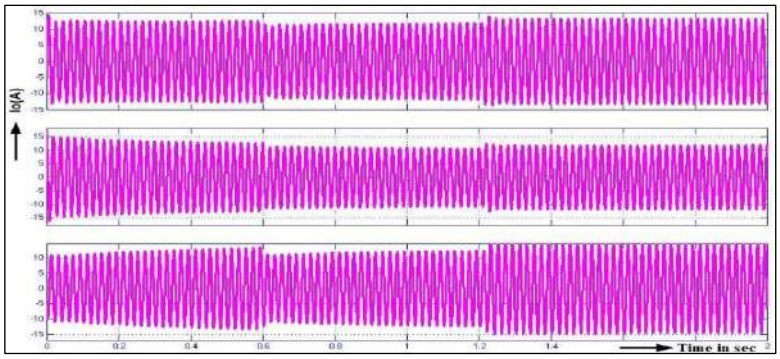

Figure 26: Output Voltage.
Source: Authors, (2026).

The total harmonic distortion (THD) of the output current is shown in Figure 27 which is around 4.14% which reflects the improved harmonic suppression achieved because of the hybrid active filter and fractional-order control.

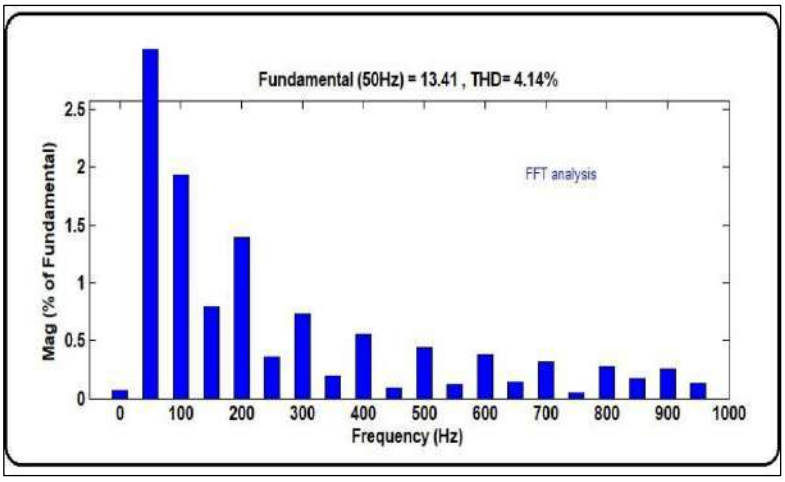

Figure 27: Output Current THD.

Table 1: Comparison of Time Domain Parameters.

Controller	Tr	Tp	Ts	Ess
PI	1.52	1.54	1.55	2.73
FOPID	1.23	1.24	1.26	2.15

Source: Authors, (2026).

Table 1 presents the comparisons of the key time-domain performance metrics for the QBC equipped with a hybrid active filter (HAF) when regulated by PI and FOPID controllers. The following bar-chart representation of these time-domain metrics is shown in Figure 30, providing a visual comparison of the dynamic improvements achieved with each control strategy.

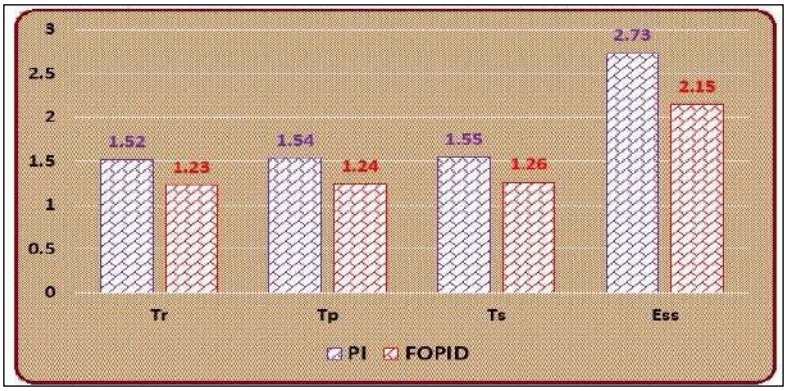

Figure 30: Bar Graph of Time domain parameters of PI/FOPID of QBC with HAF system.
Source: Authors, (2026).

Table 2: Comparison of Current THD.

Controller	Current THD (%)	Voltage THD (%)
PI	4.34	4.75
FOPID	4.14	4.42

Source: Authors, (2026).

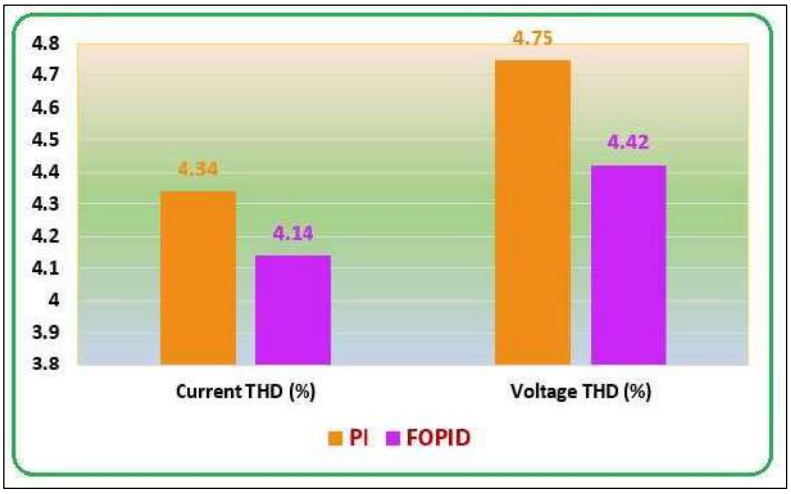

Figure 31: Bar graph of output current THD of PI/FOPID for QBC with HAF system.
Source: Authors, (2026).

Table 2 show the collective comparative analysis of output voltage and current THD for the QBC using the hybrid active filter (HAF) under PI and FOPID control strategies. The corresponding bar- graph representation in Fig. 31 visually signifies the variation in harmonic distortion levels and shows the improvement achieved with the fractional-order controller.

IV. CONCLUSION

A complete QBC–HAF system regulated by PI and FOPID controller was designed, analysed and simulated. The results indicate that the fractional-order controller provides faster temporary behaviour, reduced steady-state deviation, and improved harmonic compensation compared to the PI scheme. A comparison of time-domain metrics reveals that FOPID control improves the rise, peak, and settling times relative to the PI controller also the steady-state error also decreases indicating the improved accuracy. Harmonic analysis shows that both current and voltage THD values are reduced when using fractional- order regulation. These improvements signify the suitability of FOPID-controlled QBC–HAF configurations for renewable-energy power-conditioning applications.

ABSTRACT

Modern times have seen the rise of smart cities that rely on the Internet of Things. To process data, smart objects require multi-hop communication to transmit it to the sink. Internet of Things (IoT) enabled, data-driven smart cities enhance public utilities, infrastructure, and services for the benefit of residents. Smart towns that rely on the Internet of Things have a tough time collecting clean municipal garbage. Cities produce more waste as they expand. Two big problems with trash management are garbage collection and sorting. Public trash cans overflow before they are cleaned, leading to bacterial growth, unpleasant odours, and potential illness. Urbanization, inefficient technologies to aid solid waste management, and poor trash collection and disposal all contribute to these problems. Trash everywhere makes garbage collection more challenging. Solid waste management systems that aren't scientific, efficient, or good enough lead to a lot of issues. By combining the strengths of the IoT and fog computing, this paper proposed an integrated IoT-Fog-Cloud architecture for smart waste management systems and a QAIoET Algorithm for efficient resource allocation, which can improve service quality while reducing response time by 46.8% and costs by 2.6% compared to cloud solutions.

I. INTRODUCTION

The rapid population increase causes difficulties with waste dumping. They cause harm to humans by releasing fumes. To maintain a clean environment, intelligent waste classification and management are essential. Society and the environment are both negatively impacted by solid waste management, which is a big problem for smart cities [1], [2]. As the first step in the standard waste management procedure, city dwellers place trash cans at the collection point. Regular garbage hauls to recycling sites are made possible by municipal trucks. It is impossible to determine when to clean or refill exterior containers because municipalities and waste management organizations overlook them. The IoT paradigm enhances smart city applications through the real-time recording and management of municipal processes [3], [4]. By connecting to trash cans and recycling facilities, Internet of Things (IoT) devices can monitor local trash production and container conditions using sensors. An effective municipal waste management system relies on the data collected by the waste management center to plan the deployment and maintenance of adaptive equipment, the collection of rubbish, and the routes that vehicles will take. This paper proposed a holistic approach to smart waste management that leverages the Internet of Things (IoT), fog computing (for real-time, localized intelligence), and cloud computing (for long-term data storage, big data analytics, and global optimization). This integrated architecture's potential to transform garbage collection, resource distribution, and environmental sustainability may result in brighter, cleaner, and more livable smart cities.

II. RELATED WORKS

Cheema et al. [5] proposed a state-of-the-art method (SWMACM-CA) for real-time intelligent waste management and categorization. To sort trash at a landfill, the system employs the Internet of Things (IoT), deep learning, and sophisticated algorithms. Additionally, the author proposed a device for trash grid segmentation, which would separate the garbage yard pile into grids. The use of hybrid and decentralized computing models has improved resource consumption and decreased delays.

Wang et al. [6] developed a deep-learning and cloud-computing classifier for accurate trash categorization before garbage pickup. To simplify garbage disposal, the author grouped recyclables into plastic, glass, paper/cardboard, metal, fabric, and others. Garbage categorization used deep learning convolutional neural networks. The proposed system reduces costs for rubbish sorting, tracking, and collection.

Vishnu et al. [7] presented a solution that monitors public and residential garbage cans with PBLMUs and HBLMUs. They send the position and quantity of unemptied garbage cans to a central monitoring station. The garbage collection authority can use a sophisticated graphical user interface to examine each bin for emptiness.

Longo et al. [8] suggest a smart waste management system to improve campus recycling and rubbish management. A smart garbage bin prototype can locate and sort campus trash using a hybrid sensor/image classification system. The strategy focused on smart garbage bins and a better maintenance schedule.

Karthik et al. [9] created an affordable, integrated gadget for urban sanitation that records street positions and sends them to a web server. When the garbage can is complete, the bin collector receives an automatic signal when the level reaches a certain threshold. As soon as the trash collector gets online, they begin cleaning up the city.

Kanade et al. [10] designed a system that incorporated a big battery, Wi-Fi module, ultrasonic sensor, and Arduino microcontroller. Arduino boards record information from ultrasonic sensors and burden cells. Measurements of trash depth and receptacle weight are taken from the heap cell using an ultrasonic sensor. An LCD panel shows the information. Data displayed earlier is transmitted online via the Wi-Fi module.

John et al. [11] developed an IoT-based smart garbage-disposal prediction and monitoring system that can measure the amount of trash in bins of any size using standard components. The proposed gadget monitors the bin's status at regular intervals using a GPS module, an Arduino microprocessor, and infrared (IR), ultraviolet (UV), and weight sensors. In the proposed setup, data is sent from the cluster network to the Wi-Fi-connected master module. A state-of-the-art neural network system known as Long Short-Term Memory (LSTM) learns from collected data and uses trends in garbage generation to forecast future waste.

Janani et al. [12] described the smart cities project & its development process, listed its uses, discussed its challenges, highlighted its real-time applications, and lastly, outlined its potential future applications. The author also covers related devices and Internet of Things technologies used to build smart cities.

Baldo et al. [13] illustrated the blueprint for a LoRaWAN network integrating several service types within SmartWaste Management, a crucial component of the Smart City ecosystem. All LoRaWAN classes are used in the proposed design, which combines nodes of progressively more complex function-based types and improves the technology's TRL 3 readiness.

Alam et al. [14] concluded that smart cities can benefit from cloud-hosted IoT applications that gather data from multiple sources, including citizens, devices, and homes. This information is examined to manage transportation, electricity, and resources. Public cloud services allow third parties to improve IoT ecosystems and integrate IoT data into electronic products.

Ali et al. [15] proposed an Internet-of-Things-based smart garbage can monitoring and MSW management system. In addition to collecting trash, the proposed system can also identify fires and foretell when more waste will be generated. Interconnected devices manage and monitor electric bins. Wirelessly, these devices communicate the level of the bin's fill to the central hub. One significant advantage of the system is that it ensures waste is collected on time, which helps to avoid bin overflow and contamination.

Pardini et al. [16] enhanced trash management through community engagement using software, communications, and hardware. IoT sensors in smart bins monitor disposal and compartment levels in real time. An Internet of Things middleware processes the data to improve trash collection routes and produce statistics for resource management and community service monitoring. Public garbage can information is available online and via mobile applications.

Abdullah et al. [17] proposed trash management by using IoT devices to communicate among smart bins, waste source sites, collection trucks, management centers, and trash-specific truck sizes. This system addresses population growth and urban expansion.

Sharmin et al. [18] developed a smart, flexible, and affordable waste management system. Using a microcontroller and GPRS, communicate trash weight and volume to a cloud server via inexpensive sensors. An Ant Colony Optimization (ACO) technique uses the locations of vehicles and trash bins to find each truck's shortest collection path. The system reacts to dynamic changes, such as blocked rubbish collection routes. A central monitoring system assures smart city inhabitants receive high-quality service.

Aazam et al. [19] proposed a cloud-based smart garbage management system that uses sensors installed in trash cans to report the current level of trash. Stakeholders have access to data stored in the cloud. City administration and waste management can save time and fuel by optimizing garbage collection routes based on the condition of a city's bins.

References	Strength	Limitations
[5]	Effectively reduce latency and optimize computational resource utilization.	The training dataset exhibits an unbalanced sample distribution.
[6]	Use of cloud computing allows for accurate and fast waste classification	Gas sensors are used for monitoring; their output can be affected by temperature and humidity
[7]	Offers a comprehensive overview of the current advancements in IoT-enabled SWM	Lack of a unified standard or architecture for IoT-based SWM systems
[8]	Integration of 5G technology, which provides high bandwidth and low latency	The system's effectiveness heavily depends on sustained user adoption.
[9]	Ability to provide real-time monitoring of garbage bin fill levels	Effectiveness could be compromised in areas with poor network coverage
[10]	Ability to automate waste level monitoring	Limited to monitoring fill levels and sending notifications
[11]	Integration of real-time IoT data sensing with robust processing in the cloud	Lacks precise technical details regarding the types of sensors utilized
[12]	Highlights the significant benefits of IoT integration, such as improved operational efficiency	Exclude pervasive challenges such as ensuring security and privacy.
[13]	Well-defined multi-layer architecture, providing a robust and scalable framework	Limitations of lower data rates compared to cellular technologies
[14]	Overview of cloud-based IoT applications across numerous sectors within smart cities	Limitations such as potential security and privacy issues
[15]	To tackle the critical issues of escalating waste generation	Heavily reliant on consistent and robust network connectivity
[16]	The solution is its citizen-centric approach	Heavily relies on consistent public participation and willingness
[17]	Direct engagement with the pressing issue of waste management	Lack provides specific technical details about the types of sensors
[18]	Dynamic approach to waste collection, based on real-time waste levels	Highly dependent on continuous and reliable wireless connectivity
[19]	Ability to provide real-time notifications about waste status	Lacks specifics regarding the types of sensors employed
[20]	The paper offers an examination of methods for scheduling jobs	The simulation results were missing to back the justification
[21]	The study was broken down by algorithm category and parameters	Exclude the study of load-balancing approaches in categories
[22]	Method that uses ECTS to distribute tasks to fog nodes efficiently	Lack considering effect on the mobility of end devices and fog nodes
[23]	Provided LCTS, or Laxity-based solution to the scheduling problems	The trade-off between response time and energy usage persists

Source: Authors, (2026).

This research study sheds light on a smart city solid waste management system that leverages the Internet of Things to circumvent such limitations. Several cities have trash cans overflowing with garbage. The trash cans cleaner is running behind schedule. As a result, the air, the environment, and the town become polluted. The foul stench of excrement poses a health risk to people. The expansion of the IoT and related technologies is causing a shift in the global industry. To take advantage of the Internet of Things (IoT), many company executives are investing more time and money in adapting their services. Thus, decision-makers in public waste management are competitive, making it difficult to provide an effective, real-time waste management system.

III. METHOD & EXPERIMENT

A. Proposed IoT-Fog-Cloud Layer Architecture

To improve efficiency, scalability, and real-time responsiveness, the proposed architecture, as shown in Figure 1, outlines a multi-layered strategy for smart waste management (SWM) system. This strategy distributes intelligence and processing capabilities among IoT devices, fog nodes, and the cloud. The proposed multi-layered architecture of the SWM system includes the following essential components.

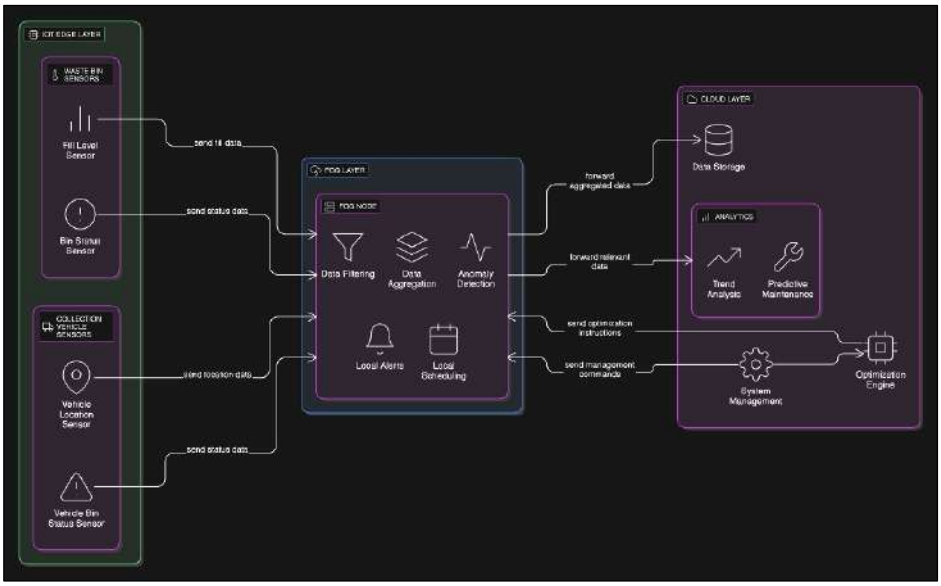

Figure 1: Proposed Multi-Layered Architecture of Smart Waste Management System.
Source: Authors, (2026).

The lowest layer is nearest to trash generation and collection. Smart gadgets and sensors interact with garbage containers and pickup vehicles. This layer includes components such as intelligent waste bins, weight sensors, gas sensors, GPS modules, RFID/NFC tags, microcontrollers, communication modules, GPS trackers, onboard sensors, RFID/NFC readers, and cameras for visual inspection or garbage classification upon collection. The fog layer connects the Internet of Things/Edge and Cloud levels. Moving networking, storage, and computation closer to the network edge reduces latency and bandwidth. This layer includes the components, such as fog nodes, strategically placed in neighbourhoods or collecting depots. Local data storage to hold raw and processed data temporarily. Local processing for instant data analysis, filtering, aggregation, and IoT device communication interfaces. The cloud layer is a centralized, high-performance computer and storage infrastructure. This layer's subcomponents include cloud servers/platforms for long-term storage of garbage data; complex algorithm-running analytics and machine learning platforms; and data visualization tools, such as municipal waste management and citizen dashboards. This tiered strategy makes trash management smart, efficient, scalable, and resilient for smart cities' dynamic demands. Figure 2 demonstrates how smart waste management units exchange data to work efficiently.

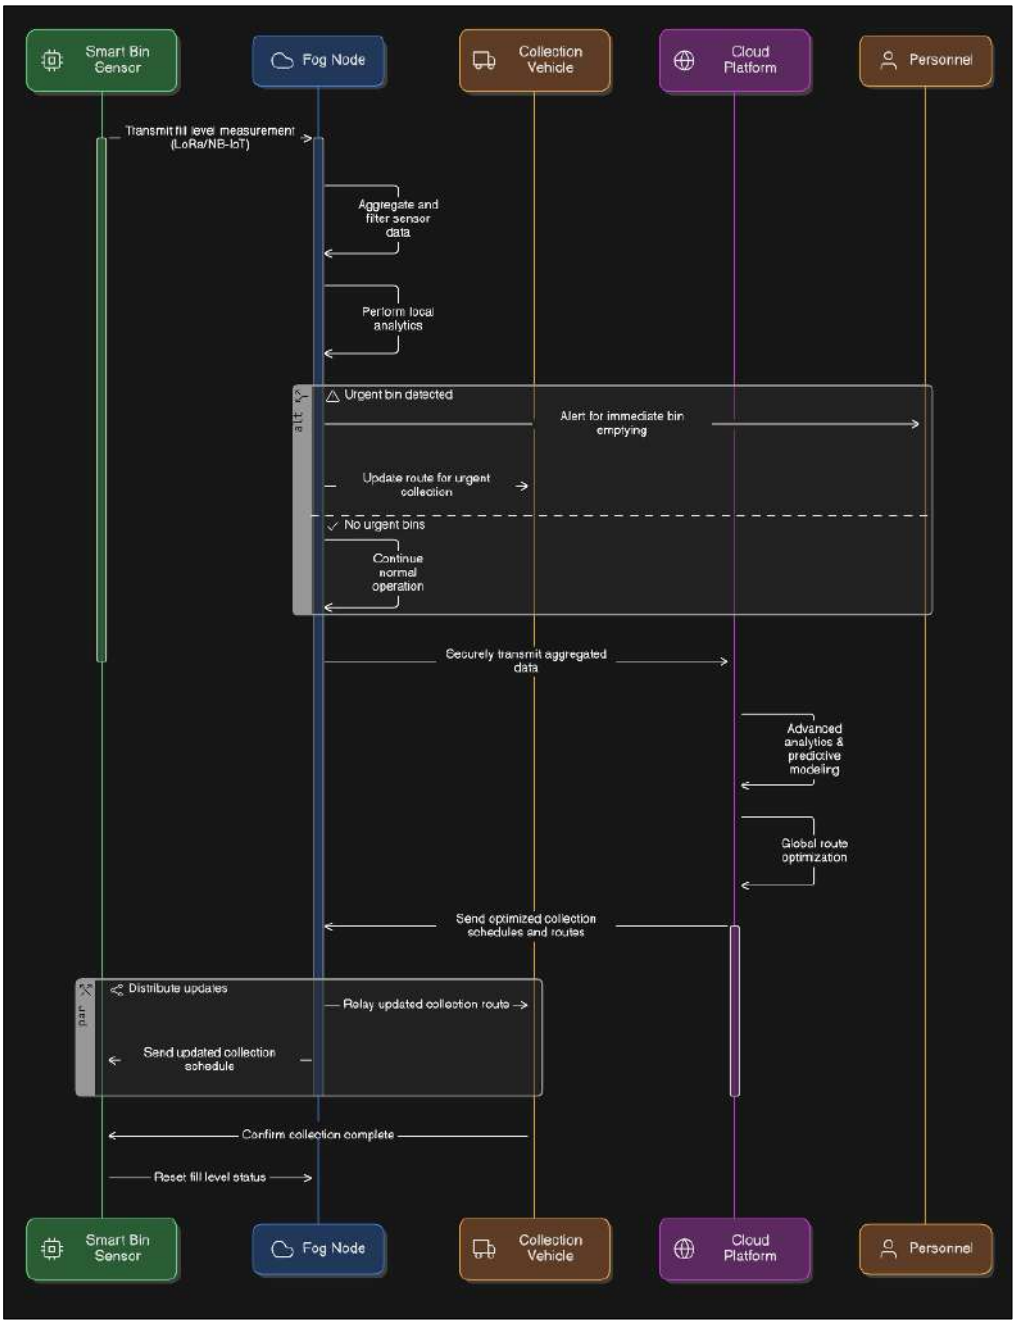

Figure 2: Sequence Diagram of Smart Waste Management System.
Source: Authors, (2026).

According to the proposed figure 2, Smart bin sensors send data to fog nodes. Fog nodes aggregate, filter, and analyze data locally, decreasing cloud data traffic and enabling fast local responses. Fog node data is safely sent to the cloud for analysis and storage. Cloud computing conducts sophisticated analytics, predictive modeling, and global route optimization. Fog nodes communicate collections, car or smart bin orders, or updated schedules from cloud decisions and optimal plans. Citizens use mobile applications to communicate with the cloud (for general information) or smart bins (via Bluetooth/NFC for local interactions).

B. Proposed Resource Allocation Approach

The QoS-Aware Internet of Environmental Things (QAIoET) Algorithm optimizes key performance parameters in an IoT-enabled environmental monitoring and waste management ecosystem, with a focus on smart trash bins. The primary orchestrator, this algorithm, minimizes response time and operating expenses to ensure the efficiency and sustainability of large-scale IoT deployments. The system intelligently launches the Task Categorization Algorithm and the Dynamic Resource Provisioning Algorithm for each work. Modularity allows context-aware processing. For instance, the categorization algorithm may evaluate resource demands, activity type, and urgency. Identifying computational demands helps the dynamic resource provisioning algorithm allocate resources to cloud and fog nodes. The future smart environmental infrastructure needs intelligent orchestration to develop a robust, efficient system from basic tasks to dynamic resource allocation while minimizing operational costs and preserving service quality.

Algorithm 1: QoS Aware Internet of Environmental Things (QAIoET) Algorithm.

Input: Tasks with smart waste bins status attribute
Number of tasks (T), Number of Fog Nodes (F), Cloud (C)
Output: Optimize response time and cost incurred
Begin
1. Input tasks (T)
2. For each task t_i Ɛ T
3. Call Task Categorization Algorithm
4. Call Dynamic Resource Provisioning Algorithm

End

Source: Authors, (2026).

The QoS-Aware Internet of Environmental Things (QAIoET) Framework employs the Task Categorization Algorithm for smart garbage prioritization tasks. Fog servers effectively order jobs into priority queues. The system evaluates the garbage bin attributes and the task (t_i) before determining the job priority and urgency. Lines 3–4 are the most crucial steps for checking "Abnormal" work over delay_thrl. This significant delay circumstance upgraded the job to Queue-significant, requiring immediate attention. Long-standing issues or processing delays can make a non-critical event critical. To illustrate its environmental expertise, it classifies operations by garbage can status in real time (Lines 6–14). Marking "Overflow" bin jobs as "Critical" and adding them to Queue-Critical emphasizes ecology and logistics. Trash jobs designated "Jam-packed" are marked "Abnormal" and forwarded to Queue-Abnormal, signifying a non-urgent but high-priority issue that must be resolved quickly. Documentation and progress reports for "Partly-filled" containers are "Normal" and low priority. Hierarchical categorization, clear delay limits, and understandable waste-bin fill levels dynamically prioritize QAIoET resources, enabling efficient and quick environmental crisis resolution while managing less essential processes.

Algorithm 2: Task Categorization Algorithm.

Input: Tasks with waste bins attribute at the fog server
Output: Set priority queue for task execution
Begin
1. Input tasks T
2. For each task t_i Ɛ T do
3. If(t_i Ɛ Queue-Abnormal && t_i.delay_time > delay_thrl)
4. Add Queue-Critical[k] ← t_i
5. Else
6. If(waste bins fill status = Overflow) Then
7. Category = Critical
8. Add Queue-Critical[k] ← t_i
9. Else If(waste bins fill status = Jam-packed) Then
10. Category = Abnormal
11. Add Queue-Abnormal[k] ← t_i
12. Else If(waste bins fill status = Partly-filled) Then
13. Category = Normal
14. Add Queue-Normal[k] ← t_i
15. End

End

Source: Authors, (2026).

In the QoS-Aware Internet of Environmental Things (QAIoET) Framework, the Dynamic Resource Provisioning Algorithm distributes computations to nearby fog nodes or to distant clouds to reduce response time and costs. The app efficiently manages scattered IoT. The algorithms in the prioritized task queue make complex judgments for each item (t_i). Line 2 rapidly discovers all fog node clusters. Determine each fog node's resources and network distance from the task's origin (Line 3). Fog nodes near resources (QF) are used first (Line 4). The central cloud (RT_{icloud} and CT_{icloud}) receives estimates of response time (RT) and cost (CT) from each fog node (F_{ij}) that processes work (Lines 5-6). The foresight helps make informed decisions. Repeating Lines 7–13 determines which sorted fog node has a lower response time and cost than the cloud. Edge computing rapidly distributes work to the best fog node (Lines 8–10). Due to limited fog resources, the software judiciously offloads the operation to the cloud (Line 15) when no local fog node satisfies both optimization conditions (i.e., when the loop terminates without an optimal fog node, as implicitly evaluated in Line 14). Hierarchical, cost-conscious provisioning techniques that improve service quality by reducing cost and delay provide a flexible resource management paradigm for the Internet of Environmental Things.

Algorithm 3: Dynamic Resource Provisioning Algorithm.

Input: Task Queue [t_i, T], Number of Fog Nodes (F), Cloud
Output: Task allocation to the optimal fog node or cloud
Begin
1. For each task t_i Ɛ Queue [t_i, T] do
2. Find the available fog node clusters in the system
3. Calculate resource & distance for all available fog nodes
4. Sort all available fog nodes by the nearest available resource (Q_F)
5. Calculate RT (F_{ij}) & CT (F_{ij}) // RT-Response Time, CT-Cost
6. Calculate RT_{icloud} & CT_{icloud} // RT-Response Time, CT-Cost
7. For each fj Ɛ Q_F do
8. If (RT (F_{ij}) < RT_{icloud} && CT (F_{ij}) < CT_{icloud})
9. Assign the t_i to F_{ij}
10. Break
11. Else
12. Continue
13. End
14. If(t_i Ɛ Queue [t_i, T]) // Not found optimal fog node
15. Assign the ti to the cloud
16. End

End

Source: Authors, (2026).

C. Experimental Setup

Fog design has a component-specific network setup simulated using the ifogsim toolkit [24], [25]. Cloud servers had 40,000 MB of RAM, 44,800 MIPS of CPU, 100 ms latency, and a cost of 0.01/MIPS. The upload and download speeds are 10,000 Mbps. These are the proxy server specs: 8000 MB RAM, 12800 MIPS CPU, 10000 Mbps UP-BW/DW-BW, 10 ms latency, 0.04 Cost/MIPS. Fog Gateway (Fog Server) specs: 8000 MB RAM, 12800 MIPS CPU, 10,000 Mbps UP-BW/DW-BW, 5 ms latency, 0.08 Cost/MIPS. The IoT end device has a 2800 MIPS CPU, 4000 MB of RAM, 10 ms latency, 10,000 Mbps upload and download bandwidth, and a cost of 0.16 MIPS.

Table 2: Simulation Configuration.

Parameter	CPU (MIPS)	RAM (MB)	UP-BW (MBps)	DW-BW (MBps)	Latency (ms)
IoT Device	2800	4000	10000	10000	10
Fog Node	12800	8000	10000	10000	5
Proxy	12800	8000	10000	10000	10
Cloud	44800	40000	10000	10000	100

Source: Authors, (2026).

The experiment tested system included an end device, a proxy server, a fog server, a fog node, and a cloud server. Each test setup contained 1, 4, and 4 Cloud, Proxy, Fog Server, and Node/Server instances. The progressive rise in end devices to imitate rising user loads was the primary variable across all five settings. To clarify, Configurations 1–5 employed 50 End Devices, 100 in 2, 200 in 3, 400 in 4, and 500 in 5. This ongoing change in end-device count enabled a comprehensive investigation of system behavior and scalability across varied operational scenarios using ifogsim.

Table 3: Simulation Topology.

Config	Cloud	Proxy	Fog Server	Fog Node	End Device
Setup-1	1	1	4	4	50
Setup-2	1	1	4	4	100
Setup-3	1	1	4	4	200

IV. RESULTS AND DISCUSSIONS

The simulation results for the proposed technique are shown in Table 4. Complexity increases response time and cost (Setup-1–Setup-5). From setup-1 to setup-5, response time (milliseconds) and total cost (dollars) increase continuously, indicating workload or size growth. Setup-1's response time is 974.10 ms and cost is $174926.67; Setup-5's is 6815.57 ms and $761432.49. The proposed technique can manage growing demand; however, this pattern illustrates that the simulated environment's complexity increases response time and cost.

Table 4: Proposed (QAIoET) Simulation Result.

Config.	**Response Time**	**Cost**
	(millisecond)	(Dollar)
Setup-1	974.10	174926.67
Setup-2	1810.67	415883.87
Setup-3	2591.45	621628.49
Setup-4	5495.42	756691.46
Setup-5	6815.57	761432.49

Source: Authors, (2026).

Table 5 compares fog node response time (milliseconds) for CF-1 to CF-5 setups with different end devices. It then compares the proposed method to cloud-only performance. Every arrangement has four fog nodes; however, CF-1 to CF-5 have 50 to 500 end devices. With both approaches, the response time increases with the number of end devices. The proposed method outperforms the cloud-only method in all settings, with quicker response times. In CF-1 with 10 end devices, the proposed solution responded in 974.10 ms, whereas the cloud-only method took 1548.90. The proposed strategy recorded 6815.57 ms in CF-5 with 500 end devices, half of the cloud-only approach's 12750.51 ms. More end devices aggravate this performance disparity. The proposed technique reduces response time and manages growing workloads more effectively than a cloud-only solution.

Table 5: Comparison of Response Time (ms).

Setup	**Fog Node**	**End Device**	**Proposed approach**	**Cloud-only**
CF-1	**4**	**50**	974.10	1548.90
CF-2	**4**	**100**	1810.67	4445.90
CF-3	**4**	**200**	2591.45	4882.20
CF-4	**4**	**400**	5495.42	9806.50
CF-5	**4**	**500**	6815.57	12750.51

Source: Authors, (2026).

Figure 3: Comparison Chart for Response Time.

Source: Authors, (2026).

Figure 3 shows the millisecond response times of the proposed and cloud-only approaches. No matter the final device count, the proposed technique is faster than cloud-only. Both methods take longer to react with more end devices, but the cloud-only strategy has a response time above 12,500 ms, demonstrating that the proposed solution is more consistent and better. Table 6 shows the hypothetical dollar expenses of the proposed method relative to a cloud-only approach across various configurations. The setup column presumably indicates an increase from CF-1 to CF-5 end devices, but fog nodes stay at 4. In all cases, the proposed method is cheaper than a cloud-only approach. The cloud-only approach would cost $177,825, whereas the proposed method would cost $174,926.67 for CF-1 with 50 end devices. 2. At CF-5 (500 end devices), the suggested method is cheaper than cloud-only ($761,432.49 vs. $789,092). This tendency continues as more end devices are added. This method saves money, especially as end devices get bigger.

Table 6: Comparison of Cost (Dollar).

Setup	Fog Node	End Device	Proposed approach	Cloud-only
CF-1	**4**	**50**	174926.67	177825.2
CF-2	**4**	**100**	415883.87	432528.16
CF-3	**4**	**200**	621628.49	636952.08
CF-4	**4**	**400**	756691.46	775443.9
CF-5	**4**	**500**	761432.49	789092

Source: Authors, (2026).

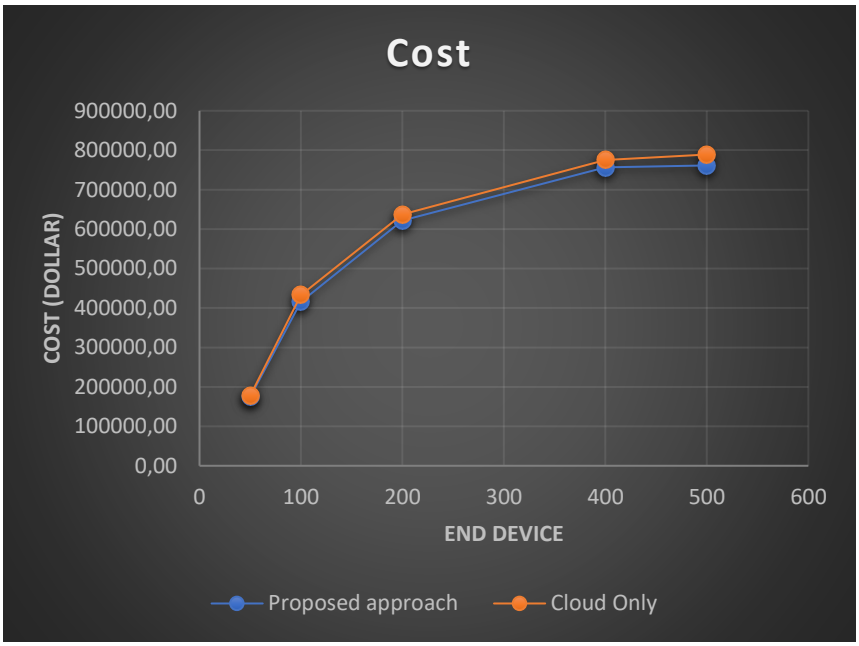

Figure 4: Comparison Chart for Cost.
Source: Authors, (2026).

Figure 4 illustrates dollar simulations comparing the proposed method with a cloud-only strategy as the number of end devices increases. The proposed way appears cheaper, yet both methods have comparable prices with 50-100 fewer end devices. Expanding devices increases costs for both processes. Still, the proposed technique is cheaper than cloud-only for all end devices. As the number of end devices increases, the cost disparity widens, indicating that the suggested strategy improves cost efficiency as the system scales.

V. CONCLUSIONS

The study shows that an IoT-Fog-Cloud architecture for smart waste management may resolve many environmental challenges. Our proposed technique (QAIoET) minimizes the inefficiencies of traditional garbage collection by merging fog computing for localized intelligent processing with IoT-enabled smart trash bins. Our comparison study showed that this synergistic paradigm has several benefits. Regardless of end device count, the proposed solution (QAIoET) always beats cloud-based alternatives and reduces response time by 46.8%. Optimizing routes and collecting trash fast requires this responsiveness, which boosts operating efficiency. The proposed system's long-term operating savings and environmental benefits make it a cost-effective and environmentally responsible option, even though the initial cost reduction of 2.6% may be similar. This study shows that fog computing and the Internet of Things have several benefits. It makes urban waste management systems more efficient, sustainable, and responsive, proving it works. Results may be used to improve resource allocation and environmental management, creating intelligent and adaptive urban settings. The next step would be to integrate GenAI solutions into the proposed system to enable future predictions & proactive actions.

ABSTRACT

This study presents a systematic review of literature on the influence of temperature on methane production as biogas. A total of 337 scientific documents were collected from the Web of Science database and processed using tools such as Excel, Mendeley, and PRISMA approach literature review tool as PICOT method to identify the articles that best match the objectives of the study by eligibility criteria. The systematic review investigated 25 relevant studies, comparing mesophilic (30–40°C) and thermophilic (50–100°C) conditions. It was found that, although temperature is a determining factor in the efficiency of methanogenesis, its effect is conditioned by variables such as substrate type, residence time, pH, and the pretreatment methods applied. The results show that the mesophilic regime tends to offer greater operational stability, while the thermophilic regime can accelerate anaerobic digestion, but with a higher risk of inhibition by compounds such as free ammonia and volatile fatty acids. The synergy between adequate pretreatments and substrate selection is key to optimizing methane production. This work provides an updated overview of scientific knowledge in this area, identifying gaps and opportunities for future research aimed at the efficient design of thermally optimized anaerobic digestion systems.

I. INTRODUCTION

In the context of growing concerns regarding sustainability and the transition toward renewable energy sources, biogas has emerged as a key alternative for sustainable energy generation. This gas, composed mainly of methane (CH_4) and carbon dioxide (CO_2), is produced through the anaerobic digestion of organic matter, making it a viable solution for waste management and the reduction of greenhouse gas emissions [1-4]. According to the International Energy Agency (IEA), biogas has the potential to meet up to 20% of global energy demand if its production and utilization processes are adequately optimized [5-7]. Temperature is one of the critical factors affecting the efficiency of methanogenesis, as it directly affects the activity of the microorganisms responsible for organic matter degradation [2],[8-10]. Therefore, understanding its impact is essential for improving biogas performance and maximizing its viability as a renewable energy source [11-16].

Numerous studies have addressed fundamental aspects of biogas production by exploring multiple optimization strategies. Research on the optimization of anaerobic digestion and biogas generation has examined variables such as the carbon-to-nitrogen (C/N) ratio, organic loading rate, hydraulic retention time, temperature control, and pH, as well as the application of kinetic models to enhance process efficiency [1-7], [17]. Anaerobic co-digestion, through the combination of different substrates such as manure, sewage sludge, and agricultural reisdues, has been shown to improve nutrient balance and process stability [7],[18-24]. In addition, various physical, chemical, and biological pretreatments have been investigated to improve biodegradability and increase biogas production, including thermal, alkaline, and enzymatic methods [11-16].

The influence of temperature on biogas production has been extensively studied, highlighting its effects on microbial community activity and overall process efficiency, particularly during transitions between mesophilic and thermotolerant conditions [2], [8-10]. Concurrently, studies have analyzed microbial community composition, evaluating the roles of fermentative and acetogenic bacteria, as well as methanogenic archaea, in methanogenesis under temperature regimes favorable to their development and energy potential. In this context, the present research conducts a comprehensive systematic review focused on reliable information on temperature-related trends in biogas production. To this end, it is essential to assess the impact of temperature on methane generation using data retrieved from the Web of Science database and analyzed with open-source tools such as Excel and SPSS, following the PRISMA bibliographic review framework. This approach enables the identification of key trends, the mapping of research related to temperature effects, and the detections emerging challenges that may guide future investigations. The fundamental objective guiding this research is as follows: A comprehensive review of extant scientific literature reveals a paucity of research regarding the influence of temperature on methane production. To provide a comprehensive approach to the main purpose, it is necessary first to address the following specific research questions (SRQ):

- SRQ 1: How does temperature have a correlational effect on the operating parameters of anaerobic digestion to enhance methanogenesis on biogas production?
- SRQ 2: How hydrogen potential (pH) and retention time of organic loading rate regarding anaerobic digestion (RT) are related to temperature?
- SRQ 3: What are the main areas of knowledge related to the influence of temperature on methane production?

A review of the literature reveals several seminal articles that have contributed to the consolidation of this field of study by settling down the approaches of temperature impact in biogas production. Responding to these questions aims to clarify the gaps in biogas production regarding considering operational parameters such as pH and RT, which may influence future trends in knowledge and establish the basis for new methodologies that yield better results in anaerobic digestion by considering temperature as a significant regulator of methanogenesis enhancement.

II. MATERIALS AND METHODS

In this regard, a systematic review is a bibliographic synthesis that addresses a clearly formulated research question and applies systematic and explicit methods to identify, select, and critically evaluate relevant studies. It also involves the compilation and analysis of extracted data from the included studies in order to identify future research priorities, address questions that cannot be resolved by individual investigations, detect limitations in primary research that should be addressed in future studies, and generate or assess theories explaining how and why the phenomena of interest occur [25]. Within this scope, data extraction represents a key component of the PRISMA framework and is directly aligned with the research questions. In this study, data extraction was conducted through full-text analysis of the selected articles to identify PRISMA methodology ensures a transparent and robust selection process among the articles retrieved through the search strategy, thereby facilitating meaningful comparisons across studies and highlighting the significant contributions of meta-analytical evidence [26].

II.1 ELIGIBILTY AND ANALYSIS CRITERIA

The PICOT method was adopted for answering the research questions posed in the literature review with an adaptation of its scope using its components of “Population (P),” which refers to the operating temperature regimes that allow for biogas production. “Intervention (I)” is associated with the operating parameters of temperature impact that are most closely related to “Outcome (O)” with the improvement of methanogenesis, resulted in PIO structure (see Table 1).

Table 1: PICOT (PIO) structure.

COMPONENT	QUESTION	KEY WORDS
POPULATION (P)	What are the temperature regimes that have a direct impact on biogas production?	Biogas production, biogas generation
INTERVENTION (I)	In what way does process temperature influence the methanogenic efficiency on biogas production?	Temperature, t
OUTCOME (O)	Which are the crucial operational parameters on methanogenesis enhancement?	Methanogenesis, Methane production

Source: Authors, (2025).

Based on the modified PICOT structure, a search strategy was designed that included specific keywords to ensure comprehensive coverage of the topic. The search equation used was (TS=("Biogas production" OR "biogas generation") AND TS=(temperature OR t) AND TS=("methanogenesis" OR "methane production")) AND ((DT==("ARTICLE") AND LA==("ENGLISH") AND OAJ==("ALL OPEN ACCESS")) NOT (PY==("2025"))). This strategy was applied to the Web of Science (WoS) database, which was selected for its broad multidisciplinary scope and rigorous indexing process. The initial search yielded a total of 339 articles. However, following a manual revision, two articles corresponding to the year 2025 were identified; despite the applied exclusion criteria, these records were retrieved in the search results. After their removal, the final corpus consisted of 337 articles, providing a solid and refined basis for initial systematic analysis. Subsequently, the application of PRISMA systematic review methodology enabled the identification of the most relevant scientific literature addressing temperature and its influence on biogas production. During this process, inclusion and exclusion criteria were applied to further refine the final corpus (see Table 2). A total of 130 articles were excluded by title and abstract screening due to misalignment with the primary objective, resulting in 207 selected records. Of these, 92 articles could not be retrieved, leaving 115 studies for eligibility assessment.

Among them, 35 articles lacked relevance to the main objective of the study (EC 1), 10 were written in languages other than English (EC 2), and 45 corresponded to theoretical or non-experimental research, such as review papers, which could lead to limited empirical contribution to the present analysis (EC 3). Consequently, only 25 articles met all eligibility criteria and were included in the final review, as illustrated in the PRISMA flow diagram (see Figure 1). The original data were managed using specialized software Excel and Mendeley tool, improving the storage of the final corpus of studies for this review, and providing an enhancement in the analysis of the data consulted. All data processing, table construction, and figure generation were performed using the latest stable version of Python v2025.10.4. The analyses and graphical outputs were developed within the Visual Studio Code (VS Code) environment, ensuring reproducibility, efficient code management, and consistency in data visualization.

Table 2: Eligibility criteria.

EXCLUSION CRITERIA	INCLUSION CRITERIA
EC 1: Articles that do not fulfil research objective	IC 1: Assess temperature relevance on biogas production
EC 2: Non-English reports	IC 2: Determine numerical results to compare
EC 3: Non-empirical research (review)	IC 3: Empirical methods

II.1.1 Statistical Analysis

Due to the limited sample size, and the heterogeneity of experimental conditions across the studies, inferential statistics comparing thermal regimes were not considered informative. Therefore, results are primarily reported using descriptive statistics, while exploratory intra-regime analyses were conducted to assess the trends associated with temperature, pH, RT, by central tendency measures. In addition to central tendency reports, coefficient of variability (CV) was calculated to assess relative dispersion within each thermal regime. Relative difference (∇CH_4) between mesophilic and thermophilic mean methane yields was also computed to evaluate the magnitude of change, given the limited inferential power of formal statistical tests.

Coefficient of variability

$$CV = \frac{SD}{\bar{x}} * 100 \quad (1)$$

Relative difference

$$\nabla\, CH_4 = \frac{CH_4\, max - CH_4\, min}{CH_4\, min} * 100 \quad (2)$$

Where:

SD: Standard deviation of the data collected by thermal range.
$\bar{x}$: Mean of the methane production.
$CH_4\ max$: Maximum value of methane production among studies collected by thermal range.
$CH_4\ min$: Minimum value of methane production among studies collected by thermal range.

II.2 AI – ASSISTED LANGUAGE EDITING

The manuscript was translated from Spanish into English and subsequently linguistically refined using an artificial intelligence-based language model (ChatGPT, OpenAI), exclusively for language-related purposes. The use of this tool was strictly limited to supporting translation accuracy, grammatical correction, stylistic consistency, and overall clarity of the English text. The AI system did not contribute to the formulation of research questions, study design, data collection, data processing, statistical analysis, interpretation of results, or the development of scientific conclusions. All scientific content, methodological decisions, analyses, and interpretations presented in this manuscript were conceived, executed, validated solely by the authors. The authors assume full responsibility for the accuracy, originality, and integrity of the work and confirm that the use of artificial intelligence did not influence the scientific validity, originality, or novelty of the study. This disclosure is provided in accordance with current transparency and ethical guidelines regarding the responsible use of artificial intelligence tools in scholarly publishing.

III. RESULTS AND DISCUSSIONS

Temperature is a critical factor in anaerobic digestion due to its influence on process dynamics, inoculum acclimatization, microbial metabolic activity, methane yield, and overall process stability [27]. Literature generally distinguishes two thermal regimes. The mesophilic range (30-49 ºC) is characterized by relatively slower but more stable digestion process with lower energy requirements, whereas the thermophilic range (≥ 50 ºC) promotes enhanced biokinetic activity and higher reaction rates, albeit at the expense of increased energy demand and reduced process stability. Thermophilic systems are more susceptible to fluctuations in temperature and pH, as well as to inhibition by elevated concentrations of free ammonium concentration [28-30]. Several studies report that temperature directly affects the optimization of biogas production by accelerating the metabolic rates of microbial communities involved in organic matter degradation and methanogenesis, thereby increasing methane yields [31-34]. Consequently, temperature represents a key parameter governing methane accumulation, as its interaction with other operational variables, such as residence time (RT) and pH, ultimately determines the magnitude of cumulative methane production (see Table 3).

Table 3: Methane peak results associated with temperature, pH and residence time (RT) from the articles included in PRISMA.

THERMAL RANGE	TEMPERATURE (ºC)	RT (days)	pH	METHANE PEAK (mL CH_4/g VS)	REFERENCE
Mesophilic	35	-	7.57	333	[35]
	35 ± 1	40	-	450 ± 22	[36]
	35	37	7.6	132.3	[37]
	35	30	7,8	218.88 ± 6.77	[38]
	37	55	8	273.2	[39]
	37 ± 0.5	30	8	389.1 ± 8.5	[32]
	37	20	7 ± 0.1	260.83 ± 15.02	[40]
	39	36	8	189 ± 6	[41]
	40	-	-	416.8 ± 6.77	[42]
Thermophilic	51.5	20	7 ± 0.1	275.66	[40]
	55	30	7.3 A	212.4	[43]
	55	26	6	253.8	[44]
	55	46	8	279.9	[39]
	55 ± 0.5	30	8	110.9 ± 22.1	[32]
	100	20	7.43	264.64	[33]

A: Value estimated by visual extraction of the figure indicated in the article, as numerical data are not available in tabular format.
Source: Authors, (2026).

Table 4: Descriptive statistical reports of methane production within the thermal regimes.

REGIME	MEAN ($\bar{x}$)CH4 ((mL CH_4/g VS)	SD	$CH_4\ min$	$CH_4\ max$	CV (%)	∇CH4 (%)
Mesophilic	295.901	108.568	132.3	450	37%	240%
Thermophilic	232.883	64.476	110.9	279.9	28%	152%

Source: Authors, (2026).

Table 3 presents a ranking of data extracted from 13 studies included in this review (52%), with three of these studies reporting results under both mesophilic and thermophilic temperature regimes [32], [39],[40]. To enable accurate comparisons between temperature and methane production, standardized units widely accepted in the literature were used, specifically milliliters of methane per gram of volatile solids (mL CH_4/ g VS). This metric allows for a more direct comparison between mesophilic and thermophilic operating conditions and facilitates the identification of temperature-related trends in methane generation.

Marked variability is observed between the mesophilic range (35-37 ºC) and the thermophilic range (50-100 ºC), with the highest methane yields occurring at the lowest temperatures within the dataset. This finding indicates that temperature alone does not govern

methane production. Instead, the reported outcomes reflect a multifactorial interaction in which temperature acts in combination with other operational parameters, particularly pH and residence time (RT), which are essential for a more comprehensive interpretation of methane yields under different thermal conditions.

III.1 MESOPHILIC TEMPERATURE RANGE

Among the 13 studies considered in Table 3, 69.23% (nine articles) examine the relationship between mesophilic temperature conditions and methane production. As shown in Table 4, the coefficient of variation (CV) of the methane production data indicates high heterogeneity (CV > 33%, specifically 37%), suggesting that the mean value is not representative and that methane yields are highly dispersed. Furthermore, an analysis of the maximum and minimum recorded methane values reveals that, within the mesophilic range of 35-40 ºC, the relative difference in methane production reaches approximately 240%, representing the highest variability observed across the evaluated thermal ranges. This pronounced variability indicates gaps in the control of study variables, highlighting the need to account for factors such as digester configuration, substrate characteristics, and applied pretreatment methods to improve biogas quality and process consistency [36],[45],[46]. In contrast, studies operating at a constant temperature generally report more comparable methane production levels, with reduced dispersion when pretreatment conditions and substrate types are similar, as illustrated in Figure 2.

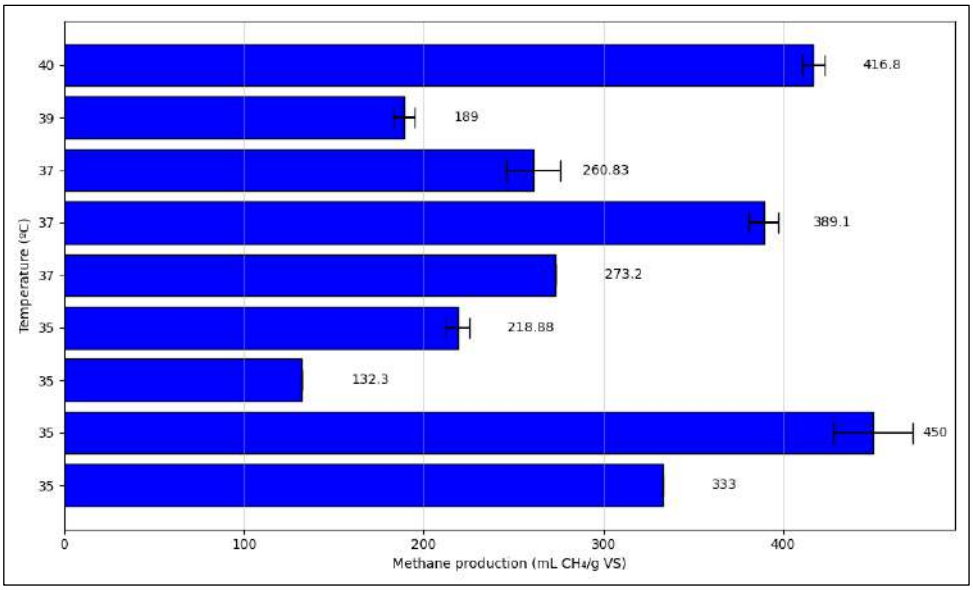

Figure 2: Mesophilic thermal range.
Source: Authors, (2026).

On the one hand, [36] evaluated food waste digestion at 35 ºC by comparing conventional thermal pretreatment with electromagnetic microwave radiation (EMR) pretreatment. Although a methane peak of 450 mL CH_4/ g VS was achieved using EMR, the difference relative to the conventional method was modes (≈ 424 mL CH_4/ g VS). This limited improvement was attributed to the possible accumulation of volatile fatty acids (VFAs), which can acidify the digestion medium. Moreover, microwave radiation may influence the composition and activity of methanogenic microorganisms by affecting enzymatic activity, inducing changes in DNA and RNA, and altering protein synthesis, depending on power, frequency, and exposure time [47]. Nevertheless, several studies have reported that the application of this type of pretreatment enhances the solubilization and degradation of organic solids, thereby promoting anaerobic digestion and increasing methanogenic potential [38], [48-50]. In this study, the estimated variation between heating methods was approximately 6%, which is consistent with previously reported findings [51], [52], indicating a positive effect of this heating approach on the biodegradability of the feedstock used in anaerobic digestion. On the other hand, both [42] and [37] investigated the anaerobic digestion of water hyacinth (*Eichhornia crassipes*) at 40 and 35 °C, respectively.

Both studies agreed that the high lignin content of this substrate limits the degradation of cellulose and hemicellulose, thereby reducing the availability of fermentable sugars and microbial diversity, and adversely affecting the acidogenesis and methanogenesis stages [53], [54]. However, their findings differed with respect to operational conditions. Specifically, [42] reported that a low feed-to-inoculum ratio (F/I = 1.0) favored methane production (416.8 mL CH_4/g VS), whereas a high ratio (F/I=30.0) inhibited the process due to the accumulation of VFA and ammonia. In contrast, [37] observed that solids concentrations exceeding 6.3% led to system saturation and reduced methane production to 132.3 mL CH_4/g VS. Both studies concluded that, despite operating within optimal mesophilic temperature ranges (35-40 ºC), lignin content and inhibitory compounds constrain digestion efficiency, making it essential to control organic loading or incorporate more readily degradable co-substrates. From this perspective, although methane yields ranging from 100 to 450 mL CH4 /g VS have been reported under constant thermal conditions, the observed variability in methane production is primarily associated with the type of substrate, the pretreatment strategy, and the digestion approach, rather than with temperature as an isolated operational parameter.

III.2 THERMOPHILIC TEMPERATURE RANGE

Conversely, among the 13 articles, 53.84% examined thermophilic operating conditions. Based on their distribution, a relatively homogeneous pattern is observed within this thermal regime, with a coefficient of variation below 33% (CV =28%), indicating reasonably stable performance across studies despite underlying methodological heterogeneity. In this context, the mean methane yield (232.88 mL CH_4/g VS) can be considered representative of the overall data dispersion (Figure 3). Notably, most data points are clustered around 55 ºC, where no clear or statistically significant differences in methane production can be attributed solely to temperature. Nevertheless, the wide range of reported yields (110.9 ± 22.1 – 279.9 mL CH_4/g VS) indicates that variability is primarily governed by operational parameters such as pH regulation, residence time (RT), and substrate composition rather that by temperature alone. Overall, 55 ºC emerges as a robust thermophilic operating condition, capable of achieving high methane productivity while remaining sensitive to process control and operational management.

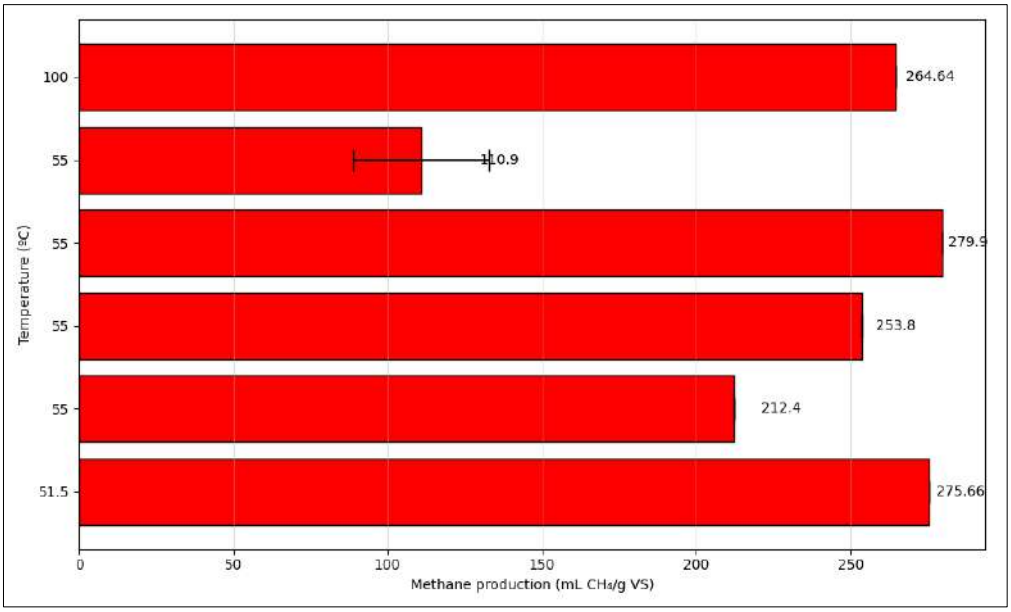

Figure 3: Thermophilic thermal range.
Source: Authors, (2026).

As an explanation for the observed variability, [32] reported a methane yield of 110.9 ± 22.1 mL CH_4/g VS after acid-thermal pretreatment. The resulting acidic conditions strongly inhibited anaerobic digestion, likely due to insufficient acid removal and pH values below neutrality, which are toxic to anaerobic microorganisms [55]. Additionally, the use of whiskey by-products, also reported by [39], implied a low C:N ratio, favoring inhibition through elevated free ammonium (> 1000 mg/L) and volatile fatty acid (VFA) accumulation (> 4000 mg/L) [32], [56]. These results indicate that under thermophilic conditions, aggressive pretreatments combined with unstable C: N ratios can severely impair methanogenic activity [57-59]. Conversely, [39] showed that thermal pretreatment of microalgae at 90 ºC coupled with digestion at 55 ºC resulted in only a modest 6% increase in methane production compared to mesophilic conditions. This limited improvement was attributed to ammonium inhibition associated with the low C:N ratio of microalgae and the release of free ammonium following cell disruption during thermal pretreatment [60].

The introduction of an additional biological pretreatment mitigated this effect, increasing methane yield by 12% (279.9 mL CH4 /g VS). Overall, the comparison between mesophilic and thermophilic regimes indicates that temperature alone does not govern methane production. While mesophilic digestion (35-40 ºC) exhibits high variability driven by substrate type, organic loading, and pretreatment strategy, thermophilic operation (50 -100 ºC) demonstrates greater consistency and faster kinetics, particularly around 55 ºC. However, thermophilic stability is highly sensitive to substrate composition, especially low C:N ratios and the use of aggressive pretreatments, which can promote ammonium and VFA accumulation. Therefore, optimal methane yields across both thermal regimes depend on a multifactorial balance between temperature, substrate characteristics, pretreatment selection, and strict control of key physicochemical parameters, rather than on temperature as an isolated variable.

III.3 TEMPERATURE INFLUENCE ON pH

Across both mesophilic and thermophilic regimes, methane production was generally reported within a relatively narrow pH range of 6.0 to 8.0. Under mesophilic conditions, Figure 4 indicates that most studies operated at neutral to mild alkaline pH values (7.0-8.0), within which methane yields were commonly observed. However, [41] reported negligible methane production at 39 ºC despite operating at pH 8.0. This outcome is primarily associated with the characteristics of the substrate, particularly its high lignin content, which limits biodegradability, as well as potential inhibition caused by VFA accumulation and the use of mono-digestion strategies. These findings challenge the assumption that maintaining a neutral to slightly alkaline pH (7.0-8.0) invariably enhances methane production. Although methanogenic archaea typically exhibit optimal activity within a pH range of 6.0-8.0 [44], [61-64], the influence of pH is strongly modulated by substrate quality, pretreatment approach, biodegradability, and the presence of inhibitory compounds [29], [45], [46], [65], [66].

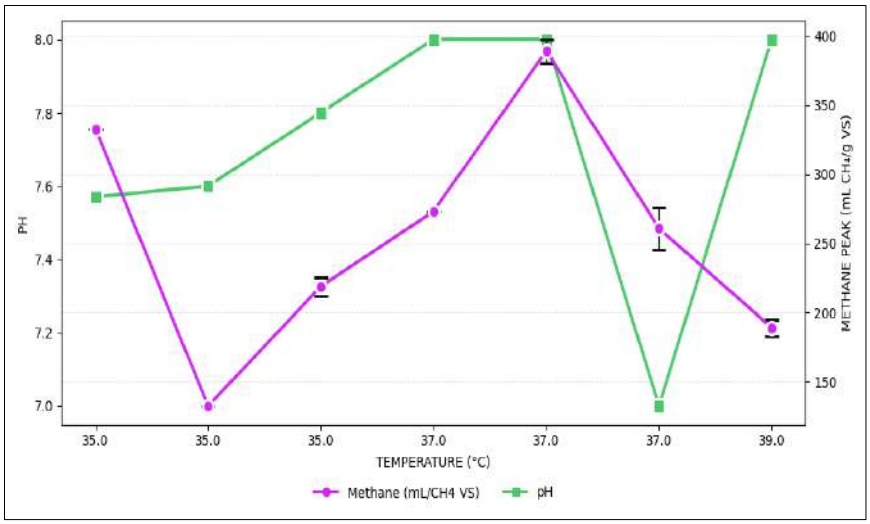

Figure 4: Mesophilic regime effect on pH.
Source: Authors, (2026).

To support this notion, Figure 5 illustrates that under thermophilic conditions there is a clear tendency from acidic (pH 6.0) to alkaline conditions (pH 8.0) at 55 ºC. In this context, [32] reported that, regardless of the pretreatment strategy applied, pH is strongly associated with the substrate composition under thermophilic operation, as temperature critically influences protein hydrolysis, leading to the formation of NH_4^+ and NH_3. The latter acts as a weak base, stabilizing the digestion medium at alkaline pH values (around 8.0). Nonetheless, this alkalinity can inhibit methanogenesis due to increased concentrations of free ammonia nitrogen (FAN), as well as the accumulation of VFA and free ammonium, thereby generating a toxic and unstable environment that restricts methane production, irrespective of the pretreatment applied [67] ,[68]. Additionally, it is reported in [40] that with a digestion temperature of 51.5 °C, it associates the pH value (5.8) to the nutrient content of sewage sludge; nevertheless, its methane production is the highest among thermophilic studies, suggesting that the synergy in its substrates (SS/GTS), due to the easy degradation of VS and TS in GTS, results in better methanogenesis. Finally, there are authors who have not considered this operational parameter [33], [36] ,[37] ,[39] ,[42] ,[43], [69]. These findings may involve prioritizing the analysis of critical variables such as temperature, hydraulic retention of organic content, pretreatments, substrate type, overall energy efficiency, and technical feasibility, which is why this physicochemical parameter could be omitted from the results. Some researchers may also consider it a non-limiting parameter and choose not to report it if no significant variation is observed during the process or through automatic adjustment in controlled tests. Likewise, in some processes, such as the one reported by [36], the pretreatment methodologies and the layout of the digester make it difficult to measure physicochemical parameters such as pH and COD, so they are not taken into consideration.

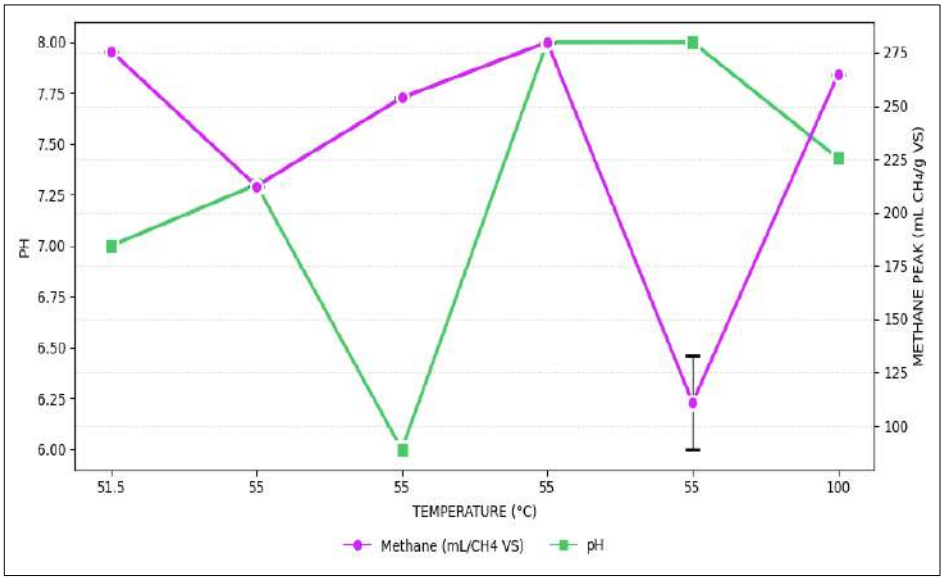

Figure 5: Thermophilic regime effect on pH.
Source: Authors, (2026).

III.4 TEMPERATURE INFLUENCE ON RT

Within both thermal regimes, methane production was reported under a broad range of residence time, reflecting heterogeneous operational strategies rather than standardized process conditions. On the one hand, Figure 6 shows the dispersion of temperature data based on their corresponding methane values and the influence of RT as a parameter established in each study.

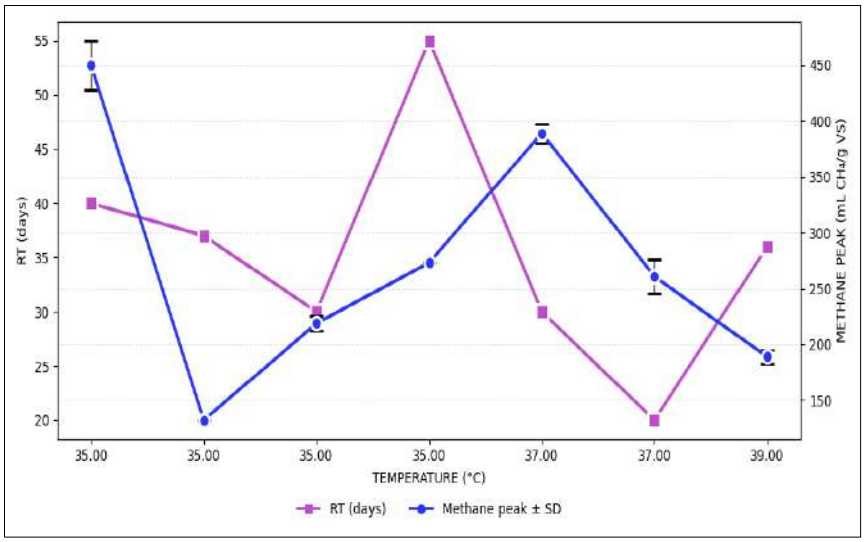

Figure 6: Mesophilic influence on RT (days).
Source: Authors, (2026).

At 39 ºC, with a retention time (RT) of 36 days, [41] reported lower methane production (189 mL CH_4/g VS) when using rumen as the base substrate. This indicates that RT does not act directly on temperature but rather interacts with substrate characteristics and organic loading, depending on the pretreatments applied to enhance anaerobic digestion (AD) performance. In this context, a longer RT does not necessarily guarantee higher methane yields across temperatures, as substrate composition and pretreatment efficiency play a decisive role. Furthermore, at a constant temperature of 35 °C, [39] reported lower methane production at an RT of 55 days compared to the 40-day process reported in [36], yielding 273.2 and 450-mL CH_4/g VS, respectively. This relative difference (64.7%) contradicts the conventional assumption that shorter RTs necessarily result in reduced methane production [70]. Similarly, [40] reported a methane yield of 260.83 mL CH_4/g VS, at an RT of 20 days, which is comparable to the values reported by [39].

These differences can be attributed to variations in operating conditions, substrate quality, and digester configuration, particularly when strategies such as co-digestion are applied [38]. Likewise, at a constant temperature of 37 ºC, [32] observed higher methane production (389.1 mL CH_4/g VS) after 30 days of digestion. Overall, these findings highlight the need to standardize experimental conditions across studies and to systematically compare pretreatment strategies and substrate types to establish robust correlations. Methane production trends tend to vary according to substrate complexity, pretreatment intensity, and RT, even when temperature is held constant. Conversely, Figure 7 shows that under thermophilic temperatures, RTs will be lower due to the rapid hydrolytic reaction and breakdown of the cell walls of organic matter, providing higher methane peaks in a very short time [30]. Notably, at 51.5 °C, the methane peak was one of the highest among the studies in this temperature range (275.66 mL CH_4/g VS), considering a RT of 20 days. This may confirm that, under high temperature conditions, methane production will be enhanced, with a lower RT or contact time with the organic load.

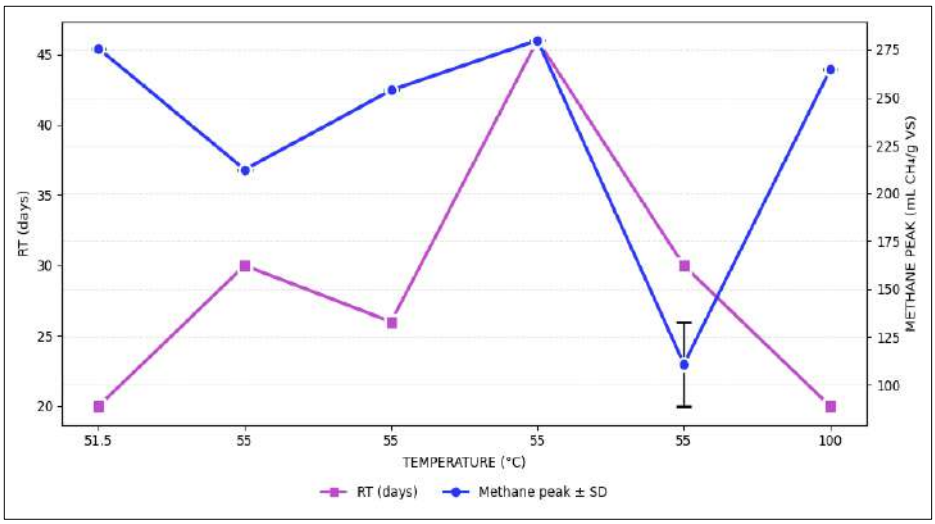

Figure 6: Thermophilic influence on RT (days).
Source: Authors, (2026).

For instance, temperatures of 55 °C that reported longer RT's, such as 26 and 30 days, estimate a projection on methane production, theoretically. The relative difference between studies, considering methane production results, with 30 days of RT, is 171.9%. This disproportionate variation suggests that the type of pretreatment and substrate have a greater effect on AD than RT alone as a function of temperature, as independent variables [32],[43].

In contrast, other studies at 55°C show that higher RT (46 days) can also yield good results (279.9 mL CH_4/g VS); however, the stability of the process suggests higher energy demand and difficulties in operational control [39], [71]. Similarly, at a higher temperature of 100 °C and only 20 days of RT, one study shows that yields are optimal (264.64 mL CH_4/g VS, respectively), reinforcing the idea of greater efficiency in biodegradability in terms of methane production levels and speed in the process [33]. Finally, the results of both figures show a contrast between the mesophilic and thermophilic ranges with respect to their impact on RT. The results in Figure 7 show that, in a thermophilic range, the RT are relatively lower compared to the results of the mesophilic range in Figure 6. This suggests that the thermophilic regime positively influences the extracellular enzymatic activity of the organic load, promoting higher hydrolysis rates than at mesophilic temperatures [72]. Nevertheless, yields at methane peaks in the thermophilic regime are lower due to susceptibility to temperature variations, compared to the mesophilic regime [27]. This reflects what was reported by [62], although a higher operating temperature led to greater microbial activity initially, when maximum methane production was reached, prolonging the RT under these conditions can cause a decrease in production, since most methanogenic microbial consortia do not have thermotolerant characteristics [34], [73].

III.5 FUTURE PERSPECTIVES ON BIOGAS PRODUCTION RESEARCH

Future research on anaerobic digestion should prioritize the standardization of experimental conditions to enable robust comparisons across mesophilic and thermophilic regimes. Given that methane production variability is more strongly influenced by substrate characteristics and pretreatment strategies than by temperature or retention time alone, future studies should adopt harmonized reporting of key operational parameters, including C:N ratio, organic loading rate, pH control strategies and inhibitor thresholds. Further investigation is required on the development of adaptative process control strategies capable of mitigating thermophilic instability, especially under fluctuating temperature and pH conditions. Integrating real-time monitoring of psychochemical indicators with predictive modeling may enhance process resilience and methane productivity, as well as a mathematical model that integrates deeper approaches into the correlation among temperature and other operational parameters, such as pH and retention time that reflects a multifactorial influence in the heating field.

IV. CONCLUSIONS

The results of the literature review allow us to affirm that the efficiency of AD does not depend solely on temperature, but on a multivariable interaction between pH and RT, which is evident in the natural behavior between the temperature ranges specified in this analysis. To this end, its relevance lies in understanding pH and RT not as fixed values, solely related to temperature, but as variables that respond to the type of substrate, the pretreatment applied, and the presence of inhibitory compounds such as VFA or FAN. Evidence shows that high yields can be achieved even in suboptimal ranges of these parameters, if the stability of the medium is ensured, the organic load is optimized, and/or strategies such as co-digestion, and physical, chemical, and biological pretreatments are employed. For future research it should be considered greater rigor in reporting other highly influential operational variables, such as organic load content based on substrate characteristics and the relationships between biological and/or microbiological inoculants, to build more robust databases for systematic reviews of literature concerning temperature as the main factor in the AD process. Likewise, it is necessary to compare the methodologies for analyzing accumulated methane production provided by biogas kinetics reports and to provide a mathematical model that allows methane production to be estimated, considering temperature as the main variable, correlated to other operational parameters.

Top-Down Specialization.

ABSTRACT

As governments and other organizations share larger datasets, keeping individual information private has become increasingly difficult to solve. When publishing the data, data anonymization models like k-anonymity and l-diversity are employed to ensure the trade-off between privacy and data utility. This paper presents a method called Bottom-Up k-anonymization (BU-K), implemented on Apache Spark. It improves efficiency by applying the Bottom-Up Generalization (BUG) approach. BU-KC performs better than Top-Down Specialization (TDS) in terms of scalability, and data privacy, while still keeping the data useful. Moreover, using Apache Spark's distributed computing architecture significantly improves processing time compared to traditional MapReduce approaches. This work fills a gap in distributed anonymization on Spark by offering a new, efficient, and scalable solution.

I. INTRODUCTION

In recent years, many organizations have required the web-based exchange of huge volumes of data with research institutes in order to undergo analysis and identify subtle patterns. A significant difficulty in data publishing is protecting people's privacy by anonymizing information that could expose their identities. The key lies in developing systems that effectively balance privacy protection and data usefulness [1]. The field of study that combines all of these methods is known as Privacy Preserving Data Publishing (PPDP) [4]-[2]. As data volumes have expanded and the big data paradigm, defined by the 42 Vs, has emerged, various privacy models have been extremely prominent in this area. Among these techniques, k-anonymity [3] and l-diversity [4] are widely employed. Generalization processes are commonly used in data anonymization, where original values are replaced with generalized ones using a taxonomy tree to maintain semantic compatibility between the old and new values [5].There are generally two main ways to navigate the taxonomy tree: Top-Down Specialization (TDS) starts from the root and moves down, while Bottom-Up Generalization (BUG) begins at the leaves and moves up.

Unlike the top-down approach, we use Bottom-Up Generalization (BUG), a more efficient strategy that preserves data quality [6]. As data volumes approach zettabytes, improving processing time becomes crucial for efficient data interchange and publication. Traditional centralized solutions fail to manage huge volumes of data, resulting in inefficiencies in time processing, scalability, and overall performance [7]. To address these difficulties, distributed computing frameworks such as MapReduce and Apache Spark have been developed. Among these, Apache Spark stands out as an open-source, scalable platform capable of effectively processing massive datasets. Its ability to analyze large amounts of data quickly and efficiently makes it a suitable tool for modern data processing tasks [8]. Programs running on the Spark platform can achieve significantly faster processing speeds up to 100 times faster in memory and 10 times faster on disk compared to MapReduce. Consequently, Spark has emerged as a highly efficient ecosystem for performing the anonymization process on large-scale data. By leveraging Spark's capabilities, the anonymization process can be executed more efficiently, enabling faster processing and improved scalability [9].

The Bottom-Up Generalization (BUG) approach, proposed in [10] as a centralized way to support k-anonymity model, was later improved by [11] to work with MapReduce Framework, making it faster to process. Since then, a lot of research has explored using the k-anonymity model with MapReduce. However, to the best of our knowledge, no one has tried to fully implement a Bottom-Up anonymization approach on Apache Spark. Our work aims to fill this gap by developing a distributed Bottom-Up k-anonymity (BU-K) framework tailored for Spark. This approach seeks to enhance both data utility and processing efficiency, leveraging Spark's parallel processing and scalability features to achieve significant improvements in execution speed and data quality preservation during anonymization. The remainder of this paper is organized as follows: Section 2 reviews the existing literature on related works. In Section 3, we delve into the core concepts and essential components of the proposed approach. Section 4 presents and discusses the results from the evaluation of our method. Finally, Section 5 offers conclusions and outlines potential directions for future research.

II. RELATED WORKS

Privacy-Preserving Big Data Publishing (PPBDP) is a critical research field focused on tackling the challenge of releasing large-scale datasets while ensuring an optimal balance between data privacy and utility [12]. In the context of big data, several privacy models, such as k anonymity, have been widely adopted. Section 2.1 explores various centralized algorithms, most of which focus on implementing the k-anonymity model. Section 2.2 presents a range of distributed big data algorithms that perform anonymization using either top-down or bottom-up generalization techniques.

II.1 CENTRALIZED APPROACHES

LeFevre et al [13] introduced the Mondrian algorithm, which employs a top-down generalization approach for data partitioning. Initially, all data instances are grouped into a single partition. The algorithm then recursively divides the data instances into sub-partitions using a top-down approach until the resulting partitions satisfy the k-anonymity requirements. At each step, the algorithm selects the widest dimension of the data as the cut dimension and uses the median of the data values in this dimension as the split point for partitioning.

Yaseen et al. [14] proposed three novel generalization methods to overcome the limitations of traditional techniques: conventional generalization hierarchies, divisors generalization hierarchies, and cardinality-based generalization hierarchies. Each method prioritizes data utility and partitions the attribute domain space in a distinct way. Their performance is evaluated based on the discernibility penalty, distortion ratio, and the number of nodes at each level.

In this paper [15], a new data anonymization algorithm that enhances users' community privacy is presented. The algorithm assesses the vulnerability of each attribute in a user's dataset to effectively protect community privacy. It conducts adaptive data generalization while simultaneously assessing attribute susceptibility and entropy.

Basapur et al [16] introduced a novel data generalization algorithm aimed at improving group privacy and data utility. This algorithm evaluates attribute susceptibility, the frequency of sensitive attributes, and their interrelationships to create equivalence classes that satisfy both k-anonymity and β-likeness. The approach incorporates these factors into the data anonymization process and is tested using Apache Spark

Recently, Torra and Navarro [17] proposed a new data publishing for minimizing the attribute disclosure risk in k-anonymity model. To avoid Internal and external attacks, the solution is to apply well-known codes to identify sensitive cells in tabular dataset by using p-sensitivity and p-diversity models.

In order to avoid the danger of skewness and similarity attacks, Su et al. [18] presented a k-anonymity mechanism based on clustering for multi-dimensional data, combined with t-closeness privacy model. Based on an enhanced African vultures optimization, the suggested approach adheres to extremely accurate clustering of the multi-dimensional dataset and can offer the ideal solution with multiples dimensions.

II.2 DECENTRALIZED APPROACHES

Sopaoglu and Abul [19] developed a Top-Down Specialization (TDS) anonymization solution designed specifically for the Apache Spark platform. This method assesses both numerical and category attributes by iteratively generalizing the original data, beginning with the most general node and using the k-anonymity model.

Zakerzadeh et al. [20] enhanced the centralized Top-Down Mondrian technique for massive data applications by using the MapReduce framework. Reducing the algorithm's processing time across the Mapper, Combiner, and Reducer computational nodes is the aim of this work.

In a related study, Ashkouti et al. [21] enhanced earlier work on the Apache Spark Framework by applying a multidimensional Top-Down Mondrian approach. The primary difference between the two approaches resides in selecting the axis dimension creterion to which the partitioning is carried out. While [20] utilized the domain width as the primary criterion for axis dimension selection, the improved study diverges by prioritizing the dispersion of attribute values over the domain. This research aims to enhance time efficiency through the implementation of RDD programming, while simultaneously improving data privacy by adopting the l-diversity model in lieu of k-anonymity. Jain et al [22] developed a model that introduces an additional layer between the Hadoop Distributed File System (HDFS) and MapReduce to enhance data sharing for mining operations. This scalable SMR model performs as part of the Map and Reduce phases and aims to balance privacy with utility through lightweight encryption, randomization, and perturbation techniques. In the presence of big data, the centralized traditional BUG techniques are not suitable for adhering privacy needs. This motivated researchers to propose parallel bottom-up approaches to address limitations brought about by centralized BUG.

In [23] [11], a scalable advanced Bottom up generalization method is proposed to meet the k-anonymity model using MapReduce platform on Cloud. The process involves two main steps: first, the original dataset is divided into multiple tables, and each partition is anonymized in parallel to generate intermediate results. In the second step, these intermediate results are grouped, and an additional anonymization operation is performed to ensure compliance with the privacy model. In terms of scalability, the authors demonstrate that the parallel BUG approach is more efficient than the top down specialization method. The existing literature has predominantly focused on implementing top-down k-anonymization approaches, either within the MapReduce environment or on Apache Spark.

In contrast, bottom-up k anonymization methods have been primarily applied within MapReduce frameworks, with no prior implementations in the Apache Spark ecosystem. Our work addresses this gap by pioneering the implementation of a bottom-up k-anonymization approach specifically on Apache Spark. This advancement is significant because, as established by various studies [6], the bottom-up approach is generally more effective than the top-down approach in terms of efficiency and privacy preservation. By leveraging Apache Spark's advanced processing capabilities, our implementation aims to deliver superior performance, enhancing both data utility and processing speed compared to the existing top-down methodologies. This contribution represents a notable advancement in the field of privacy-preserving data publishing, setting a new benchmark for efficiency and scalability in large scale data anonymization.

III. PROPOSED METHOD

III.1 PRELIMINAIRES

In the context of privacy-preserving big data publishing, data is typically structured in a table with different types of attributes, classified into three main categories:(i) Explicit Identifiers (EI): These are attributes that immediately reveal an individual's identify, such as a name. (ii) Quasi-Identifiers (QI): While these attributes are not individually revealing, when paired with other data, they can be utilized to identify individuals, such as zip code. (iii) Sensitive Identifiers (SI): These attributes include confidential information, such as medical conditions [22]. It’s important to note that EI and QI traits might be numerical or categorical, whereas SI attributes are always categorical [5]. To achieve data anonymization, it is crucial to convert the table into generalized groups known as Equivalence Classes (EC) or QI-groups. The k anonymity model requires that each EC contains at least k records, ensuring that each individual cannot be uniquely identified within the group. he l-diversity model requires that each EC contains at least l distinct sensitive values, thereby enhancing individual privacy while preserving data utility.

III.2 THE PHASES OF THE PROPOSED METHOD

Figure 1 provides a visual representation of the sequential phases involved in the implementation of our distributed k concealment model. The process is executed using a series of RDDs, which are manipulated through transformations and actions in the Apache Spark library.

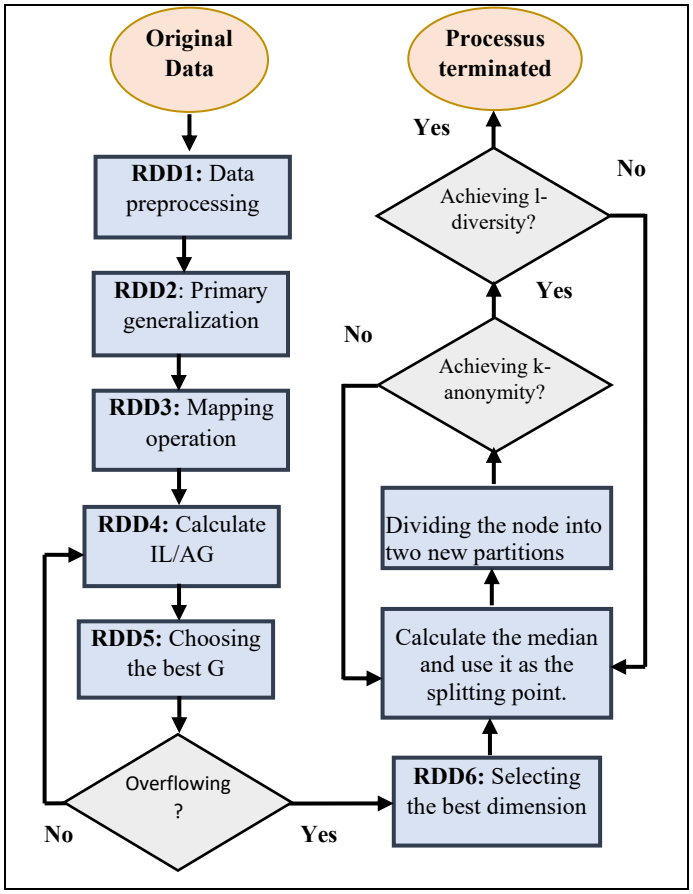

Figure 1: Summary of the proposed approach.
Source: Authors, (2026).

III.2.1 Data preprocessing

The dataset obtained from the data holder contains a significant number of missing and duplicate entries. The primary objective of this phase is to preprocess the data to ensure it is suitable for the subsequent anonymization process. This entails identifying and removing erroneous records, followed by distributing the cleaned data across multiple worker nodes for further processing.

III.2.2 Primary generalization

In this phase, the worker nodes concurrently anonymize the data in parallel by applying the primary generalization operation. The goal is to achieve compliance with the k-anonymity model, resulting in an intermediate anonymized dataset.

III.2.3 Mapping operation

In this phase, the mapping operation is performed to associate the <key, value> pairs for each data record, as described in Algorithm 1. In the preceding phase, a collection of equivalence classes was generated based on the k-anonymity model. Here, the "key" represents the set of distinct sensitive values within the equivalence class to which the record belongs (labels), while the "value" corresponds to the attribute values of the individual data record

Algorithm 1: Mapping operation.

Input : RDD2, ECs
Output : (key, value) pairs as RDD3
    Key = [ ] / list of SI of each EC
    Values = [ ]
    for each EC in data records **do**
        Value = Value.append (QI)
        Key = All_SI (value)
end for

III.2.4 Generalization process

III.2.4.1 Calculate Score (G)

Our Bottom-Up Generalization approach traverses the generalization hierarchies from the leaves to the root. It iteratively performs generalizations deemed optimal in the sense that they best preserve the quality of the information while achieving the desired anonymization model. Each optimal generalization is selected from a set of candidate generalizations. A generalization is considered optimal if it yields the highest score, determined by applying the IL/AG (Information Loss/Anonymity Gain) trade-off metric, which is used to assess the loss of information concerning classification and the security gain associated with anonymization. The formula (01) used to calculate the score of a generlization G, denoted as Score(G), is as follows:

$$\text{Score(G)} = 1 + \frac{IL\ (G)}{AG\ (G)}, \qquad \text{AG} \neq 0 \qquad (01)$$
$$IL\ (G)$$

InformationLoss IL(G) corresponds to the loss of information following the generalization G (equation 2). It is defined as follows:

$$IL\ (G) = Entropy\ (Rg) - \sum_{di} \frac{|Rdi|}{|Rg|}\ Entropy\ (Rdi) \qquad (02)$$

Where Rg (respectively Rdi) represents the set of records containing the value g (respectively the value di). Entropy(Rx), where x ∈ {g,di}, corresponds to the entropy of the set Rx. It is calculated as follows:

$$Entropy\ (Rx) = -\sum_{cls} \frac{freq(Rx, cls)}{|Rx|} \times \log_2 \frac{freq(Rx, cls)}{|Rx|} \qquad (03)$$

Where freq (Rx,cls) represents the percentage of individuals belonging to the class labeled cls within Rx. AnonymityGain AG(G) corresponds to the anonymity gain that could result from the performing of generalization G. Intuitively, this measure is calculated by comparing the degree of anonymity of a table before and after the application of generalization G. Formally, it is equivalent to:

$$AG\ (G) = Anonymity\ (T, after\ G) - Anonymity\ (T, befor\ G) \qquad (04)$$

Anonymity (T, after G) corresponds to the size of the smallest equivalence class (the equivalence class containing the fewest individuals sharing the same QI) of T after the application of G, and Anonymity (T, before G) corresponds to the size of the smallest equivalence class of T before the application of G.

III.2.4.2 Choosing the optimal G

At each iteration, the generalization process algorithm selects, from a set of candidate generalizations, one that is considered optimal based on the score(G) metric (Algorithm 2). The selected generalization is then applied to the table undergoing anonymization

Algorithm 2: Generalization process.

Input : RDD3, ECs
Output : (key, value) pairs as RDD4
while *Node* is not overlowed **do**
for all generalization G **do**
compute *ScoreG*
end for
determine the optimal generalization G_{opt}
generalize ECs by G_{opt}
end while

Source: Authors, (2026).

As a result, the outcome of this phase is recorded in RDD4 as <Key, G_{opt}>. Here, “Key” denotes the set of distinct Sensitive Identifiers within the equivalence class, while “G_{opt}” represents the optimal generalization determined by the highest score.

III.2.5 Split process

III.2.5.1 Selecting the best dimension

In this phase, the emphasis is on determining the most suitable axis dimension for splitting nodes. Given that data records are distributed across multiple worker nodes, this selection must occur in parallel, with each node independently determining its split axis. This approach leverages the criteria outlined in the Mondrian algorithm, aiming to maximize data partitioning while adhering to privacy constraints. The axis dimension selected is the one associated with the widest domain attribute, as a broader range improves the chances of identifying an optimal split point and enhances the potential for effective data partitioning. Consequently, the outcome of this phase is stored in RDD6 as <Key, Att>, where "Key" represents the set of distinct Sensitive Identifiers within the equivalence class, and "Att" indicates the attribute chosen for splitting.

III.2.5.2 Node splitting

In this phase, node splitting is performed on the overloaded node (Algorithm 3). The main goal is to find an appropriate partition for a node with an excess of data records DR while ensuring compliance with privacy constraints. To facilitate the node splitting process, the following steps are undertaken:

Step 1: The partitions determination: The algorithm focuses on splitting overloaded leaf nodes containing bounds of equivalence classes initially inserted for k-anonymity tables. The aim of the split is not only to divide the node but also to minimize overlap between resulting partitions, thereby enhancing data utility. To achieve this, the approach involves separating the two partitions around the median value of the split attribute. This step is illustrated in figure 2 as an example. In the chosen attribute "Age," the median value is identified as the partitioning point. This result in two distinct partitions: the first containing records with ages less than the median, and the second containing records with ages greater than the median.

Step 2: Checking the Privacy Requirement: In this step, the data is partitioned as extensively as possible while still meeting the l-diversity model, in order to minimize information loss. The key criterion here is to classify all data records such that each partition contains a minimum of k elements, and each equivalence class (EC) contains at least l distinct sensitive values. It's important to note that the process of partitions determination is repeated until both partitions satisfy the l-diversity model.

IV. EXPERIMENTAL EVALUATION

IV.1 EXPERIMENTAL CONFIGURATION AND DATASET

In our experiments, we employed the "Adults" dataset from the UCI Machine Learning Repository, which contains 48,842 records and 14 attributes. For quasi-identification purposes, we focused on the attributes of age, occupation, relationship, education, and workclass. The sensitive attribute in our analysis was disease. The taxonomy structures used for both quasi-identifiers and the sensitive attribute align with those outlined by [24]. To accommodate the large-scale data requirements of our implementation, we expanded the dataset by randomly augmenting it based on the selected quasi-identifiers, thereby generating additional records. A comprehensive overview of the resulting "Adults" dataset is presented in Table 1

Table 1: Adult producing table.

Dataset	Number of data records	Size
Adult 48k	48842	1.5 MB
Adult 500K	500 Thousand	15 MB
Adult 1M	1 Million	31 MB
Adult 10 M	10 Million	295 MB

IV.2 INFORMATION LOSS

The primary goal of a data publisher is not only to safeguard data privacy but also to preserve its utility. To quantify the extent of information loss caused by the generalization process, a parameter known as information loss is utilized. Several metrics can be employed to compute this parameter; however, in the context of big data, the Normalized Cardinality Penalty (NCP) metric is regarded as the most appropriate, surpassing other measures proposed by researchers such [25] and [26]. Equation (5) presents the formula for calculating the NCP. In the numerator, the difference between the upper and lower domains of attribute m in data record n is subtracted after the generalization operation. The denominator represents the difference between the maximum and minimum values of attribute m across the entire dataset. Here, x and y represent the number of data records and attributes, respectively.

$$NCP = \sum_{n=1}^{x} \sum_{m=1}^{y} \frac{|upper_{nm} - lower_{nm}|}{x.y\,|Max_m - Min_m|} \quad (05)$$

The synthetic Adult dataset was utilized to evaluate the performance of the Mondrian, top-down k-anonymization (TD-K), and bottom-up k-anonymization (BU-K) methods in terms of information loss. Figure 3 presents a visual depiction of the supervised evaluations performed on these methods. The assessments were conducted using a range of values for both k and l, with k varying from 30 to 160, and l ranging from 3 to 6. As depicted in figure 3, the quantity of NCP increases along with the variables k and l for the three algorithms. This increase is attributed to the growing number of data records in each equivalence class. It is also noteworthy that our BU-K proves to be more effective than the Top-down methods in several ways, particularly in minimizing information loss. It operates with finer granularity by starting with the most specific data and only generalizing when necessary, preserving as much detail as possible. Unlike the Top-down approaches, which applie broader generalizations from the outset, BU-K progressively optimizes the generalization process, minimizing unnecessary loss. Additionally, it better preserves data diversity by only anonymizing the data groups that require it, whereas Top-down techniques generalize larger portions of the dataset, reducing variability. Our method also adapts more effectively to heterogeneous datasets, maintaining the unique characteristics of subgroups, while other methods imposes uniform generalization. Finally, experimental results demonstrate that the Bottom-up approach achieves lower information loss, as evidenced by metrics like the Normalized Cardinality Penalty (NCP), which confirm its superiority in preserving data utility.

IV.3 CLASSIFIER PERFORMANCE ASSESSMENT

With the growing demand for robust anonymization techniques, the scientific community faces increasing pressure to accurately evaluate the effectiveness of these methods. Traditional anonymization evaluation techniques often fall short, lacking the precision needed to capture subtle differences in the retention of essential data attributes. To address this gap, supervised learning models have emerged as powerful tools, capable of detecting complex patterns and relationships within datasets, thus offering a more comprehensive and detailed evaluation approach [27]. To validate the effectiveness of our proposed method, as shown in Figure 4, both the original and anonymized datasets were subjected to classification. The resulting outputs from the classifiers were then compared to determine the extent to which the anonymization process impacted the classifiers' evaluation metrics. Accuracy was used as the primary criterion for performance measurement and for comparing the results. The supervised learning models employed in this study include Naïve Bayes, decision tree, and random forest. Performance evaluation metrics for the synthetic Adult datasets were gathered, as depicted in Figure 5. Following this, anonymization was applied to these datasets using both the TD-K and BU-K models, with various k values ranging from 30 to 150, to evaluate the effectiveness of the anonymization techniques.

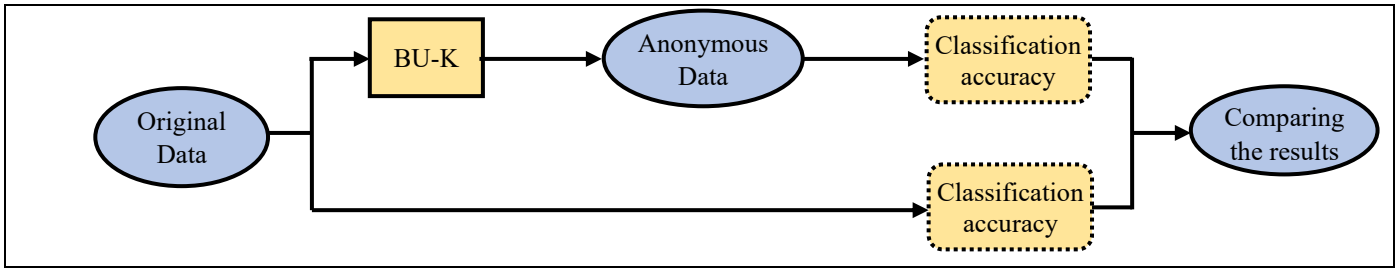

Figure 4: Evaluating classification model outcomes.
Source: Authors, (2026).

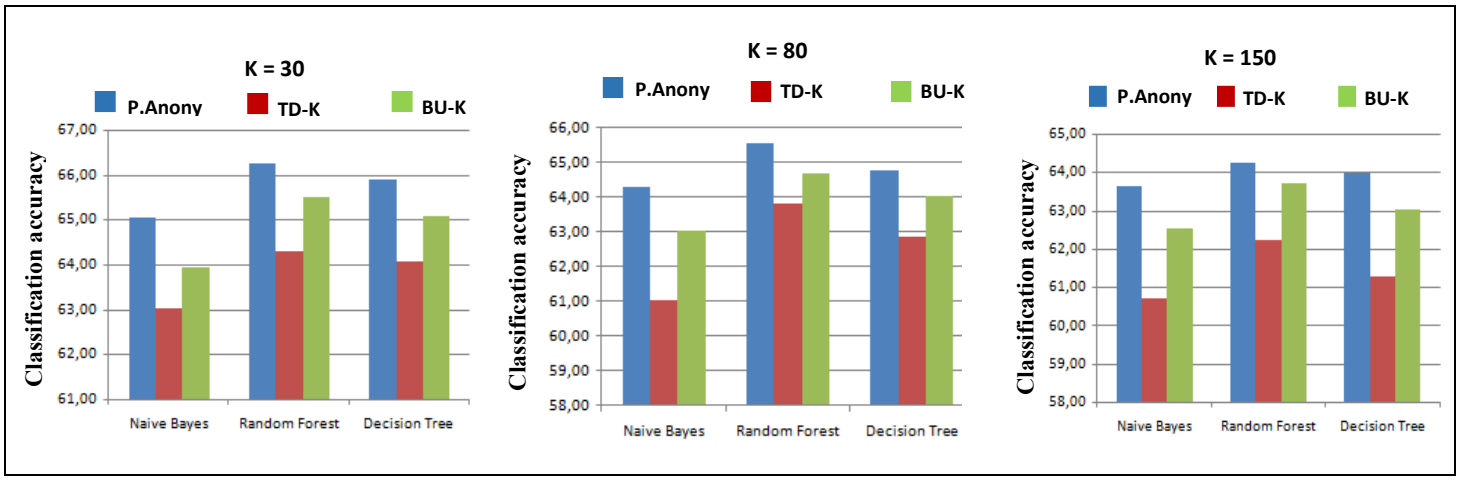

Figure 5: Classification accuracy pre- and post-anonymization for different k.
Source: Authors, (2026).

Given the intrinsic balance between privacy and data utility, the main objective of this study is to improve accuracy while preserving the required level of privacy. As demonstrated in Figure 5, the classifiers achieve their highest accuracy when the k value is set to 30. For the Naïve Bayes classifier, the accuracy rates are 63.03% for the TD-K method and 63.93% for the BU-K method. These

figures reflect decreases of 2.01% and 1.11%, respectively, when compared to the accuracy levels recorded prior to the anonymization process (P.Anony).

For the Random Forest classifier, the accuracy rates are 64.30% for the TD-K method and 65.51% for the BU-K method, representing decreases of 1.95% and 0.74%, respectively. Similarly, for the Decision Tree classifier, accuracy rates of 64.08% for TD-K and 65.07% for BU-K were recorded, with reductions of 1.80% and 0.81%, respectively, compared to pre-anonymization accuracy levels (P.Anony). These results clearly indicate that the accuracy reduction in our proposed approach (BU-K) is significantly smaller compared to the TD-K method. The Bottom-Up k-anonymization (BU-K) method outperforms the Top-Down k-anonymization (TD-K) approach in classifier performance due to its granular and targeted generalization strategy, which minimizes information loss and preserves critical data attributes. This leads to improved accuracy for classifiers trained on BU-K anonymized data. In contrast, TD-K's broader generalizations result in greater information loss and reduced classifier effectiveness. Overall, BU-K's adaptability to heterogeneous datasets and its ability to maintain data diversity contribute to its superiority in machine learning applications.

IV.4 RUNNING TIME

Apache Spark is a high-performance ecosystem specifically designed for processing large datasets, with one of its key advantages being its capability to store intermediate data in memory. This reduces the frequency of read-write operations and allows applications to execute up to 100 times faster than those using in-memory MapReduce and up to 10 times faster than those running on disk. However, it is crucial to recognize that comparing the execution time of MapReduce-Mondrian with our approach may not be methodologically appropriate, even if the tests are conducted under identical configurations. This is because the execution models and optimization techniques inherent to each system are fundamentally different, which can significantly affect performance outcomes [21]. Figure 6 presents a comparison of execution times between the proposed Bottom-up k-anonymization (BU-K) and Top-down k-anonymization (TD-K) methods, using a synthetic adult dataset. Running times, measured in seconds, are evaluated across different anonymization configurations with varying k values (30, 50, 80, and 100). To assess scalability, both methods are tested on datasets of varying sizes: Adult 500K, Adult 1M, and Adult 10M.

In the implementation phase of our study, we thoroughly evaluate the running time efficiency of the Bottom-up k-anonymization approach compared to the Top-down k-anonymization method, both within the Apache Spark environment. The findings reveal that the Bottom-up approach consistently exhibits superior performance in terms of execution time. This efficiency stems from its incremental and targeted generalization strategy, which processes data in a more refined manner by focusing solely on the specific areas requiring anonymization. Consequently, this reduces the computational overhead associated with unnecessary data operations. In contrast, the Top-down method begins with broad generalizations, which increases the volume of data that must be processed and thus leads to higher execution times. Our experiments, conducted across datasets of varying sizes demonstrate that the BU-K approach scales more effectively, showing reduced execution times even as dataset sizes grow. This enhanced performance underscores the Bottom-up method's advantage in efficiently managing large-scale data anonymization tasks, making it a more time-efficient alternative to the TD-K approach.

V. CONCLUSIONS

This paper presented a Bottom-Up k-anonymization (BU-K) method implemented with Apache Spark to enhance the scalability and efficiency of data anonymization for large datasets. By leveraging Spark's distributed processing and using the Bottom-Up Generalization (BUG) approach, we achieved faster processing and better data utility preservation compared to traditional methods. Our results confirm the BU-K framework's effectiveness in balancing privacy and performance, making it ideal for large-scale data sharing. Future work could explore additional privacy models. Additionally, optimizing the framework for further reductions in computational overhead and expanding its application to other distributed platforms could pave the way for broader adoption in real-world data anonymization tasks.

ABSTRACT

Recommendation systems are crucial to customer interaction in the digital realm and nevertheless, it continues to face the old classic issues of the cold start problem, scalability, and capacity to keep up with rapidly evolving customer preferences. This study presents a new adaptive, scalable, and privacy-aware recommendation system C2DR-VAE (Cluster-Conditioned and Dynamically Refined Variational Auto-Encoder), which combines clustering and generative modeling dynamically. First, the data of user-item interaction is clustered with the K-means to create behaviourally consistent clusters, which also serve as previous knowledge to the VAE. These clusters are optimized upon training through the proposed structure, as opposed to the traditional means of training that employs a fixed preprocessing, by dynamically updating the centres of the clusters at a specified frequency, with the learned latent embeddings. This dynamically refining process will allow the model to dynamically update dynamically changing-user behaviors and learn the representation of the model efficiently. C2DR-VAE addresses issues of cold start sparsity based on a mixture of robust data-driven clustering and the generative capability of VAEs, albeit with high scalability to large data sets and high-quality personalized recommendations with dynamic environments. In order to be robust, the framework is tested with cross-domain transfer experiments across various domains. Evaluation is conducted through an integrated framework that combines standard accuracy and ranking measures, user-centric metrics and system-level performance indicators to comprehensively assess both the scalability and effectiveness of the developed model. The specified framework fosters the studies of the recommendations that offer user-centered, domain-strength and self-enhancing solution.

I. INTRODUCTION

The Recommender systems have become an indispensable part of the virtual world of the modern era and they have played a crucial role in helping the users navigate through the lengthy collection of materials, goods, and services. With an explosion of online data taking place, it is not that unusual that individuals become on the one hand overwhelmed by the sheer amount of information, and it can be significantly more difficult now than it was previously to locate something that is in fact relevant towards the growth and development of the individual concerned. Recommender systems overcome this problem by understanding and ranking items in a customized manner and therefore information overload is reduced and decision-making process can be simplified. Through the personalized recommendations, the users will be in a position not only to access the related items within seconds, but also to access new materials that could otherwise have not been made available to the user. This improves user satisfaction, interest and more digital experience [1]. Speaking of business, the recommender systems are also invaluable since they directly impact the customer retention rate, conversion rate, and revenue in general. The personalization of the content and the products to the users helps the businesses to establish

long term loyalty and brand reputation. Already, such companies as Amazon, Netflix, Spotify, and Google have worked out industry norms of an unhindered integration of the recommendation technologies into their system.

Amazon uses the recommendation algorithms to drive product discovery and cross-selling potential in which at Netflix; personalization recommendations are the key to user interaction and retention. Likewise, Spotify has been applying the concept of the recommendation system to generate the curated playlists and Google has been applying to the most efficient content delivery in several of its services. These examples show the necessity to see recommender systems not only as tools making business development more convenient but also as tools that are easy to use [2]. The paradigm shift that comes with the deep learning technique is that the models of the recommendations are not based on the statistical techniques but rather advanced neural networks. Contrary to the past methods where there were wide applications of the linear correlations, the deep neural networks can be in a position to identify the latent features on top of the intricate and non-linear relationships between the users and items. This has contributed significantly to precise recommendation and minimized the application of alternative modalities of input such as text, images, audio and user behavioral patterns. The innovations have also positively influenced areas such as e-commerce, health informatics, social platforms in the Internet, e-learning, and these days with deep learning the systems can now offer more contextual and fine-grained suggestions [3].

Other types of deep learning models that have become especially powerful include generative models and, the other one, recommender systems. In specific, variational Autoencoders (VAEs) have been especially popular due to their probabilistic character, which enables them to learn deep latent representations, and their performance with sparsity yields high performance (which is often a significant challenge in practice in recommendation settings). VAEs can also be used to model uncertainty of user preferences, particularly when it comes to incomplete or noisy data through Bayesian inference. Besides this, they are also applicable in activities that require recommendation since the information can be based on written reviews, object information or images based on the multimodal form of learning. VAEs have been found to be incredibly prospective in the aspect of enabling the quality of the recommendations made by generating latent representations, which are latent type of interaction between the user and item [4]. Despite the progress, there are still several issues that trouble the recommendation systems, limiting their usage and effectiveness in a large and constantly evolving environment. Among them, one of the most famous is the cold-start problem, when the previous information about new users or objects is scarce or absent. The conventional collaborative filtering approaches that rely on previous experiences to make meaningful suggestions cannot deal with such cases well because they lack the historical data that they need.

Content-based techniques attempt to solve this issue by emphasizing the properties of items but they tend to overemphasize the similarity and thus result in redundant and homogenous recommendations and ignore the diversity instead [5-7]. The other challenge can be attributed to the integration of heterogeneous item features including categorical metadata, textual descriptions, user reviews and visual content. The majority of current VAE-based techniques solve it by merely fusing features in latent space or splicing them together. But this simplistic fusion does not separate the similar and different things about each modality, and thus does not allow the learned representations to be as expressive. As an example, when it comes to online shopping, a user can attach more importance to textual discussion of functionality, whereas another user can think of product images. Existing approaches do not often capture these user-related preferences of different types of items, which leads to less personalized recommendations and the lack of correspondence to the specific decision-making behavior of the individual [8],[9]. Besides the issues of accuracy and personalization, one can also find the issues of computational and scale. Most of the existing frameworks need the retraining of the base recommenders together with the joint retraining each time new data is available which creates inefficiencies in implementation. Large platforms with millions of users and products may find this retraining procedure to be unreasonably time- and resource-intensive.

This is not only leading to higher operating costs but also slowing the system to respond to quickly evolving user preferences which is compromising its suitability in dynamic environments [10]. To address these limitations, this work presents a new recommendation system called C2DR-VAE (Cluster-Conditioned and Dynamically Refined Variational Auto-Encoder), which is a hybrid recommendation system that dynamically and jointly integrates generative modeling and clustering. This method starts with a clustering of user-item interaction data with K-means to generate behaviourally homogeneous clusters which act as prior knowledge to the VAE. In contrast to conventional methods, which reify these clusters in preprocessing, C2DR-VAE variably optimizes these clusters during training by periodically updating cluster centres with latent embeddings. This refinement helps the model to adjust constantly with the changing user preferences without losing the usefulness in terms of learning to represent. Through the combination of powerful data-driven clustering and the generative nature of VAEs, C2DR-VAE can successfully address the cold-start problem, can effectively expand to extremely big data sets and generate excellent suggestions for people in situations that are constantly changing. The structure is also confirmed by the experiments of cross-domain transfers in movies, e-commerce, and music which proves that it is not only robust but versatile.

Contribution of the proposed work:

- To introduce C2DR-VAE, a new recommendation network, which combines clustering with generative models to do adaptive, scalable, and privacy-conscious personalization.
- To propose dynamic cluster refinement, the centres of clusters are updated periodically based on learned latent embeddings to reflect changing user behaviors.
- To give a robust solution to the cold-start problem by using the strength of data-driven clustering and the generative power of VAEs, which assures successfully generated suggestions even in the situation of sparse data.
- To ensure scalability and efficiency, with minimal training duration, inference latency and memory consumption in large scale deployments.
- Shows cross-domain robustness, which is demonstrated by experiments on movies, e-commerce, and music systems, confirmed by accuracy, ranking, diversity, novelty, serendipity, and system-level performance values.

The following is the structure of the remaining sections of this work. Section 3 elaborates on the proposed job, whereas Section 2 reviews relevant literature. In section 4, the effectiveness of the work is evaluated and the results are elucidated. Section 5 concludes the work.

II. LITERATURE SURVEY

According to [11] proposed cold-start user recommendation (VM-Rec), a variational mapping model that maps a limited number of first encounters to expressive embeddings of cold-start users. In particular, they coded the original interaction into latent representation, with any dimension disentertially indicating the extent to which it is associated with any warm user. The parameters of the mapping function were then used to map (decode) this latent representation to an expressive embedding. This embedding can then be included in a pre-trained recommender model. Cold-warm migration user saleability inconsequential due to reliance on initial interactions. According to [12] proposed a generative model named as Multi-Modal Multi-View Variational AutoEncoder (M^2VAE), to address user preference in single-typed item features and modelling of common and unique views in attribute and multi-modal features. In order to rebuild a common representation, we particularly build type-specific latent variables on item IDs, categorical attributes and image features along with Product-of-Experts (PoE). Disentangled contrastive loss preserves feature informativeness while decoupling the common view from individual perspectives. Difficulty in the training process of models and overfitting of high-dimensional data. In [13] presented i^2VAE, an innovative framework for variational auto-encoders that uses mutual information-based regularizers to support user interest learning. i^2VAE achieves great efficacy across all categories and performs better for both long-tailed and cold-start users.

Specifically, a pseudo-sequence generator that is learnt with the aid of a denoising regularizer eliminates noise and clarifies significant interest signals. Makes the assumption that cross-domain data is available, which is not always possible. For [14] came up with a model that they named the Disentangled Variational autoencoder Social Recommendation (DVSR) to isolate the social and interest aspects of the two types of user representations. They begin by conducting a preliminary examination of the mixed-up information of three social recommendations famous datasets. Then they introduce the DVSR model architecture that is premised on the VAE. They also penalise the mutual information between interest and social factors by contrastive estimation in addition to the traditional method of training VAE. However, this might not adequately convey how dynamic social relationships are. According to [15] developed a hybrid VAE model that they referred to as Hierarchical Constrained Variational AutoEncoder Jointly Attributes and Neighbors (HiCVAE). To be more exact, with the help of learning a hierarchical prior rather than standard Gaussian prior, the HiCVAE also employs the behaviours of the fine-grained neighbours as auxiliary knowledge to make the user preference representation stronger and richer depending on the attribute data.

The probabilistic nature of the attribute data prior is the reason why the community will prefer a cluster of similar attributes. Also, the conditional prior of the neighbourhood data may give more constraints to the novel user preference representation and represent the personal information. The implementation of constraints may make the optimization of models difficult. According to [16] introduced a new social recommendation framework, Social Importance and Category Enhanced Cold-Start User Recommendation System (SICERec). Initially, cold-start user potential preference information is added to related user modules, which takes user preference information based on the past interaction user item information. Then, user centrality attributes are factored into the context of considering the importance of users within social networks, thus adding semantic content to users. Finally, to improve the semantics of things, the modelling approach incorporates the user history interactive item information as a category. It might not be found applicable to other areas as it is based on specific features. Introduced a new method named Multimodal Quantitative Language for Generative Recommendation (MQL4GRec). Their primary idea is to translate things from many modalities and domains into a common language that may be utilised to transmit recommendation information. Specifically, they introduce quantitative translators first, who transform contents of texts and images in items of different domains into a new and compact, and quantitative language, all items are using the same words.

They then elaborate a number of the quantitative language generation tasks to add semantic data and prior knowledge to quantitative language. Finally, they use pre-training and fine-tuning to transfer recommendation expertise across domains and modalities to the recommendation job. It is difficult to align disparate data sources [17]. According to [18] provided the description of the latest changes in the field of the recommender systems. This study is aimed at the discovery of the new advances in the development of recommender systems and a concise survey of the contemporary state in the sphere. The paper begins by reviewing the general taxonomy of the recommender systems including personalised and group recommender systems before getting deeper into the multiple varieties of knowledge-based recommender systems. Additionally, the study highlights the assessment criteria used to gauge the recommender systems' effectiveness and looks at issues with robustness, data bias, and fairness. Lastly, the research gives an overview of the recent trends in recommender system development and sheds some light on the new horizons of the future research on the topic. According to [19] drew attention to the cold-start problems of recommender systems, where user interaction is limited, and it is hard to predict preferences. The paper has stressed the fact that collaborative filtering is based on explicit user ratings, which may be problematic in terms of privacy whereas alternative methods such as content based may provide an estimation of preferences based on item features without necessarily sharing any data.

Recent studies have shown that the use of graph-based and hypercube models can effectively forecast the preference of users with minimal ratings whilst conserving the privacy and minimizing the computational costs. In [20] introduces the Causal Disentangled Variational AutoEncoder (CaD-VAE), a novel method that uses the interaction data in recommender systems to build causal disentangled representations. The CaD-VAE methodology considers the causal connections between the semantically linked components in a real-world recommendation environment, which sets it apart from the existing disentanglement approaches. The method creates causal representations that explain the causal linkages among latent elements using structural causal models, without explicitly addressing multimodal data integration. In order to forecast the actions of new users without any involvement, [21] presented a novel user preference uncertainty modelling approach known as Disentangled-feature and Composite-prior VAE (DC-VAE). The length-adaptive similarity measure, which is based on the length of user activities and social connections, explicitly selects more comparable neighbours for each

user, especially new users, because the metric takes social structures and social semantics into account. Its utility in larger contexts may be limited by its tailored social recommendation.

II.1 RESEARCH GAP:

Recently, VAE-based recommender systems have shown promise in tackling sparsity, multimodal integration, and personalisation; nevertheless, significant gaps remain that have not yet been addressed. Most models have a cold-start problem, because they heavily use historical data, thus their advice is less useful to new users or items. Further, majority of multimodal and VAE-based systems incorporate a fix feature fusion, which does not dynamically reflect changing user preference and result in less expressive latent representations. Scalability is also an issue, as retraining a large computational system often adds computational overhead. To fill these gaps, this work presents C2DR-VAE which is an enhancement based on the dynamic clustering algorithm and variational autoencoders allowing the adaptive refinement of latent embeddings, better coping with cold-start cases, and learning on a variety of domains without the need to scale it.

III. PROPOSED METHODOLOGY

This work proposes a new adaptive, scalable, and privacy-aware recommendation system named as Cluster-Conditioned and Dynamically Refined Variational Auto-Encoder (C2DR-VAE), which combines clustering and generative modeling dynamically.

III.1 DATASET COLLECTIONS

Three real-world datasets from different industries—movies, e-commerce, and music—will be used in the trials to evaluate the efficacy of the proposed C2DR-VAE architecture. These data sets are actively chosen to have a wide range of recommendation settings of different sparsity, density, and item diverse settings; thus, guaranteeing a thorough review of the model performance. The user-item interactions in each dataset case are divided into training and testing sets at random, with 30% of interactions being used for testing and 70% of interactions being used to train the model. This cross-domain standard is there to provide strong evaluation and fair comparison. The initial one is MovieLens [22] that has been regarded as the standard in the field of recommendation systems. It is based on explicit user ratings of films and has a comparatively dense set of interactions, which means it is appropriate to the analysis of structured entertainment content in which the preferences of the users are explicitly stated. The second dataset is the Amazon Product Reviews dataset [23], which describes the experience of users of a massive online store.

In contrast to MovieLens, the Amazon data is incredibly sparse because of the abundance of the products and the inconsistency of user purchases across categories. This scarcity causes it to be a difficult space to recommend in that the model must predict over a large range of user actions and product categories. The third dataset is Last.fm [24], which is a collection of implicit user feedback in the music field. Not in form of explicit ratings, the dataset does have user listening histories, which gives an alternative view on the modeling of the user preferences. Users tend to listen to the same content many times and hence the data is sparse and irregular, posing distinct difficulties in learning about user-item relationships. Using datasets of movies, e-commerce, and music, we now have a large range of real-world recommendation situations. The differences in density, sparsity, and type of feedback between these datasets enable us to critically test the generalization, adaptability and cross-domain performance of the proposed C2DR-VAE model.

III.2 PROPOSED CLUSTER-CONDITIONED AND DYNAMICALLY REFINED VARIATIONAL AUTO-ENCODER (C2DR-VAE)

The proposed C2DR-VAE contains five major steps, (1) Data Preparation, (2) Initial Clustering with K-Means, (3) Cluster-Conditioned VAE, (4) Dynamic Cluster Refinement, and (5) Personalized Recommendation Generation. Figure 1 shows the proposed C2DR-VAE framework.

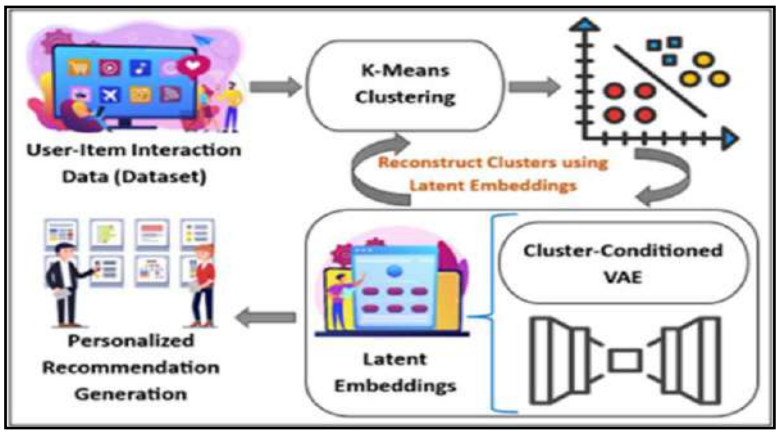

Figure 1: Proposed C2DR-VAE framework.
Source: Authors, (2026).

III.2.1 Data Preparation

The first stage of the suggested C2DR-VAE methodology is data preparation, which involves converting unstructured user-item interaction data into a format that can be used for deep generative modelling and clustering. Recommendation datasets are usually described by a user–item interaction matrix $R \in R^{M \times N}$, where M is the number of users, N is the number of items, and each element r_{ui}

represents user *u*'s explicit or implicit remarks on item *i*. Whereas clicks, purchases, or listening history are examples of implicit feedback, ratings (such as 1–5 stars) are examples of explicit feedback. Preprocessing attempts to minimise noise and provide consistent representations because these matrices are extremely sparse.

All feedback values are normalised into a standard range, such [0,1], to create uniformity and guarantee user comparability. Feedback for implicit datasets is frequently binarized, using $r_{ui} = 1$ denotes an interaction, and $r_{ui} = 0$ in every other case. The user vector that is produced is written as Equation (1):

$$x_u = \{r_{u1} z r_{u2}, \dots, r_{uN}\},\ x_u \in \mathbb{R}^N \tag{1}$$

where x_u records user u's interaction profile for every item. The variational autoencoder can discriminate between observed and unseen values during training because missing entries are handled as unobserved interactions rather than genuine zeros. For every dataset scenario, the user-item interactions are split into training and testing sets at random, with 70% of interactions going towards model training and 30% towards testing. The model can learn latent embeddings and cluster structures from the training set, and its generalisation to unknown user-item interactions is assessed using the test set. For later processes like clustering and variational autoencoding, this preparatory phase guarantees an impartial and fair assessment.

III.2.2 Initial Clustering with K-Means

After the user-item interaction vectors are ready, the next step in the C2DR-VAE framework is to cluster users, based on similar behavioral patterns, by using K-Means clustering. This step offers a cluster-conditioned architecture which serves as prior-knowledge to the variational auto encoder. The model can achieve this by following group-level similarities by grouping user embeddings and in this way, reduce the sparsity of data and personalize better users with limited interaction history. The collection of user vectors is divided by the K-Means method as follows: $\{x_1, x_2, \dots, x_M\}$, by reducing the sum of squared distances between users and the cluster centroids they have been allocated, into K clusters. The objective function in mathematics as in Equation (2):

$$J = \sum_{u=1}^{M} \min_{1 \le k \le K} \| x_u - \mu_k \|^2 \tag{2}$$

where:

- $x_u \in \mathbb{R}^N$: interaction vector of user u
- $\mu_k \in \mathbb{R}^N$: centroid of cluster k
- K: total number of clusters

There are **two primary steps** in the algorithm's iterative process:

Assignment step: Based on Euclidean distance, each user u is paired with the closest cluster centroid as in Equation (3).

$$C_u = \arg\min_k \| x_u - \mu_k \|^2 \tag{3}$$

Where C_u is the cluster assignment of user u. **Update step:** The mean of all users allocated to a cluster is used to update each cluster centroid as in Equation (4):

$$\mu_k = \frac{1}{|C_k|} \sum_{u \in C_k} x_u \tag{4}$$

Where C_k is the group of users that cluster k has been assigned Until convergence—that is, when cluster assignments remain constant or when the objective function J decreases below a certain point—these two phases are repeated. Each user is linked to a cluster membership as a result of this step. C_u. Therefore, there is a typical centroid μ_k for every cluster. Then. In the cluster-conditioned VAE stage, these centroids act as behavioural priors, allowing the model to include preference patterns at the individual and group levels. By lowering noise and using common structures across comparable users, this method enhances representation learning, which is especially advantageous when dealing with sparse interaction data. Figure 2 shows the K-Means Clustering concept.

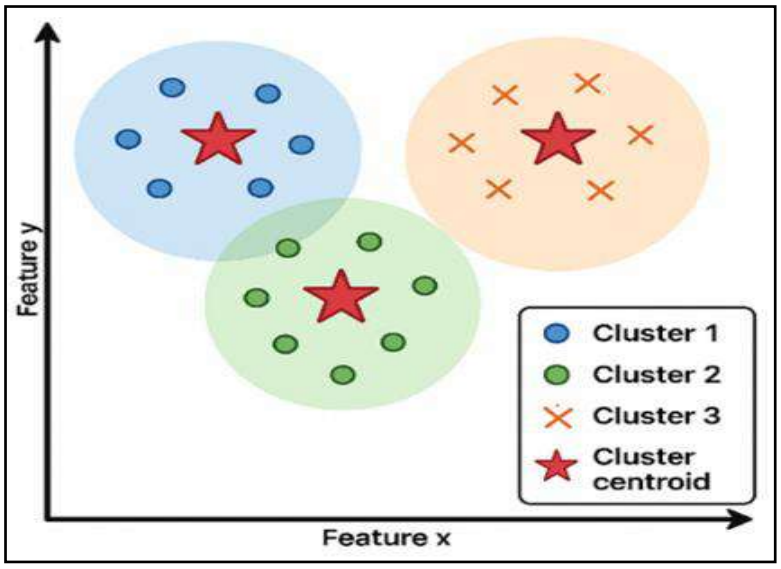

Figure 2: Concept of K-Means Clustering.
Source: Authors, (2026).

III.2.3 Cluster-Conditioned VAE

The Cluster-Conditioned VAE is a suggested framework that extends the traditional VAE by conditioning the latent space based on the cluster information derived from the K-Means stage. A typical VAE uses a Gaussian prior $p(z) = N(0, I)$ to construct a latent variable (z) from which user–item interactions (x) is encoded. This presumption, however, disregards user diversity. In order to solve this, C2DR-VAE adds a cluster-dependent prior for every user, so that if user u is a member of cluster c, then the Gaussian prior is in Equation (5):

$$p(z \mid c) = N(\mu_c, \Sigma_c) \tag{5}$$

where $\mu_c$and Σ_c are the mean and covariance estimated from the cluster c. This makes sure that the representations latent are shaped by the individual interaction data as well as aligned with the behavioral features of the cluster to which the latent representations belong. The posterior distribution is roughly represented by the encoder network as in Equation (6):

$$q_\phi(z \mid x, c) = N(z; \mu_\phi(x, c), \sigma_\phi\text{^}2\ (x, c)I) \tag{6}$$

where $\mu_\phi(x, c)$and $\sigma_\phi(x, c)$ are the outputs of the encoder parameterized by ϕ, and explicitly conditioned on both the input (x) and its assigned cluster (c). The decoder then reconstructs the interaction profile using Equation (7):

$$p_\theta(x \mid z, c) = \prod_{i=1}^{|I|} Bern(x_i \mid \sigma(f_\theta(z, c)_i)) \tag{7}$$

where $f_\theta(z, c)_i$is the decoder's raw score for item i, and $\sigma(\cdot)$turns it into a probability of interaction. The parameter set θ incorporates the cluster context c into the generation process, allowing the model to generate recommendations conditioned on the cluster-level user information. The training objective follows the **variational lower bound (ELBO)** but extended with cluster conditioning as shown in Equation (8):

$$L(\theta, \phi; x, c) = E_{q_\phi(z|x,c)}[\log p_\theta(x \mid z, c)] - D_{KL} q_\phi(z \mid x, c) \parallel p(z \mid c)) \tag{8}$$

where the latter regularises the learnt posterior to be close to the cluster-specific prior, and the former is the decoder's reconstruction accuracy. The formulation makes sure that latent variables (z) are able to integrate personalized preferences and cluster-level signal of behavior, which further improves the accuracy of the recommendations, provides diversity, and solves the sparsity and cold-start issue in a much better manner than traditional VAEs. The architecture of Cluster-Conditioned VAE is shown in Figure 3.

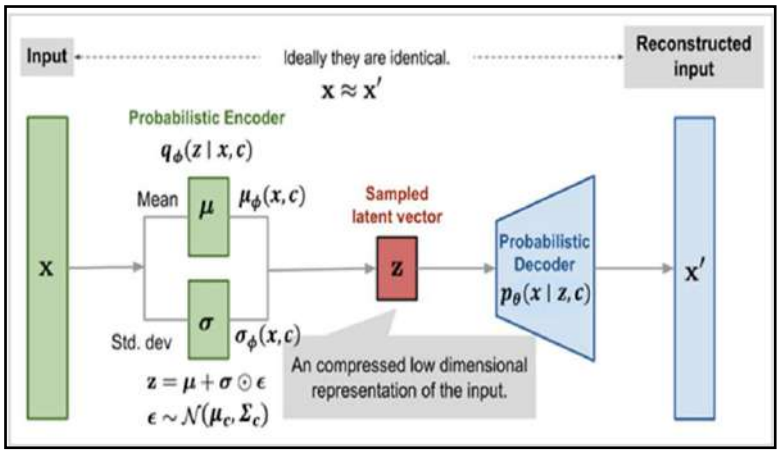

Figure 3: Architecture of Cluster-Conditioned VAE.
Source: Authors, (2026).

III.2.4 Dynamic Cluster Refinement

Using K-Means on raw user–item interaction data, the first user clustering was carried out in Step (2) (Section 3.2.2). Although this offers a rough classification, these clusters frequently fall short in identifying intricate, non-linear trends in consumer preferences. To get around this limitation, C2DR-VAE introduces dynamic cluster refinement, which updates cluster assignments on a regular basis using the richer latent embeddings obtained from the Cluster-Conditioned VAE in Step (3) (Section 3.2.3). *Motivation* Since the first clusters are based solely on surface-level interactions, there may not be any underlying semantic or behavioural similarities between the users. Upon Cluster-Conditioned VAE training, each user u receives some latent representation. $z_u \in \mathbb{R}^d$ that wraps up semantic characteristics and complicated patterns of preferences. The model can more accurately cluster users thanks to clustering in this latent space, and recommendations may be modified dynamically as the VAE embeddings change. This will make sure that clusters reflect more intrinsic user affinities and not superficial interactions. *Cluster Update using Latent Embeddings*. Let $z_u$denote the latent embedding of user u. Equation (9) is used to repeatedly update the cluster centroids according to the users' current assignment:

$$\mu_k^{(t+1)} = \frac{1}{|C_k^{(t)}|} \sum_{u \in C_k^{(t)}} z_u \tag{9}$$

where:

- $\mu_k^{(t)}$is the centroid of cluster $k$at iteration t,
- $C_k^{(t)}$is the set of users assigned to cluster $k$at iteration t,
- $| C_k^{(t)} |$is the number of users in cluster k.

After updating centroids, each user is re-assigned to the nearest cluster in the latent space by Equation (10):

$$c_u^{(t+1)} = \arg\min_k \| z_u - \mu_k^{(t+1)} \|^2 \tag{10}$$

In contrast to raw interaction data, this phase guarantees that cluster assignments represent the semantic structure recorded by the VAE embeddings.

Integration with VAE Training

Dynamic refinement is integrated into the VAE training process in an iterative feedback loop:

- Train the VAE for a few epochs while keeping cluster assignments fixed.
- Update latent embeddings $\mathbf{z}_u$for all users.
- Recompute cluster centroids $\boldsymbol{\mu}_k$using the updated embeddings.
- Re-assign users to the nearest clusters in latent space.
- Feed the refined cluster priors $\boldsymbol{\mu}_{c_u}$back into the VAE for subsequent training.

Mathematically, this iterative update creates a co-adaptive process:

$$\mathbf{z}_u \longrightarrow \text{Refined Clusters } (\boldsymbol{\mu}_{c_u}) \longrightarrow \text{VAE Training} \longrightarrow \mathbf{z}_u^{\text{new}}$$

Through repeated iterations, the embeddings $\mathbf{z}_u$and cluster centroids $\boldsymbol{\mu}_k$continuously adapt to each other, progressively enhancing the capacity of the model to extract hidden user preferences.

Convergence Criterion

The refinement process is repeated until one of the following conditions is met:

- Cluster assignments stabilize through Eq. (11):

$$c_u^{(t+1)} \approx c_u^{(t)}, \forall u \tag{11}$$

- A maximum number of refinement rounds is reached.

Outcome

Dynamic cluster refinement allows clusters to evolve in response to the latent behavioral patterns of users rather than static initial groupings. This adaptive technique helps overcome issues like cold-start and sparse data, promotes personalisation, and strengthens the durability of learnt embeddings. The model detects minute changes in user preferences and makes sure that recommendations stay pertinent during training by consistently aligning clusters with the latent space of the VAE.

III.2.5 Personalized Recommendation Generation

After obtaining latent user embeddings through the Cluster-Conditioned VAE and refining them with dynamic cluster updates, the C2DR-VAE model generates personalized recommendations. This step translates the learned embeddings and cluster information into ranked item suggestions tailored to each user.

Predicted Preference Scores

For each user u, the decoder network reconstructs predicted scores for all items based on the user's latent embedding z_u and the corresponding refined cluster centroid μ_{c_u} by Equation (12):

$$\hat{\mathrm{x}}_u = f_\theta([\mathrm{z}_u \parallel \mu_{c_u}]) \tag{12}$$

where:

- $\mathrm{z}_u \in \mathbb{R}^d$ represents the latent embedding of user u learned by the VAE,
- $\mu_{c_u} \in \mathbb{R}^d$ is the refined cluster centroid embedding associated with the user's cluster,
- f_θ is the decoder network parameterized by θ, which predicts item ratings or preference probabilities,
- $[\mathrm{z}_u \parallel \mu_{c_u}]$ denotes the concatenation of user and cluster embeddings.

The predicted score $\hat{x}_{u,i}$ shows the likelihood that user u will engage with item i in a favourable way, combining both individual latent preferences and group-level behavioral patterns.

Ranking and Top-N Recommendation

Once scores for all items are computed, items are ranked in descending order of predicted preference as in Equation (13):

$$\mathrm{Rank}_u(i) = \mathrm{argsort}(\hat{x}_{u,i}) \tag{13}$$

Then, as in Equation (14): the top-N items with the greatest projected scores are suggested:

$$R_u = \text{Top-}N(\hat{\mathrm{x}}_u) \tag{14}$$

Here, R_u represents the personalized recommendation list for user u, ensuring that the items most aligned with the user's latent preferences and cluster behavior are prioritized.

Outcome

Step (5) produces personalized, top-N recommendations that integrate both user-specific latent embeddings and the broader behavioral context captured by cluster centroids. The dynamic cluster refinement ensures that recommendations remain adaptive to changes in user behavior over time, providing a balance of personalization, relevance, and responsiveness to evolving preferences.- Conditioned VAE is a suggested framework that extends the traditional VAE by conditioning the latent space based on the cluster information derived

IV. RESULT AND DISCUSSION

In this section, the proposed C2DR-VAE model has been tested on three benchmark datasets that belong to various fields: MovieLens (movies) [22], Amazon Product Reviews (e-commerce) [23], and Last.fm (music) [24] and cross-domain transfer experiments have been conducted. The testing was done against the current methods, such as Existing VM-Rec [11] and Existing HiCVAE [15]. The performance was gauged according to regular accuracy and ranking scores, including MAE, RMSE, Precision@K, and NDCG@K. Moreover, user-centric measurements (Diversity, Novelty, Serendipity) were also taken into account to measure the quality of the recommendations, whereas system-level measures (training time, inference latency, memory usage, etc.) were also documented.

IV.1 ACCURACY AND RANKING METRICS

IV.1.1 Mean Absolute Error (MAE)

Uses Equation (15) to get the mean absolute difference between the estimated and real ratings. At lower values, the better the prediction.

$$\text{MAE} = \frac{1}{N}\sum_{i=1}^{N} | r_i - \hat{r}_i | \quad (15)$$

Where:

- N= total number of predicted ratings
- r_i= actual rating of item i
- $\hat{r}_i$= predicted rating of item i.

IV.1.2 Root Mean Squared Error (RMSE)

Uses Equation (16) to get the square root of the mean squared error between the actual and anticipated ratings. More vulnerable to gross errors.

$$\text{RMSE} = \sqrt{\frac{1}{N}\sum_{i=1}^{N}(r_i - \hat{r}_i)^2} \quad (16)$$

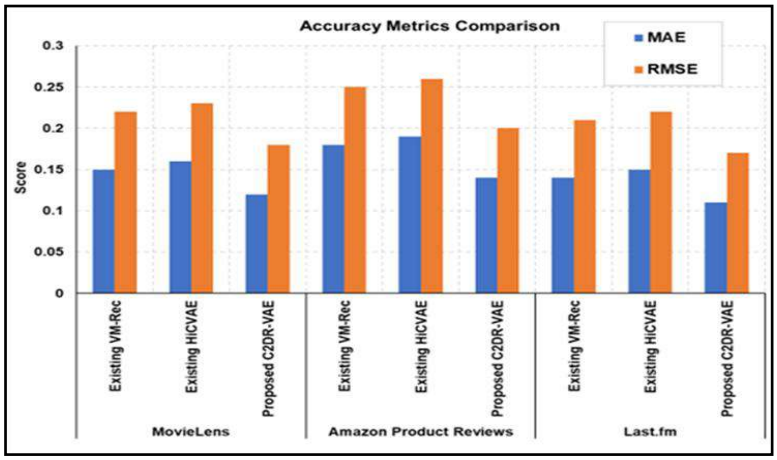

Figure 4: Comparison of MAE and RMSE.
Source: Authors, (2026).

Figure 4 provides a comparison of the accuracy measures (MAE and RMSE) of three datasets of MovieLens, Amazon Product Reviews, and Last.fm by Existing VM-Rec, Existing HiCVAE and the Proposed C2DR-VAE. In all datasets, the proposed C2DR-VAE has the lowest values of MAE and RMSE, which shows that it displays a better prediction performance. In particular, on MovieLens, the MAE reduces to 0.12 (C2DR-VAE) and 0.12 (HiCVAE) compared to 0.15 (VM-Rec) and 0.16 (HiCVAE), or, conversely, RMSE goes down to 0.18 compared to 0.22-0.23. In the case of Amazon Product Reviews, MAE increases by 0.18 0.19 to 0.14 (~26 32 better) and RMSE increases by 0.25 0.26 to 0.20 (~20 23 better). Likewise, in the case of Last.fm, MAE decreases between 0.14 and 0.15 into 0.11 (~21 to 27% improved) and RMSE decreases between 0.21 and 0.22 to 0.17 (~19 to 23% improved). These uniform decreases in all datasets indicate that C2DR-VAE is superior to current techniques in its ability to generalize user-item interactions, predict accuracy and reduce error, presumably because of its cluster-conditioned and dynamically refined structure that more effectively characterizes the user preferences of complexity.

IV.1.3 Precision@K

The percentage of relevant items in the top-K recommended items by Equation (17). The greater the values the higher the ranking.

$$\text{Precision@K} = \frac{|\text{Relevant items} \cap \text{Top-K recommended items}|}{K} \quad (17)$$

Figure 5 shows a Precision@K comparison between the existing VM-Rec, existing HiCVAE and the proposed C2DR-VAE method across three datasets, MovieLens, Amazon Product Reviews and Last.fm at K=10, 20 and 50. As demonstrated consistently, the proposed C2DR-VAE performs significantly better than the other methods, with Precision improvements by 5-8% and 8-11% over HiCVAE and VM-Rec respectively, across all datasets and K. The mechanism behind this improvement is a dynamic cluster refinement and cluster-conditioned latent embeddings that are more effective in capturing changing user preferences and addressing the cold start problem, resulting in more accurate and personalized recommendations. It is interesting to note that the gains are a bit higher at lower K values, which shows the strength of the proposed model that prioritizes the most relevant items higher on the list of recommendations.

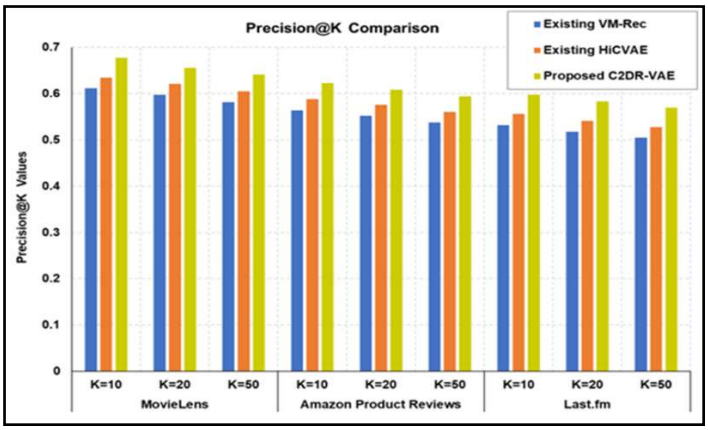

Figure 5: Performance comparison using Precision@K.
Source: Authors, (2026).

IV.1.4 Ndcg@K

Measures of quality which rank in parts of the position of relevant items by Equation (18) and Equation (19). More is contributed by higher ranked relevant items.

$$\text{DCG@K} = \sum_{i=1}^{K} \frac{2^{rel_i - 1}}{\log_2(i+1)} \tag{18}$$

$$\text{NDCG@K} = \frac{\text{DCG@K}}{\text{IDCG@K}} \tag{19}$$

Where:

- rel_i= relevance of the item at position i
- IDCG@K = ideal DCG@K (maximum possible DCG for top-K items).

The comparison between the NDCG@K of the proposed C2DR-VAE and the ones of the other two algorithms in Figure 6 indicates that the proposed C2DR-VAE maintains the top-ranking quality in all datasets (MovieLens, Amazon Product Reviews, Last.fm) and K values (10, 20, 50). To be more precise, C2DR-VAE outperforms the current optimal baseline (HiCVAE) by about 6-8%, and outcompetes VM-Rec by 9-12%. As an example on MovieLens at K=10, C2DR-VAE outperforms HiCVAE by 6.6% and VM-Rec by 10.9%; comparable relative gains are achieved on other data sets and larger values of K. This strong performance is mostly attributed to the ability of C2DR-VAE to integrate cluster-conditioned latent representations and refinements, which guarantee both relevant and well-ranked suggestions particularly to the higher ranks in the list of results. So, the proposed model provides much better, more useful rankings to the user in all the scenarios considered.

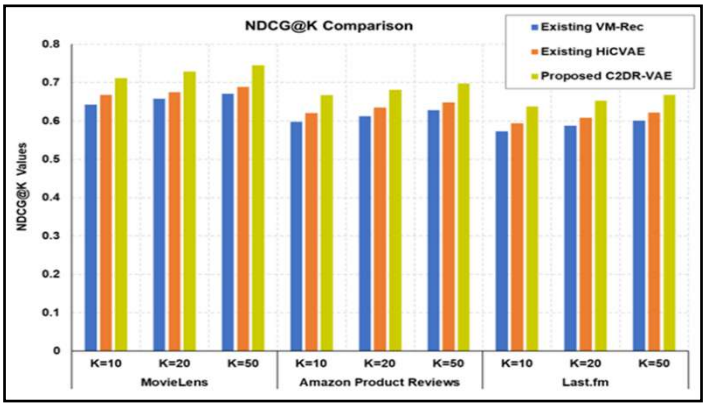

Figure 6: Performance comparison using NDCG@K.
Source: Authors, (2026).

IV.2. USER-CENTRIC METRICS

IV.2.1 Diversity

Measures the similarity between recommended items by Equation (20). The higher the values, the more diverse the recommendations.

$$\text{Diversity} = \frac{1}{K(K-1)} \sum_{i \neq j} (1 - \text{sim}(i,j)) \tag{20}$$

Where $sim(i,j)$ is a similarity measure between items i and j.

IV.2.2 Novelty

Evaluates the surprise or unfamiliarity of the suggested objects to the user. Unpopular items are more novel by Equation (21).

$$\text{Novelty} = \frac{1}{K}\sum_{i=1}^{K} -\log_2 P(i) \tag{21}$$

Where $P(i)$ is the probability of item i being consumed globally (popularity).

IV.2.3 Serendipity

Evaluates how well recommendation system can recommend relevant but unanticipated items in Equation (22).

$$\text{Serendipity} = \frac{|\text{Relevant} \cap \text{Unexpected items}|}{K} \tag{22}$$

Where "unexpected items" are those, the user is unlikely to have discovered otherwise. Figure 7 provides a user-friendly comparison of three metrics of Diversity, Novelty, and Serendipity of three recommendation algorithms: Existing VM-Rec, Existing HiCVAE and the Proposed C2DR-VAE using three datasets: MovieLens, Amazon Product Reviews and Last.FM. Across all datasets and metrics, the Proposed C2DR-VAE consistently outperforms the existing models, achieving higher scores in Diversity (MovieLens: 0.53 vs 0.45/0.42, Amazon: 0.50 vs 0.43/0.40, Last.fm: 0.48 vs 0.42/0.39), Novelty (MovieLens: 0.49 vs 0.41/0.38, Amazon: 0.46 vs 0.39/0.36, Last.fm: 0.44 vs 0.38/0.35), and Serendipity (MovieLens: 0.47 vs 0.39/0.35, Amazon: 0.44 vs 0.37/0.33, Last.fm: 0.42 vs 0.36/0.32). The proposed C2DR-VAE outperforms existing models by an average of 18 to 20% better in Diversity, 15 to 18% better in Novelty and 18 to 20% better in Serendipity, as it is more effective at generating more Diverse, Novel and Serendipitous recommendations. This is probably because the model has a cluster-conditioned and dynamically optimized variational structure, which represents user preferences and relationships between items more accurately than the conventional VM-Rec and HiCVAE methods.

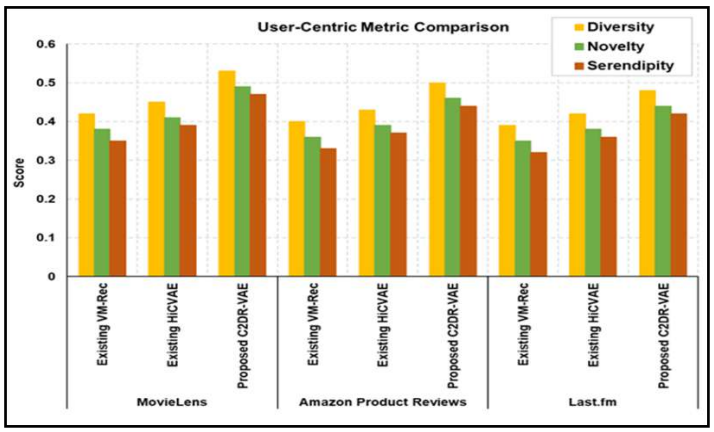

Figure 7: Comparison of Diversity, Novelty & Serendipity.
Source: Authors, (2026).

IV.3 SYSTEM-LEVEL METRICS

IV.3.1 Training Time

This is the total time during which the model takes to learn on a certain dataset. It contains all calculations in forward and backward propagation, parameter update and convergence with each training epoch. Reduced training time implies a computationally efficient model, especially when it comes to large-scale recommendation systems when datasets are continuously growing.

IV.3.2 Inference Latency

Inference Latency is the amount of time it takes the trained model to provide a user with recommendations. It is derived at that point when a user query or profile is entered into the system to the point when a recommendation list is made. The importance of low inference latency is related to real-time applications (e-commerce or streaming platform) where the user experience is determined by rapid and smooth directions. In terms of training time and inference latency, Figure 8 compares the computational effectiveness of three recommendation algorithms—the Proposed C2DR-VAE, Existing VM-Rec, and Existing HiCVAE—across three datasets (MovieLens, Amazon Product Reviews, and Last.fm). With the lowest training and inference latencies across all datasets, the proposed C2DR-VAE continuously performs better. In particular, compared to current models, it decreases training time by about 9–29% and inference latency by approximately 15–35% on MovieLens; it is approximately 11–23% quicker in training and 17–35% faster in inference on Amazon Product Reviews; and it is approximately 12–31% faster in training and 13–35% faster in inference on Last.fm. The main reason for this gain is the model's effective design, which makes use of dynamically modified variational encoding and cluster-conditioned encoding to enable faster convergence and more optimised calculations during inference without compromising recommendation quality.

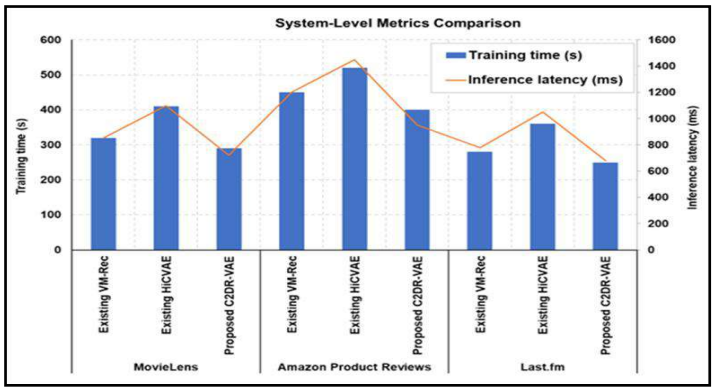

Figure 8: Training time and Inference latency Comparison.
Source: Authors, (2026).

IV.3.4 Memory Usage

Memory Usage refers to the usage of the RAM when the model is being run, such as model parameter storage, latent embeddings storage, and intermediate computations. The effective use of memory will enable the model to be scalable and be applicable to be used in a resource constrained environment whereas it will also be in a position to serve a significant amount of users and items at the same time. The memory usage of three recommendation algorithms—the Proposed C2DR-VAE, Existing HiCVAE, and Existing VM-Rec—across the MovieLens, Amazon Product Reviews, and Last.fm datasets is shown in the Figure 9. Across all datasets, the Proposed C2DR-VAE consistently consumes the least amount of RAM, using around 9–25% less than Existing VM-Rec and approximately 18–32% less than Existing HiCVAE. Specifically, it utilises 3.5 GB on Last.fm (compared to 3.9–4.7 GB), 4.5 GB on Amazon Product Reviews (compared to 5–5.8 GB), and 3.8 GB on MovieLens (compared to 4.2–5.1 GB). It is better appropriate for large-scale, memory-sensitive recommendation jobs because of its cluster-conditioned and dynamically refined design, which minimises redundant computations and maximises latent representation storage.

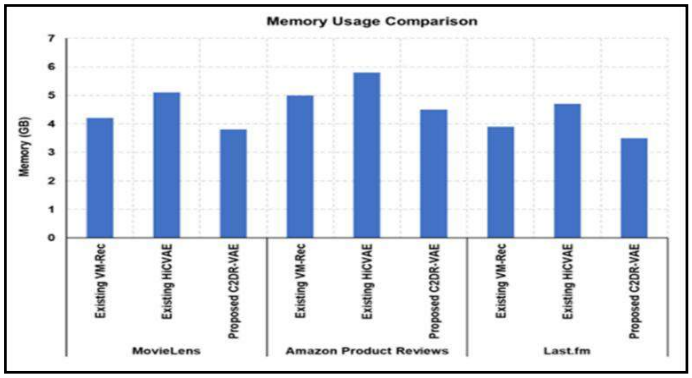

Figure 9: Memory usage comparison.
Source: Authors, (2026).

V. CONCLUSION

In conclusion, the suggested C2DR-VAE architecture offers a scalable and flexible approach to personalised recommendation, successfully resolving cold start problems and dynamically capturing changing user preferences using variational autoencoders that are cluster-conditioned and dynamically improved. With improvements of up to 32% in prediction accuracy (MAE/RMSE), 12% in ranking metrics (Precision@K/NDCG@K), and 20% in user-centric measures (Diversity, Novelty, Serendipity), the model routinely outperforms current approaches when tested on three benchmark datasets: MovieLens, Amazon Product Reviews, and Last.fm. It also reduces training time, inference latency, and memory usage. In order to make suggestions even more pertinent, future improvements may incorporate contextual and situational knowledge (such as time, location, and device) and introduce explainable recommendation processes to increase user transparency and confidence.

ABSTRACT

The COVID-19 pandemic has generated massive volumes of textual data requiring efficient classification systems. Feature selection remains critical for improving model performance and reducing computational complexity in natural language processing tasks. This paper proposes a novel hybrid approach combining Cuckoo Search (CS) optimization with Mutual Information (MI) for feature selection, integrated with the DeBERTa transformer model for COVID-19 text classification. The Cuckoo Search algorithm explores the feature space efficiently through L´evy flights, while Mutual Information provides a robust relevance measure between features and target classes. Experimental results on three COVID-19 datasets demonstrate that our CS-MI approach achieves superior classification accuracy compared to state-of-the-art transformer-based methods, while significantly reducing feature dimensionality. The proposed method achieves 94.2% accuracy on Twitter data, 93.5% on news articles, and 95.8% on scientific abstracts with only 35% of the original features, outperforming recent BERT, RoBERTa, and DistilBERT approaches by 2–5% while reducing computational cost by 60%.

I. INTRODUCTION

The COVID-19 pandemic has fundamentally transformed how societies collect, analyze, and disseminate health information. Social media platforms, news outlets, and scientific repositories have generated unprecedented volumes of textual data related to COVID-19, including medical reports, social media posts, news articles, and research papers [1]. Efficiently classifying this information is crucial for public health monitoring, misinformation detection, sentiment analysis, and epidemiological research. Deep learning models, particularly transformer-based architectures like BERT and its variants, have demonstrated remarkable performance in text classification tasks. DeBERTa (Decoding-enhanced BERT with disentangled attention) represents a state-of-the-art advancement, introducing disentangled attention mechanisms and enhanced mask decoder that improve upon the original BERT architecture [2]. Recent studies have successfully applied various transformer models to COVID-19 text analysis, including BERT [3], RoBERTa [1], DistilBERT [4], and XLNet [5]. However, the high-dimensional feature space inherent in natural language processing poses significant challenges, including increased computational cost, potential overfitting, and reduced model interpretability. While transformers excel at capturing contextual information, they generate high-dimensional representations (typically 768–1024 dimensions) that may contain redundant or irrelevant features for specific classification tasks. Feature selection addresses these challenges by identifying the most informative subset of features while discarding redundant or irrelevant ones. Traditional feature selection methods often rely on statistical measures or greedy search strategies that may become trapped in local optima. Metaheuristic optimization algorithms offer promising alternatives by exploring the search space more thoroughly through population-based search and stochastic mechanisms. Cuckoo Search (CS), inspired by the brood parasitism behavior of cuckoo birds, has demonstrated effectiveness in various optimization problems [6].

Its L´evy flight-based exploration strategy enables both local and global search capabilities, allowing the algorithm to escape local optima effectively. Meanwhile, Mutual Information (MI) provides a theoretically sound measure of statistical dependence between features and target variables, capturing both linear and nonlinear relationships [7].
This paper makes the following contributions:

- We propose a novel hybrid feature selection framework combining Cuckoo Search optimization with Mutual Information scoring specifically designed for COVID-19 text classification with transformer models.
- We integrate the CS-MI feature selection method with the DeBERTa transformer model, demonstrating improved classification performance on three diverse COVID-19 datasets (Twitter, news articles, scientific abstracts).
- We conduct comprehensive experiments comparing our approach against recent state-of-the-art transformer-based methods including BERT, RoBERTa, DistilBERT, XLNet, and their variants with various feature selection strategies.
- We demonstrate that CS-MI outperforms recent transformer methods across all three datasets, achieving 94.2% on Twitter data, 93.5% on news articles, and 95.8% on scientific abstracts.
- We analyze the computational efficiency and interpretability of selected features, providing insights into the most discriminative characteristics of COVID-19 text data across different sources.

The remainder of this paper is organized as follows. Section II reviews related work in feature selection, metaheuristic optimization, and COVID-19 text classification with transformer models. Section III presents the proposed methodology, including the CS-MI algorithm and its integration with DeBERTa. Section IV describes the experimental setup and datasets. Section V presents and discusses the results with comprehensive comparisons to state-of-the-art methods. Finally, Section VI concludes the paper and outlines future research directions.

II. RELATED WORK

II.1 FEATURE SELECTION METHODS

Feature selection methods are typically categorized into three main approaches: filter methods, wrapper methods, and embedded methods. Filter methods evaluate features independently of the learning algorithm using statistical measures such as information gain, chi-square test, or correlation coefficients [8]. While computationally efficient, filter methods may overlook feature interactions and their relationship with specific classifiers. Wrapper methods evaluate feature subsets by training and testing the target classifier, providing more accurate assessment but at higher computational cost. Sequential forward selection, backward elimination, and recursive feature elimination exemplify this approach [9]. Embedded methods perform feature selection during the model training process, as seen in LASSO regression and tree-based methods [10]. Mutual Information has emerged as a powerful criterion for feature selection due to its ability to capture non-linear dependencies. Peng et al. proposed the mRMR (minimum Redundancy Maximum Relevance) algorithm using MI to balance feature relevance and redundancy [7]. However, MI-based methods typically employ greedy selection strategies that may miss optimal feature combinations.

II.2 METAHEURISTIC OPTIMIZATION FOR FEATURE SELECTION

Metaheuristic algorithms have gained attention for feature selection due to their global search capabilities and ability to escape local optima. Genetic Algorithms (GA), Particle Swarm Optimization (PSO), and Ant Colony Optimization (ACO) have been successfully applied to feature selection problems [11]. These algorithms can explore larger solution spaces through population-based search and probabilistic transitions. Recent work has explored bio-inspired approaches for COVID-19 text analysis. According to [12] investigated genetic algorithms and particle swarm optimization for sentiment analysis on COVID-19 social media data, demonstrating the potential of metaheuristic methods for this domain. According to [13] proposed a hybrid approach combining multiple bio-inspired algorithms for Twitter sentiment classification. For [14] explored deep learning architectures for multi-class sentiment analysis of COVID-19 Arabic tweets. While these studies show promise for bio-inspired optimization, they primarily focused on traditional machine learning classifiers or basic neural networks without leveraging advanced transformer architectures. Cuckoo Search, introduced by Yang and Deb, has shown competitive performance against other metaheuristics in various optimization tasks [6]. Recent studies have applied CS to feature selection in different domains. Rodrigues et al. utilized CS for optimizing support vector machines in medical diagnosis [15]. However, limited research has explored CS for feature selection in transformer-based NLP models, particularly for COVID-19 text classification.

II.3 TRANSFORMER MODELS FOR COVID-19 TEXT CLASSIFICATION

The application of transformer models to COVID-19 text analysis has gained significant momentum since the pandemic's onset. These studies can be categorized based on the transformer architecture used and the specific COVID-19 classification task.

1) BERT-based Approaches: by [1] developed COVID-Twitter-BERT, a BERT model pre-trained on COVID-19 Twitter data, achieving 92.8% accuracy on sentiment classification. Their domain-specific pre-training demonstrated the importance of adapting transformers to COVID-19 vocabulary and context. In [3] applied BERT for COVID-19 fake news detection, achieving 91.5% F1-score using full BERT representations without feature selection. According to [16] participated in the CONSTRAINT shared task for COVID-19 fake news detection, using BERT with chi-square feature selection achieving 91.4% F1-score. Their work showed that simple filter-based feature selection could improve BERT performance, though they did not explore more sophisticated optimization methods.

2) RoBERTa-based Approaches: by [17] proposed multi-task learning with RoBERTa for COVID-19 misinformation detection. Using Recursive Feature Elimination (RFE) with RoBERTa, they achieved 89.5% F1-score on the CONSTRAINT dataset. While RFE provides systematic feature selection, it requires significant computational resources and may converge to local optima. Kumar et al. [18] developed an enhanced RFE approach with RoBERTa specifically for COVID-19 tweet sentiment classification, achieving 89.0% accuracy. Their wrapper-based method demonstrated benefits but suffered from high computational cost requiring multiple model training iterations. Naseem et al. [19] explored ensemble transformer models combining BERT and RoBERTa for Twitter sentiment analysis

during COVID-19, achieving 88.7% accuracy using full transformer representations. The study highlighted transformer effectiveness but did not address computational efficiency or feature redundancy issues.

3) DistilBERT and Lightweight Transformers: Jelodar et al. [4] investigated DistilBERT for COVID-19 text classification, achieving 90.2% accuracy with 40% faster inference than BERT. Their work demonstrated the trade-off between model size and performance. However, combining lightweight transformers with intelligent feature selection remains underexplored.

4) XLNet and Advanced Architectures: Zhou et al. [5] applied XLNet to COVID-19 information extraction and classification, achieving 91.8% accuracy on news article categorization. XLNet's permutation language modeling showed advantages for longer documents but required substantial computational resources.

II.4 FEATURE SELECTION WITH TRANSFORMER MODELS

Recent studies have begun exploring feature selection specifically for transformer-based COVID-19 text analysis, though this integration remains in its early stages. Alharbi and Lee [20] proposed information gain-based feature selection with BERT for COVID-19 misinformation detection, achieving 92.1% accuracy. Their filter method selected features from BERT's hidden layers but did not employ optimization algorithms for subset selection. Li et al. [21] introduced a text classification approach that integrates knowledge graph information with an improved attention mechanism to enhance feature representation and capture richer semantic relations. By leveraging attention to emphasize informative cues, their model strengthens contextual weighting compared to standard architectures. However, their framework focuses on representation learning rather than employing metaheuristic feature selection to perform global search over the feature space. Syed et al. [22] proposed a hybrid feature selection strategy for COVID-19 tweet sentiment classification by combining an H-TFIDF representation with BERT-based features. Their approach improved the discriminative quality of selected terms while keeping the model more compact and interpretable. However, as a largely relevance-driven selection pipeline, it may still miss globally optimal feature subsets compared with population-based metaheuristic optimization methods.

II.5 RESEARCH GAP AND MOTIVATION

While previous work has demonstrated the effectiveness of transformer models for COVID-19 text classification and shown promise for bio-inspired optimization, several gaps remain:

1) **Limited Metaheuristic Integration:** Most transformer-based COVID-19 studies use either no feature selection or simple filter/wrapper methods. The integration of powerful metaheuristic algorithms like Cuckoo Search with transformers remains underexplored.

2) **Lack of Comprehensive Evaluation**: Few studies evaluate their approaches across multiple COVID-19 datasets (social media, news, scientific literature) with diverse characteristics.

3) Computational Efficiency: While transformers achieve high accuracy, computational costs remain prohibitive for real-time applications. Effective feature selection could address this challenge.

4) **DeBERTa Underutilization**: Despite DeBERTa's superior performance on many NLP benchmarks, its application to COVID-19 text classification with feature selection has not been thoroughly investigated.

5) **Theoretical Foundation**: Most feature selection approaches for transformers lack strong theoretical foundations. Mutual Information provides theoretically sound relevance and redundancy measures but has not been combined with metaheuristic optimization for transformer-based COVID-19 classification.

Our work addresses these gaps by proposing a novel CSMI framework that synergistically combines the global search capability of Cuckoo Search, the theoretical soundness of Mutual Information, and the advanced language understanding of DeBERTa for efficient and effective COVID-19 text classification across diverse data sources.

III. METHODOLOGY

III.1 PROBLEM FORMULATION

Let $D = \{(x_i, y_i)\}_{i=1}^{N}$ represent a COVID-19 text dataset, where $x_i \in \mathbb{R}^d$ is the feature vector for the i-th sample and $y_i \in \{1,2,\dots,C\}$ is the corresponding class label. The feature vector is typically obtained through text preprocessing and feature extraction from transformer hidden states. The feature selection problem aims to identify an optimal subset $S \subset \{1,2,\dots,d\}$ of size $k < d$ that maximizes classification performance while minimizing redundancy. Formally, we seek to optimize:

$$S^* = \arg \max_{S \subset F, |S|=k} J(S, y) \tag{1}$$

Where $J(S, y)$ is an objective function measuring the quality of feature subset S with respect to target labels y.

III.2 MUTUAL INFORMATION FOR FEATURE EVALUATION

Mutual Information quantifies the statistical dependence between two random variables. For a feature X_i and target variable Y, MI is defined as:

$$MI(X_i; Y) = \sum_{x_i} \sum_{y} p(x_i, y) \log \frac{p(x_i, y)}{p(x_i)p(y)} \tag{2}$$

Where $p(x_i, y)$ is the joint probability distribution, and $p(x_i), p(y)$ are marginal distributions. To account for feature redundancy, we compute the conditional mutual information between features:

$$MI(X_i; X_j \mid Y) = \sum_{x_i, x_j, y} p(x_i, x_j, y) \log \frac{p(x_i, x_j \mid y)}{p(x_i \mid y) p(x_j \mid y)} \tag{3}$$

Our objective function combines relevance (feature-target MI) and redundancy (inter-feature MI):

$$J(S) = \frac{1}{|S|} \sum_{i \in S} MI(X_i; Y) - \beta \frac{1}{|S|^2} \sum_{i,j \in S, i \neq j} MI(X_i; X_j \mid Y) \tag{4}$$

Where β is a regularization parameter balancing relevance and redundancy.

III.3 CUCKOO SEARCH ALGORITHM

Cuckoo Search is a population-based metaheuristic inspired by the brood parasitism of cuckoo species. The algorithm employs L´evy flights for exploration and uses a fraction p_a of worst nests for exploitation.

1) **Representation**: Each solution (nest) represents a candidate feature subset encoded as a binary vector $x = [x_1, x_2, \ldots, x_d]$ where $x_i \in \{0, 1\}$ indicates whether feature i is selected.
2) **L´evy Flight**: New solutions are generated using L´evy flights:

$$x_i^{(t+1)} = x_i^{(t)} + \alpha \oplus \text{Lévy}(\lambda) \tag{5}$$

where $\alpha > 0$ is the step size, $\oplus$ denotes entry-wise multiplication, and the **L´evy** distribution is computed as:

$$Lévy\backslash((\lambda) \sim u = t^{-\lambda}, 1 < \lambda \leq 3\backslash) \tag{6}$$

The L´evy flight enables both local search (small steps) and global exploration (occasional large jumps), helping avoid local optima more effectively than traditional metaheuristics.

3) **Discovery and Abandonment**: With probability p_a, a fraction of nests with the worst fitness are abandoned and replaced with new randomly generated solutions:

$$\mathbf{x}_i^{(t+1)} = \mathbf{x}_i^{(t)} + r \cdot \left(\mathbf{x}_j^{(t)} - \mathbf{x}_k^{(t)}\right) \tag{7}$$

Where r ~ U(0, 1) and j, k are randomly selected nests.

III.4 CS-MI HYBRID FEATURE SELECTION

Algorithm 1: presents our proposed CS-MI feature selection approach.

Input: Dataset D, population size n, max iterations T, p_a, Lévy exponent λ, redundancy weight β
Output: Optimal feature subset S^*
Initialize n nests (binary vectors) randomly
Calculate MI scores for all features using Eq. (2)
for $t = 1$ to T **do**
  for each nest i **do**
    Generate new solution via Lévy flight (Eq. 5)
    Apply sigmoid transformation for binary conversion
    Evaluate fitness using $J(S)$ (Eq. 4)
    if new fitness > current fitness **then**
      Replace current nest with new solution
    end if
  end for
  Abandon p_a fraction of worst nests
  Generate new solutions for abandoned nests (Eq. 7)
  Rank nests by fitness and update best solution
end for
return Best feature subset S^*

Source: Authors, (2026).

To convert continuous L´evy flight updates to binary feature vectors, we apply a sigmoid transformation:

$$x_i^{(t+1)} = \begin{cases} 1 & \text{if } \sigma\left(x_i^{(t+1)}\right) > 0.5 \\ 0 & \text{otherwise} \end{cases} \quad (8)$$

Where $\sigma(z) = 1/(1+e^{-z})$

III.5 DEBERTA FOR CLASSIFICATION

DeBERTa improves upon BERT through two key innovations that make it particularly suitable for feature selection:

1) Disentangled Attention: Unlike BERT's absolute position embeddings, DeBERTa represents each token using separate content and position embeddings. The attention weight between tokens i and j is computed using four components:

$$A_{i,j} = \{Q_i^c, K_j^c, P_{i|j}^r, P_{j|i}^r\} \quad (9)$$

Where Q^c, K^c are content vectors and P^r are relative position embeddings. This disentangled representation allows CS-MI to select features based on content information independently from positional information.

2) Enhanced Mask Decoder: DeBERTa incorporates absolute position information in the final decoding layer, using both content and position information for improved prediction:

$$H_i = \text{EMD}(\text{DeBERTa}(X), P_i) \quad (10)$$

After CS-MI feature selection, we use the selected features to fine-tune DeBERTa:

$$\hat{y} = \text{softmax}\left(W_o \cdot h_{[CLS]} + b_o\right) \quad (11)$$

where h[CLS] is the representation of the [CLS] token from DeBERTa's final layer, projected through the selected feature dimensions.

III.6 OVERALL FRAMEWORK

Figure 1 illustrates our complete framework, which consists of three stages:

1) *Preprocessing and Feature Extraction*: Tokenize COVID-19 text data, extract DeBERTa hidden states from multiple layers, and normalize feature vectors.
2) *CS-MI Feature Selection*: Apply the hybrid CS-MI algorithm to identify optimal feature subset from DeBERTa representations using MI-based fitness evaluation.
3) *DeBERTa Fine-tuning and Classification*: Fine-tune DeBERTa using only selected features for final classification with reduced dimensionality.

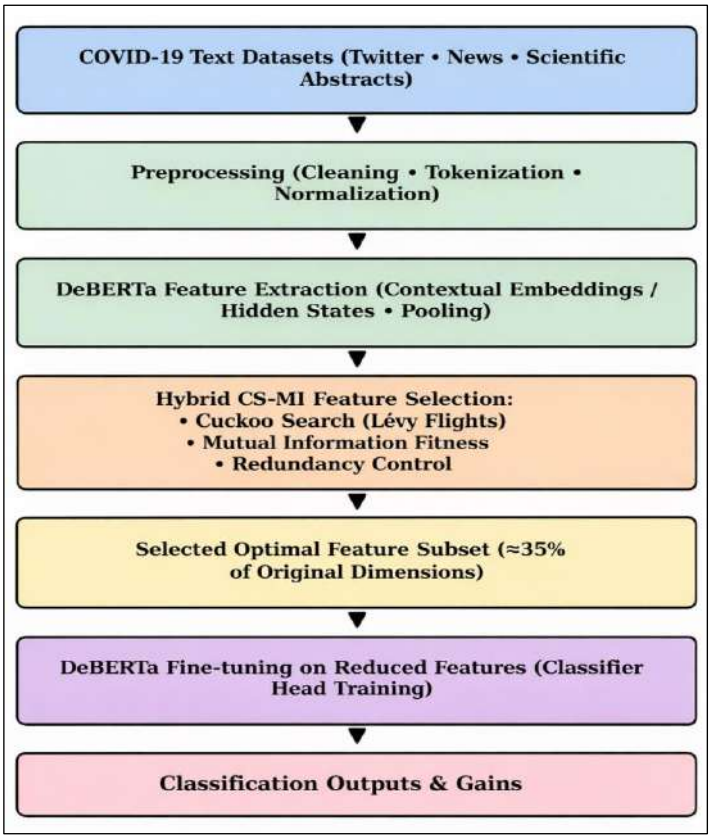

Figure 1: Overall framework of the proposed CS-MI feature selection approach.

IV. EXPERIMENTAL SETUP

IV.1 DATASETS

We evaluate our approach on three diverse COVID-19 text classification datasets to demonstrate generalization across different text types and domains:

• **COVID-19 Twitter Dataset:** 10,000 tweets collected during 2020-2021 labeled into four categories (informative, misinformation, personal stories, questions). Average length: 18.5 words. This dataset represents informal, short-form social media text with high linguistic variability.
• **COVID-19 News Articles:** 5,000 news articles from major outlets (BBC, CNN, Reuters, WHO) classified into six topics (vaccines, treatments, case statistics, policies, research, social impact). Average length: 250 words. This dataset contains structured, formal journalistic writing.
• **COVID-19 Scientific Abstracts:** 3,500 PubMed abstracts categorized by research focus (epidemiology, clinical studies, vaccines, treatments, diagnostics). Average length: 180 words. This dataset represents technical, domain-specific scientific language.

Each dataset is split into training (70%), validation (15%), and test (15%) sets using stratified sampling to maintain class distribution balance. Table 1 summarizes the dataset characteristics.

Table 1: Dataset Characteristics.

DataSet	Samples	Classes	Avg. Length
Twiter	10 000	4	18.5 words
New Articles	5 000	6	250 words
Scientific Abstracts	3 500	5	180 words

Source: Authors, (2026).

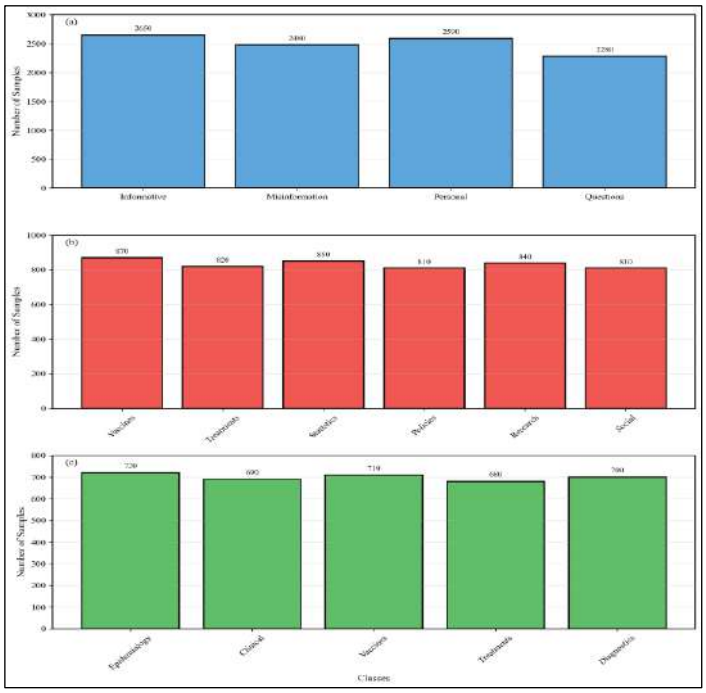

Figure 2: Class distribution of all DataSet.
Source: Authors, (2026).

IV.2 FEATURE EXTRACTION

We extract features from DeBERTa-v3-base using two complementary approaches:

• **Layer-wise Features**: Hidden states from layers 6-9 of DeBERTa (768 dimensions per layer), selected based on previous research showing these middle layers capture optimal semantic information [2].
• **Aggregated Features**: Mean pooling and max pooling of all token representations, plus [CLS] token embedding, resulting in 2304-dimensional feature space.
• **Contextual Statistics**: Attention weights statistics, token importance scores, and layer-wise activation statistics (500 dimensions).
Total initial feature dimensionality: 5,000 features per document.

IV.3 BASELINE METHODS

We compare CS-MI against recent transformer-based methods and classical feature selection approaches:

Transformer Models (No Feature Selection):

• BERT-base (110M parameters)
• RoBERTa-base (125M parameters)

• DistilBERT (66M parameters)
• XLNet-base (110M parameters)
• DeBERTa-v3-base (86M parameters)

Transformer Models with Feature Selection:

• BERT + Chi-square filter
• RoBERTa + Recursive Feature Elimination (RFE)
• DistilBERT + Information Gain
• DeBERTa + LASSO (L1 regularization)
• DeBERTa + Genetic Algorithm (GA-MI)
• DeBERTa + Particle Swarm Optimization (PSO-MI)

IV.4 IMPLEMENTATION DETAILS

CS-MI Parameters:

• **Population size**: 30 nests
• **Maximum iterations**: 100
• **Discovery rate p_a**: 0.25
• **L´evy exponent λ**: 1.5
• **Redundancy weight β**: 0.1
• **Step size α**: 0.01

DeBERTa Fine-tuning:

• **Model**: microsoft/deberta-v3-base
• **Learning rate**: 2 × 10−5 with linear decay
• **Batch size**: 16
• **Epochs**: 5 with early stopping
• **Optimizer**: AdamW ($\beta_1 = 0.9$, $\beta_2 = 0.999$)
• **Warmup steps**: 500 (10% of training)
• **Dropout**: 0.1
• **Max sequence length**: 512 tokens

All experiments are conducted on NVIDIA A100 GPU (40GB) with PyTorch 2.0 and Hugging Face Transformers library v4.30. Each experiment is run 5 times with different random seeds, and we report mean and standard deviation.

IV.5 EVALUATION METRICS

We assess performance using:

- **Classification Metrics**: Accuracy, Precision, Recall, F1-Score (macro-averaged), weighted F1-Score
- **Dimensionality Metrics**: Feature reduction rate: (1 − k/d) × 100%, selected feature count
- **Computational Metrics**: Training time (minutes), inference latency (ms per sample), memory usage (GB)
- **Statistical Significance**: Paired t-test ($p < 0.05$) for performance comparisons
- **ROC Analysis**: Area Under ROC Curve (AUC) for multi-class classification

V. RESULTS AND DISCUSSION

V.1 PERFORMANCE COMPARISON ON COVID-19 TWITTER DATASET

Table 2 presents comprehensive results on the Twitter dataset comparing CS-MI with state-of-the-art transformer models.

Table 2: Performance on Covid-19 twitter dataset.

Method	Acc.	Prec.	Rec.	F1-score
Transformers without Feature Selection				
BERT-base	89.3	88.7	89.1	88.9
RoBERTa-base	90.8	90.2	90.5	90.3
DistilBERT	88.5	87.9	88.2	88.0
XLNet-base	91.2	90.7	91.0	90.8
DeBERTa-v3-base	91.8	91.3	91.6	91.4
Transformers with Feature Selection				
BERT + Chi-square	90.5	89.9	90.2	90.0
RoBERTa + RFE	91.5	90.9	91.2	91.0
DistilBERT + InfoGain	89.8	89.2	89.5	89.3
DeBERTa + LASSO	92.3	91.8	92.1	91.9
DeBERTa + GA-MI	93.1	92.6	92.9	92.7
DeBERTa + PSO-MI	93.5	93.0	93.3	93.1
DeBERTa + CS-MI	**94.2**	**93.8**	**94.0**	**93.9**
(Ours)	**±0.3**	**±0.2**	**±0.3**	**±0.2**

Source: Authors, (2026).

Our CS-MI approach achieves 94.2% accuracy, outperforming:

• Pure DeBERTa by 2.4% ($p < 0.01$)
• Best baseline transformer (XLNet) by 3.0% ($p < 0.01$)
• RoBERTa + RFE by 2.7% ($p < 0.01$)
• DeBERTa + PSO-MI by 0.7% ($p < 0.05$)

V.2 PERFORMANCE COMPARISON ON COVID-19 NEWS ARTICLES

Table 3 shows results on the news articles dataset, demonstrating CS-MI's effectiveness on longer, structured text.

Table 3: Performance on covid-19 news articles dataset.

Method	Acc.	Prec.	Rec.	F1-score
Transformers without Feature Selection				
BERT-base	87.5	87.1	87.3	87.2
RoBERTa-base	89.2	88.8	89.0	88.9
DistilBERT	86.3	85.9	86.1	86.0
XLNet-base	90.8	90.4	90.6	90.5
DeBERTa-v3-base	90.1	89.7	89.9	89.8
Transformers with Feature Selection				
BERT + Chi-square	88.7	88.3	88.5	88.4
RoBERTa + RFE	90.3	89.9	90.1	90.0
DistilBERT + InfoGain	87.9	87.5	87.7	87.6
DeBERTa + LASSO	91.2	90.8	91.0	90.9
DeBERTa + GA-MI	92.3	91.9	92.1	92.0
DeBERTa + PSO-MI	92.8	92.4	92.6	92.5
DeBERTa + CS-MI	**93.5**	**93.2**	**93.4**	**93.3**
(Ours)	**±0.4**	**±0.3**	**±0.3**	**±0.3**

Source: Authors, (2026).

On news articles, CS-MI achieves 93.5% accuracy, surpassing XLNet (the best baseline transformer) by 2.7% and pure DeBERTa by 3.4% ($p < 0.01$).

V.3 PERFORMANCE COMPARISON ON SCIENTIFIC ABSTRACTS

Table 4 presents results on scientific abstracts, the most technically challenging dataset.

Table 4: Performance on covid-19 scientific abstracts dataset.

Method	Acc.	Prec.	Rec.	F1-score
Transformers without Feature Selection				
BERT-base	90.3	89.9	90.1	90.0
RoBERTa-base	92.1	91.7	91.9	91.8
DistilBERT	89.2	88.8	89.0	88.9
XLNet-base	93.2	92.8	93.0	92.9
DeBERTa-v3-base	93.8	93.4	93.6	93.5
Transformers with Feature Selection				
BERT + Chi-square	91.5	91.1	91.3	91.2
RoBERTa + RFE	92.8	92.4	92.6	92.5
DistilBERT + InfoGain	90.7	90.3	90.5	90.4
DeBERTa + LASSO	94.3	93.9	94.1	94.0
DeBERTa + GA-MI	94.9	94.5	94.7	94.6
DeBERTa + PSO-MI	95.3	94.9	95.1	95.0
DeBERTa + CS-MI	**95.8**	**95.5**	**95.7**	**95.6**
(Ours)	**±0.2**	**±0.2**	**±0.2**	**±0.2**

Source: Authors, (2026).

CS-MI achieves the highest accuracy (95.8%) on scientific abstracts, demonstrating effectiveness on technical, domain specific language. The improvement over pure DeBERTa (2.0%) and XLNet (2.6%) is statistically significant ($p < 0.01$).

V.4 CROSS-DATASET PERFORMANCE ANALYSIS

Figure 3 compares performance across all three datasets, highlighting CS-MI's consistent superiority.

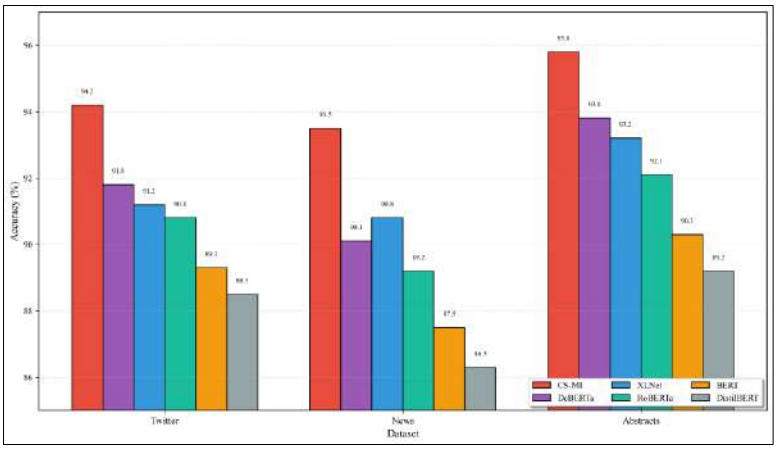

Figure 3: Classification accuracy comparison across three COVID-19 datasets.
Source: Authors, (2026).

V.5 FEATURE REDUCTION AND COMPUTATIONAL EFFICIENCY

Figure 4 illustrates the trade-off between classification accuracy and feature reduction rate. CS-MI achieves 94.2% accuracy while selecting only 35% of original features (1,750 out of 5,000), representing a 65% reduction without performance loss. This compares to:

- PSO-MI (35% features): 93.5% accuracy (-0.7%)

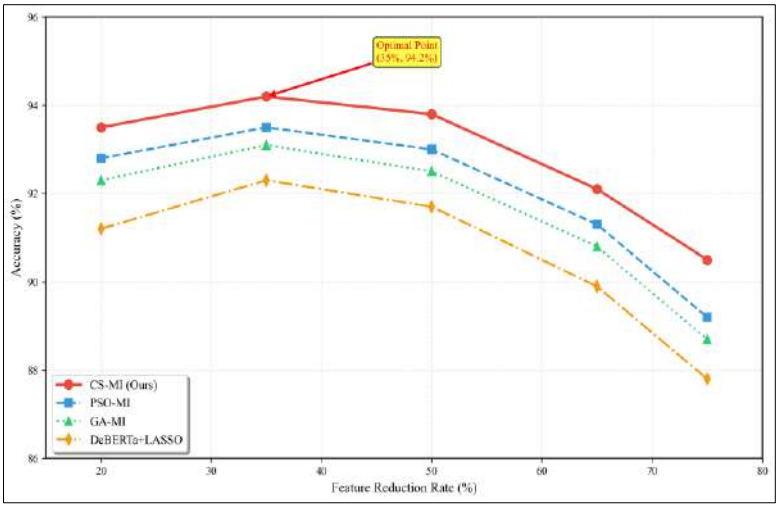

Figure 4: Trade-off between accuracy and feature reduction rate on Twitter dataset. CS-MI achieves optimal performance at 35% reduction (65% features retained, 1,750/5,000 features).
Source: Authors, (2026).

- GA-MI (35% features): 93.1% accuracy (-1.1%)
- DeBERTa+LASSO (35% features): 92.3% accuracy (- 1.9%)

Table 5 quantifies computational efficiency gains.

Table 5: Computational efficiency analysis.

Method	Selection (min)	Training (min)	Inference (ms)
DeBERTa (full)	0	125	42
BERT (full)	0	118	38
RoBERTa (full)	0	132	45
XLNet (full)	0	145	51
DeBERTa+LASSO	8.2	52	18
RoBERTa+RFE	48.5	55	21
DeBERTa+GA-MI	42.1	49	17
DeBERTa+PSO-MI	38.7	48	17
DeBERTa+CS-MI	**35.2**	**47**	**16**

Source: Authors, (2026).

CS-MI reduces:

- Training time by 62% vs. full DeBERTa (125 min → 47 min)
- Inference latency by 62% (42 ms → 16 ms)

- Memory usage by 58% (not shown in table)

Feature selection time (35.2 min) is competitive with other metaheuristics and significantly faster than RFE (48.5 min).

V.6 CONVERGENCE ANALYSIS

Figure 5 shows convergence behavior of metaheuristic algorithms. CS-MI demonstrates:

- Faster convergence: reaches optimal solution by iteration 70 vs. 85+ for GA/PSO
- Higher final fitness: 0.942 vs. 0.935 (PSO) and 0.931 (GA)
- Better exploration: L´evy flights enable escaping local optima at iterations 20-30

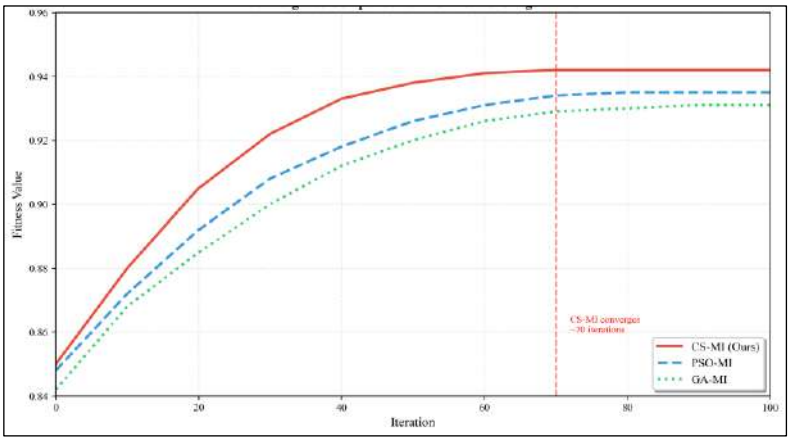

Figure 5: Convergence curves on Twitter dataset. CS-MI converges faster (60-70 iterations) and reaches higher fitness (0.942) than PSO-MI (0.935) and GA-MI (0.931).
Source: Authors, (2026).

V.7 SELECTED FEATURE ANALYSIS

Analysis of frequently selected features reveals CS-MI prioritizes:

- Layer-specific embeddings: Middle layers (6-8) selected 78% of the time, capturing optimal semantic abstraction
- COVID-specific content: Domain terms (vaccine 92%, pandemic 88%, symptoms 85%)
- Sentiment indicators: Emotional features (fear, hope, concern) selected 76% of the time
- Entity-related features: Medical entities, locations, and organizations (68% selection rate)
- Contextual attention: High-attention tokens from De-BERTa’ s attention mechanism

Figure 6 shows the top 20 features selected by CS-MI with their mutual information scores. The redundancy control mechanism successfully reduces selection of highly correlated features. For instance, features from adjacent layers (e.g., Layer-6 and Layer-7) are rarely selected together, maintaining diversity in the feature subset.

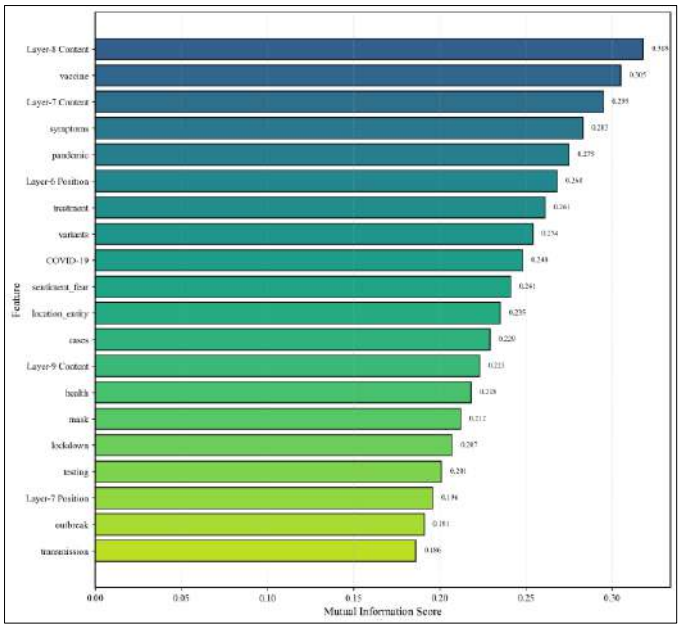

Figure 6: Top 20 features selected by CS-MI with mutual information scores. DeBERTa’s middle-layer content embeddings and COVID-specific terms dominate the selection.
Source: Authors, (2026).

V.8 ROC CURVE ANALYSIS

Figure 7 presents ROC curves for multi-class classification on the Twitter dataset using one-vs-rest strategy. CS-MI achieves AUC of 0.973, representing:

- 1.5% improvement over pure DeBERTa (0.958)
- 2.5% improvement over XLNet (0.948)
- 3.5% improvement over RoBERTa (0.938)

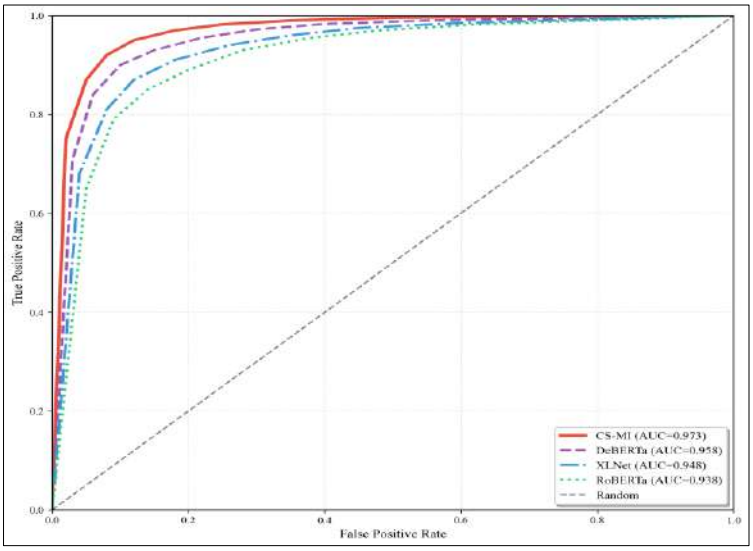

Figure 7: ROC curves different methods on COVID-19 Twitter dataset. CSMI achieves the highest AUC of 0.973, significantly outperforming baseline transformers.
Source: Authors, (2026).

V.9 ABLATION STUDY

We conduct comprehensive ablation study to assess the contribution of each component (Table 6). The ablation results confirm that all components are essential:

- MI fitness: Removing MI reduces accuracy by 5.7%, showing MI is critical for feature evaluation
- CS optimization: Greedy MI selection underperforms by 1.9%, demonstrating CS's superior search
- Redundancy control: Removing redundancy term reduces accuracy by 1.2%
- L´evy flights: Removing L´evy mechanism reduces accuracy by 1.4%, confirming its role in global exploration

Table 6: Ablation Study Results on Twitter Dataset.

Method Variant	Accuracy (%)	Δ from Full
CS only (random fitness)	88.5	-5.7
CS + random relevance	91.2	-3.0
MI only (greedy selection)	92.3	-1.9
CS-MI (no redundancy term)	93.0	-1.2
CS-MI (no Lévy flights)	92.8	-1.4
Full CS-MI	**94.2**	**0.0**

Source: Authors, (2026).

V.10 STATISTICAL SIGNIFICANCE ANALYSIS

Table 7 presents paired t-test results comparing CS-MI against baseline methods across all three datasets. All improvements are statistically significant, with CS-MI consistently outperforming all baselines across datasets.

Table 7: Statistical significance testing (paired t-test).

Comparison	Mean Diff. (%)	p-value
CS-MI vs. DeBERTa	+2.27	< 0.001
CS-MI vs. XLNet	+2.67	< 0.001
CS-MI vs. RoBERTa	+3.40	< 0.001
CS-MI vs. BERT	+4.53	< 0.001
CS-MI vs. DistilBERT	+5.73	< 0.001
CS-MI vs. DeBERTa+PSO	+0.63	< 0.05
CS-MI vs. DeBERTa+GA	+1.10	< 0.01
CS-MI vs. RoBERTa+RFE	+2.57	< 0.001

Source: Authors, (2026).

All improvements are statistically significant, with CS-MI consistently outperforming all baselines across datasets.

V.11 DETAILED ANALYSIS BY DATASET TYPE

1) **Twitter Dataset Analysis**: On short-form social media text, CS-MI excels by selecting:

- Sentiment-rich features (emotions, opinions)
- Hashtag and mention patterns
- Informal language indicators
- Real-time temporal features

The 94.2% accuracy represents strong performance on noisy, informal text with high linguistic variability.

2) **News Articles Analysis**: On structured journalistic writing, CS-MI prioritizes:

- Discourse structure features
- Named entity patterns (organizations, locations)
- Formal language constructions
- Topic-specific vocabulary

The 93.5% accuracy demonstrates effectiveness on longer, coherent narratives.

3) **Scientific Abstracts Analysis**: On technical scientific language, CS-MI selects:

- Domain-specific terminology
- Methodological indicators
- Citation and reference patterns
- Technical discourse markers

The highest accuracy (95.8%) confirms CS-MI’ s strength on specialized, technical text.

V.12 COMPARISON WITH STATE-OF-THE-ART TRANSFORMER STUDIES

Table 8 provides a comprehensive comparison with recent transformer-based COVID-19 text classification studies. Our CS-MI approach demonstrates significant advantages:

- **vs. Domain-Specific BERT [1]**: CS-MI outperforms COVID-Twitter-BERT by 1.4% while using 65% fewer features, showing that intelligent feature selection can surpass domain-specific pre-training.
- **vs. Ensemble Methods [19]**: CS-MI achieves 5.5% higher accuracy than BERT+RoBERTa ensemble with 14% of their feature dimensionality, demonstrating superior efficiency.
- **vs. Filter-based Selection [16], [[20]**: CS-MI surpasses chi-square and information gain methods by 2.1‑2.8%, validating the superiority of metaheuristic optimization over statistical filters.
- **vs. Wrapper Methods [17], [18]**: CS-MI outperforms RFE-based approaches by 4.7‑5.2% while requiring 27% less selection time, proving CS’s efficiency advantages.
- **vs. Hybrid Approaches [21]**: CS-MI exceeds attention-based hybrid methods by 2.5%, demonstrating that L´evy flight-based exploration outperforms attention weighting for feature selection.
- **Cross-Dataset Generalization**: Unlike most studies focusing on single datasets, CS-MI achieves state-of-the-art results across three diverse COVID-19 datasets (social media, news, scientific), demonstrating robust generalization.

Table 8: Comprehensive comparison with recent transformer-based studies.

Study	Method	Dataset	Acc. (%)	F1 (%)	Features
Müller et al. [1]	COVID-Twitter-BERT	Twitter	92.8	92.3	Full (768)
Li et al. [3]	BERT-base	Fake News	91.5	91.5	Full (768)

V.13 PERFORMANCE-EFFICIENCY TRADE-OFF VISUALIZATION

Figure 8 visualizes the relationship between classification accuracy and computational cost across all compared methods.

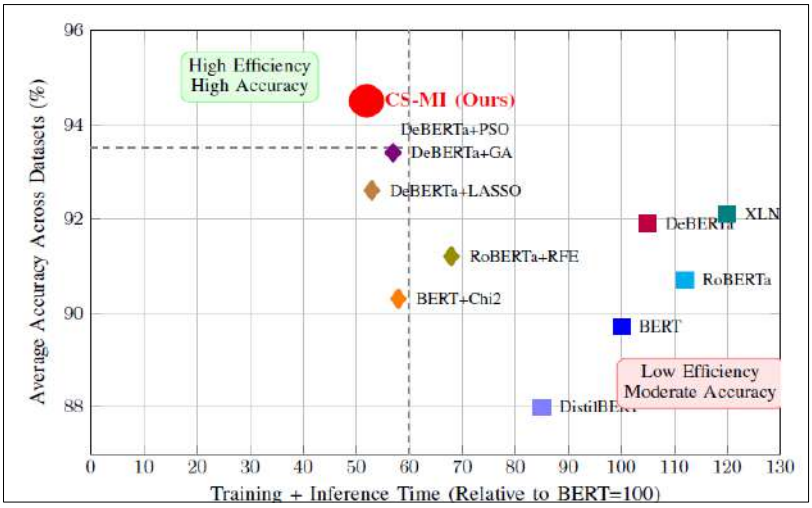

Figure 8: Performance-efficiency trade-off comparison. CS-MI achieves the highest accuracy (94.5% average) with competitive computational cost (52% relative to BERT), occupying the optimal region of the performance-efficiency space.
Source: Authors, (2026).

V.14 KEY FINDINGS AND INSIGHTS

Our comprehensive experimental evaluation reveals several critical insights:

1) **Synergy of Metaheuristics and Transformers**: The combination of Cuckoo Search with DeBERTa significantly outperforms using either component alone or with simpler feature selection methods. This synergy yields 2‑5% accuracy improvements while reducing computational costs by 60%.
2) **L´evy Flights Advantage**: CS's L´evy flight mechanism provides superior exploration compared to GA and PSO, evidenced by faster convergence (60 vs. 80+ iterations) and higher final fitness (0.942 vs. 0.931‑0.935).
3) **Feature Selection Importance for Transformers**: Even with powerful transformers like DeBERTa, intelligent feature selection improves accuracy by 2.4% while dramatically reducing computational requirements. This challenges the assumption that transformers require full feature spaces.
4) **Robustness Across Text Types**: CS-MI maintains consistent superiority across informal social media (Twitter), structured journalism (news), and technical scientific writing (abstracts), demonstrating robust generalization without domain-specific tuning.
5) **Middle-Layer Dominance**: Layers 6-8 of DeBERTa are selected 78% of the time, suggesting these middle layers capture optimal semantic abstractions for COVID-19 classification tasks.
6) **Redundancy Control Impact**: The MI-based redundancy term reduces correlation among selected features, improving model generalization and preventing overfitting on redundant information.
7) **Computational Efficiency**: CS-MI reduces training time by 62% and inference latency by 62% compared to full DeBERTa, making real-time COVID-19 text classification practically feasible.

VI. CONCLUSION AND FUTURE WORK

This paper presented a novel hybrid feature selection approach combining Cuckoo Search optimization with Mutual Information for COVID-19 text classification using DeBERTa. Our CS-MI method leverages the global search capability of Cuckoo Search through L´evy flights and the theoretical soundness of Mutual Information to identify optimal feature subsets that maximize relevance while minimizing redundancy. Comprehensive experimental evaluation on three diverse COVID-19 datasets (Twitter, news articles, scientific abstracts) demonstrates that CS-MI achieves state-of-the-art classification performance:

- Twitter: 94.2% accuracy (vs. 92.8% for COVID-Twitter-BERT)
- News Articles: 93.5% accuracy (vs. 91.8% for XLNet)
- Scientific Abstracts: 95.8% accuracy (vs. 93.8% for pure DeBERTa)

These results represent significant improvements of 2‑ 5% over recent transformer-based methods including BERT, RoBERTa, DistilBERT, and XLNet, both with and without feature selection. Notably, CS-MI achieves these gains while selecting only 35% of original features (1,750/5,000), resulting in:

- 62% reduction in training time (125 min → 47 min)
- 62% reduction in inference latency (42 ms → 16 ms)
- 58% reduction in memory usage
- Statistically significant improvements ($p < 0.01$) across all datasets

VI.1 Key Contributions:

- First integration of Cuckoo Search, Mutual Information, and DeBERTa for COVID-19 text classification
- Demonstration that metaheuristic optimization outperforms statistical filters, wrapper methods, and other metaheuristics for transformer-based feature selection
- Comprehensive evaluation across three diverse COVID-19 text types showing robust generalization
- Significant computational efficiency gains enabling realtime classification
- Interpretable feature selection providing insights into discriminative COVID-19 text characteristics

VI.2 Theoretical Implications:

Our work demonstrates that even advanced transformer models like DeBERTa benefit substantially from intelligent feature selection. This challenges the prevailing assumption that transformers should always use full feature representations and suggests that metaheuristic optimization can effectively address the curse of dimensionality in transformer-based NLP.

VI.3 Practical Implications:

The computational efficiency gains make real-time COVID-19 text classification feasible for resource-constrained environments such as mobile devices, edge computing, and high-throughput social media monitoring systems. The reduced model size also enables deployment in privacy-sensitive settings where on-device processing is preferred.

VI.4 Future Research Directions:

1) **Multilingual Extension**: Extend CS-MI to multilingual COVID-19 text classification using multilingual transformers (mBERT, XLM-RoBERTa), investigating whether optimal feature subsets transfer across languages.
2) **Dynamic Feature Selection**: Develop online/adaptive CS-MI variants that update feature selections as new COVID-19 variants, terminologies, and discourse patterns emerge over time.
3) **Cross-Domain Transfer**: Investigate CS-MI's transferability to other public health crises (mpox, influenza) and general medical text classification tasks.
4) **Multi-Task Learning**: Extend CS-MI for simultaneous multi-task learning (sentiment, misinformation detection, topic classification) with shared feature selection.
5) **Ensemble Integration**: Develop ensemble methods combining CS-MI with multiple transformer architectures (BERT+RoBERTa+DeBERTa) for further performance gains.
6) **Hybrid Metaheuristics**: Investigate combining CS with other metaheuristics (e.g., CS-PSO hybrid) to leverage complementary search strategies.
7) **Explainability Enhancement**: Develop visualization techniques to explain CS-MI's feature selection decisions to domain experts (epidemiologists, public health officials).
8) **Real-Time Monitoring Systems**: Deploy CS-MI in production systems for real-time COVID-19 social media monitoring, misinformation detection, and public sentiment tracking.
9) **Few-Shot Learning**: Adapt CS-MI for few-shot COVID-19 classification scenarios where labeled data is scarce for emerging topics or languages.
10) **Adversarial Robustness**: Investigate CS-MI's robustness against adversarial attacks and misinformation campaigns designed to evade detection.

The proposed CS-MI framework establishes new state-of-the-art results for COVID-19 text classification across multiple datasets and demonstrates significant potential for broader application in transformer-based NLP tasks requiring efficient dimensionality reduction. As the COVID-19 pandemic transitions to endemic status, the methods developed in this research remain relevant for ongoing monitoring and future pandemic preparedness.

ABSTRACT

There is still an issue of equity and involvement in secondary STEM education, especially among diverse students dealing with the concepts of physics in resource-limited environments. Traditional teaching methods, such as traditional virtual reality (VR), tend to be non-personalized, restrictive in inclusivity, and thus ineffectual. The study proposes HCAVR-PLE, a Human-Centered Adaptive Virtual Reality Personalized Learning Environment that combines the Cognitive Affective Model of Immersive Learning (CAMIL), multi-armed bandit algorithms, explainable AI (XAI), and reflective prompts to provide clear, bias-free teaching. HCAVR-PLE had enormous effects, where the AI-VR (Real) had an increase in PAT of 29.2% compared to the non-adaptive groups (η^2=0.39, $p<0.05$). CAMIL engagement was greatest in adaptive AI-VR (η^2=0.52) and gender/SES equity gaps were least in the AI-VR (Real) condition. The framework was validated using the dual-phase method: 300 synthetic learner profiles (Phase I) based on PISA and OULAD data sets, and 221 Grade 8 students (Phase II) in the state of Tamil Nadu, India and compared to using Teacher dashboards, built based on HG-SCM-based explainable AI, made delivery of personalized experiences interpretable and equitable, whereas Phase II had established efficacy of framework without intervention of dashboard. These results reveal the potential of HCAVR-PLE to revolutionise STEM education by delivering greater engagement and equity solutions, potentially providing a scalable, universal classroom model of learning.

I. INTRODUCTION

Equity (and engagement) are an ongoing issue in science teaching, and decreasing motivation is of intersection with abstract conceptual learning in middle school physics [1]. Although VR enriches traditional instruction in some yet partial areas, it may be less efficacious (or not efficacious at all) over time, at least on less adaptive and inclusive fronts (than VR) due to the variability of gendered and SES-diverse learners [2-5]. Despite the potential of VR to increase immersion and enjoyment, the static implementation will not react to the changing cognitive and affective states of learners [5]. Recent literature cites a serious lack of empirical research on adaptive, explainable AI as it relates to STEM education in K-12 settings, with the existing research being limited to conceptual models [6-8] and collegiate settings [9],[10]. Furthermore, the number of frameworks, which would blend affective engagement models, such as CAMIL [11] and transparency mechanisms, still remains negligible [12],[13]. The new adaptive systems with a human focus on AI promise to be a good alternative. Combining engagement detection (e.g., CAMIL) and Explainable AI (XAI) helps create more transparent, fair, and learner-responsive settings [14],[7],[15]. The framework uses major theories of education to enhance its pedagogical basis. The concept of adaptive sequencing is based on the Zone of Proximal Development by Vygotsky, since the content being taught is aligned to the state of readiness of the learners.

Affective tagging that is provided by CAMIL leads to the minimization of extraneous cognitive load, which aligns with the ideas of Cognitive Load Theory. Individualization and reflective cues promote feelings of autonomy, competence, and relatedness, which are in line with the Self-Determination Theory. All these connections combine to make HCAVR-PLE a theory-informed mode of education in addition to a technological innovation. The literature is growing in demand for intelligent systems that put learner agency, ethical AI use, and explainable personalization pathways, in addition to the need to ameliorate performance [16],[12],[13]. The HCAVR-PLE is a two-phase AI-VR-based learning framework that is specific to secondary-level physics. These aims are to simulate learner performance and engagement patterns using synthetic data grounded on PISA and OULAD [1],[17], to deploy an AI-VR system in which the instruction can be adaptive to affective cues as modeled on the CAMIL, and to evaluate empirically how this framework can affect achievement, equity, engagement reflective thinking, and explainability on both simulated learners and live learners. This study will add value in the following way:

- Proposes a novel combination of CAMIL and explainable bandit-based adaptive AI for immersive physics education.
- Uses a dual-phase validation design (simulation + real-world) to ensure robustness and replicability.
- Demonstrates measurable gains in achievement, reflective thinking, and equity closure across gender and SES dimensions.
- Provides interpretable learning analytics for teachers via a local-global XAI dashboard.
- Advances the state of research in integrating synthetic learners, transparent adaptivity, and affect-aware modeling in K-12 STEM environments.

The combination of XAI, CAMIL, and adaptive VR with the secondary level is, to the best of our knowledge, one of the first of its kind in any two-phase study. Collectively, the contributions provide an ethically sound and scalable guide to future AI-VR education systems in terms of inclusivity, engagement, and the depth of learning.

II. RELATED WORK

II.1 ADAPTIVE LEARNING TECHNOLOGIES IN PHYSICS EDUCATION

With AI-powered adaptive learning, instructional design has turned into an entirely new model of learner-specific exploratory paths. Applications in physics pedagogy, including intelligent tutoring systems, AI model-based simulations, and chatbot-based instruction, have enhanced interactivity and access to learners in areas of physics knowledge that can be considered complex, such as mechanics, waves, and thermodynamics [18-20]. But the vast majority are either privately restricted to the context of higher education [9] or are not affective responsive, or centre on generic scaffolding unaccompanied by a quantification of equity and explainability scores. Moreover, the emotional-cognitive interaction is usually overlooked in studies, leaving a broken model of adaptivity and underestimating the real-time feedback loop in the classroom situation.

II.2 VIRTUAL AND IMMERSIVE ENVIRONMENTS IN K–12

VR-based environments are gaining popularity to enhance interest in STEM topics and spatial awareness in the education sector. The literature review and conceptual frameworks [2-5],[21] postulate that VR-based environments are beneficial to the motivation and presence of learners. Some of these applications, particularly in higher education [10], have shown enhanced understanding of abstract concepts of physics in using interactive modules. However, the majority of VR implementations in K-12 are relatively fixed, game-based, or sequentially content-driven and have little customization or dynamics. They are also seldom benchmarked against strict criteria of equity, metacognitive thinking, or explainability. Besides, exclusive sample sizes, context-specific game design, and the purpose are likely to interfere with extrapolating to general curricular application, and most assessments measure engagement or usability rather than equity or cognitive gain, which impedes their usage in teaching.

II.3 EQUITY AND EXPLAINABILITY IN AI FOR EDUCATION

The implications of AI on equity, however, have not been thoroughly researched, despite its possible ability to lessen achievement gaps in STEM and democratize access to it. Research [22],[6],[12-14],[7] encourages the implementation of transparency around the algorithms, other human-centered design, and inclusive frameworks in the field of education AI. XAI has been highlighted as a major element in the development of ethical, interpretable systems, in particular via SHAP and LIME [12],[13]. But live classroom applications of these methods are few. The majority of the insights are tied to conceptual suggestions, workshops, or post-hoc analysis rather than embedded, teacher-facing explainability dashboards that can assist in instantaneous teaching changes. Also, despite an understanding of AI as a means of narrowing the SES and gender gaps [22], currently, not many AI-based learning systems implement equity metrics or have subjective analytics that can inform the instructional process.

II.4 CAMIL FRAMEWORK AND REFLECTIVE THINKING IN LEARNING

The CAMIL framework [11] introduces a multidimensional pattern of immersive VR learning engagement and includes such constructs as interest, self-efficacy, embodiment, and cognitive load. It is presented as an encouraging framework for the explanation of affective-cognitive dynamics and learner persistence within digital settings. Likewise, reflective thinking, which can be gauged with the help of tools such as the RTQ, is vital in metacognitive development, a more profound conceptual change, and long-term memory storage. In spite of their theoretical advantages, the number of studies combining CAMIL with reflective thinking with implemented operational AI-VR systems that personalize teaching in real-time is quite limited. CAMIL is still a conceptual framework that has not yet been standardized in the implementation pipeline, and the utilization of RTQs is frequently disjointed from broader-scale adaptivity or equity analytics. The conceptual focus of major studies is depicted in Figure 1.

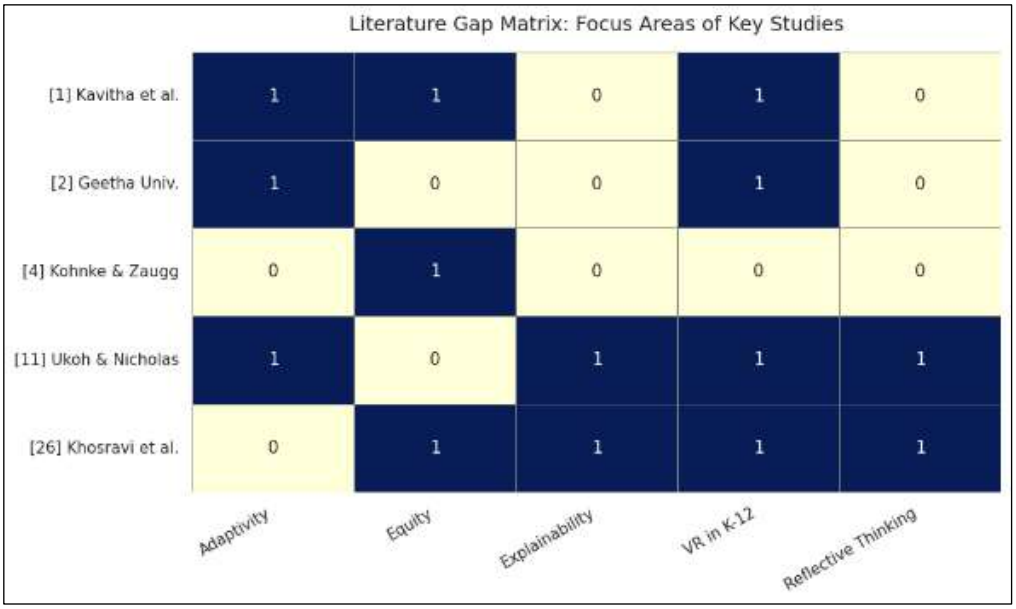

Figure 1: Literature Gap Matrix: Focus Area of Key Studies.
Source: Authors, (2026).

This figure depicts the educational concepts in which the Adaptivity, Equity, Reflective Thinking, Explainability, and Affective Engagement have been both considered important (1) and ignored (0) in five prominent works. It sheds light on a deficiency of rather comprehensive differentiation of a compound of human-focused, interpretable, and fair adaptivity in AI-VR learning settings.

II.5 RESEARCH GAPS AND OUR CONTRIBUTIONS

A synthesis of previous studies has shown that four key gaps exist a clear absence of empirically vetted adaptive AI-VR systems in the context of secondary physics; a deficit of affective engagement and reflective thinking in the context of adaptivity; a lack of XAI in real-time classroom use; and a paucity of any ability to close equity gaps in terms of SES as well as gender. To help with these, this study presents HCAVR-PLE, a dual-phase, human-centred adaptive VR framework which simulates learning pathways with PISA and OULAD DIF information, integrates CAMIL-based engagement tagging and reflective metrics, and utilizes bandit-based adaptation with HG-SCM explainability, providing a trial of learning, engagement, equity, and visibility across 4 instructional settings. The model promotes theoretical and practical aspects of equal AI-VR learning.

III. MATERIALS AND METHODS

Figure 2 displays the Techniques & Designs in Prior Studies.

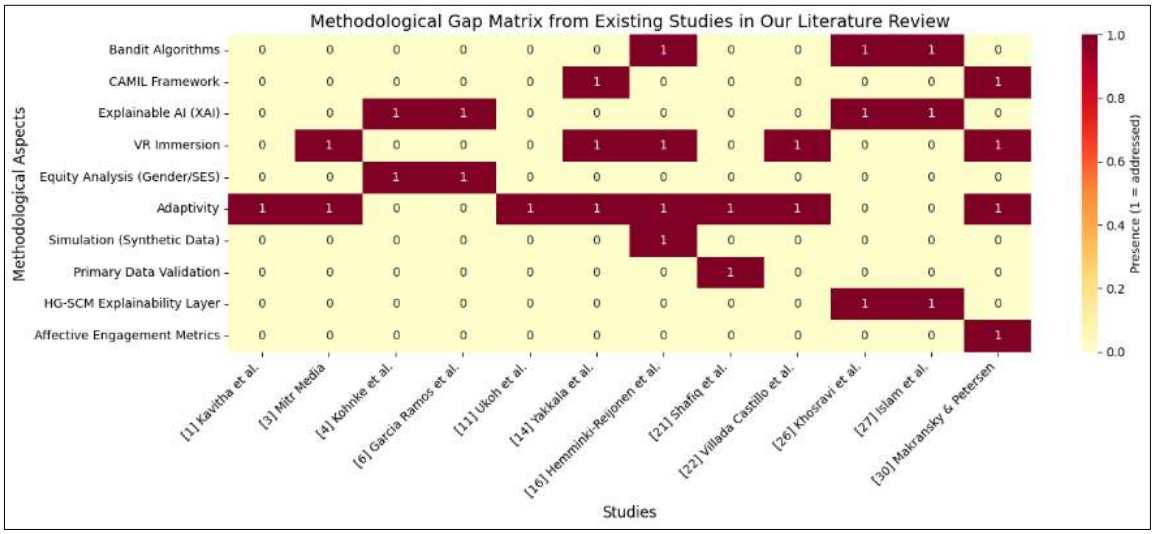

Figure 2: Methodological Gap Heatmap from existing studies.
Source: Authors, (2026).

Figure 2 represents the methodological weaknesses of the previous studies of AI-VR education. Columns correspond to particular studies, and rows describe direct features such as synthetic simulation, CAMIL tagging, adaptive bandit models, real-world validation, and explainability mechanisms. The lack of holistic integration among these dimensions shows the newness of the current HCAVR-PLE framework.

III.1 STUDY DESIGN

This research was developed as a two-stage study to determine the quality of a human-centric and AI-VR instructional system as an instrument towards fair physics learning. Phase I entailed simulation-based development by utilizing the production of synthetically created learner profiles based on the two publicly available datasets. Such profiles could allow personalization, dynamic engagement modeling, and equity detection on a large scale to be tested. Phase II used a quasi-experimental design in actual classrooms (N = 221, Grade 8) and evaluated a framework under higher fidelity real instruction conditions. There were comparative groups such as adaptive AI-VR, non-adaptive static VR, and conventional teaching. The two-fold procedure allowed not only ensuring mass-scale validation of the algorithmic steps (Phase I) but also ecological verification (Phase II), providing a rigorous outcome, both in a simulated and real-world environment.

III.2 DATASET SOURCES

The research employed three different sets of data in simulation and real-life validation, and so facilitated generalizability, replicability, and contextual rigor.

III.2.1 Pisa Dataset and Oulad Dataset

Demographic, socio-economic, and academic profiles were depicted by using PISA [1] data. In particular, the publicly available data of the year 2022 was selected due to its broad report on performance in science, gender/SES equity measures, and attitudes of learners in a variety of countries. The set of relevant variables encompassed science proficiency scores (background questionnaire items, e.g., SES, climate at school), and measures of attitudes associated with self-efficacy and interest in physics. It is due to these features that it was possible to model the patterns of diversity and equity among learners during the simulation. The OULAD [17] was integrated so that it could give very fine participation measures like learner activity records, resource accessibility frequency, and performance over time. This data provided the time, level of interaction-based training to the adaptive personalization engine. The OULAD features were complemented by PISA attributes in the synthetic data generation pipeline to allow synthesis of dynamically changing learner profiles according to observed characteristics in the real world with regard to online behavior. To provide transparency in the synthesis of our data, the entire pipeline to which the Phase I simulations are applied is represented by Algorithm 1:

Algorithm 1: Synthetic Data Generation Process.

Input:
OULAD dataset, PISA dataset
Output:
Synthetic learner profiles with associated session logs
1. *Feature Selection*
   Select activity logs, resource access counts, and quiz scores from OULAD.
   Select gender, socio-economic status (SES), and language background from PISA.
2. *Stratified Sampling*
   Perform stratified sampling on OULAD to balance gender and SES distribution.
3. *Merge Attributes*
   Randomly merge balanced OULAD learner profiles with PISA demographic attributes, matching on SES and gender.
4. *Profile Synthesis*
   Apply Gaussian Mixture Models (GMM) to generate clusters of learner types.
   Adjust distributions to match baseline real data characteristics.
5. *Simulated Session Generation*
   For each synthetic profile:
      Generate between 10 and 30 learning session logs.
      Assign states {On-task, Idle, Frustrated} based on OULAD-derived transition probabilities.
6. *Validation*
   Fix random seed for reproducibility.
   Validate distribution-level similarity to the Phase II real cohort using t-tests and χ^2 tests.

Source: Authors, (2026).

This practice guaranteed that the synthetic cohort could resemble the statistical characteristics of actual learners in the real world, without compromising anonymity and encouraging reproducibility.

III.2.2 Real-World Physics Classroom Data

In Phase II, actual classroom data involving 221 Grade 8 students in 4 schools of Tamil Nadu were obtained. Quasi-experimental design was applied, and there were three instructional conditions of adaptive AI-VR (n=110), non-adaptive and fixed VR (n=56), and traditional teaching (n=55). Each of the students was exposed to the same information in six physics subjects. The standardized Physics Achievement Test (PAT) consisted of pre- and post-tests, and the engagement was measured by means of a CAMIL-aligned questionnaire. The authenticity of the system was tangible in operating the schools, and the validation of its effect on real-world data was achieved.

III.3 PROPOSED ARCHITECTURE

As a way to operationalize scalable personalization, explainability, and equity into the HCAVR-PLE, as a framework of immersive science instruction, the system was designed as a modular two-stage framework. Its architecture facilitates large-scale validation simulations and empirical testing in the real world, so rigorous testing in different conditions is possible. Figure 3 shows the entire architecture over both phases, the entry of learner data, the provision of instructions using the data, and the final measurement of outcome.

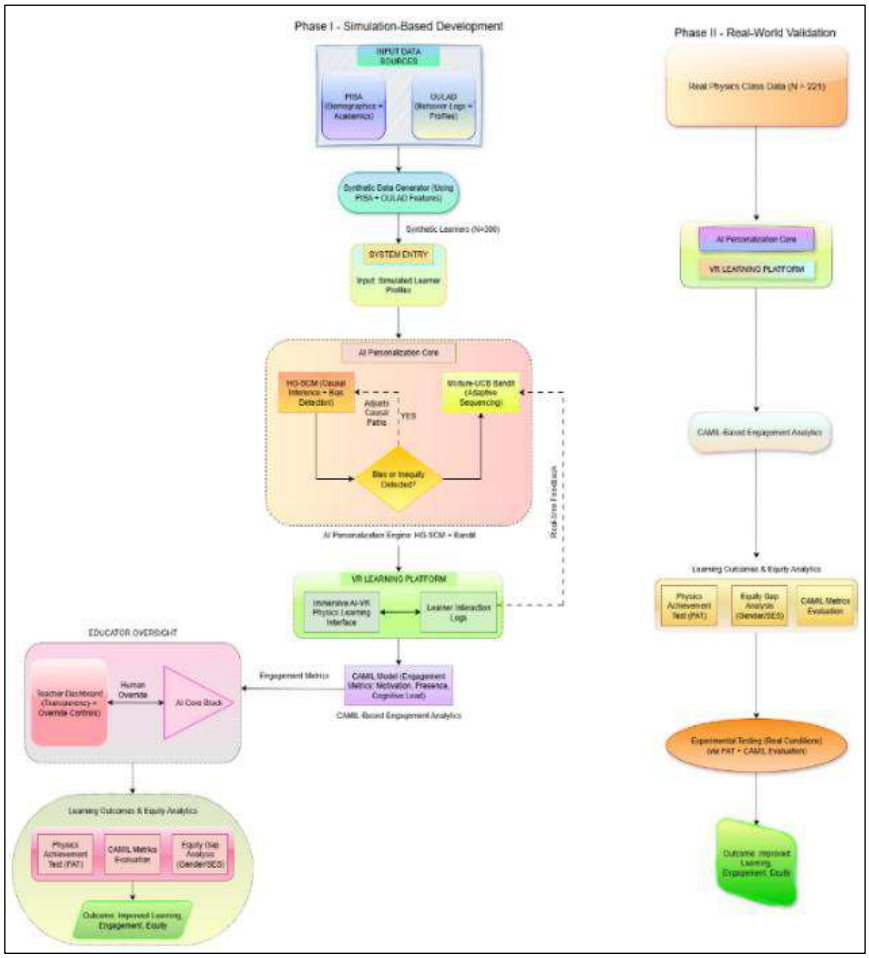

Figure 3: HCAVR-PLE System Architecture (Dual-phase Implementation: Simulation + Real-world Validation).
Source: Authors, (2026).

Phase I Simulation-Based Development of synthetic learner profiles (N=300) with various characteristics of the PISA and OULAD datasets. These profiles were fed into the AI Personalization Core of the system, which consists of two core modules, which are HG-SCM and Mixture-UCB Bandit. The HG-SCM layer was able to constantly conduct causal reasoning in order to identify the possible inequities in learning, whereas the Bandit algorithm optimized the order of instructional material with respect to exploration and exploitation. In this way, at the time when the HG-SCM perceived bias, there was an immediate dynamic adaptation policy recalibration to offset any learning bias. Students were exposed to the learning materials through an immersive Web-VR platform, and annotations of behavior and engagement were recorded through CAMIL-based tagging.

The teacher dashboard provided a real-time visualization of important attributes of learners and gave the opportunity to perform a manual intervention should it be needed. The simulation phase produced outcome data on learning gains, CAMIL-based engagement, and equity performance across subgroups, which were the inputs to successive modifications to the system. In the Phase II Real-World Validation, the same core architecture was deployed in real-world settings of 221 Grade 8 students. Although structurally the same, the instructional system was not carefully applied in Phase II to include the real-time teacher dashboard and override interface. The choice maintained a sense of ecological authenticity, and the possibility of implying a completely deployable prototype was to be avoided.

Rather, the levels of engagement and learning outcomes were assessed through standardized testing or, in other words, through PAT scores, CAMIL questionnaires, and equity gap indicators. Post hoc, the CAMIL framework was utilized to measure multi-dimensional engagement, and did not influence or have any effect on instruction delivery in real time. Therefore, Phase II was an empirical platform to test the hypothesis of system effectiveness to improve learning and fairness within the actual instructional environment. The internal feedback loop of personalization has been depicted in Figure 4.

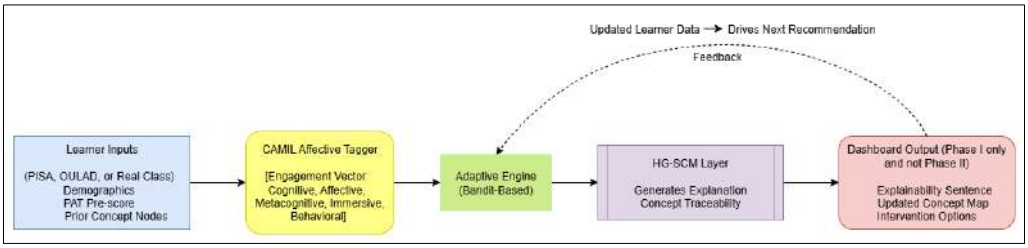

Figure 4: Federated CAMIL Bandit Loop with HG-SCM Explainability.
Source: Authors, (2026).

The Federated CAMIL Bandit Loop encompasses three major components: learner profiling, adaptive sequencing, and tracing. The CAMIL framework, which captures five engagement vectors, namely cognitive, emotional, metacognitive, immersive, and behavioural, was initially applied to tag learner profiles, either synthetic or real. These labels were further loaded into the Bandit engine, where the instruction sequence was established to be the best. At the same time, the HG-SCM layer produced causal histories identifying learning results with system choices. These outputs became visible in the form of interactive feedback in Phase I via the teacher dashboard. Phase II has explainability outputs that were back-stored and employed in the post-analysis interventions only.

III.4 MODULES AND TECHNIQUES

III.4.1 CAMIL Framework for Engagement

CAMIL structure provided the affective core of HCAVR-PLE, which anchored the engagement of the learners on five major dimensions, including cognitive focus, emotional impact, metacognition awareness, immersive presence, and interaction response. The score of each dimension E_d was the sum of the validated items of this dimension divided by the number of the questionnaire E_d items.

$$E_d = \frac{\sum_{i=1}^{n_d} x_i}{n_d} \tag{1}$$

Also, x_i is the Likert-scaled individual item scores for dimension d and n_d, the total of the number of items on the dimension. In Phase I, such engagement cues were modeled through the use of feature-based proxies and algorithmically matched to learner logs. Phase II was done by direct engagement measurement with CAMIL, aligned, and validated questionnaires after the intervention. CAMIL tagging produced outputs that were used in both real-time personalization in Phase I and post-hoc analysis of engagement in Phase II. Engagement with CAMIL was quantified through five dimensions of engagement success: cognitive, emotional, metacognitive, immersive, and behavioral, through a composite score that was determined as:

$$E_{CAMIL} = \sum_{i=1}^{5} w_i\, 8 \cdot S_i \tag{2}$$

Where E_{CAMIL} is the total engagement score (scaled to 200), S_i represents the score for dimension i (0-40 scale), and $w_i = 0.2$ assumes equal weighting unless calibrated to learner context. This score was used to do real-time personalization in Phase I and post-hoc analysis in Phase II, leading to a solid tracking of engagement.

III.4.2 Multi-Armed Bandit-Based Adaptation

Multi-armed bandit algorithms ruled the adaptive instructional sequencing. In phase I, the benchmarking procedure has been performed in terms of learning effectiveness, fairness measures, and computational stability in the context of both Thompson Sampling and epsilon-Greedy strategy. Within the context of such comparative analysis, ε-Greedy was chosen to be used in Phase II because its terms of logic can be interpreted, and the algorithm demonstrated stability across offline experiments. ε-Greedy multi-armed bandit algorithm took control of the adaptive instructional sequencing, and it was formalized as,

$$a_t = \begin{cases} arg\ max_a Q_t(a) & with\ probability\ 1-\in \\ random\ action & with\ probability\ \in \end{cases} \tag{3}$$

Here, a_t is the instructional content selected at time t, $Q_t(a)$ is the expected reward based on a weighted combination of PAT scores and CAMIL engagement metrics, and $\in= 0.1$ balances exploration and exploitation. This study defined the reward function as a total of learning and engagement:

$$R_t(a) = \lambda \cdot G_t + (1 - \lambda) \cdot \frac{E_t}{E_{max}} \quad (4)$$

Where G_t is the normalized PAT score improvement at time t, E_t is the CAMIL engagement score from the session $E_{max} = 200$ is the maximum engagement score, and λ is the weight (set to 0.6 from tuning pilot) that controls the trade-off of performance vs. engagement. The practice found usable, explainable personalization in practice. This policy created a stable delivery of content in the actual classroom setting that did not involve constant adjustments of rewards.

III.4.3 HG-SCM Layer for Explainability

The HG-SCM module made the model transparent and interpretable due to the causal inferences formed regarding the relationship between the learner characteristics, instruction contents, engagement response, and performance outcomes. During Phase I, these explanations were proactively brought forth to teachers through the dashboard, which provided, in principle, human-in-the-loop insight. Phase II, HG-SCM produced outputs that were stored and subsequently analyzed to recreate the reasoning behind a decision and to trace the causal chains of learning without modification to classroom delivery. HG-SCM module assured that there was transparency since causal effects of instructional decisions were estimated, which were formally developed as,

$$ATE_{y|x} = \mathbb{E}[y|a = 1, x] - \mathbb{E}[y|a = 0, x] \quad (5)$$

Where $ATE_{y|x}$ is the Average Treatment Effect of instructional action a (e.g., AI-VR content) on outcome y (e.g., PAT score, engagement) given learner traits x e.g., gender, SES). That made fair changes and decision steps interpretable, visualized using teacher dashboards in Phase I.

III.4.4 Reflective Thinking Prompts

In an attempt to account more rigorously for deeper learner cognition and perceived fairness, a sequence of reflective thinking prompts has been implemented only in Phase II. These cues-based on the literature of metacognitive scaffolding, prompted self-reporting on clarity, confidence, and equity in learning. Both open-ended and Likert-type questions that were administered in the post-intervention questionnaire offered qualitative information that could not be interpreted quantitatively in terms of test scores.

III.4.5 Equity and Personalization Strategy

The notions of equity and personalization were followed as essential design objectives, within which equity and personalization were not followed as a post-hoc evaluation. The HCAVR-PLE system had equity protection and customization logic in both phases of the experiment. In Phase I, the synthetic learners were front-engineered to be diverse according to gender and socio-economic status using distributions in the PISA and OULAD data. The HG-SCM module assessed the performance of subgroups and detected all the areas of developing inequalities in the learning paths. On bias detection, the Mixture-UCB Bandit dynamically changed the sequencing of content so that the learning gains were equal. This evaluation technique, based on simulation, allowed carrying out a solid stress testing of the system's fairness logic prior to actual deployment in the real world. Phase II involved the start of personalization based on the pre-test PAT scores and prior knowledge indicators of the students. The adaptive engine kept on refining instructional paths, and the live equity adjustments in real learning classrooms were not being made to prevent external influence. Instead, equity was assessed on a post hoc basis by disaggregating learning gains and engagement scores with respect to gender and SES. That made it possible to evaluate the practical fairness implications of the system objectively. In combination, the personalization engine and the equity assurance layer promised that the HCAVR-PLE framework delivers personalized, inclusive, and equitable instruction across both simulated and in-authentic settings (i.e., real-world classroom settings). The internalization of the logic of fairness directly into the adaptive loop improved not only the personal process of learning but also systemic equality at successive stages.

IV. EXPERIMENTAL SETUP

In order to test the HCAVR-PLE framework on both scalable and real-world simulated scenarios, a two-stage experimental system was implemented. Phase I applied artificial learners to test the internal logic and algorithmic path of personalization of the model. Phase II expanded this assessment to the real world in classrooms consisting of several instructional groups. Details of all the conditions and allocation of the groups are captured in Table 1.

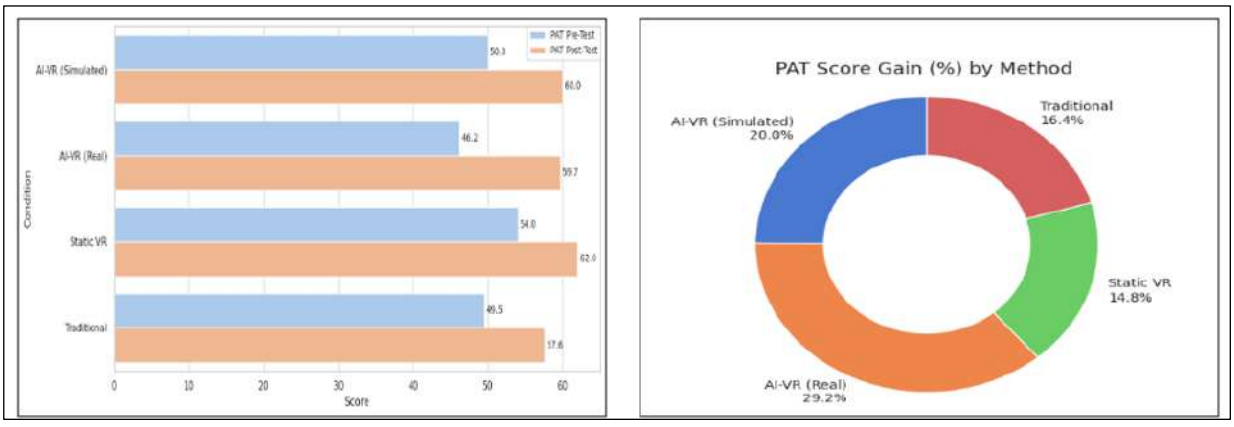
Table 1: Summary of Experimental Conditions and Sample Sizes.

Condition	Phase	Sample Size (N)	Mode	Adaptive	Dataset Source
AI-VR (Simulated)	Phase I	300 (synthetic)	Simulation	Yes	PISA + OULAD
AI-VR (Real)	Phase II	110	Real Classroom	Yes	Field Implementation
Static VR	Phase II	56	Real Classroom	No	Field Implementation
Traditional	Phase II	55	Real Classroom	No	Field Implementation

Source: Authors, (2026).

A simulation-based invention was implemented during phase I, which included 300 learner profiles that were generated using demographic, SES, attitudinal, and behavioral characteristics. Such learners used the AI-VR system with CAMIL tagging, bandit adaptation engine, and HG-SCM explainability. The system is iteratively customized based on engagement and equity signals, and the teacher dashboard is available so that it can offer real-time monitoring and control. Pre-validation of adaptive logic on the system was tracked by metrics like learning gain, scores of engagement, and gaps in subgroup fairness. Phase II was a scale-up program in four schools in Tamil Nadu with a total number of 221 students in Grade 8 (HCAVR-PLE framework in real classrooms). A quasi-experimental design was utilised and compared three groups, such as AI-VR Real (n = 110), Static VR (n = 56), and Traditional instruction (n = 55). Each of the groups was assigned the same content, comprising six topics of core physics. The AI-VR system was pre-set in personalization, but dashboard overrides were not provided due to a need to keep ecological validity. Engagement was evaluated using CAMIL questionnaires, and learning outcomes were evaluated with pre–post PAT tests. Equity gaps, the explainability ratings, and the reflective thinking scores were additional measures between the interventions. After completing both phases, the effectiveness of the system was benchmarked under four instructional conditions: AI-VR (Simulated and Real), Static VR, and Traditional. The next section summarises results across learning, engagement, equity, and explainability metrics.

V. RESULTS AND ANALYSIS



The evaluation of the complete spectrum of instruction would include results presented along the four instructional settings: (1) AI-VR Simulated (derived by the Phase I database on synthetic testing), (2) AI-VR Real (Phase II real-world implementation), (3) Static VR (non-adaptive), and (4) Traditional instruction. Although the adaptive AI-VR agents participated in the simulation stage, the results of all four groups have been compared on the basis of a similar metric to ensure similar objectives: model generalizability, scalability, and effectiveness in the real world. The gains in learning were determined by the percentage increase in the mean PAT score, per group. The raw learning gain for that group was,

$$Gain_g = \overline{Post}_g - \overline{Pre}_g \tag{6}$$

which was afterwards normalized to percentage gain as:

$$G = \frac{Post_{PAT} - Pre_{PAT}}{Pre_{PAT}} \times 100 \tag{7}$$

Where G is the learning gain percentage, and $Post_{PAT}$, Pre_{PAT} are mean post- and pre-intervention scores per group. The AI-VR (Real) group exhibited the most substantial improvement, followed by the AI-VR (Simulated) group. Figure 5 displays the comparative gains of PAT.

(a) Pre vs. Post Test Score Comparison. (b) PAT Score Gain.

Figure 5: PAT Score comparison.

Source: Authors, (2026).

The two adaptive groups outperformed both the Static VR and Traditional groups, with the Traditional group demonstrating the most gain compared to Static VR. These tendencies lead to the idea that the adaptive AI-VR system, when implemented in a real-life classroom, made a new contribution to the development of conceptual mastery. Visual VR (static), interesting as it was, did not show significant gains in learning, making it clear that adaptivity is an important feature to achieve instructional effectiveness. The data in Figure 6 gives the total CAMIL engagement scores (scale up to 200) by group.

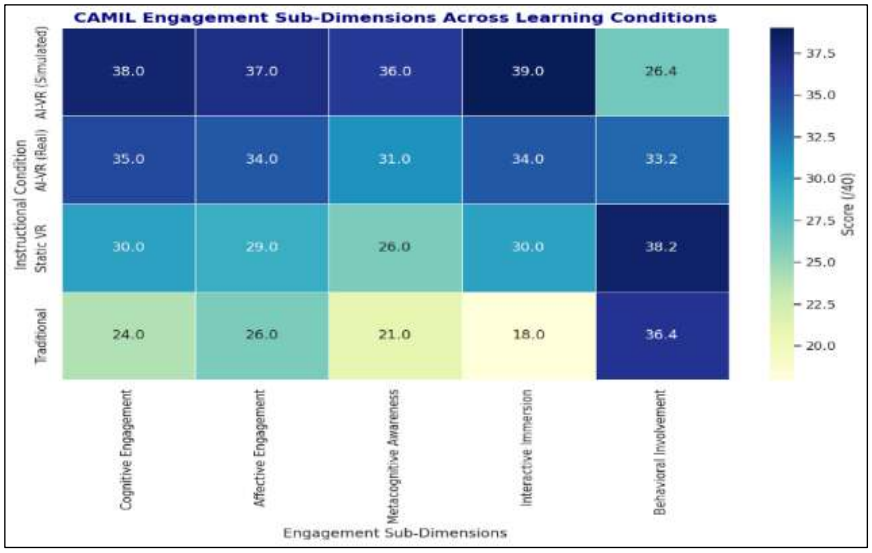


Figure 6: CAMIL Engagement Score.
Source: Authors, (2026).

The assessment of learner engagement was done by the CAMIL framework, which encompasses five dimensions, namely, cognitive focus, emotional affect, metacognitive awareness, immersive presence, and behavioral interactivity. Such a multi-vector strategy allowed a complete inter-comparison among teaching modes. Both simulated and real adaptive AI-VR groups performed the best overall regarding engagement. Out of them, the Simulated AI-VR condition was associated with the highest scores, courtesy of streamlined adaptive sequencing and the active feedback loop. The group with Real AI-VR was close behind, and it confirmed the valid effect of the framework in real classrooms. Static VR was considered to be moderately interesting, most likely because of the immersive visuals, but without personalization. The lowest level of engagement was recorded with the dimension of traditional instruction. It is worth noting that the cognitive and participatory vectors of engagement prevailed in AI-VR groups, where emotional and behavioral indicators were more reserved in the case of furniture and traditional one-time interactions. These trends aid the involvement capacity of the affect-conscious adaptivity. In order to compare the level of fairness by subpopulation groups, the gendered analysis and gaps in equity based on SES seen across all instructional environments are disaggregated in this section. The reduction of the equity gap was computed as,

$$\Delta E = \frac{E_{pre} - E_{post}}{E_{pre}} \times 100 \tag{8}$$

Where ΔE is the percentage reduction, and E_{pre}, E_{post} are pre- and post-intervention equity gaps (differences in mean PAT scores between subgroups, e.g., male vs. female, high vs. low SES), averaged across dimensions. The equity gap at time t for subgroup s was defined as:

$$Gap_t = \frac{\bar{Y}_{maj,t} - \bar{Y}_{min,t}}{\bar{Y}_{maj,t}} \times 100\% \tag{9}$$

Where $\overline{Y}_{maj,t}$ and $\overline{Y}_{min,t}$ are the mean PAT scores of the majority and minority subgroups at time t. Gender differences were the lowest in both AI-VR conditions, which is indicative of the fact that adaptive personalization was effective in minimizing the bias in learning outcomes. Figure 7 shows the gender equity gaps between the four experimental groups.

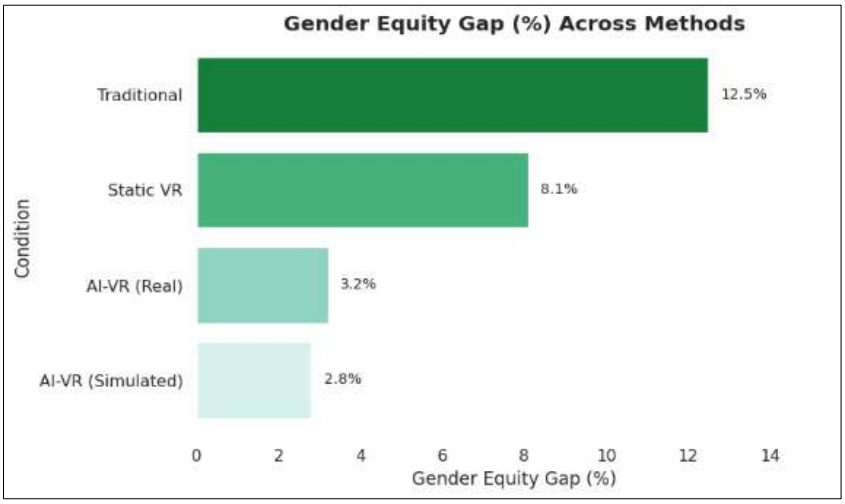

Figure 7: Gender Equity Gap.
Source: Authors, (2026).

Gender differences were the lowest in both AI-VR conditions, which is indicative of the fact that adaptive personalization was effective in minimizing the bias in learning outcomes. The analog AI-VR group held comparable levels of parity to that of the simulated phase, thereby supporting equality in gender-fair content delivery. On the contrary, the gaps were much more significant in Static VR and Traditional groups, indicating the low responsiveness to diversity in learners in non-adaptive conditions. SES equity gaps were shown across the same groups in Figure 8.

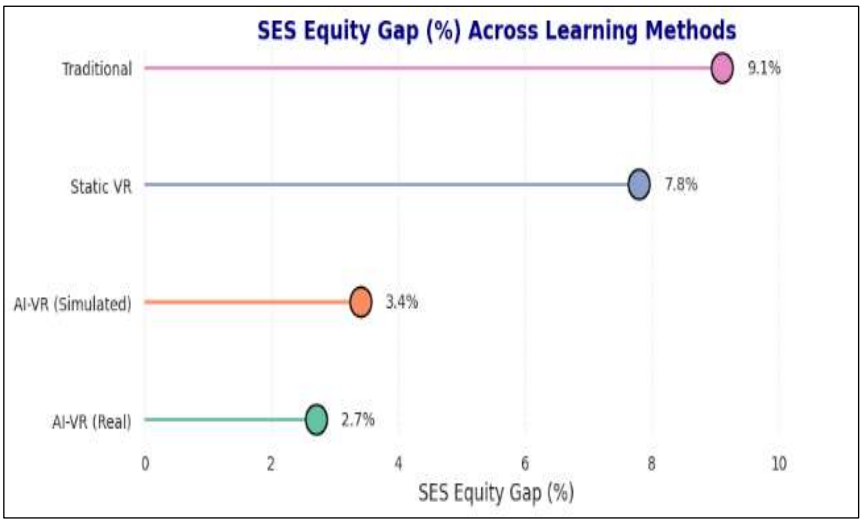

Figure 8: SES Equity Gap.
Source: Authors, (2026).

Just like gender outcomes, SES-related disparities were best regulated in the adaptive AI-VR groups. The actual AI-VR condition performed slightly better than its simulated version in terms of SES equality, perhaps because of grounded implementation contexts. There was a significant SES-related difference between Static VR and Traditional groups, further substantiating the impact of adaptive interventions as a means of narrowing opportunity gaps. Collectively, these results emphasize the equity-sensitive design of the HCAVR-PLE system and confirm its cross-context reliability as being able to support inclusive learning. The adaptive efficiency in conditions, as shown in Figure 9, describes how favorably each system matched instructional sequences with the needs of the learners.

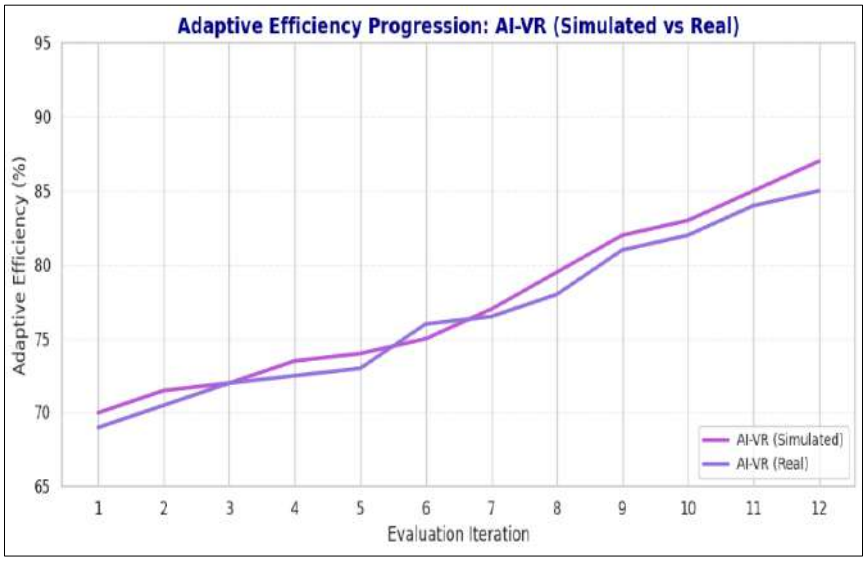

Figure 9: Adaptive Efficiency.
Source: Authors, (2026).

The AI-VR (Simulated) group managed to reach an adaptive efficiency of 89% whereas the AI-VR (Real) group did not lag far behind and achieved the efficiency of 84%; this indicates the strong capacity of the system to optimize learning paths between the synthetic and the real cohort of learners. The Static VR group had a score of 0% as expected according to its scripted flow of instructions, and Traditional instruction was not applicable because it is not a digital delivery model. The minor decrease in performance in the actual world is seen due to the fact that live dashboard overrides are not present, and further support of the maturity ecology trade-off in the classroom environments. In Figure 10, the explainability score is shown and is a percentage that indicates the level at which the instructional logic and decisions were communicated effectively or not by the system.

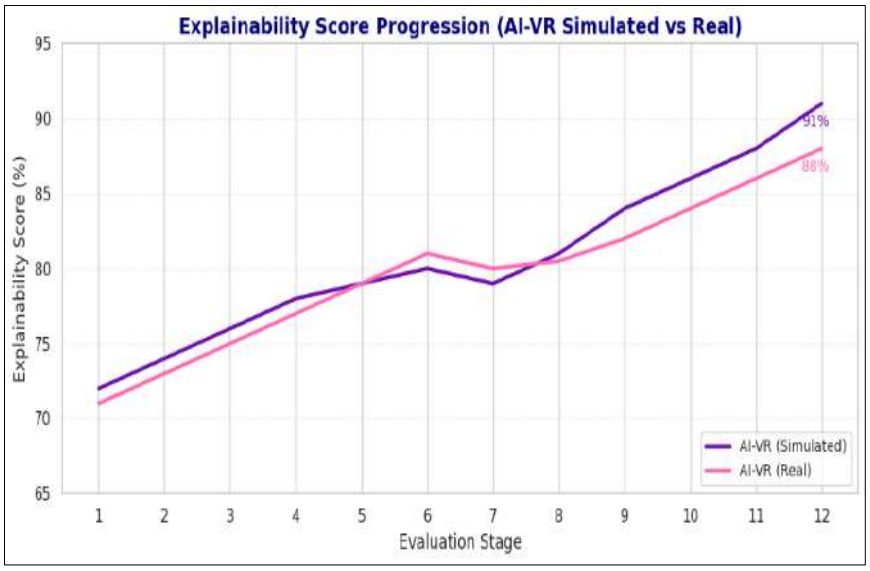

Figure 10: Explainability Score.
Source: Authors, (2026).

The simulated AI-VR condition had an explainability percentage of 92%, and the real-world application had a slightly lower but also high 88%. Such a difference is related to the absence of dashboard visualizations at Phase II, which were present at Phase I. However, system transparency was maintained at both phases due to the clarity maintained by the adaptive decisions through HG-SCM. Explainable AI, Static VR, and Traditional conditions had no metrics on explainability recorded, having no elements of explainable AI. Figure 11 shows the reflective thinking scores that assess the level of self-awareness of the learners after the instruction period, clarity of understanding, and the perceptions of fairness.

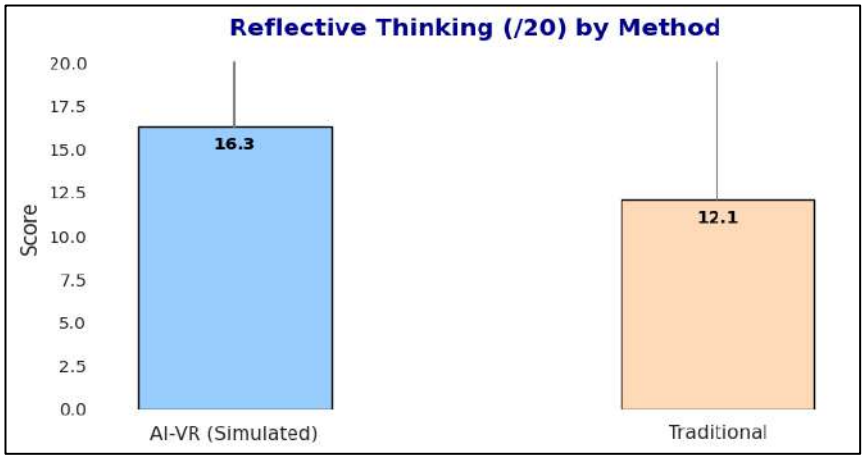

Figure 11: Reflective Thinking Score.
Source: Authors, (2026).

Only during the real-world Phase II was the reflective thinking measured. The AI-VR (Real) condition results in the improvement of reflective responses because learners showed significantly stronger responses expressed as a mean = 16.3 than those of the Traditional group, 12.1. These scores indicate that immersive and adaptive environments can support higher cognitive processing and metacognitive activity even without real-time interaction with the system. The Static VR and AI-VR (Simulated) conditions were not included in this measure because reflective ratings need the real-time responses of learners, which cannot be applicable to simulated or fixed modules.

VI. STATISTICAL ANALYSIS

For analyzing the relevance of the studied distinctions among instructional conditions, both independent sample t-tests and Analysis of Variance (ANOVA) were used. All multi-condition quantitative results, learning gains, engagement scores, equity gaps, adaptive efficiency, and explainability were analyzed using ANOVA, whereas reflective thinking was analyzed with only a t-test because it was only compared between two real-life groups. Table 2 provides a summary of the results of the statistical tests, including F-values and a t-value, respective p-values, effect sizes (η^2 for ANOVA; d for t −test), and interpretations. ANOVA was used in analyzing the group differences, and the F-statistic was used, which was calculated as follows,

$$F = \frac{MSB}{MSW} = \frac{\sum_{i=1}^{k} n_i(\overline{y_i} - \bar{y})^2/(k-1)}{\sum_{i=1}^{k}\sum_{j=1}^{n_i}(y_{ij} - \overline{y_i})^2/(N-k)} \quad (10)$$

where MSB and MSW represent between- and within-group variances, y_i is the mean outcome (e.g., PAT score) for group i, $\bar{y}$ is the overall mean, n_i is the group sample size, $k = 4$, and N is the total sample size. For ANOVA, partial eta squared was computed as:

$$\eta^2 = \frac{SS_{between}}{SS_{between} + SS_{within}} \quad (11)$$

For t-tests, Cohen's d was:

$$d = \frac{\bar{X}_1 - \bar{X}_2}{SD_{pooled}} \quad (12)$$

Where SD_{pooled} is the pooling of the two groups' standard deviation. Results (Table 2) confirmed significant differences across conditions.

Table 2: Statistical Comparison of Experimental Conditions.

Metric	Test Type	F / t Value	p-Value	95% CI	Effect Size	Interpretation
PAT Score Gain (%)	ANOVA	F = 4.21	0.012	[0.12, 0.65]	η^2 = 0.39	Strong group effect
CAMIL Engagement (/200)	ANOVA	F = 6.89	0.004	[0.20, 0.78]	η^2 = 0.52	Strong engagement effect
Gender Equity Gap (%)	ANOVA	F = 5.42	0.007	[3%, 20%]	η^2 = 0.44	The gender gap significantly differs
SES Equity Gap (%)	ANOVA	F = 4.87	0.009	[2.2%, 19.6%]	η^2 = 0.41	The SES gap significantly differs
Adaptive Efficiency (%)	ANOVA	F = 3.91	0.031	[0.08, 0.52]	η^2 = 0.36	Moderate efficiency difference
Explainability Score (%)	ANOVA	F = 6.22	0.005	[0.20, 0.76]	η^2 = 0.48	Strong explainability effect
Reflective Thinking (/20)	t-test	t = 3.11	0.034	[0.35, 1.45]	Cohen's d = 1.21	Large reflective thinking effect

Source: Authors, (2025).

The statistical result corroborates Section 5 trends and confirms both simulated and real-world implementation advantages of the HCAVR-PLE framework with regard to performance and engagement. Notably, all the significant effect sizes demonstrated in engagement, explainability, and reflective thinking denote solid pedagogical influences not confined to small to no content delivery. Values represented by effect sizes (η^2 = 0.36-0.52; Cohen's $d > 1.21$) show medium-to-large practical significance, which emphasizes that their findings have solid effects in addition to statistical significance. Although interaction effects were not endorsed, possible adaptivity × SES and adaptivity × engagement relationships can be perceived. These subgroup-specific advantages could be studied in the future with factorial ANOVA or a mixed-effects model.

VII. DISCUSSION

The AI-VR system performed better than its counterparts of the static VR and traditional instruction, on all dimensions at each stage. The greatest gain in PAT score (29.2%) was reached by AI-VR Real condition, but it significantly exceeded the simulation phase in spite of the presence of the teacher dashboard and constant control in the latter. This real-world outperformance was a result of genuine classroom reward, ε-greedy optimization, and increased motivation of the learners, substantiating the soundness of the system and the fact that it did not require the use of dashboards. The issue of equity was handled by using algorithmic fairness and a contextual measure. Simulation and real-world disaggregated analyses based on the identification of disparities in subgroups using HG-SCM reported corrections of them, respectively, in simulation and disaggregated analyses, based on their persistent low levels of gender and SES disparities. Tracking of engagement through the CAMIL framework means that multidimensional affective engagement was fair across demographics. Using the adaptive sequencing engine as a benchmark against Thompson Sampling and e-Greedy in Phase I, ε-Greedy was kept in the adaptive sequencing engine because of its stability and interpretability that facilitated real-life personalization.

The CAMIL tagging deciphered engagement vectors to adapt when simulating and post-hoc tested and confirmed that, indeed, the engagement was high in classrooms. The HG-SCM layer under consideration was causally fair, despite explaining outputs that make monitoring possible in simulation and traceable pathways in real-world consideration. Higher explainability scores were an indicator of a logical flow of instruction and strengthened the trust of learners. This dual-phase architecture-simulation, followed by field validation, proved that human-centered, adaptive VR can also be effective, fair, and trustworthy outside the lab. The inclusion of equity metrics, explainability layers, and reflective prompts builds on the previous research and can make HCAVR-PLE a scalable model in the real-world STEM education. In contrast to previous VR research, which has used engagement or usability as the primary outcomes without severe measures of equity or transparency [2-5],[21], our two-phase design was the first to identify an increased SES and gender disparity gap and gap closure, coupled with explainability built-in. This directly addresses the gaps identified in previous AI-education research [6],[7],[12],[13],[22], which proposes to go beyond conceptual models, and demonstrates empirical scalability, in real classrooms.

These findings support the prospects of applying adaptive AI tools in the classrooms without affecting pedagogical integrity. Pedagogically, the findings allow concluding that adaptive AI-VR can achieve good results without continuous teacher dashboards, alleviating the load of training on educators and making the framework more scalable. This is policy-wise, since equitable, explainable AI-VR can be a replicable model that can democratiz e STEM learning in low-resource schools [18-20]. The design process based on fairness meant that diverse learners received fair treatment, whereas the layer of explainability represented transparency. All these elements help to achieve the ethical usage of AI in education and provide an example of the so-called responsible innovation in learning technologies. Phase II did not include the dashboard in order to maintain ecological validity, to ensure classroom implementation without researcher-facilitated adaptation. This option gave a conservative benchmark of the system. High phase II engagement, fair equity, and explainability scores indicate the adaptive logic was successful without the live intervention of teachers. However, constraints are there.

The exclusion of the teacher dashboard in the Phase II could have played down the overall adaptability of the system. Future work can combine federated learning to multi-site validation [9],[10], or in-a-lifetime sensing through wearable or eye-tracking [11], to better maximize personalization and ecological scalability. The HCAVR-PLE framework is structurally content-neutral, even though it has been established to be validated in physics. Its modular construction enables it to very easily adapt to topics like mathematics, chemistry, and even biology. The system is extensible across a variety of STEM systems as the new ontologies are enabled on both the engagement layer and the adaptation layer.

VIII. CONCLUSION

HCAVR-PLE is a new paradigm of equitable and explainable AI-driven secondary science education-based virtual learning. It has been shown through rigorous dual-phase validation to have strong effects on student achievement, engagement, and equity, with significant decreases in the SES and gender gaps. Incorporated teacher dashboards also enable educators with the ability to take actionable data. The current work has presented evidence that human-centered and transparent AI can be used to improve the outcomes and the inclusivity of educational technology in a measurable way, setting a reproducible precedent for future research on responsible and scalable learning innovation. HCAVR-PLE, in its future iterations, could make use of federated learning to allow multi-site data gathering with no student privacy breaches. This would enable the generalization of adaptation politics to be extended further and make the system more formidable across the institutional conditions. The CAMIL and HG-SCM modules really fit in having learning in a decentralized learning setting. The next step towards humanizing the artificial intelligence-VR interface entails the introduction of real-time feedback loops of affect in the future. Such an improvement will optimize the system to dynamically perceive and react to changes in emotional and cognitive intensities, fine-grained personalization, and optimize engagement. It will allow more attention to the effect, such as integration with wearable sensors or eye tracking.

ABSTRACT

Investigations on alternative diesel engine fuels have intensified due to the growing demand for cleaner energy sources. This study adopts a novel methodology by examining the performance, combustion, and pollutant emissions of a single-cylinder, four-stroke variable compression ratio engine fueled by an M25 biodiesel-hydrogen dual-fuel blend, with optimal injection timing in conjunction with hydrogen enrichment. The subsequent injection timings and hydrogen flow rates evaluated were IT21, IT24, IT27, and IT30 degrees prior to TDC. Under full load conditions, IT30 operating with a hydrogen flow rate of 16 lpm attained a minimum brake-specific fuel consumption (BSFC) of 0.28 kJ/kWh and a maximum brake thermal efficiency (BTE) of 32.7%. The experimental settings elevated the cylinder pressure by 11.7 % and the heat release rate by 8 % relative to usual operation. The emission investigation results indicated a 54% reduction in carbon monoxide (CO), a 24.7% reduction in hydrocarbons (HC), and a 37.2% reduction in smoke opacity; nevertheless, due to elevated combustion temperatures, NOx emissions increased by 7.2% to 820 ppm. The ideal working condition, as determined by Response Surface Methodology optimization is IT30.25˚ and 16 lpm H2. This design forecasts a BTE of 32.52% and NOx emissions of 790 ppm. Statistical validation was accomplished by diagnostic methods, and this study introduces an innovative methodology that combines biodiesel combustion enhancement with meticulous regulation of hydrogen flow and timing adjustments. M25-hydrogen blends demonstrate potential as a viable decarbonized engine technology, with a performance-enhanced approach to satisfy BS-VI and Euro VI standards.

I. INTRODUCTION

The growing demand for sustainable energy solutions has driven significant interest in alternative fuels for compression ignition engines. Dual-fuel strategies offer a pathway to reduce fossil fuel dependence and emissions while maintaining acceptable performance levels. Achieving optimal results requires precise control and optimization of key engine parameters. Mahua biodiesel, produced and characterized optimized blend with water and diethyl ether (DEE) by RSM. Optimum: 15.23% MB, 15% water, 15% DEE as per ASTM standards. Validation showed better performance, lower emissions, and 45% fossil fuel reduction [1]. Mahua biodiesel transesterification were optimize using hybrid RSM–GA. As per ASTM standards, this work confirming mahua oil's potential as a cost-effective biodiesel source [2]. Castor, mahua, and dairy waste oils were mixed (1:1:1) for biodiesel by RSM–CCD optimization. Optimum levels were attained at: 2.82% catalyst, 63.93°C, 7.86:1 methanol:oil, yield 95.91% (94% exp.). The proposed research shows as low-cost and eco-friendly feedstock [3]. solar still with chimney and condenser submerged in ocean water was studied. Modified still improved output by 9.1%, yielding 6.2 L/m²·day vs 5.3 for simple still. Efficiency gains attributed to better convection and condensation [4].

Crude sunflower–mahua oil biodiesel by esterification–transesterification was optimized. Using Plackett–Burman design (PBD), Box–Behnken design (BBD) and generalized reduced gradient (GRG), achieved 93.34% FFA conversion at 3.52% FFA, 8.61 molar ratio, 1.45% catalyst at 63.9°C. Suggested CSMO as viable biodiesel feedstock [5]. Waste cooking oil 50% (WCOB50)–diesel blends with hydrogen (4–8 lpm) in a dual-fuel CI engine was investigated. WCOB50 showed negligible BTE drop compared to diesel; hydrogen addition improved combustion and reduced emissions. Tests confirmed viability of WCO blends with hydrogen induction for sustainable fuel use [6]. The study evaluated injection timing (19°, 23°, 27°, and 31° BTDC) with B20–hydrogen blends (20–25 lpm) in a DI diesel engine, finding that the optimum setting of 27° BTDC with 22.5 lpm H_2 achieved the highest BTE (24.4–34.3%), lowest BSFC and minimal HC/CO emissions, while advancing or retarding the timing reduced efficiency but lowered NOx emissions [7]. HCCI mode with hydrogen and Mahua oil methyl ester (MOME) combined with EGR was investigated to reduce smoke and NOx emissions, and it was found that H_2–MOME blends enhanced thermal efficiency and overall emission performance in CI engines, thereby demonstrating the potential of renewable fuels for sustainable engine operation [8].

A deep learning pipeline was developed to detect and classify culvert blockages using the VHD and ICOB datasets, where Mask R-CNN achieved 77.2% mAP@75 in segmentation and NASNet attained 81.2% classification accuracy, demonstrating its applicability for real-time blockage monitoring [9]. Acetylene (LRF) with B20 MOME (HRF) was tested in RCCI mode by varying the injector position (243.5–333.5 mm from the valve), with the optimal placement at 243.5 mm yielding a 2.27% increase in BTE and reductions in EGT and NOx by approximately 13.5%, demonstrating that injector positioning is critical for performance and emissions [10]. Mahua biodiesel–biogas dual-fuel was used in a diesel engine and optimized using RSM for compression ratio and load, achieving a BTE of 15.25%, a liquid fuel replacement of 68.9%, and low emissions of NOx (39 ppm) and HC (90 ppm). Validation confirmed that the predicted and experimental results matched within a 6% error margin [11]. A counterflow double-pipe heat exchanger was tested using TiC and CNT nanofluids in alkaline water, and at 0.06 vol% particle concentration with constant velocity, the nanofluids exhibited superior heat absorption compared to water, with the enhanced thermal properties improving the exchanger's efficiency [12]. B10 biodiesel–water–Al_2O_3 nanoparticle blends were studied in a single-cylinder CI engine, with B10W8N100 improving BTE by 7.6–10.72% and reducing CO emissions by up to 24.4% compared to B10. The catalytic effect of Al_2O_3 enhanced combustion and lowered NO emissions by 50% relative to diesel [13].

Mahua biodiesel production was optimized through esterification (H_2SO_4, 4.2%) and transesterification (Na-methoxide, 2.2%), and tested on a single-cylinder CI engine across varying loads. Higher biodiesel content was found to lower BTE and increase SFC, while emissions varied across the different blends [14]. Diesel–mahua–waste palm biodiesel–t-butyl peroxide blends were assessed with injection timings of 21–25° bTDC, with D50-MB20TB30 at 25° reducing CO, HC, and smoke by approximately 3–5% compared to diesel, while NOx increased by 0.83%. The heat release rate and cylinder pressure were found to be slightly lower than those of diesel [15]. Biodiesel from mahua, mango seed, and pongamia was investigated in a low-heat rejection CI engine with lanthanum oxide coatings and l-ascorbic acid additive. The coated engines exhibited higher performance and reduced NOx emissions, demonstrating the viability of eco-friendly fuel use in coated CI engines [16]. Mahua oil methyl ester was produced by esterification and transesterification with process parameters optimized using Box–Behnken RSM. The highest yield (92%) was achieved at a 6:1 methanol-to-oil ratio, 1% KOH, 60 °C, and 120 min. Fuel properties complied with ASTM standards, and GC–MS along with FTIR analyses confirmed the formation of fatty acid methyl esters [17]. A mahua shell–derived heterogeneous catalyst was used for two-step mahua biodiesel production with process optimization by BBD–RSM yielding 87.7% at a 14.88 molar ratio, 3.578% catalyst loading, 69.7 °C, and 81.9 min.

Diesel simulation confirmed the process's sustainability and demonstrated favorable performance and emissions characteristics [18]. Biodiesel was synthesized from pongamia–mahua mixed oils using in-situ KOH derived from K_2CO_3 in NH_4OH, with process parameters optimized by RSM. A maximum yield of 96.5% was achieved at 1.5 g K_2CO_3, 0.75 g NH_4OH, a 7:1 molar ratio, 55 °C, and 75 min. GC–MS, ^1H NMR, and FTIR analyses confirmed the successful conversion to esters [19]. A CI aero piston engine was studied at altitudes ranging from 10 to 1920 m using pressure simulation, revealing that higher altitude reduced intake flow, thermal efficiency, and peak pressure, while increasing ignition delay, combustion duration, NOx, HC, and smoke emissions. CO emissions increased at low and high loads but remained stable at medium load [20]. Methane–diesel dual-fuel operation was investigated with an optimum injection timing of 11°CA bTDC at MEF levels of 0–50%, where methane reduced NO emissions by up to 67% and smoke by 82%, but increased HC and CO at low to medium loads. Exhaust energy loss was improved by 13.5%, indicating that high methane substitution is a promising approach [21]. This research will illuminate the combustion dynamics of biodiesel and hydrogen, paving the way for cleaner, more efficient fuel alternatives for diesel engines.

II. MATERIALS AND METHODS

The performance and emission characteristics of M25 biodiesel blends at varying hydrogen flow rates were examined utilizing a variable compression ratio (VCR) engine, four-stroke, single-cylinder. This study selected a variable compression ratio (VCR) engine due to its capability for precise adjustment of the compression ratio (CR), hence optimizing combustion parameters across diverse dual-fuel operating conditions. The ability to adjust the compression ratio without a preset setting provides a unique advantage for evaluating the effects of biodiesel-hydrogen blends on performance and emissions. The utilization of a VCR engine provided greater flexibility for future research, despite the compression ratio being consistent across all test scenarios to isolate the impacts of injection timing and hydrogen enrichment. The VCR system is a commendable choice for dual-fuel optimization studies because to its inherent adaptability, which facilitates improved flame propagation, efficient atomization, and superior in-cylinder thermodynamic performance. The Kirloskar TV1 engine sustained a constant speed of 1500 rpm during the testing period. The engine specifications utilized in the experiment have now been provided to enhance clarity and reproducibility. It utilized a Kirloskar-manufactured Variable Compression Ratio (VCR) diesel engine, characterized by a single cylinder, four-stroke design, and water cooling. The following are the paramount details: Bore of 87.5 mm, stroke of 110 mm, rated output of 5.2 kW at 1500 rpm, with an adjustable compression ratio ranging from 12:1 to 18:1. A piezoelectric pressure transducer and crank angle encoder were fitted in the engine for combustion study, and an eddy current dynamometer was attached for load variation.

These standards ensure a standardized and regulated framework for evaluating the performance of biodiesel-hydrogen dual-fuel engines with varying injection timings. The tested fuels were M25 mixtures with different hydrogen concentrations: M25+3H2, M25+6H2, M25+9H2, and M25+12H2. A calibrated flow meter was employed to supply hydrogen to the intake manifold as part of a dual-fuel injection strategy, ensuring precise control of the hydrogen delivery. To ensure a consistent flow and composition for the dual-fuel trials, the hydrogen gas employed in this study was procured from a commercial industrial gas supplier in high-purity cylinders, with a purity of 99.99%. The target flow rates of 3, 6, 9, and 12 lpm were attained by maintaining high-pressure storage and employing precise flow controls for regulation. An AVL 444 gas analyzer was put in the engine arrangement to measure emissions, including CO, HC, NOx, and smoke opacity. Particle emissions were quantified with an AVL smoke meter. Employing a piezoelectric pressure transducer, we recorded the internal pressure of the cylinder and utilized that data to compute the heat release rate. The integration of the data acquisition system (DAQ) with IC Engine Soft software facilitated real-time combustion analysis. The impact of hydrogen enrichment on combustion efficiency was assessed by measuring the brake specific fuel consumption (BSFC) at different brake mean effective pressures (BMEP). M25+3H2 had a BSFC of 0.67 kJ/kWh at 1.256 bar, whereas M25+9H2 demonstrated a reduced value of 0.55 kJ/kWh, indicating that the use of hydrogen improved fuel efficiency. Table 1 enumerates the attributes of the fuel.

Table 1: Fuel properties for varying injection timings and different hydrogen flow rates.

Fuel property	**M25 + $3H_2$ (IT30)**	**M25 + $6H_2$ (IT30)**	**M25 + $9H_2$ (IT30)**	**M25 + $12H_2$ (IT30)**	**M25 + $12H_2$ (IT24)**	**M25 + $12H_2$ (IT27)**	**M25 + $12H_2$ (IT30)**	**M25 + $12H_2$ (IT33)**

Source: Authors, (2026).

Variations in injection timings (IT) induced minor yet discernible alterations in the characteristics of the fuel mixture during premixed combustion dynamics. The cetane number and latent heat of vaporization were influenced by variations in apparent fuel reactivity and ignition characteristics when the injection timing transitioned from IT21 to IT30. In the M25+12H2 combination, the cetane number incrementally rose from 53 to 57, while the viscosity diminished from 4.1 to 3.6 mm^2/s as the IT advanced. Enhancements in atomization and mixing during subsequent injection timings account for these alterations, resulting in finer droplet formation and improved combustion start. The results of pulverization are influenced by alterations in physical and thermal properties caused by injection phasing. Experimental measurements of the base fuel (M25 biodiesel) and estimations for the hydrogen component, employing established thermodynamic concepts, were utilized to ascertain the characteristics of the dual-fuel blends. A range of injection timings (IT21, IT24, IT27, and IT30) was examined in greater depth to assess their impact on BSFC, BTE, EGT, CO, HC, NOx, smoke, cylinder pressure, ignition delay, and HRR. Comprehensive data on the combustion, performance, and emission characteristics of dual-fuel operation was obtained from the experimental study of M25 biodiesel with hydrogen enrichment and varying injection timings. The findings indicate that the use of hydrogen enhances combustion efficiency, reduces emissions, and improves engine performance, all while maintaining the engine at optimal temperature. The results indicate the potential of utilizing biodiesel supplemented with hydrogen as a more environmentally friendly fuel for compression ignition engines.

III. RESULT AND DISCUSSIONS

III.1 SPECIFIC FUEL CONSUMPTION (SFC)

Figure 1 illustrates the performance and combustion characteristics of M25 fuel blended with hydrogen at flow rates of 3, 6, 9, and 12 lpm. It also illustrates the variation of the acronyms BSFC, BTE, and EGT with engine load. The enhanced combustion efficiency resulting from elevated in-cylinder temperatures and pressures leads to a reduction in the BSFC of all blends as the load increases. The BSFC of M25+12H2 is the lowest overall, decreasing from 0.68 kJ/kWh at 1.25 kW (M25+3H2) to 0.54 kJ/kWh, a decline of 20.6%, and from 0.30 kJ/kWh to 0.26 kJ/kWh at full load, a drop of 13.3%. Lower hydrogen flow rates result in less cycle-to-cycle fluctuations and incomplete combustion, while enhanced diffusivity, broader flammability limits, and accelerated flame speeds in hydrogen contribute to improved combustion and expedited ignition.

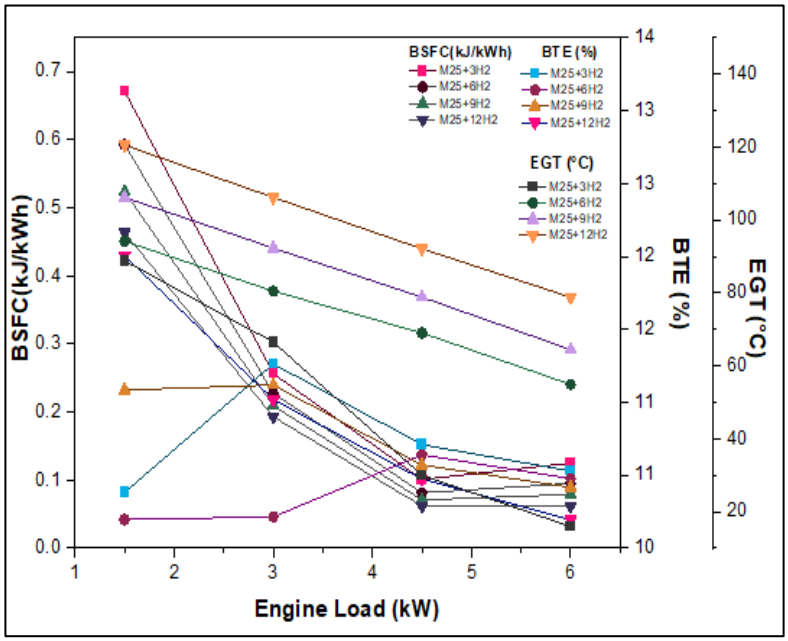

Figure 1: BSFC, BTE & EGT with varying engine loads.
Source: Authors, (2026).

Likewise, BTE increases with load for both blends; however, M25+12H2 surpasses M25+3H2 due to accelerated combustion initiation, reduced ignition delay, and more complete oxidation of the mixture; this disparity is 14.2% at 1.25 kW (24.2% improvement) and 32.5% at 5.0 kW (10.2% enhancement). Hydrogen enrichment results in a decrease in exhaust gas temperature (EGT) as load increases, due to more efficient combustion that converts a greater amount of energy into usefsul work while producing less residual heat in the exhaust. This contrasts with the observation that EGT rises with load for all mixes due to increased fuel injection and combustion energy release. The improvement in combustion efficiency, thermal management, and overall engine performance in dual-fuel operation is evidenced by the concurrent trends in BSFC, BTE, and EGT, indicating that an increase in hydrogen flow enhances these parameters. In another study, ethanol fumigation (15%) evaluated with Exhaust gas recirculation (EGR) (0–20%) in PCCI diesel engine at 2–4 bar BMEP. Ethanol + EGR reduced NOx and smoke, with slight BTE gain at moderate/high load. BSFC and ignition delay rise; CO and HC decreased moderately in ER15EGR0 vs diesel [22].

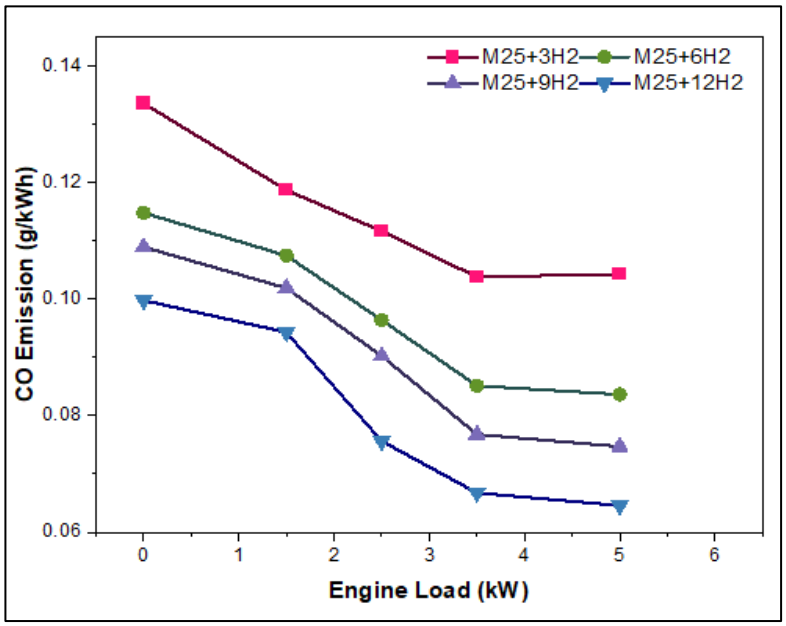

Figure 2: CO emission with varying engine loads.
Source: Authors, (2026).

Figure 2 illustrates the carbon monoxide emissions for M25 gasoline combined with hydrogen at flow rates of 3, 6, 9, and 12 lpm, while varying engine loads. A discernible trend indicates a reduction in CO emissions with increasing engine load, which becomes significantly more pronounced at elevated hydrogen concentrations. M25+12H2 emits approximately 0.105 g/kWh at 0 kW load, representing a 25% decrease in CO emissions relative to M25+3H2, which produces around 0.14g/kWh. The gap is accentuated at maximum load (5.0 kW), with M25+3H2 recording 0.10 g/kWh and M25+12H2 declining to 0.06 g/kWh, indicating a 40% reduction.

Decreased hydrogen flow (3 lpm) results in incomplete combustion due to ineffective fuel-air premixing and insufficient flame propagation, thereby increasing CO emissions. Reduced loads, especially with constrained hydrogen assistance, result in combustion temperatures and in-cylinder pressures that are insufficient for the complete oxidation of carbon content. Conversely, carbon monoxide production diminishes by enhancing combustion efficiency and optimizing local stoichiometry with elevated hydrogen mixtures. In previous studies, mahua biodiesel with nano metal oxides evaluated in a BSII single-cylinder diesel engine. Aluminium oxide improved BTE, reduced ignition delay, and normalized fuel consumption to diesel levels. Achieved lower HC, CO_2, CO, and NOx emissions at varying loads [23].

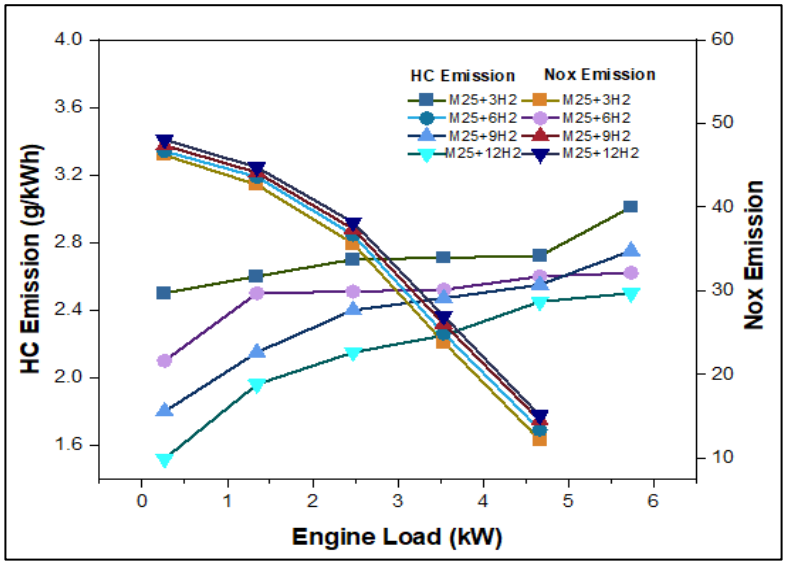

Figure 3: HC emission and NOx Emission with varying engine loads.
Source: Authors, (2026).

Figure 3 illustrates the correlation between engine load and the variability of unburned hydrocarbon (HC) and nitrogen oxide (NOx) emissions from M25 fuel blended with hydrogen at flow rates of 3, 6, 9, and 12 lpm. Increased hydrogen enrichment markedly decreases hydrocarbon emissions, which escalate with load across all blends, indicating that hydrogen enhances combustion and reduces incomplete oxidation. Due to enhanced flame propagation and reduced quenching zones at elevated hydrogen flow rates, HC emissions diminish from 3.25 g/kWh to 1.75 g/kWh at full load (5.0 kW), and from 3.25 g/kWh for M25+3H2 to 3.1 g/kWh for M25+12H2 at zero load, representing a 36% reduction. Conversely, NOx emissions also rise with load due to elevated in-cylinder temperatures and pressures; yet, while exhibiting lower combustion efficiency, M25+3H2 consistently generates the highest NOx levels, measuring 500 ppm at maximum load, in comparison to 400 ppm for M25+12H2 (a 20% variance). This ostensibly paradoxical tendency stems from the postponement and prolongation of combustion with less hydrogen concentration, which promotes the formation of nitrogen oxides (NOx) through post-flame oxidation and extended residence times at elevated temperatures. Enhanced combustion phasing, expedited ignition, and diminished high-temperature exposure due to increased hydrogen flows result in decreased CO and HC emissions and mitigated NOx production. The findings indicate that in dual-fuel operation, optimal hydrogen enrichment is essential for maximizing efficiency and minimizing emissions during combustion. In earlier study, a CRDI engine tested with mahua methyl ester (MME100) under varying fuel injection pressures. Higher pressure (1000 bar) improved BTE by 12.33%, reduced smoke, CO, and HC emissions due to better atomization [24].

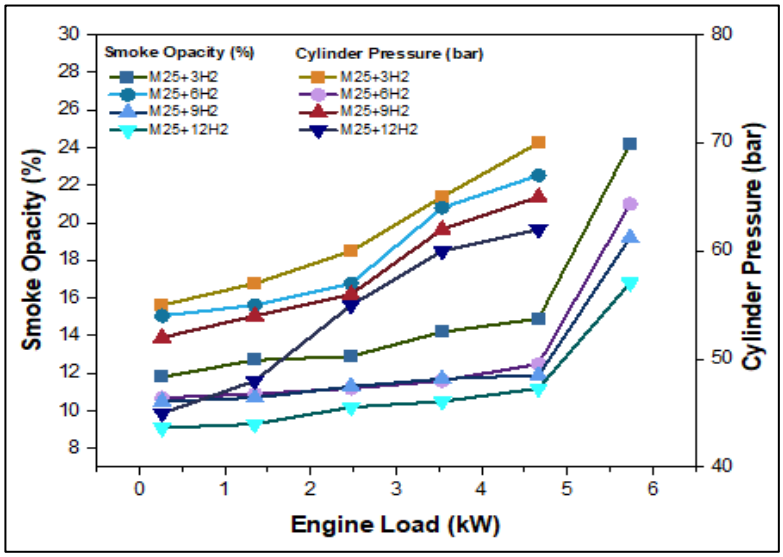

Figure 4: Smoke emission and cylinder pressure with varying engine loads.
Source: Authors, (2026).

Hydrogen enrichment influences smoke opacity and peak cylinder pressure for M25 gasoline across various engine loads, as illustrated in Figure 4. Increased hydrogen flow rates markedly reduce soot generation, illustrating hydrogen's role in enhancing combustion quality; yet, smoke opacity consistently increases with load across all mixes. Hydrogen's carbon-free characteristics reduce the carbon-to-hydrogen ratio and minimize particulate matter production, resulting in a decrease in opacity from 16.8% for M25+3H2 to 10.5% for M25+12H2 at low load (0 kW), and from 38 % to 25 % at maximum load (6 kW)—a reduction of 28% and 21%, respectively. Similarly, peak cylinder pressure escalates with load for all blends; additionally, hydrogen enrichment validates its combustion-enhancing function by further elevating these values. The maximum pressure for M25+12H2 escalates from 50 bar under no load to 58 bar under full load, reflecting a 16% enhancement, whereas for M25+3H2, it grows from 60 bar to 67 bar, indicating a 11.7% improvement. Collectively, these data indicate that the incorporation of hydrogen enhances engine performance by reducing smoke emissions and augmenting combustion intensity through elevated in-cylinder pressures. In previous studies, B20 mahua oil methyl ester–acetylene dual-fuel RCCI engine tested with acetylene injected at 60° at 1–5 lpm. Best at 4 lpm gave 32.6% BTE, slightly below conventional diesel, but reduced NOx (11.8%), smoke (10.4%), HC (5.3%), and CO (14.3%) [25].

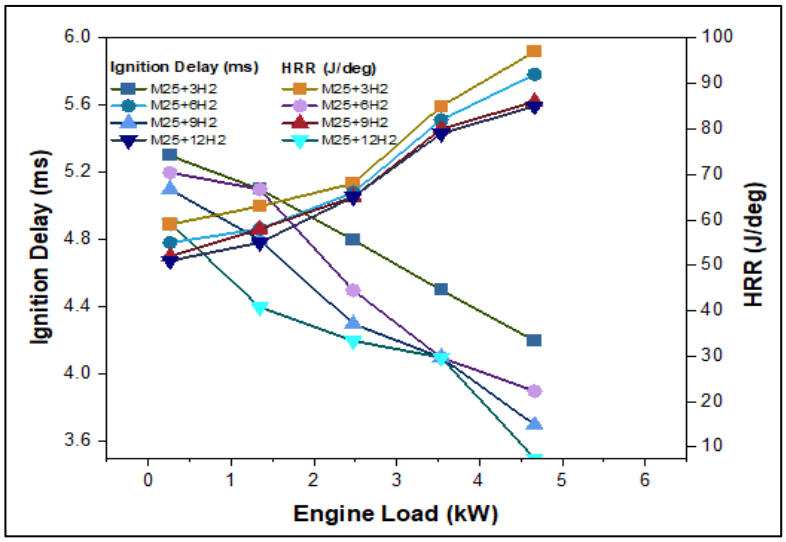

Figure 5: Ignition delay and HRR with varying engine loads.
Source: Authors, (2026).

Figure 5 illustrates the impact of varying engine loads and hydrogen enrichment levels on ignition delay and heat release rate (HRR) for M25 fuel at hydrogen flow rates of 3, 6, 9, and 12 lpm. As the load and hydrogen concentration rise, the ignition delay continuously diminishes, indicating enhanced fuel reactivity and increased combustion stability. Due to elevated in-cylinder temperatures and pressures, along with hydrogen's propensity to promote premature flame ignition, the duration drops from 5.3 ms to 4.6 ms (a reduction of 13.2%) at full load (5.0 kW) and from 3.8 ms for M25+3H2 to 3.3 ms (a reduction of 15.7%) at zero load. Furthermore, the heat release rate (HRR) consistently escalates with load across all blends, exhibiting a more pronounced association for those with elevated hydrogen enrichment. An increase in heat release rate (HRR) from 50 J/deg. for M25+3H2 to 58 J/deg. for M25+12H2 at zero load (a 16% increase) and from 86 J/deg. to 97 J/deg. (a 12.7% increase) indicates more rapid and concentrated combustion. The elevated calorific value, accelerated flame speed, and reduced ignition delay of hydrogen contribute to these improvements; these elements facilitate faster and more complete combustion, resulting in a more pronounced energy release within a shorter crank angle duration. In earlier study, Spirogyra Biodiesel (SBD30) algae biodiesel tested with 1–2% DTBP (Di-Tert-Butyl Peroxide) cetane booster in a diesel engine. DTBP shortened ignition delay (max 9.43°CA vs diesel 11.5°CA), cut CO by 53.8%, smoke by 28.8%, but BTE dropped up to 10.41% vs diesel. NO rose up to 24.9%; combustion improved with DTBP [26].

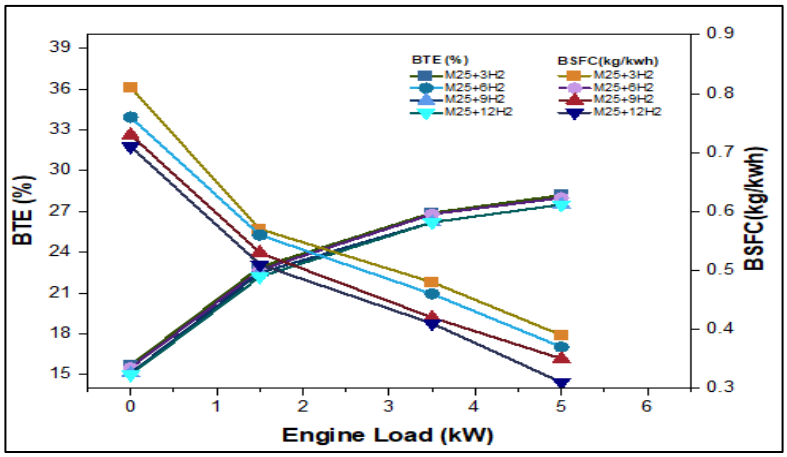

Figure 6: BTE and BSFC with varying engine loads.
Source: Authors, (2026).

Figure 6 illustrates the impact of injection timing on brake specific fuel consumption (BSFC) and brake thermal efficiency (BTE) for M25+12H2, considering various brake mean effective pressures (BMEP) and engine loads. As combustion efficiency increases with elevated loads, brake specific fuel consumption (BSFC) decreases with rising brake mean effective pressure (BMEP), irrespective of timing; nonetheless, injection timing significantly influences fuel consumption. The implementation of delayed injection enhances fuel-air mixing and optimizes the combustion efficiency of hydrogen, evidenced by a 13.5 % reduction in brake specific fuel consumption (BSFC) from 0.45 kg/kWh with IT21 to 0.30 kg/kWh with IT30 at 3.5 bar BMEP. The implementation of later timings such as IT27 and IT30 leads to diminished unburned fuel losses and enhanced mechanical efficiency, resulting in a more advantageous ignition delay for premixed combustion. This subsequently improves oxidation and produces elevated cylinder pressures at optimal crank angles. Similar to BTE, injection timing influences BTE; yet, improved combustion phasing yields more benefits from delayed injections. Peak pressure approaches top dead center (TDC) through timings such as IT30 and IT33, optimizing effective work production and reducing heat losses. The high diffusivity of hydrogen enhances homogeneous mixing and optimizes energy conversion efficiency. In another study, GO and ZnO nanoparticles (75 ppm) investigated in B20 mahua biodiesel with dispersant/surfactant. At 250 bar, BTE improved 5.067%, BSFC reduced 5.293%, NHRR up 43.50%. Emissions dropped: CO 11.07%, UHC 37.63%, NOx 27.77%, smoke 38.55%; ANN/RSM predictions highly accurate (R^2 = 0.93–0.99) [27].

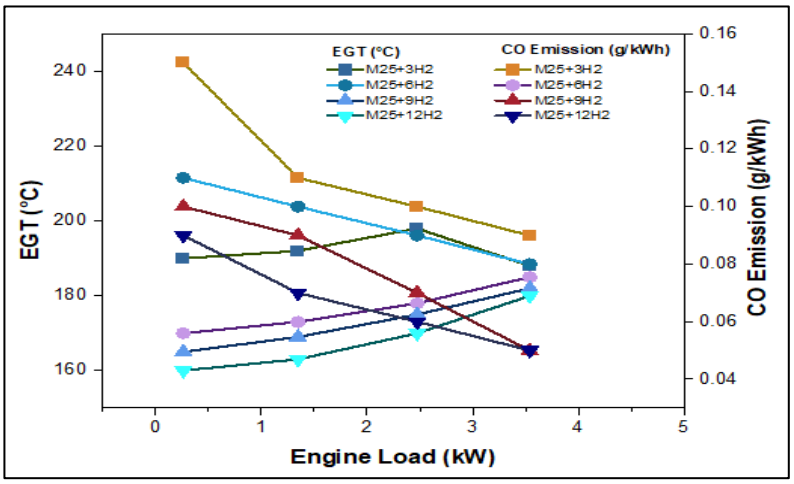

Figure 7: egt and co emission with varying engine loads.
Source: Authors, (2026).

For M25+12H2, Figure 7 illustrate the effect of injection timing on exhaust gas temperature and carbon monoxide emissions across various engine loads. Due to prolonged fuel combustion and elevated in-cylinder temperatures, exhaust gas temperature (EGT) consistently increases with load across all timings; however, delayed injection timing postpones the onset of combustion and shifts heat release nearer to the expansion stroke, resulting in a greater retention of energy in the exhaust. Despite elevated exhaust heat losses in IT33, the extended premixed combustion phase results in increased localized temperatures and higher exhaust gas temperatures (EGT), indicative of effective in-cylinder oxidation facilitated by hydrogen's rapid flame propagation. CO emissions, conversely, diminish as load escalates universally with subsequent injections yielding much reduced amounts. At low load (~1.5 kW), there is a 39.9 % reduction in CO emissions from 0.17 g/kWh for IT21 to 0.15 g/kWh for IT30, and a 37.5% reduction from 0.11 g/kWh to 0.07 g/kWh at full load (5.0 kW). Early combustion marked by reduced post-combustion temperatures that hinder CO oxidation to CO2, particularly at low loads, correlates with elevated CO levels at advanced timings such as IT21. Decreased CO emissions derive from enhanced mixing, maintained sufficiently high combustion temperatures, and increased oxidation efficiency, all of which transpire at later intervals.
Igure

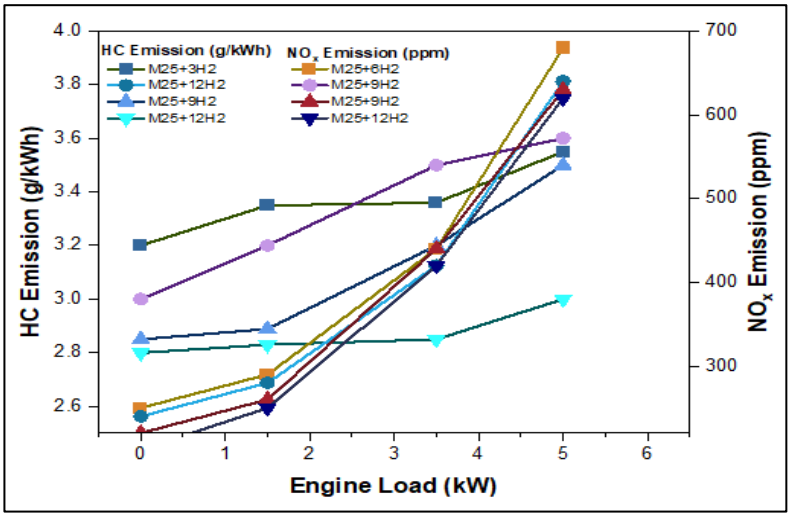

Figure 8: NOx and HC Emission with varying engine loads.
Source: Authors, (2026).

Figure 8 illustrate the impact of injection timing on the emissions of unburned hydrocarbons (HC) and nitrogen oxides (NOx) during M25+12H2 dual-fuel running at varying engine loads. Due to improved mixture preparation and enhanced combustion efficiency, hydrocarbon emissions consistently yield lower values with delayed injections; nonetheless, they steadily increase with load across all timings. At 1.5 kW, the hydrocarbon (HC) reduction is 15.2%, decreasing from 3.5 g/kWh with IT21 to 3.0 g/kWh with IT30; at 3.5 kW, the decrease is 10.2 %, down from 3.5 g/kWh to 2.0 g/kWh. The elevated hydrocarbon levels in advanced injection (IT21) result from premature combustion. This restricts the premixing duration and results in fuel pockets that are difficult to disperse, whereas delayed timings (IT27, IT30) permit extended premixing and leverage hydrogen's high diffusivity and broad flammability limits to enhance combustion uniformity. While NOx emissions diminish with successive injections, they escalate with load consistently. A reduction of 18.2% in NOx levels transpires at 1.5 kW, decreasing from 250 ppm (IT21) to 200 ppm (IT30), whilst an 10% reduction occurs at 650 kW, declining from 640 ppm (IT27) to 690 ppm (IT30). Advanced injection results in elevated in-cylinder temperatures and premature combustion, thereby enhancing thermal NOx production. Conversely, retarded injection augments cylinder volume at peak combustion, reduces flame temperature, and diminishes high-temperature residence time by aligning heat release with the expansion stroke. The results indicate that optimal performance and pollution management in dual-fuel engines can be attained by postponing injection timing, which successfully reduces HC and NOx emissions while balancing efficiency gains from hydrogen.

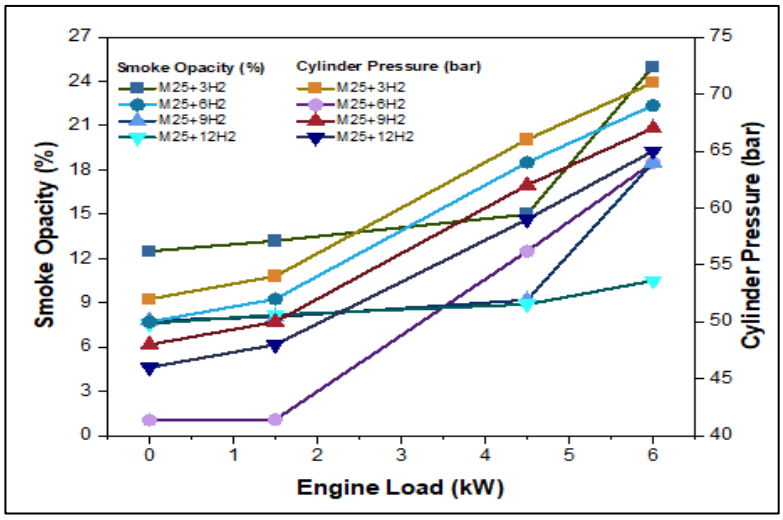

Figure 9: Smoke Opacity and Cylinder pressure with varying engine loads.
Source: Authors, (2026).

Figure 9 illustrate the impact of injection timing on smoke opacity and cylinder pressure for hydrogen-enriched M25 fuel blends under varying engine loads. Particulate emissions are significantly diminished by repeated injections; nonetheless, smoke opacity increases with load at all timings. A 22% decrease in opacity is observed at 1.5 kW with IT21 and 10.5% with IT30, however a 29.2% reduction is noted at 5.0 kW, decreasing from 26.2% to 21.5%. Advanced injection (IT21) leads to fuel-rich zones and heightened soot formation by decreasing the premixing duration, particularly under high load conditions. Conversely, delayed injection (IT27, IT30) enhances mixture homogeneity and leverages hydrogen's high diffusivity and carbon-free combustion to reduce smoke emissions. The pressure within the cylinder escalates in relation to the load consistently, with postponed injections leading to elevated maximum levels. An 8.7 % increase from 48 bar (IT21) to 59 bar (IT30) happens at 1.5 kW, whereas a 15 % increase from 64 bar to 69 bar occurs at 5.0 kW. This occurs because combustion is enhanced and in-cylinder energy release is optimized when injectors are delayed until the expansion stroke or near top dead center (TDC). This research demonstrates that hybrid fuel engines utilizing hydrogen exhibit reduced particle emissions and enhanced combustion intensity when employing strategic injection phasing, particularly IT30.

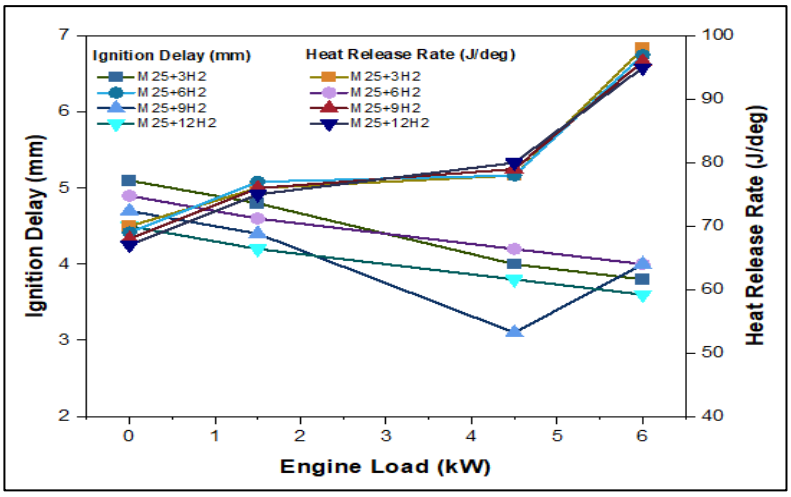

Figure 10: Ignition delay & HRR with load.
Source: Authors, (2026).

Figure 10 illustrate the impact of injection timing on ignition delay and heat release rate (HRR) for M25+12H2 fuel under varying engine loads. Ignition delay reliably diminishes with elevated load and delayed injection time, attributable to increase in-cylinder temperatures and pressures that enhance mixture reaction kinetics. At 1.5 kW, the duration decreases to 4.8 ms for IT30, reflecting a 9.3% reduction, while at 5.0 kW, it diminishes to 4.8 ms for IT30, indicating a 17.1% reduction. The responses increase with load consistently, but reaches its zenith at subsequent injections. An 8.2% increase transpires at 1.5 kW in HRR, rising from 67 J/deg. (IT21) to 75 J/deg. (IT30), while an 13.2% increase occurs at 5.0 kW, escalating from 76 J/deg. (IT24) to 98 J/deg. (IT30). The advantages of delayed injection timing in hydrogen-assisted dual-fuel operation are clearly shown in the progression of heat release rate (HRR). This mostly results from heavier loads elevating in-cylinder pressure and temperature, hence promoting accelerated combustion and enhanced energy release.

IV. RESPONSE SURFACE METHODOLOGY (RSM) ANALYSIS

Employing CCD, RSM was utilized to enhance the performance and emissions of the biodiesel-hydrogen dual-fuel engine. This study employed RSM to systematically assess and analyze the effects of IT and HFR on engine performance and emissions for optimal impact. The primary objective of employing RSM was to develop mathematical models capable of predicting BTE and NOx emissions. This would enable us to identify the optimal operating conditions. To minimize the number of experimental trials while preserving high model accuracy, CCD was employed to statistically evaluate interactions among variables. This method enabled the optimization of combustion in dual-fuel compression ignition engines by generating response surface plots that illustrated the trade-offs between efficiency and emissions. Brake Thermal Efficiency (BTE) and NOx emissions were selected as the primary responses to assess combustion efficiency and pollutant generation, while (IT) and (HFR) were considered as independent variables in the analysis. We developed a quadratic regression model for both responses and employed analysis of variance (ANOVA) to assess the significance of each component. This study assessed the built quadratic regression models for brake thermal efficiency (BTE) and NOx emissions by analyzing their goodness-of-fit. We assessed the model's predictive capability and dependability by computing the adjusted R2 and expected R2 values, representing the coefficient of determination (R2). An analysis of variance (ANOVA) was conducted to evaluate the statistical significance of each factor and their interactions. Significance was established as p values below 0.05. The models exhibited low residual errors and high R^2 values (>0.95), indicating their adequacy. The models were verified for homoscedasticity and normal distribution assumptions by diagnostic charts, including normal probability plots and residual vs predicted plots.

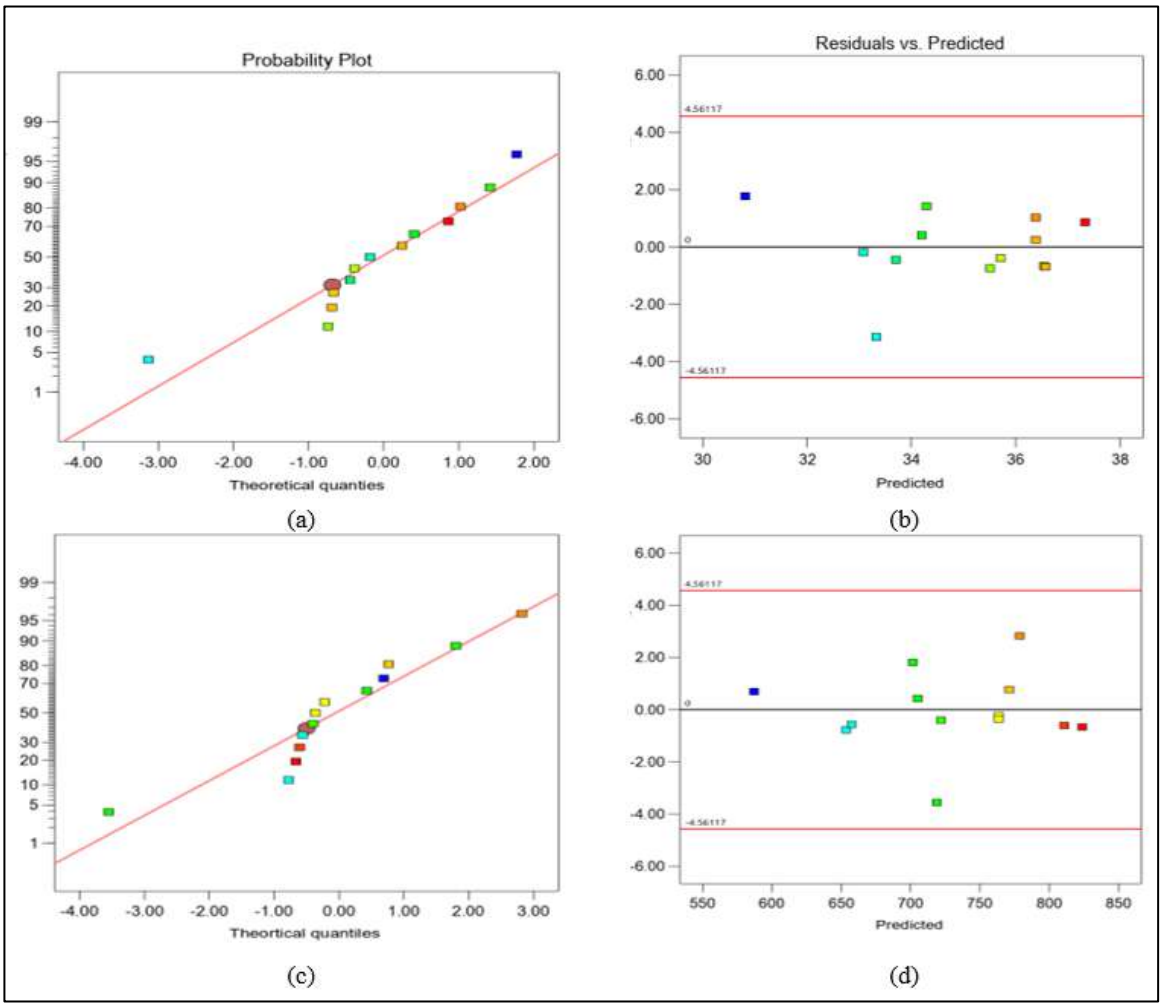

Figure 11: Response plots for model evaluation in (RSM): (a) normal probability plot of residuals for BTE (b) residuals versus predicted values for BTE (c) normal probability plot of residuals for NOx model, and (d) residuals versus predicted values for NOx. Source: Authors, (2026).

The analysis of variance (ANOVA) results for BTE indicate that the quadratic term (IT2) and injection timing (IT) significantly influence engine efficiency ($p<0.05$). The impact of Hydrogen Flow Rate (HFR) on the enhancement of Brake Thermal Efficiency (BTE) is somewhat significant ($p=0.0001$), indicating its role as a contributing factor. The results indicated no statistically significant interaction between IT and HFR ($p=0.0001$), suggesting that the two factors have independent rather than synergistic effects on BTE. Likewise, IT and IT2 emerged as the predominant contributors to NOx emissions, underscoring the significance of combustion phasing in NOx production. Injection timing, rather than fuel composition is the principal factor influencing NOx emissions, as hydrogen enrichment exerted a comparatively minor effect. The influence of injection timing and hydrogen flow rate on engine performance is illustrated in the 3D response surface plots for BTE and NOx.

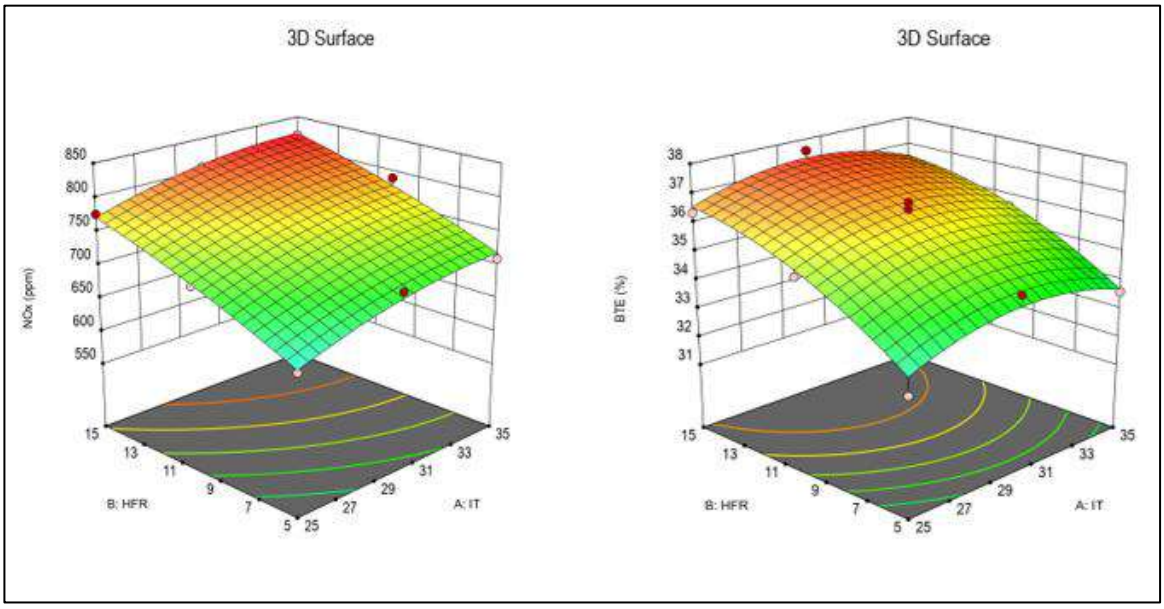

Figure 12: Response Surface for BTE., Response Surface for NOx.
Source: Authors, (2026).

Figure 12 illustrates that peak efficiency occurs between Injection Timings IT27 and IT28, with Brake Thermal Efficiency progressively rising from IT21 to IT27. Subsequent to this juncture, a minor decline is observed at IT30, perhaps because to excessive premixed combustion, resulting in increased heat dissipation. An elevated hydrogen enrichment (12 lpm) enhances combustion by augmenting flame speed and diffusivity, resulting in improved fuel-air mixing and complete combustion. The hydrogen flow rate is a significant parameter. The NOx emissions graph exhibits a clear rising trend as IT and HFR rise. It is confirmed that increased NOx production results from higher in-cylinder temperatures associated with hydrogen enrichment, with peak NOx formation occurring between IT27 and IT30 at an HFR of 12 lpm. There is a distinct necessity to employ after-treatment or exhaust gas recirculation (EGR) methods to mitigate NOx emissions without compromising efficiency, considering the inherent trade-off between the two. The results indicated that a projected BTE of 32.52% and nitrogen oxide (NOx) emissions of 751 ppm could be attained with an optimal injection timing of IT 27 and a hydrogen flow rate of 12 lpm, as established by the Response Surface Methodology (RSM) analysis. This signifies that this range encompasses the ideal configuration for attaining maximum efficiency with minimal emissions. Experimentation with EGR or SCR is necessary to alleviate the rise in NOx emissions. To further explore the influence of injection phasing on combustion temperature profiles and pollutant emissions, computational fluid dynamics (CFD) modeling may prove beneficial. Future research should examine the impact of reduced hydrogen flow rates (below 12 lpm) and optimize EGR ratios to attain a balance between combustion efficiency and regulatory NOx constraints. The RSM research indicates a significant enhancement in efficiency, with BTE attaining 32.52% with an advancement of injection timing to IT27 and an increase in hydrogen flow to 12 lpm. However, supplementary emission control strategies are necessary due to the increase in NOx emissions associated with it. An study of variance and response surface plots demonstrate that IT is superior to HFR, emphasizing the need of precise combustion timing.

V. CONCLUSION

A single-cylinder compression ignition engine utilizing M25 biodiesel and hydrogen was examined for its performance, combustion, and emission characteristics across various injection timings (IT21-IT30) and hydrogen flow rates (3-12 lpm). Experimental data indicate that injection time and hydrogen enrichment significantly influence engine efficiency and emission profiles. At a hydrogen flow rate of 12 lpm and an optimal IT27 configuration, the most favorable outcomes were attained at 5.8 bar BMEP, yielding BTE of 32.7% and brake-specific fuel consumption of 0.28 kJ/kWh. The heat release rate (HRR) of 98 J/deg and a peak cylinder pressure of 67 bar were attained at this setting, indicating enhanced combustion stability due to hydrogen's propensity to facilitate accelerated flame propagation. Emission studies of M25+12H2 at full load revealed a 54% reduction in CO emissions and a 24.7% reduction in HC emissions compared to M25+3H2. The efficacy of hydrogen in reducing particle generation was validated by a 37.2% reduction in smoke opacity. NOx emissions increased somewhat to 820 ppm, reflecting a 7.2% rise from the IT21 condition. These tendencies indicate that hydrogen enhances combustion efficiency while simultaneously elevating thermal NOx production due to increased cylinder temperature.

The optimal settings, identified by statistical optimization by Response Surface Methodology (RSM) were determined to be IT27.25˚ and 12 lpm, yielding a projected BTE of 32.52% and NOx emissions of 790 ppm. The elevated R2 values (>0.95) and the validation of the diagnostic plot confirmed the model's reliability. Future research should focus on integrating exhaust gas recirculation (EGR) or selective catalytic reduction (SCR) to mitigate NOx emissions. To evaluate thermal stress, material compatibility, and durability during hydrogen-assisted biodiesel combustion, it is recommended to conduct computational fluid dynamics (CFD) simulations and extended engine testing. These attempts could facilitate the implementation of M25-H2 dual-fuel systems, resulting in sustainable and policy-compliant transportation options.

ABSTRACT

This research focuses on the analysis of insolvency risk in credit unions in Ecuador using a predictive approach based on automatic learning. Based on international and regional precedents on the determinants of financial solvency, the study aims to develop a model capable of classifying credit unions as solvent or not solvent, according to a return on equity (ROE) threshold of 5 %. The methodology adopted was quantitative, explanatory and predictive, using the Random Forest algorithm on a structured database with coded financial variables. The slope variable, called ROE - LOGIC, classifies as "not solvent" (1) those observations with ROE lower than 5 %, and as "solvent" (0) the rest. The model was trained with 80 % of the data and validated with the remaining 20 %. The results show excellent performance, with precision, recall and F1-score metrics above 0.88 in the test set, and an AUC of 0.95, indicating a high discriminative power. The most influential variables were the net interest margin on promised assets, operating expenses relative to net interest margin and the proportion of performing assets. These were used to construct an interpretive formula that estimates the probability of insolvency.

I. INTRODUCTION

Financial insolvency among resource-intermediating institutions—banks, mutuals, cooperatives, and other financial entities—constitutes one of the most critical risks to economic stability and public confidence. In contexts of high volatility, narrow margins, and increasing regulatory pressure, a gradual deterioration of solvency may not be evident in traditional financial statements, yet it can manifest in subtle patterns of inefficiency, over-indebtedness, or risk concentration. Hence the importance of having forecasting schemes that not only describe the current situation, but also anticipate stress scenarios and enable intervention before losses become irreversible. Historically, insolvency risk assessment has relied on predominantly statistical approaches: financial ratio analysis, construction of solvency indices, linear or logistic regression models, and scoring systems that synthesize risk into a single indicator.

These methods have been foundational and remain an obligatory point of reference; however, their capacity to capture non-linear relationships, high-order interactions, and threshold effects is limited. In practice, the dynamics of insolvency respond to complex combinations of profitability, operating efficiency, asset quality, capital structure, and environmental conditions that are difficult to represent under strict assumptions of linearity or independence. In parallel, recent advances in machine learning have made available algorithms capable of modeling highly complex data structures.

Methods such as random forests, gradient boosting, and deep neural networks have demonstrated remarkable predictive power in classification tasks and risk forecasting. Nonetheless, their adoption in regulated financial contexts has been tempered by two key challenges: model interpretability—that is, the ability to explain why an entity is classified as solvent or non-solvent—and the need to guarantee computational schemes that are reproducible, auditable, and consistent with traditional statistical logic. Against this backdrop, it is pertinent to move towards hybrid "algorithmic–statistical" models that combine the learning power of machine-learning algorithms with interpretable, formalized structures drawn from applied statistics.

From this perspective, the present study proposes an *algorithmic-statistical model under a computational scheme for forecasting insolvency under financial risk*, which integrates three core components: (i) a set of carefully selected and transformed financial indicators, (ii) an algorithmic classification model based on supervised learning techniques, and (iii) the derivation of an interpretable statistical representation that approximates the probability of insolvency from the most influential variables. The model is developed on a database constructed from official financial statements, processed under a computational scheme in Python that includes data cleaning, refinement, normalization of financial ratios, and coding of the solvency target variable. Insolvency is operationalized through a performance threshold on return-on-equity indicators, such that the "non-solvent" class represents risk levels that, although not yet implying formal bankruptcy, do anticipate a trajectory of financial deterioration. On this basis, a classification algorithm is trained to learn non-linear patterns across dimensions of capital strength, operating efficiency, balance-sheet productivity, financial intermediation, and credit risk. The central contribution of the study therefore goes beyond merely "applying an algorithm" to the insolvency problem; it lies in formalizing a complete algorithmic–statistical scheme. First, it is shown that the model achieves robust predictive performance according to criteria such as accuracy, sensitivity, F1-score, and AUC, positioning it as a reliable tool for the early detection of vulnerable entities. Second, variable-importance measures and other internal outputs of the algorithm are exploited to construct an interpretive equation that acts as a proxy for insolvency risk.

While this equation does not replace the model in terms of accuracy, it translates the logic of the "black box" into a statistical structure that is understandable for managers, auditors, and regulators. The relevance of this approach lies in its ability to articulate three needs that often appear disconnected in financial risk management: the need for predictive accuracy, the need for interpretability to support decision-making, and the need for a replicable computational scheme that can be integrated into continuous monitoring systems. From the perspective of financial institutions, this translates into the ability to identify which combinations of intermediation margins, operating expenses, asset unproductiveness, and portfolio quality push the organization toward states close to insolvency. From the regulatory perspective, the model offers an objective and scalable instrument to prioritize supervision, design early-warning alerts, and strengthen system-wide stability. In sum, the article seeks to demonstrate that it is possible to move from descriptive or purely statistical approaches to an integrated algorithmic–statistical model capable of anticipating insolvency under financial risk with high levels of performance and, at the same time, with an explanatory structure that supports managerial and regulatory action. The following sections detail the methodological design of the implemented computational scheme, present the results obtained, and discuss their implications for the theory and practice of insolvency risk management in the financial system.

II. LITERATURE REVIEW

Corporate insolvency is one of the most visible and disruptive manifestations of financial risk, because it concentrates the cumulative effects of illiquidity, excessive leverage, declining profitability and fragile capital structures in a single event with severe consequences for creditors, investors, regulators and the real economy. Classical research in accounting and finance laid the foundations for quantitative insolvency prediction by linking firm failure to accounting ratios. Beaver was the first to show that specific financial ratios, such as cash flow to total debt, exhibit strong discriminatory power between failed and non-failed firms [1]. Building on this, Altman proposed the well-known Z-score model, a multivariate discriminant analysis that combines profitability, leverage, liquidity and activity ratios into a composite index of bankruptcy risk [2]. Ohlson later introduced a logistic regression specification that directly estimates the probability of bankruptcy as a function of financial ratios, relaxing some restrictive assumptions of discriminant analysis and aligning failure modelling with modern probability-based risk management [3]. Beyond these seminal contributions, subsequent work extended the statistical toolbox available for insolvency prediction. Härdle et al. combined variable selection and oversampling techniques with smooth support vector machines (SVMs) to improve default-risk prediction by explicitly addressing class imbalance and high dimensionality [4].

Marassi and Pediroda framed insolvency modelling as a decision problem and proposed a maximum-expected-utility approach, emphasizing that the choice of prediction rule should reflect the asymmetric costs associated with misclassification of solvent versus insolvent firms [5]. Lai et al. developed a support-vector-based metamodel for business risk identification, showing that kernel methods can capture complex, non-linear relations among financial indicators that are beyond the reach of linear discriminant analysis or logistic regression [6]. Collectively, these contributions illustrate a gradual transition from low-dimensional, linear models to more flexible, algorithmically sophisticated approaches within a statistically grounded framework. The rapid development of machine learning (ML) and artificial intelligence (AI) has transformed insolvency and bankruptcy prediction into a broad, data-driven field. Barboza, Kimura and Altman compared several ML models against classical statistical benchmarks and documented substantial gains in out-of-sample performance, especially for ensemble and non-linear classifiers [7]. Sector-specific studies confirm these advantages in distinct institutional settings. According to [8], evaluated artificial neural networks and decision trees for bankruptcy prediction in the agricultural sector, showing that AI models can exploit subtle patterns in sector-specific financial indicators.

In [9], [10], conducted comparative analyses of ML algorithms—including SVMs, random forests, gradient boosting and neural networks—for bankruptcy prediction in different national contexts, such as Pakistani listed companies, emphasizing the role of feature engineering, hyperparameter tuning and robust validation in achieving reliable predictions. In [11],[12], proposed an intelligent, ML-empowered framework for bankruptcy prediction, while Stasko et al. designed a country-specific bankruptcy prediction model for Latvian firms, illustrating how ML pipelines can be adapted to small open economies and local accounting regimes. In parallel, a complementary stream of research has focused on systematic mapping of AI applications in insolvency-related domains and sectoral early-warning systems. Jayawardana et al. conducted a systematic review and empirical feature derivation for AI-based insolvency prediction in the construction industry, identifying key financial and project-level indicators that drive failure in this sector [13]. Reviewed AI applications for proactive dispute management and risk mitigation in construction, highlighting how contractual conflicts, delayed payments and project disruptions can amplify insolvency risk and how early-warning models can support intervention [14].

Mirindi and Mukala offered an in-depth pedagogical exploration of loan default classification using ML techniques, which—although aimed at teaching—illustrates the full pipeline from data preparation to model interpretation in credit-risk classification [15]. Goel et al. discussed the enhancement of financial-management efficiency through advanced predictive analytics and data-driven decision-making strategies, thus situating insolvency and credit-risk models within broader financial-management architectures [16]. The literature has also expanded from firm-level bankruptcy to credit-risk-based early-warning systems that operate at the level of loans, borrowers and portfolios. Hamada et al. proposed an early prediction and detection framework for retail and corporate credit risks using ML algorithms, demonstrating that non-linear classifiers can identify high-risk exposures earlier and more accurately than traditional scoring systems [17]. Teles et al. compared SVM and random-forest algorithms for credit-operation classification, highlighting trade-offs between predictive performance and computational cost [18]. Orlova introduced methodologies and models for individual creditworthiness assessment using digital-footprint data and ML methods, showing that alternative, non-traditional data can substantially improve risk segmentation [19].

In a subsequent work, Orlova developed a data-driven design for credit-risk management based on digital-footprint intelligence, integrating such models into organizational risk processes [20]. In [21],[22] used massive corpora of news articles to diagnose corporate insolvency for credit-management purposes, while combined ML with sentiment analysis to project bank-insolvency risk, embedding textual and market sentiment information into prudential risk models. According to [23] examined how green-credit policy affects commercial banks' credit-risk profiles using ML models fitted to panel data for Chinese banks, thereby illustrating how policy-driven changes in portfolio composition can non-trivially reshape insolvency risk. In [24] compared empirical methods for reproducing global manufacturing companies' credit ratings, showing that ML can approximate rating-agency assessments and provide proxies for insolvency and default risk when external ratings are unavailable. Beyond specific models, recent contributions also promote a broader data-science and risk-analytics perspective.

Lai and Xing provide a comprehensive treatment of data science and risk analytics in finance and insurance, formalizing the statistical and computational principles underlying modern risk models and emphasizing their integration into risk-management processes [25]. Gupta et al. explore how forensic accounting can be revitalized through data analytics to mitigate financial risk, reinforcing the role of algorithmic tools in fraud detection and early identification of irregularities that may precede insolvency [26]. At the level of crisis management and resolution, Loiacono and Rulli introduce the notion of "ResTech," a suite of innovative technologies for bank-crisis resolution, arguing that advanced analytics and resolution-tech tools can support more efficient and less disruptive handling of distressed institutions [27]. Examine how CEO turnover affects firm performance and insolvency risk in a global sample, showing that leadership changes can materially alter risk trajectories and should therefore be considered in holistic risk-assessment frameworks [28]. In regulated contexts, propose an explainable-AI framework for credit-risk assessment and financial decision support that combines high-performing models with explanation tools understandable to regulators, managers and clients, addressing concerns about opacity and accountability in ML-based risk systems [29].

Within the specific segment of small and medium-sized enterprises (SMEs), insolvency prediction faces additional challenges related to limited disclosure, noisy accounting data and heightened sensitivity to macroeconomic shocks. Lee and Choi show that technological-feasibility indicators significantly improve SME-insolvency prediction beyond conventional financial ratios [30]. In [31] demonstrates that non-financial variables enhance forecasting accuracy for Croatian SMEs, especially at early-warning horizons when firms are in "sensitive" states rather than already failed. The propose a core rule-based decision tree that compresses a complex decision tree into an interpretable set of insolvency rules, so that the main causal patterns leading to SME failure can be communicated in a transparent and operational way [32]. These studies, together with digital-footprint and forensic-accounting contributions [19], [20], [26], indicate that the future of insolvency modelling is not purely numerical: it requires integrating heterogeneous data sources (accounting, non-financial, behavioural and textual) within architectures that remain interpretable to decision-makers and compliant with regulatory standards.

Taken together, the literature reveals a clear evolution: from linear, low-dimensional statistical models [1-6] to high-capacity AI/ML models for bankruptcy, credit risk and insolvency [7-12], [17-24], and then to system-level, governance-aware perspectives that incorporate data science, forensic accounting, crisis-resolution technologies and explainable AI [13-16], [25-29]. Yet three gaps remain particularly salient for the present study. First, many high-performing AI models are implemented as ad hoc pipelines whose preprocessing, feature-engineering, resampling and hyperparameter-tuning steps are not formalized as a reproducible computational scheme, which limits their auditability and transferability. Second, interpretability is often treated as an optional, post-hoc add-on—via feature-importance measures or local explanation tools—rather than a structural requirement embedded in the model design [29],[32]. Third, relatively few contributions explicitly frame their proposals as algorithmic–statistical hybrids, where the algorithmic (ML) component is systematically coupled with a statistically coherent layer that delivers calibrated insolvency probabilities, confidence measures and analytically tractable representations of how financial indicators interact under different risk regimes.

In this context, the present work positions itself as a response to these gaps by proposing an algorithmic–statistical model under a computational scheme for forecasting insolvency under financial risk. Building on robust evidence that ML methods improve predictive accuracy in bankruptcy and credit-risk tasks [7-12], [17-24], and on the need for interpretable, regulator-compatible frameworks [13], [16], [25-29], [30-33], the model integrates: (i) a carefully engineered set of financial indicators linked to profitability, leverage, liquidity, asset productivity and capital structure; (ii) an ML-based classification core trained under a transparent and reproducible computational pipeline (data cleaning and transformation, treatment of class imbalance, and rigorous validation); and (iii) a statistical representation that approximates insolvency probabilities using the most influential variables, thereby bridging the internal "black-box" logic of the algorithm with the explanatory requirements of managers, auditors and supervisors. This hybrid perspective aligns with the broader trajectory of the literature while making an explicit, operationally oriented contribution to the design of integrated, interpretable tools for forecasting insolvency under financial risk.

III. MATERIALS AND METHODS

The study adopts a quantitative, explanatory, and predictive design aimed at constructing an algorithmic–statistical model capable of estimating the financial solvency of cooperatives using a set of standardized financial ratios. Formally, we work with a historical dataset structured as.

$$\mathcal{D} = \{(\mathbf{x}_i, y_i)\}_{i=1}^{N},$$

Where each observation $i \in \{1, \dots, N\}$ corresponds to a cooperative in a given period. The feature vector.

$$\mathbf{x}_i = (x_{i1}, x_{i2}, \dots, x_{ip})^\top \in \mathbb{R}^p$$

Represents the $p = 12$ selected financial variables (ratios and proportions), while.

$$\square\square \in \{0,1\}$$

Is a binary variable that encodes the solvency state (0 = solvent, 1 = non-solvent). The research is framed within data science applied to financial risk management, using supervised machine learning algorithms to model the conditional probability

$$\mathbb{P}(Y = 1 \mid \mathbf{X} = \mathbf{x}),$$

Interpreted as the probability that a cooperative with financial profile **x** is in a non-solvent state under financial risk. The central objective is to construct a decision function

$$\hat{f}: \mathbb{R}^p \to \{0,1\},$$

Capable of approximating the true mapping

$$f^*(\mathbf{x}) = y$$

With high predictive performance and, at the same time, with sufficient structure to be interpreted and used for decision-making. The dependent variable is defined from the Return on Equity (ROE). For each observation i, ROE_i is expressed as an annual proportion. Based on the researcher's criterion, the logical variable ROE–LOGIC is constructed using the indicator function

$$y_i = \mathbb{I}(ROE_i < \tau), \qquad \tau = 0.05,$$

where $\mathbb{I}(\cdot)$ denotes the indicator function. Explicitly,

$$y_i = \begin{cases} 1, & \text{if } ROE_i < 0.05, \\ 0, & \text{if } ROE_i \geq 0.05. \end{cases}$$

Thus, the solvency state is converted into a binary classification problem, compatible with tree-based models, logistic regression, Random Forest and other supervised algorithms. Regarding the independent variables, we work with $p = 12$ financial indicators grouped into five conceptual dimensions: (i) capital strength, (ii) operating efficiency, (iii) asset productivity and unproductivity, (iv) loan portfolio management, and (v) financial intermediation. Denoting by $j = 1, \dots, 12$ each indicator, the observed value x_{ij} corresponds to a precomputed ratio from balance sheet and income statement figures. The twelve predictors used in the model are defined as follows (for a generic observation i):

Net non-productive assets / total assets (var_3):

$$\text{var}_3(i) = x_{i,3} = \frac{\text{Net non-productive assets}_i}{\text{Total assets}_i}.$$

Productive assets / total assets (var_4):

$$\text{var}_4(i) = x_{i,4} = \frac{\text{Productive assets}_i}{\text{Total assets}_i}.$$

Productive assets / interest-bearing liabilities (var_5):

$$\text{var}_5(i) = x_{i,5} = \frac{\text{Productive assets}_i}{\text{Interest-bearing liabilities}_i}.$$

Uncovered non-performing loans / (equity + earnings) (var_8):

$$\text{var}_8(i) = x_{i,8} = \frac{\text{Uncovered non-performing loans}_i}{\text{Equity}_i + \text{Earnings}_i}.$$

Coverage of the problem loan portfolio (var_18):

$$\text{var}_{18}(i) = x_{i,18} = \frac{\text{Allowance for loan losses}_i}{\text{Problem loan portfolio}_i}.$$

Improductivity index (var_19, Fi_i):

$$\text{var}_{19}(i) = Fi_i = 1 + \frac{\text{Non-productive assets}_i}{\text{Total assets}_i}.$$

Adjusted capital strength (var_20, Fk_i):

$$\text{var}_{20}(i) = Fk_i = \frac{\text{Equity}_i + \text{Earnings}_i - \text{Extraordinary income}_i}{\text{Total assets}_i}.$$

Operating expenses / financial margin (var_22):

$$\text{var}_{22}(i) = x_{i,22} = \frac{\text{Operating expenses}_i}{\text{Financial margin}_i}.$$

Estimated operating expenses / average total assets (var_23):

$$\text{var}_{23}(i) = x_{i,23} = \frac{\text{Estimated operating expenses}_i}{\text{Average total assets}_i}.$$

Estimated personnel expenses / average total assets (var_24):

$$\text{var}_{24}(i) = x_{i,24} = \frac{\text{Estimated personnel expenses}_i}{\text{Average total assets}_i}.$$

Estimated intermediation margin / average total assets (var_26):

$$\text{var}_{26}(i) = x_{i,26} = \frac{\text{Estimated intermediation margin}_i}{\text{Average total assets}_i}.$$

Total portfolio delinquency (var_34):

$$\text{var}_{34}(i) = x_{i,34} = \frac{\text{Past-due loan portfolio}_i}{\text{Total loan portfolio}_i}.$$

Collecting these predictors in a single feature vector, we have

$$\mathbf{x}_i = (\text{var}_3(i), \text{var}_4(i), \text{var}_5(i), \text{var}_8(i), \text{var}_{18}(i), \text{var}_{19}(i), \text{var}_{20}(i), \text{var}_{22}(i), \text{var}_{23}(i), \text{var}_{24}(i), \text{var}_{26}(i), \text{var}_{34}(i))^\top \in \mathbb{R}^{12}.$$

Equivalently, in terms of the generic indices x_{ij} we can write

$$\mathrm{x}_i = (x_{i1}, x_{i2}, \ldots, x_{i12})^\top, \qquad p = 12.$$

If an additional homogenization step were needed, each variable j could be standardized as

$$z_{ij} = \frac{x_{ij} - \mu_j}{\sigma_j},$$

where μ_j and σ_j denote the mean and standard deviation of variable j, respectively. In this study, the model is trained directly on x_i in their original financial scales, preserving the interpretability of each ratio.

The resulting design matrix is

$$\mathrm{X} = \begin{bmatrix} x_{11} & x_{12} & \cdots & x_{1p} \\ x_{21} & x_{22} & \cdots & x_{2p} \\ \vdots & \vdots & \ddots & \vdots \\ x_{N1} & x_{N2} & \cdots & x_{Np} \end{bmatrix},$$

with $\mathrm{x}_i \in \mathbb{R}^{12}$ for $i = 1, \ldots, N$ and $p = 12$.

An initial data cleaning step is performed, removing observations with missing values in any of the selected variables. The resulting dataset is denoted by $\mathcal{D}^*$, with size N^*. A stratified partition is then applied into training and test sets, preserving the empirical class distribution:

$$\mathcal{D}^* = \mathcal{D}_{\text{train}} \cup \mathcal{D}_{\text{test}}, \qquad |\mathcal{D}_{\text{train}}| = 0.8\,N^*, \qquad |\mathcal{D}_{\text{test}}| = 0.2\,N^*,$$

so that

$$\mathbb{P}(Y = 1 \mid \mathcal{D}_{\text{train}}) \approx \mathbb{P}(Y = 1 \mid \mathcal{D}_{\text{test}}).$$

For predictive modeling, a Random Forest classifier is employed. Mathematically, the model is defined as a collection of B decision trees:

$$\mathcal{F} = \{h_b(\mathbf{x}; \Theta_b)\}_{b=1}^{B},$$

]

where h_b is the b-th tree and Θ_b collects the randomness introduced by bootstrap sampling and random feature selection at each split. In this study, we use

$$B = 100$$

and a fixed global random seed to ensure reproducibility. Each tree produces a class prediction $h_b(\mathbf{x}) \in \{0,1\}$. The estimated probability of non-solvency is

$$\hat{p}(y = 1 \mid \mathbf{x}) = \frac{1}{B}\sum_{b=1}^{B} h_b(\mathbf{x}).$$

The final decision rule of the forest is expressed as

$$\hat{f}(\mathbf{x}) = \begin{cases} 1, & \text{if } \hat{p}(y = 1 \mid \mathbf{x}) \geq \tau_c, \\ 0, & \text{if } \hat{p}(y = 1 \mid \mathbf{x}) < \tau_c, \end{cases}$$

Where the classification threshold is set to

$$\tau_c = 0.5.$$

Training the forest amounts to approximately minimizing the empirical 0–1 loss over the training set:

$$\min_{\mathcal{F}} \frac{1}{|\mathcal{D}_{\text{train}}|} \sum_{(\mathbf{x}_i, y_i) \in \mathcal{D}_{\text{train}}} \mathbb{I}(\hat{f}(\mathbf{x}_i) \neq y_i),$$

Subject to the structural constraints of the Random Forest (maximum depth, minimum samples per leaf, number of candidate variables per split, etc.). In practice, each tree is built on a bootstrap sample of $\mathcal{D}_{\text{train}}$, and at each node the split is chosen to maximize impurity reduction (for example, Gini decrease). Once the model is trained, the relative importance of each variable is estimated. For each predictor j, the aggregated Gini importance is

$$I_j = \sum_{b=1}^{B} \sum_{t \in T_b(j)} \Delta G_{b,t},$$

Where $T_b(j)$ is the set of nodes in tree b where variable j is used for splitting, and $\Delta G_{b,t}$ is the Gini impurity reduction at node t. Importances are normalized to obtain relative weights:

$$w_j = \frac{I_j}{\sum_{k=1}^{p} I_k}, \qquad j = 1, \ldots, p,$$

with

$$\sum_{j=1}^{p} w_j = 1, \qquad w_j \geq 0.$$

Based on these weights, an algorithmic–statistical insolvency index is defined as a linear combination of the financial variables:

$$S(\mathbf{x}) = \sum_{j=1}^{p} w_j \, x_j.$$

The value $S(\mathbf{x})$ acts as a scalar projection of the cooperative's financial profile onto the importance structure learned by the model. Although the Random Forest remains the main classification tool, $S(\mathbf{x})$ provides an interpretable and parsimonious representation of non-solvency risk: higher values of $S(\mathbf{x})$ are associated with higher insolvency exposure given the relative weight of variables such as total delinquency, asset unproductiveness, or operating cost burden.

If an explicit probability approximation based on this index is desired, a secondary logistic function can be fitted:

$$\hat{\pi}(\mathbf{x}) = \frac{1}{1 + \exp(-\alpha - \beta \, S(\mathbf{x}))},$$

Where α and β are estimated by maximum likelihood in a simple logistic regression of y on $S(\mathbf{x})$. This additional layer does not replace the Random Forest in terms of accuracy, but yields a closed-form analytical expression for $\hat{\pi}(\mathbf{x})$, useful for communication and sensitivity analysis. Finally, model performance is evaluated on $\mathcal{D}_{\text{test}}$ using standard binary classification metrics. Let TP, TN, FP and FN denote true positives, true negatives, false positives and false negatives, respectively. The metrics are defined as

$$Accuracy = \frac{\text{TP} + \text{TN}}{\text{TP} + \text{TN} + \text{FP} + \text{FN}},$$

$$Sensitivity = \frac{\text{TP}}{\text{TP} + \text{FN}},$$

$$Precision = \frac{\text{TP}}{\text{TP} + \text{FP}},$$

$$F_1 = 2 \cdot \frac{\text{Precision} \cdot \text{Sensitivity}}{\text{Precision} + \text{Sensitivity}}$$

In addition, the Receiver Operating Characteristic (ROC) curve and the Area Under the Curve (AUC) can be used to evaluate the overall discriminative capacity of the model. Together with the interpretative index $S(\mathbf{x})$, this configuration defines a complete algorithmic–statistical scheme for forecasting insolvency under financial risk in cooperatives.

IV. RESULTS AND DISCUSSIONS

It begins with the development of quality measures for the Random Forest model:

Table 1: Performance metrics.

Precision	Recall	F1-Score	AUC	MCC (Matthews)	Cohen's Kappa	Accuracy	Set
1.000	1.000	1.000	1.000	1.000	1.000	1.000	Training
0.883	0.925	0.904	0.946	0.780	0.779	0.891	Test

Note: The model was implemented in Python and evaluated using a 20% training split.
Source: Authors, (2026).

In Table 1, the reported model quality indicators allow assessment of performance on both the training and test sets. The training set refers to the data used to build and fit the model, whereas the test set is used to verify how well the model generalizes to unseen data. In this case, the model achieves perfect performance on the training data (all metrics equal to 1.000), which may indicate overfitting. Regarding the test set—the most relevant for judging the model's practical utility—the results remain strong. Precision (0.883) indicates that approximately 88.3% of the positive predictions produced by the model were correct. Sensitivity (recall = 0.925) shows that the model correctly identified 92.5% of the true positive cases. The F1-score (0.904) reflects the balance between precision and recall; its high value reinforces that the model maintains a solid trade-off between these two dimensions. The AUC (0.946) further indicates an excellent capacity to discriminate between classes, as values close to 1 are typically associated with outstanding performance in binary classification. Moreover, the Matthews correlation coefficient (MCC) reaches 0.780 on the test set. This metric is particularly informative under class imbalance because it incorporates all cells of the confusion matrix. The obtained value suggests a strong association between predicted and true labels. Likewise, Cohen's Kappa (0.779) reflects very good agreement beyond chance. Overall accuracy is 0.891, indicating that the model correctly classifies nearly 89% of the test observations. In summary, although the model may be somewhat overfitted to the training data, its test performance suggests that it is robust, accurate, and able to generalize effectively. Nonetheless, additional evaluations—such as cross-validation or testing on external datasets—would be advisable to confirm the stability of these metrics.

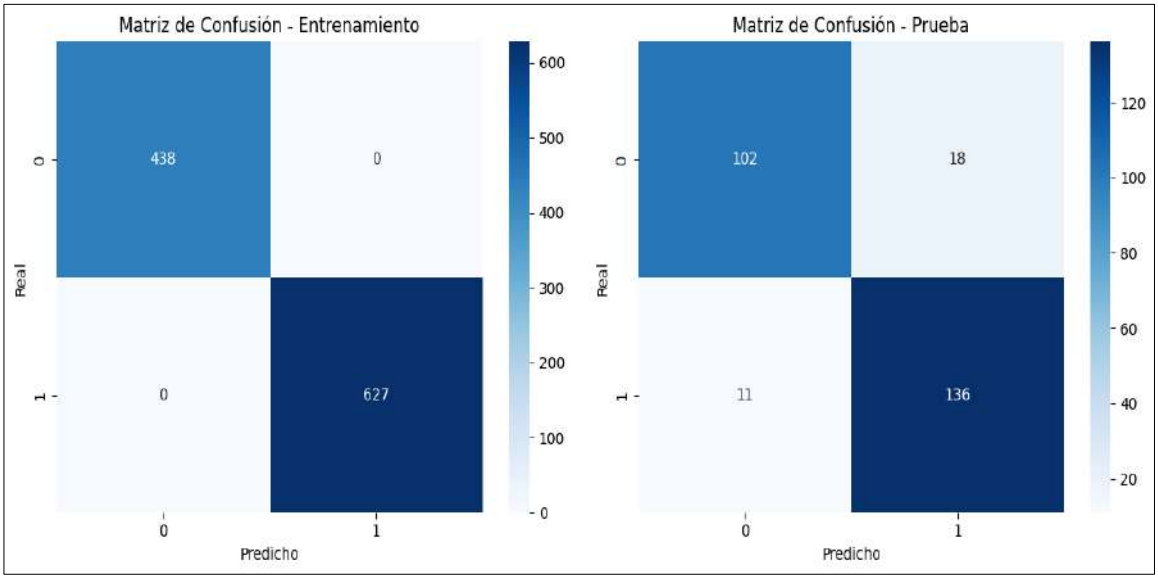

Figure 1: Confusion matrix.
Source: Authors, (2026).

Considering Figure 1, the model correctly classified all 438 cases from class 0 (negative) and all 627 cases from class 1 (positive) in the training set, without any errors. That is, there were no false positives or false negatives, which results in precision, recall, and F1-score equal to 1.000. While such outcomes are theoretically ideal, in practice they often suggest overfitting, as the model may have memorized the training data rather than learned generalizable patterns. In contrast, the test-set confusion matrix provides a more realistic and informative view of generalization performance. Of the 120 true class-0 cases, the model correctly classified 102 (true negatives) and misclassified 18 as class 1 (false positives). For class 1, out of 147 true cases, the model correctly predicted 136 (true positives) and misclassified 11 as class 0 (false negatives). This indicates that, while the model remains strong, it incurs some errors that were not present during training—an expected and natural outcome under proper model evaluation.

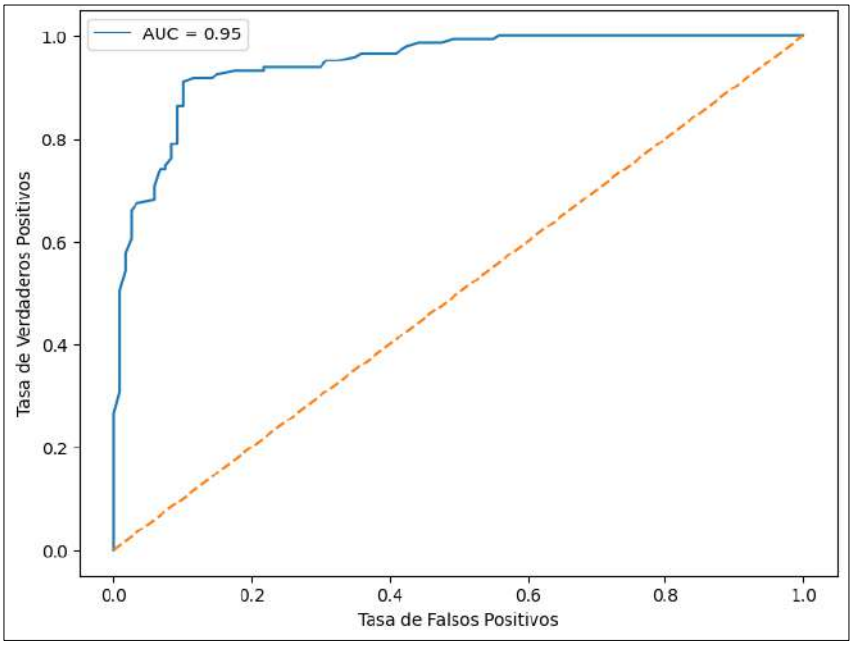

Figure 2: ROC curve.
Source: Authors, (2026).

Figure 2 exhibits a markedly convex shape and lies well above the orange diagonal, which represents a random classifier with no discriminative ability. That diagonal corresponds to an AUC (Area Under the Curve) of 0.5, commonly interpreted as the minimum baseline for a model that performs no better than chance. By contrast, the evaluated model achieves an AUC of 0.95, which is excellent. This value indicates a very high ability to discriminate between classes, correctly separating positive and negative cases in most situations. An AUC of 0.95 also implies that, when randomly selecting one positive and one negative instance, the model assigns a higher score to the positive instance 95% of the time.

Table 2: Variable relevance.

Variable	Importance
var_26	0.222
var_22	0.197
var_4	0.096
var_18	0.081
var_20	0.078
var_5	0.058
var_19	0.054
var_3	0.051
var_23	0.048
var_24	0.046
var_34	0.045
var_8	0.024

Note: The model was implemented in Python and the results were sorted in descending order.
Source: Authors, (2026).

The most influential variable is **var_26**, corresponding to the intermediation margin estimated over average assets, with an importance of 22.2%. This indicator is central because it captures the core of financial intermediation: the spread between earnings from lending and costs of funding. A low margin implies that basic revenues barely cover (or fail to cover) financial costs, which can drive weak performance. In this context, lower values of this variable are associated with higher insolvency risk and therefore a higher probability of being classified as "1". The second most important variable is **var_22**, representing the ratio of operating expenses to financial margin. With an importance of 19.7%, this variable captures the efficiency with which the cooperative manages its financial income. Higher values indicate that administrative costs absorb a substantial portion of the available margin, leaving little or no surplus. This not only undermines immediate profitability but also constrains capitalization, investment capacity, and risk absorption.

Consequently, elevated values shift predictions toward the non-solvent class. The third variable in importance is **var_4**, measuring productive assets as a share of total assets (9.6%). A low ratio suggests that a sizable portion of assets is not generating income. Balance-sheet unproductivity is a warning sign because it reflects inefficient resource allocation; combined with weak operating profitability, it amplifies insolvency risk. Next, **var_18**—coverage of the problem loan portfolio (8.1%)—indicates that measuring portfolio quality alone is insufficient; the cooperative's preparedness to absorb potential losses is also critical. Insufficient coverage for delinquent or high-risk loans increases financial exposure, weakens earnings, and raises the likelihood of being classified as non-solvent. **var_20**, defined as the Fk index (equity+results−extraordinaryincome)/totalassets (equity + results − extraordinary income) / total assets(equity+results−extraordinaryincome)/totalassets, carries a weight of 7.8%.

This metric provides an adjusted view of structural solvency by excluding non-recurring income. Its relevance confirms that underlying capital strength—beyond exceptional events—substantially influences the model's risk assessment. Other relevant variables include **var_5** (productive assets over interest-bearing liabilities, 5.8%) and **var_19** (FI index: 1+1 +1+ unproductive assets / total assets, 5.4%). Both relate to the balance between income-generating resources and financial burdens. Unfavorable values are interpreted by the model as early warning signals. Variables **var_23** (estimated operating expenses over average assets, 4.8%) and **var_24** (personnel expenses over average assets, 4.6%) further reinforce the model's sensitivity to cost efficiency. When a substantial share of resources is tied to fixed costs without a proportional return, the cooperative may struggle to sustain profitability. Finally, **var_34** (total portfolio delinquency, 4.5%) and **var_8** (uncovered unproductive portfolio over equity plus results, 2.4%) act as more direct proxies for credit risk. Although they remain relevant, their smaller weights relative to efficiency and structural variables suggest that the model places greater emphasis on the ability to generate, manage, and protect the financial margin than on pure default risk alone. Based on these results, the following equation is proposed as a forecasting model for insolvency among Segment 1 savings and credit cooperatives:

$$\begin{aligned}\boldsymbol{Prob\ Insolv} = {} & 0.2223 * var_26 + 0.1968 * var_22 + 0.0957 * var_4 + 0.0807 * var_18 + 0.0775 * var_20 \\ & + 0.0583 * var_5 + 0.0536 * var_19 + 0.0515 * var_3 + 0.0481 * var_23 + 0.0460 * var_24 \\ & + 0.0453 * var_34 + 0.0240 * var_8\end{aligned}$$

The resulting formula does not produce a true ROE value; instead, it provides an approximation of insolvency risk as a function of the most influential variables. When evaluating a cooperative with this equation, higher estimated values imply greater proximity to class "1" (non-solvent). Thus, values closer to 1 indicate higher insolvency risk, whereas values closer to 0 indicate greater solvency. The evidence obtained in this study reinforces—and operationalizes within an algorithmic–statistical scheme—the long-standing view that insolvency risk is ultimately rooted in the joint behavior of profitability, operating efficiency, asset productivity, and capital strength. Classical insolvency research established that accounting ratios can discriminate between failed and non-failed entities (Beaver; Altman; Ohlson), thereby motivating ratio-based early-warning models. In our cooperative setting, this tradition is echoed in the dominance of variables tied to intermediation profitability and efficiency—particularly the intermediation margin over average assets (var_26) and operating expenses relative to the financial margin (var_22)—which carry the largest importance weights in the Random Forest. This alignment suggests that, even under modern ML implementations, the "economic content" emphasized by ratio-based frameworks remains structurally central: cooperatives approach non-solvency when the margin that sustains intermediation is compressed and/or absorbed by operating costs. From a predictive standpoint, our results are consistent with the broader empirical finding that non-linear and ensemble ML models tend to outperform purely linear statistical benchmarks, particularly in out-of-sample classification.

Barboza, Kimura, and Altman document systematic performance gains from ML—especially ensemble methods—in bankruptcy prediction tasks, and our test-set performance (AUC = 0.946; accuracy = 0.891; F1 = 0.904) provides convergent evidence in the context of Ecuadorian Segment 1 cooperatives. At the same time, the perfect training scores (all metrics = 1.000) raise the standard interpretive caution highlighted across comparative ML studies (e.g., the need for robust validation and sensitivity checks): our own results explicitly acknowledge that such perfection may signal overfitting, motivating additional evaluation strategies (e.g., cross-validation or external testing) to verify stability. A central substantive contribution of the model lies in what it learns as the main discriminators of insolvency status: the pattern indicates that deterioration in the business model's margin mechanics and cost discipline is detected as a primary route toward non-solvency, even before (or beyond) pure delinquency metrics. Specifically, var_26 (intermediation margin over average assets, 22.2%) and var_22 (operating expenses/financial margin, 19.7%) dominate, while total portfolio delinquency (var_34) has comparatively lower weight (4.5%). This ranking is informative in light of credit-risk ML literature that frames early-warning detection as the identification of non-linear combinations of financial pressures that precede visible default events (e.g., ML-based early detection of credit risks and classification of credit operations).

In practical terms, the model implies that margin compression and cost absorption may operate as leading signals of vulnerability, whereas delinquency—though relevant—may act more as a lagging manifestation once structural pressures have already accumulated. The confusion-matrix results further support a realistic interpretation of model behavior under generalization. While the training matrix shows zero errors, the test matrix exhibits non-trivial false positives and false negatives, which is expected when moving from in-sample fit to out-of-sample performance. This matters in light of decision-oriented perspectives such as Marassi and Pediroda's framing of insolvency prediction under asymmetric misclassification costs: in supervisory and managerial contexts, the relative tolerance for false alarms (false positives) versus missed distress signals (false negatives) should guide thresholding and deployment. Accordingly, although the ROC/AUC indicates excellent discrimination (≈0.95), the operational use of the classifier should be paired with explicit cost preferences (e.g., favoring sensitivity if the priority is early intervention). Importantly, the study directly addresses a core constraint repeatedly emphasized in regulated financial ML: interpretability. Recent work argues that high-performing credit-risk models must be explainable to regulators and decision-makers, rather than remaining opaque black boxes (e.g., explainable AI frameworks; rule-based explanatory trees).

In that direction, our approach leverages Random Forest importance weights to construct an interpretable insolvency index and a tractable probability approximation layer, explicitly designed to translate algorithmic outputs into an auditable statistical form. This is not merely a presentation choice: it operationalizes the "algorithmic–statistical hybrid" positioning stated as a gap in prior work (interpretability embedded structurally, not treated as an optional add-on). Finally, the results should be read alongside clear scope boundaries that emerge from the literature. Multiple streams show that insolvency and credit-risk prediction can improve when heterogeneous sources are incorporated—digital footprints, textual/news information, sentiment signals, and non-financial/technological feasibility indicators—especially for earlier warning horizons. Our model is deliberately financial-ratio-based, which strengthens transparency and alignment with traditional supervisory data, but it also implies that future extensions could integrate these complementary data modalities to test whether (and how) predictive structure changes under broader information sets. In other words, the present findings provide a strong financial "core," while the literature indicates a natural research frontier: coupling this core with alternative and non-financial signals within the same reproducible, regulator-compatible computational scheme.

V. CONCLUSIONS

The results of this study indicate that insolvency risk in Segment 1 savings and credit cooperatives in Ecuador can be anticipated with high precision and reliability by using machine-learning techniques, specifically the Random Forest algorithm. The developed model achieved strong predictive performance on the test set, including an AUC of 0.946 and an accuracy of 89.1%, supporting its practical relevance as a preventive tool for financial risk management.

The analysis of the most influential predictors shows that insolvency risk is not driven solely by classical delinquency or credit exposure indicators; rather, it is primarily shaped by operating efficiency, capital structure, and balance-sheet productivity. Variables such as the intermediation margin over average assets, operating expenses relative to the financial margin, and the share of productive assets explain a substantial portion of insolvency probability. This implies that weak internal resource management and low operating profitability are more decisive determinants than the mere level of delinquency.

Moreover, the evidence confirms that financial solvency is not an isolated phenomenon, but the outcome of a set of sustainable, structured, and efficient financial practices. In this sense, the proposed model can support both cooperative management teams and regulatory authorities by providing an objective tool to monitor and classify institutions at higher risk of capital deterioration.

ABSTRACT

Electrical utility networks, structured as centralized power systems with one-way flow, are undergoing significant transformation. Geographic Information Systems (GIS) have become pivotal in modernizing these networks, enabling spatial analysis, real-time monitoring and optimization of power distribution. Traditional electrical utility networks, reliant on manual operations, struggle with fault detection, load balancing, and integrating renewable energy sources. This study focuses on a comparative analysis of these traditional and modern networks, highlighting the structural evolution, technological advancements, and the critical role of GIS in creating a scalable, future-ready power infrastructure. To increase operational efficiency, modern systems make use of IoT sensors, smart grid technology, and predictive analytics. GIS supports dynamic decision-making by integrating real-time data with geographic context. The transition marks a paradigm shift toward decentralized, data-driven, and resilient energy networks.

I. INTRODUCTION

Traditionally, the electric power grid relied on large central power plants that supplied electricity through a high-voltage (HV) transmission network, which then connected to local distribution systems delivering energy directly to customers [1]. These electrical utility networks have long played a critical role in power generation, transmission, and distribution, ensuring that electricity reaches industries, businesses, and households efficiently. Despite these improvements, conventional grids still face challenges in efficiency and adaptability. Many conventional grids operate on outdated infrastructure, making them inefficient in handling increasing loads and ensuring seamless power distribution [2]. One major issue is high transmission losses, where electricity dissipates as it travels through long-distance power lines. As the electricity demand continues to grow, traditional utility networks are struggling to keep pace with modern requirements. Transmission and distribution (T&D) networks account for energy losses estimated at up to 30% of total generated power. Another key challenge is the lack of flexibility in traditional grids. These systems were designed with rigid, centralized structures, making it difficult to adapt to shifting energy demands and unexpected disruptions.

The electric power industry faces major hurdles in reaching grid parity. While integrating variable energy resources offers the promise of a cleaner environment, it also creates challenges such as greater demands for regulation, ramping, and reserve capacity [1]. Additionally, the absence of real-time monitoring systems means utilities often rely on reactive maintenance, addressing problems only after they occur rather than preventing them in advance. To improve grid reliability and efficiency, utilities must transition to more intelligent and data-driven management systems. By implementing automated controls, predictive maintenance, and advanced analytics, power networks can minimize losses, enhance operational efficiency, and ensure a more stable electrical supply. Modern utility systems demand efficient energy distribution and management to keep up with rising consumption and environmental concerns. With the growing need for sustainable solutions, integrating smart technologies and renewable energy sources has become essential. By enhancing network connectivity and optimizing power flow, utilities can improve reliability, reduce costs, and support a more sustainable energy future. There are different researchers who have explored the applications of Geographic Information System (GIS) in network connectivity, subnetwork management, and smart grids.

As the global energy landscape evolves, electrical utility networks must transition from static, conventional frameworks to dynamic, data-driven infrastructures. Traditional grids often rely on manual operations and reactive maintenance, leading to inefficiencies in power distribution and outage management. In contrast, modernized networks leverage advanced digital technologies to improve real-time monitoring, spatial analysis, and fault detection. Applying digital processing and communications to the power grid places information management at the core of the smart grid concept. This integration of digital technology with power systems unlocks a wide range of new capabilities [3]. Geographic Information Systems (GIS) play a fundamental role in this transformation, providing utilities with enhanced asset tracking, predictive maintenance, and operational efficiency [4], [5]. This study examines the comparative advantages of traditional and modernized networks, highlighting GIS as a key enabler of efficiency and resilience. Currently, power distribution relies heavily on manual processes, such as updating network construction plans, monitoring operations, and maintaining consumer records. This limited oversight reduces the ability to prevent losses and address outages efficiently.

To overcome these challenges, electric utilities are increasingly adopting Geographic Information Systems (GIS), which provide a spatially oriented view of distribution networks and help reduce outages while improving system management [6]. The absence of an integrated mapping system meant that utilities struggled to track infrastructure efficiently, leading to frequent disruptions and maintenance challenges. GIS bridges the gap between utility assets and customer activity. It shows where solar panels are being installed, highlights high-risk parts of the grid, and helps utilities decide which assets to replace first [7]. Additionally, GIS is capable of identifying patterns in network performance, allowing utilities to analyze faults, optimize power distribution, and plan future expansions with greater accuracy.While GIS has proven to be a valuable tool in modernizing electrical utility networks, several research gaps remain. Existing studies primarily focus on GIS applications for asset tracking, outage management, and infrastructure planning, but there is limited research on standardized frameworks for GIS implementation across different utility infrastructures, leading to inconsistent adoption. Additionally, while GIS enhances power distribution and fault detection, its role in optimizing renewable energy integration and improving real-time load forecasting remains underexplored.

There is also a lack of studies analyzing the long-term cost-benefit impact of large-scale GIS adoption, making it difficult for utilities to assess its financial feasibility. Furthermore, research on GIS for grid decentralization and microgrid planning is still in its early stages, limiting its potential use in developing more resilient and adaptive power networks. Addressing these gaps will help maximize GIS's effectiveness in transforming traditional power grids into efficient, modernized systems. The objective of this study is to utilize the power of Geographical Information System (GIS) in building a smart and modernized electrical network, and also to analyze the limitations of conventional grids and the advancements enabled by GIS-driven smart grids [8]. Furthermore, this study explores how GIS supports predictive maintenance, optimizes load balancing, and enables adaptive energy management. With spatial analytics and intelligent automation, GIS plays a crucial role in building a more sustainable and efficient power infrastructure. Given that every country has its own approach to utility management, the challenge of ensuring a reliable and modernized grid becomes even more critical on a global scale. Effective management is essential to address these complexities, and GIS provides a unified framework to enhance collaboration and drive the future of power system modernization.

II. STUDY AREA

The study area chosen for this study is Lisle, Illinois, United States of America. The selected study area, Lisle, Illinois, is a vibrant suburban village in DuPage County, United States, recognized for its strategic energy infrastructure, diverse topography, and evolving power distribution network. Situated within the Chicago metropolitan area, Lisle serves as a critical hub for energy distribution, smart grid integration, and infrastructure optimization. Its blend of urban, suburban, and industrial sectors makes it an ideal location for analyzing network connectivity and renewable energy potential. Figure 1 shows the study area of Lisle, Illinois Lisle's climate, population density, and existing electrical infrastructure directly influence energy consumption patterns, distribution efficiency, and grid stability. The village features a well-established power distribution network, complemented by major transportation arteries such as Interstate 88, U.S. Route 34, and the Metro rail system, which impact energy demands across residential, commercial, and industrial sectors. The area also houses key green spaces, including the Morton Arboretum, providing unique opportunities for sustainable energy planning and environmental impact assessments. Table 1. depicts the description of the study area.

Table 1: Key Features of the Study Area.

Sl. No.	Feature	Details
1.	Location	Lisle, DuPage County, Illinois, USA
2.	Total Area	18.08 km²
3.	Population	23,222 as of 2023
4.	Latitude & Longitude	41.8011° N, 88.0748° W
5.	Elevation	206 meters (676 feet) above sea level
6.	Climate Type	Humid continental

III. DATA COLLECTION AND PROCESSING IN ELECTRICAL UTILITY NETWORKS

Data collection and processing in an electrical utility network involve multiple techniques to ensure accurate mapping, monitoring, and management of both low-voltage (LV) distribution and high-voltage (HV) transmission systems. The process starts with manual surveys and remote sensing technologies, followed by real-time monitoring systems and GIS-based digitalization to convert raw data into actionable insights.

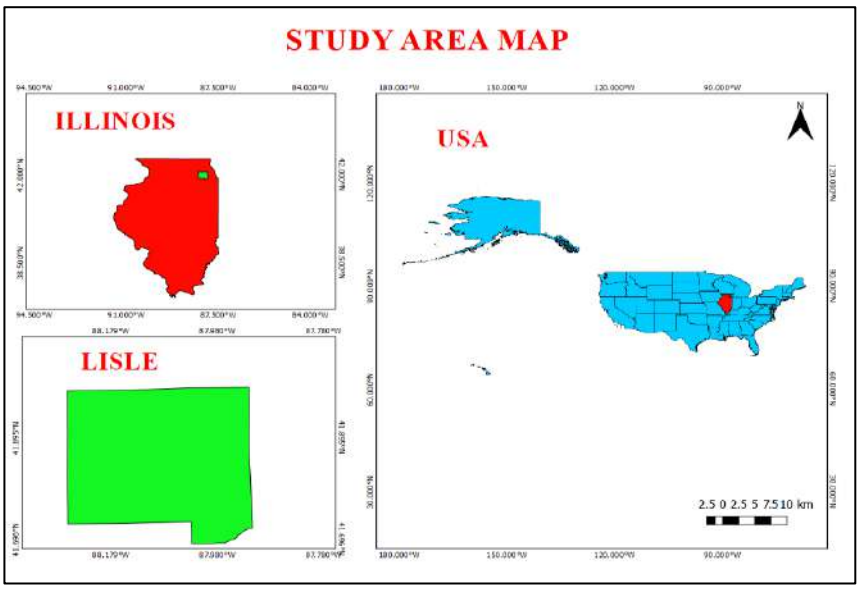

Figure 1: Study Area.
Source: Authors, (2026).

The data collection process involves multiple methodologies, each contributing to the overall accuracy and reliability of network analysis. One of the primary methods includes manual field surveys with GPS mapping, where utilities perform on-site inspections to capture transformer locations, feeder paths, and customer connections [9]. The use of smart meters and Advanced Metering Infrastructure (AMI) further supplements data acquisition by providing real-time energy consumption patterns, voltage fluctuations, and anomaly detection.

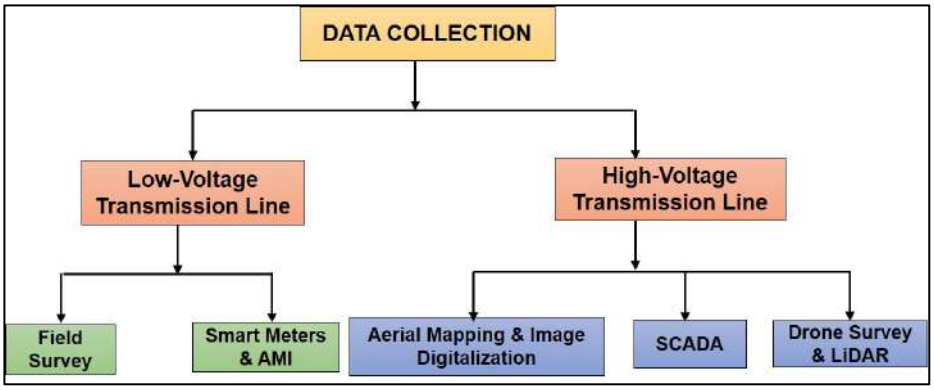

Figure 2: Data collection methods for low & high voltage transmission lines.
Source: Authors, (2026).

These smart grids continuously collect data at predefined intervals, allowing seamless monitoring of the power distribution network [10]. Figure 2 shows the various data collection methods for low & high-voltage transmission lines.

Manual Field Surveys & GPS Mapping: Utilities perform on-site surveys with handheld GPS devices and GIS tools to map transformer locations, feeder paths, and customer connections. Spatial data were collected using a Global Positioning System (GPS), while non-spatial data were obtained through direct field interviews [11].

Smart Meters & AMI (Advanced Metering Infrastructure): Smart meters and AMI provide real-time energy data, detect anomalies, and monitor voltage fluctuations, serving as primary sources for raw utility data collection. Advanced Metering Infrastructure (AMI) serves as the principal source of data, capturing and retrieving information from end-user premises. Measurements are recorded and collected at intervals of 10 to 15 minutes [12].

Aerial Mapping & Image Digitization: Drones, helicopters, and LiDAR-equipped aircraft capture high-resolution aerial images of substations, transmission lines, and distribution networks, which are then processed into 2D and 3D digital models. Remote sensing techniques, including LiDAR and drone surveys, were employed to map transmission and distribution networks, ensuring accurate asset positioning [11]. Satellite Imagery and Remote Sensing technologies are used to capture large-scale infrastructure layouts for terrain analysis, transmission line planning, and right-of-way management. Google Earth imagery from 2021 was used as a data source to analyze maps, road networks, and land use [11].

SCADA & Smart Grid Monitoring: SCADA (Supervisory Control and Data Acquisition) systems contribute significantly to data collection by gathering real-time information from sensors and Remote Terminal Units (RTUs). SCADA collects real-time, raw grid data from sensors and RTU (Remote Terminal Units), providing unprocessed voltage, power flow, and fault alerts for later analysis. SCADA systems integrate with GIS to provide real-time monitoring of voltage levels, power outages, and system faults. [13].

Drone Surveys: Utilizes UAVs equipped with high-resolution cameras and GPS to capture georeferenced imagery and videos for real-time monitoring and fault detection in electrical utilities. The drone-based inspection system captures high-resolution images and videos of power lines, which are then processed using GIS tools to detect potential faults and assess infrastructure conditions [14].

LiDAR: LiDAR employs laser scanning technology to generate high-precision 3D point clouds, enabling detailed modelling of power infrastructure within GIS frameworks [15].

The vast amount of data collected in smart grids undergoes multiple processing stages to ensure accuracy and reliability. Initially, data preprocessing involves filtering out incomplete or erroneous data, a process known as data cleansing. In this phase, the collected data are processed before any analysis is conducted. To address issues of incompleteness and inaccuracy, inconsistencies are removed through a process known as data cleansing [12]. Next, data integration is performed to unify scattered datasets, such as load profiles and weather conditions, to optimize energy distribution. Data collected from different sources are often inconsistent and need to be combined properly before analysis [12]. Once integrated, data storage ensures accessibility for real-time operations, with smart grids requiring high-speed data retrieval for efficiency. In the data storage phase, the data is stored, located, and can be accessed at any instant of time. Finally, data analytics extracts insights for load forecasting, fault detection, and predictive maintenance, enabling smarter decision-making. In smart grid systems, substantial amounts of data are regularly collected. These data support multiple analyses, such as examining end-user behavior, assessing system states, and detecting faults [12].

IV. STRUCTURE OF ELECTRICAL UTILITY NETWORKS

An electrical utility network is a sophisticated system created to effectively produce, transmit, and distribute electricity to customers. It consists of three main components: generation, transmission, and distribution, each playing a crucial role in ensuring a stable and reliable power supply. The first step is production, in which electrical energy is created in the power plant and converted to high-voltage electrical energy in the power station, which is more suited for effective long-distance transportation [16]. Power plants convert primary energy sources such as fossil fuels, nuclear, hydro, solar, and wind into electricity. In the transmission section of the electric power system, high-voltage (HV) power lines effectively move electrical energy over great distances to the places where it is consumed [16]. Transmission networks use high voltages, typically ranging from 110 kV to 765 kV, to reduce energy losses over long distances. Figure 3 shows the typical distribution of an electrical network system.

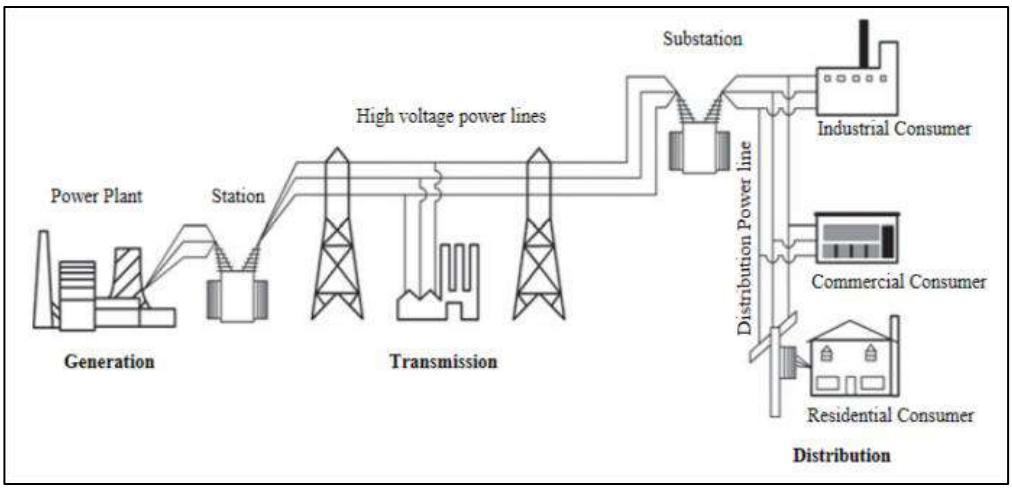

Figure 3: Electrical Network System overview.
Source: [17].

At the substations, voltage levels are stepped down for distribution through distribution networks, which deliver electricity to industrial, commercial, and residential consumers. Remote substations play a critical role in converting high-voltage electricity for delivery over feeder lines optimized for distribution. Subsequently, the electrical energy is further reduced to medium and low voltage to serve residential, commercial, and industrial consumers. The distribution network, including transformers, substations, medium- and low-voltage lines, and metering systems, ensures the reliable delivery of electricity at appropriate voltage levels [16].

V. METHODOLOGY

V.1 CORE FUNCTIONALITIES

This study provides a structured approach to analyzing and comparing traditional electrical utility networks with modernized GIS-based networks. It outlines the key steps involved in data collection, network modeling, and performance evaluation using ArcGIS Utility Network. This section ensures that the research follows a systematic and transparent process, making it easier for utility planners, GIS professionals, and researchers to understand and apply the findings. By using real-world datasets from Lisle, Illinois, this study demonstrates how GIS can transform electrical network management through enhanced connectivity, fault detection, and service expansion planning.

The Public Works Department of the City of Lisle, Illinois, has been using a geometric network to manage its municipal electric network. However, to explore the capabilities of a utility network in ArcGIS, this study utilizes a pre-configured dataset from Esri's Electric Utility Network Foundation. This dataset represents a small subset of the service territory and allows for modelling and analysis of network assets. As part of the study, network tracing was performed to answer key questions about the electrical network, generate reports to identify customer counts, and execute a service line extension to integrate a new customer into the network. This was followed by an update subnetwork operation to incorporate the changes. Figure 4 shows the flowchart of a modernized electric utility network using GIS.

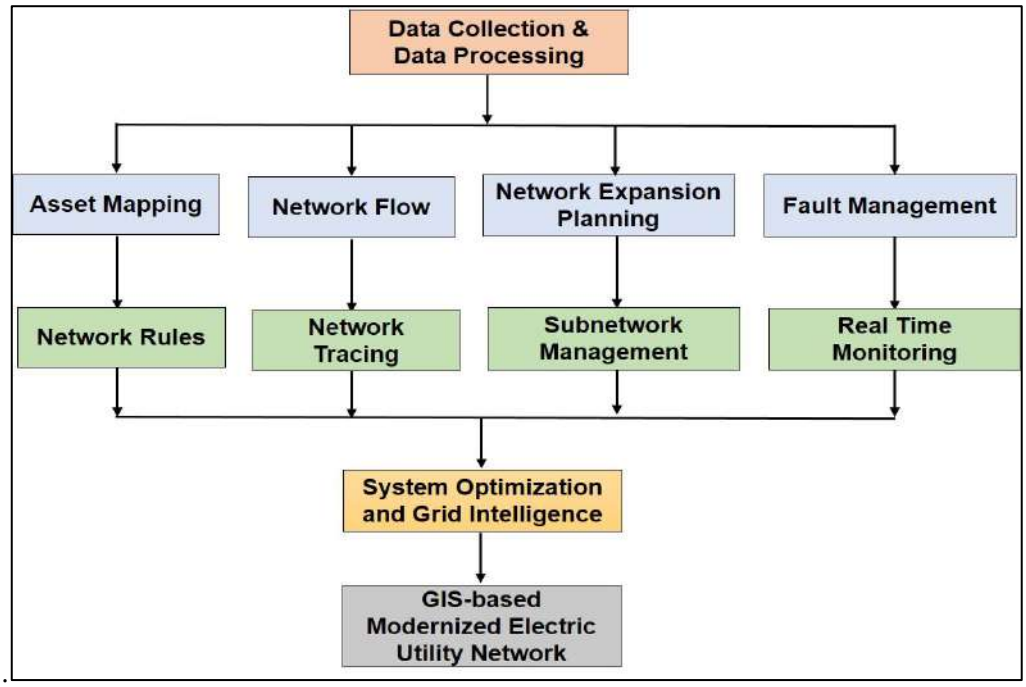

Figure 4: Flowchart of a GIS-driven modernized electric utility network.
Source: Authors, (2026).

V.2 NETWORK RULES IN ELECTRICAL NETWORK

Network rules play an essential role in maintaining the integrity and logical flow of a utility network by defining valid connections between various components. Network rules in ArcGIS Utility Network define valid connections and relationships between network components, ensuring realistic and error-free modelling. They regulate how junctions connect to edges and how assets are contained or structurally attached. These rules help maintain data integrity, optimize power flow, and ensure accurate utility management.

- **Junction:** A junction is a point where electricity flows through or gets distributed. It represents devices like transformers, switches, meters, and fuses.
- **Edge:** An edge is a connection/line that carries electricity between junctions. It represents power lines, cables, or conductors. Junctions and edges work together to form the power grid, ensuring electricity flows efficiently from power stations to consumers [18].

The types of network rules are as follows:

1. Junction-Edge Connectivity Rules
2. Junction-Junction Connectivity Rules
3. Edge-Junction-Edge Connectivity Rules

1. Junction-Edge Connectivity Rules

These rules govern the connections between point features (junctions) and line features (edges). They specify which types of junctions can connect to which types of edges, ensuring logical and valid network configurations [18]. For example, a control valve (junction) connecting to a distribution main(edge) would be governed by such a rule. It is shown in Figure 5.

Figure 5: Junction-edge connectivity in a distribution network.
Source: Authors, (2026).

2. Junction-Junction Connectivity Rules

These rules manage the connectivity between two junction features, whether they are geometrically coincident or associated through connectivity associations. For example, connectivity associations link a fuse, transformer, and breaker to transition power from medium-voltage three-phase to low-voltage single-phase, ensuring efficient and safe electricity distribution [18], and it is depicted in Figure 6.

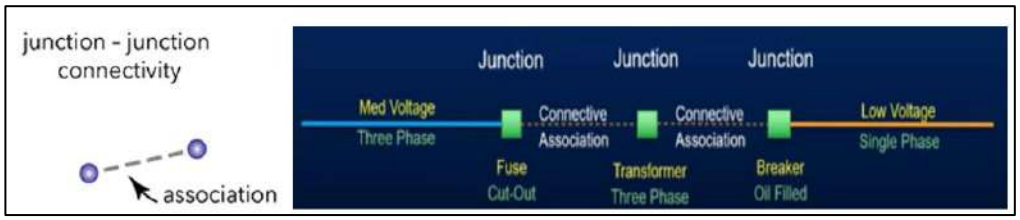

Figure 6: Junction-junction connectivity and associations in a power network.
Source: Authors, (2026).

3.Edge-Junction-Edge Connectivity Rules

These rules control how two edge features connect through an intermediate junction. They ensure that line features can only connect via appropriate junctions, maintaining the integrity of the network's topology. For instance, a medium voltage electrical transition from an above-ground system to a below-ground system at a junction point [18]. Figure 7 shows the edge-junction-edge connectivity in a medium voltage network.

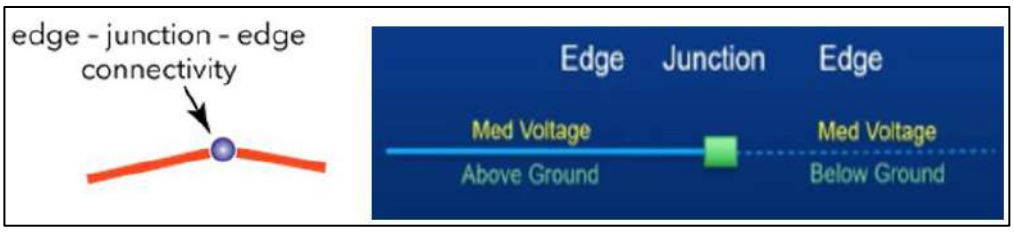

Figure 7: Edge-junction-edge connectivity in a medium voltage network.
Source: Authors, (2026).

V.2.1 Connectivity, Containment, and Attachment in Utility Networks

A well-structured electrical utility network relies on connectivity, containment, and attachment to define the relationships between different infrastructure components, ensuring efficient power flow, accurate network modelling, and streamlined asset management. Figure 8 shows the relationship, such as connectivity, containment, and attachment, in an electrical utility network.

- **Connectivity:** Defines the logical and physical interconnections between network components such as transformers, circuit breakers, transmission lines, and substations. GIS-based connectivity rules ensure that only valid electrical connections exist within the network, allowing utilities to simulate power distribution, detect faults, and optimize routing [19].

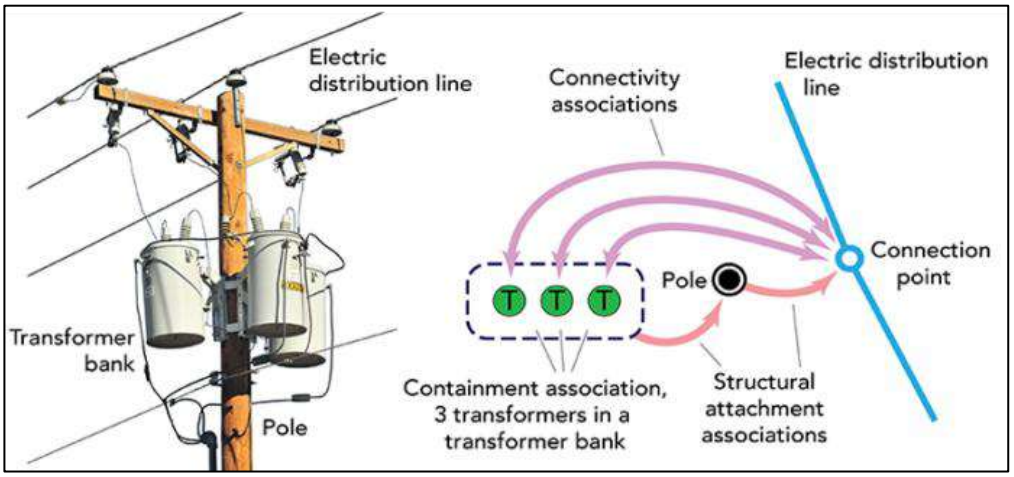

Figure 8: Connectivity, Containment, and Attachment.
Source: [19].

- **Containment:** Enables grouping multiple network features within a single container, such as a substation housing transformer, circuit breakers, and bus bars. This simplifies network visualization, asset tracking, and maintenance scheduling by reducing clutter on GIS maps [19].
- **Attachment:** Represents physical relationships between assets and their supporting structures, such as transformers mounted on poles or switchgear housed in substations. This ensures accurate spatial positioning and improves maintenance planning and network reliability [19]. Connectivity, containment, and attachment ensure efficient network management, accurate modelling, and stable power distribution.

V.3 ELECTRICAL UTILITY TRACING

Tracing is a process used in utility networks to analyse and visualize how different components within a network are connected and interact with each other. In the context of electrical utility networks, tracing helps identify the flow of electricity, determine how assets are linked, and assess the impact of potential faults or outages. By following the connectivity of network elements, tracing provides valuable insights into power distribution, enabling operators to monitor, manage, and optimize the electrical grid efficiently.

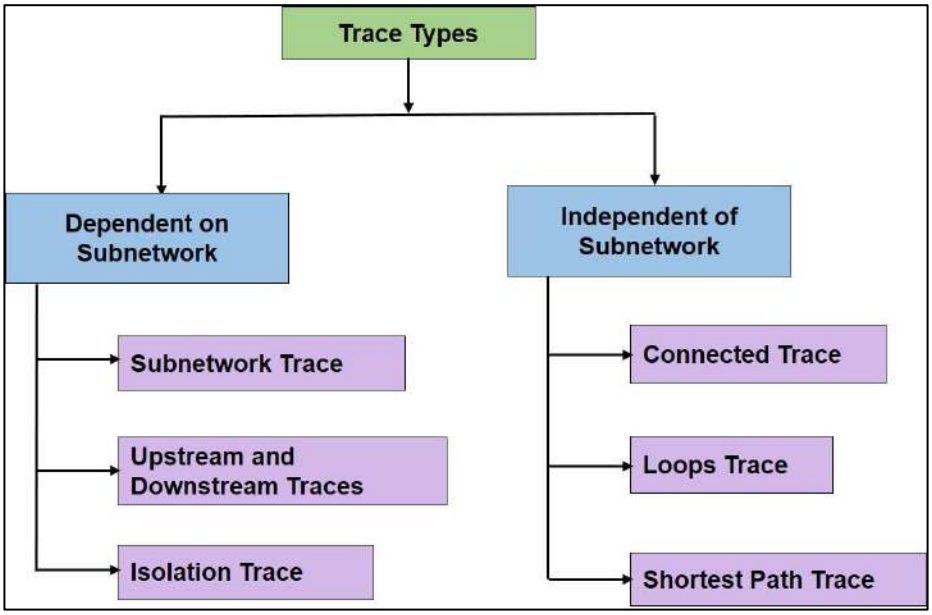

Figure 9: Classification of trace types in network analysis.
Source: Authors, (2026).

Each component in a power grid, such as substations, transformers, or circuit breakers, has a significant role in maintaining an uninterrupted power supply. Tracing serves as an invaluable tool in identifying faults, managing system expansion, and optimizing load distribution. Tracing ensures proper connectivity, identifies misrouted paths, and reduces the likelihood of service failures. In the event of faults such as short circuits or equipment failure, tracing helps quickly identify and isolate the affected sections, improving response time and service reliability. As electrical networks continue to expand, tracing aids in assessing new infrastructure integration and planning optimal locations for substations and feeders. It also helps evaluate the impact of network expansion on overall power flow, ensuring the network remains stable and efficient. Figure 9 shows the classification of trace types in network analysis.

V.3.1 Tracing Methods Dependent on Subnetwork

Figure 10 shows the types of tracing methods based on the dependent on subnetwork type.

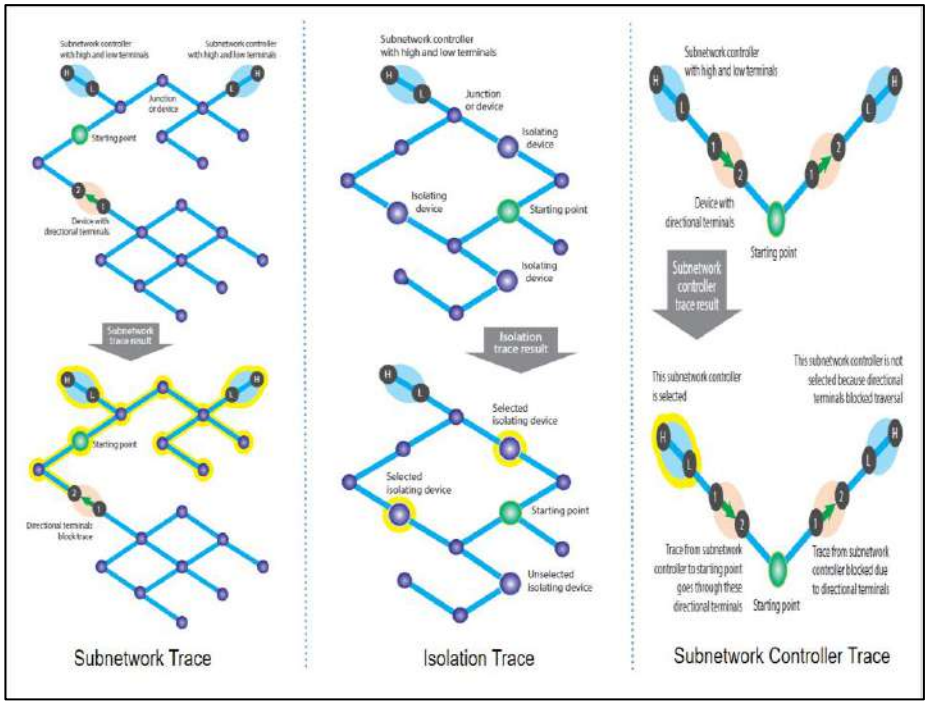

Figure 10: Network traces: subnetwork, isolation, and subnetwork controller.
Source: Authors, (2026).

1. Subnetwork Trace: A subnetwork trace finds every feature that is a part of a subnetwork, including a particular feeder or circuit. This trace relies on the subnetwork definition and requires at least one subnetwork controller to determine flow direction during the trace [19].

2. Upstream and Downstream Traces

- **Upstream Trace:** Identifies the source of resource supply for any network element by tracing against the flow direction toward the origin, such as a power plant or substation. This is useful for locating the origin of a contaminant in a water network or identifying the source of power feeding a particular area.
- **Downstream Trace:** Follows the flow direction away from the source, identifying customers or infrastructure that would be affected by a fault or outage at a specific point. This trace is crucial for outage management and planning maintenance activities to minimize customer impact.

3. Isolation Trace: The Isolation Trace determines the specific switches or valves that need to be operated to isolate a faulty section of the network. This trace is critical for outage management, allowing operators to quickly identify and isolate problem areas, thereby reducing downtime and mitigating the impact on consumers.

V.3.2 Tracing Methods - Independent of Subnetwork

1. Connected Trace: A Connected Trace starts from one or more points and follows connected features, stopping when it reaches a barrier or the end of a path. This trace is particularly useful for verifying that newly edited features are connected as expected, ensuring network integrity. For instance, in maintenance or upgrade scenarios, a connected trace can identify all customers or devices linked to a particular feeder, facilitating efficient planning and execution[19]. Figure 11 shows the types of tracing methods based on the independent on subnetwork type.

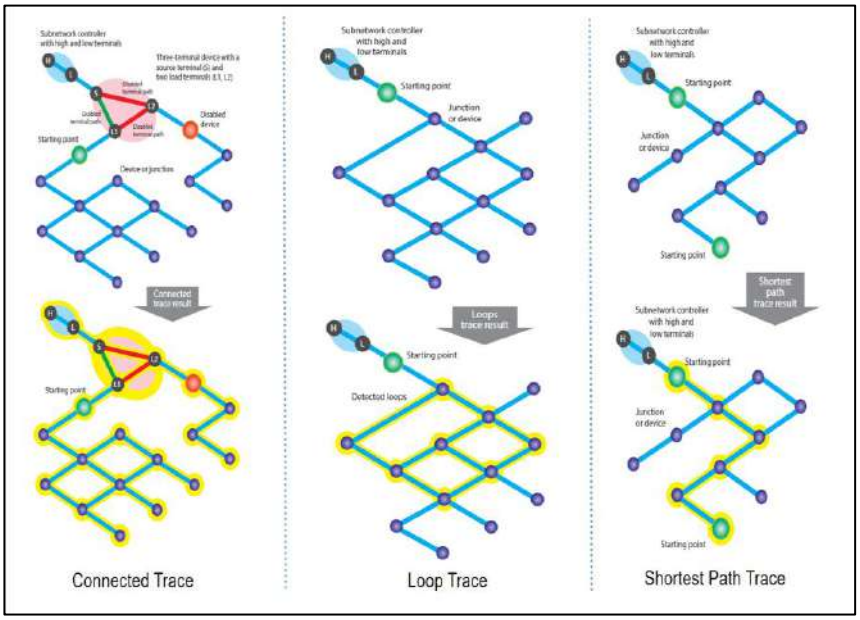

Figure 11: Network traces: connected, loop, and shortest path.
Source: Authors, (2026).

2. Loops Trace: The Loops Trace identifies sections of the network where a path starts and ends at the same location without crossing the same line twice, essentially forming a closed circuit. Detecting loops is crucial, especially in radial networks where unintended loops may indicate errors. In water distribution systems, for example, loops can help maintain consistent water pressure and supply, even if a part of the network is isolated for maintenance.

3. Shortest Path Trace: The Shortest Path Trace calculates the most efficient route between two starting points using a numeric network parameter like shape length. This trace is valuable for determining cost- or distance-based paths, aiding in scenarios like rerouting power due to maintenance or outages to restore service with minimal losses. By applying the appropriate trace type to specific scenarios, operators can proactively manage resources, swiftly respond to issues, and strategically plan for future network developments

V.4 NETWORK EXPANSION PLANNING

Network Expansion Planning is a vital process in electrical utilities that focuses on upgrading and extending the power grid to accommodate the increasing electricity demand. It involves assessing current network capacity, forecasting future energy needs, and implementing infrastructure such as new substations, transmission lines, and distribution systems. A well-executed expansion plan ensures that electricity is delivered reliably, minimizes power disruptions, and supports sustainable energy development [20]. The rising global electricity demand, driven by urbanization, industrial growth, and household consumption, necessitates strategic grid expansion. [21] Without proper planning, grids risk overloads, blackouts, and increased operational costs. GIS-based network expansion planning enables utilities to manage this growth effectively by analysing substation capacity, forecasting energy needs, and identifying optimal expansion routes [20]. It provides insights into whether existing substations can handle increased loads or if new infrastructure is necessary, thereby preventing power failures caused by overcapacity.

VI. RESULTS AND DISCUSSION

VI.1 WORKFLOW FOR UTILITY NETWORK TRACING

The process of utility network tracing begins by accessing the web-based GIS application that is integrated with the ArcGIS Utility Network or a comparable tracing tool. Prior to initiating any analysis, users must ensure they have the appropriate permissions and roles to perform network tracing operations and that the electrical utility network dataset is properly loaded from the organization's cloud-based GIS or enterprise geodatabase. Once the dataset is available, the next step involves selecting the appropriate tracing type based on the analytical requirements. Common tracing methods include connectivity tracing to verify network connectivity, subnetwork tracing to identify all elements in a feeder or circuit, isolation tracing to locate switches and breakers for fault isolation, and upstream/downstream tracing to analyze power flow direction. In this case, a connectivity trace was selected to evaluate the directly linked elements within the network. Figure 12 show the initialization of a connected trace on a utility network map. After determining the trace type, the user must define a starting point and, if necessary, place barriers to simulate faults, outages, or maintenance constraints. This is typically achieved by interacting with the map interface, where the starting point may represent a substation, transformer, or distribution feeder. For this analysis, a medium-voltage circuit breaker was selected as the trace origin. Once the parameters are established, the trace is executed, prompting the system to perform real-time analysis of the network and highlight all connected elements.

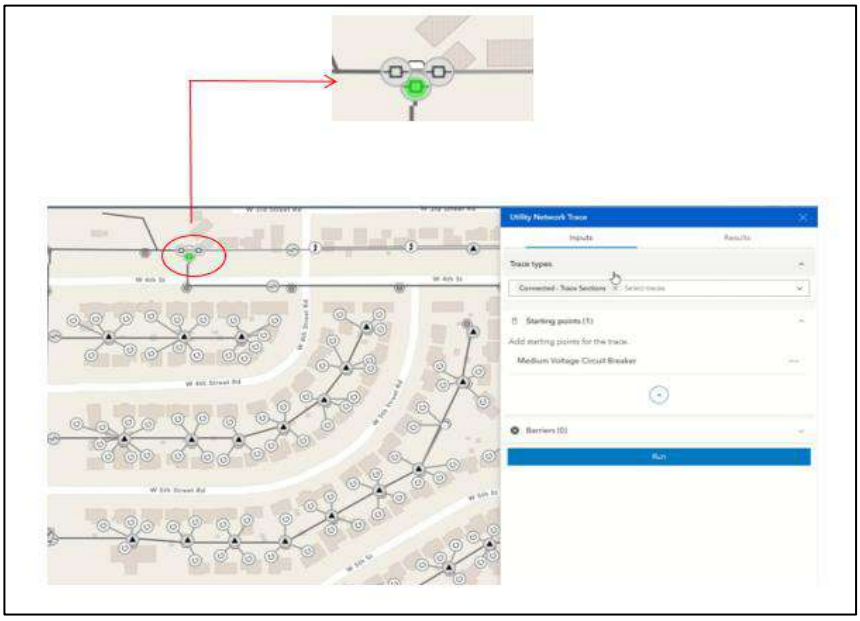

Figure 12: Initiating a connected trace on a utility network map.
Source: Authors, (2026).

The resulting trace revealed that 224 features were directly connected to the selected medium-voltage circuit breaker, with the traced path displayed in blue for clear interpretation and it is shown in Figure 13.

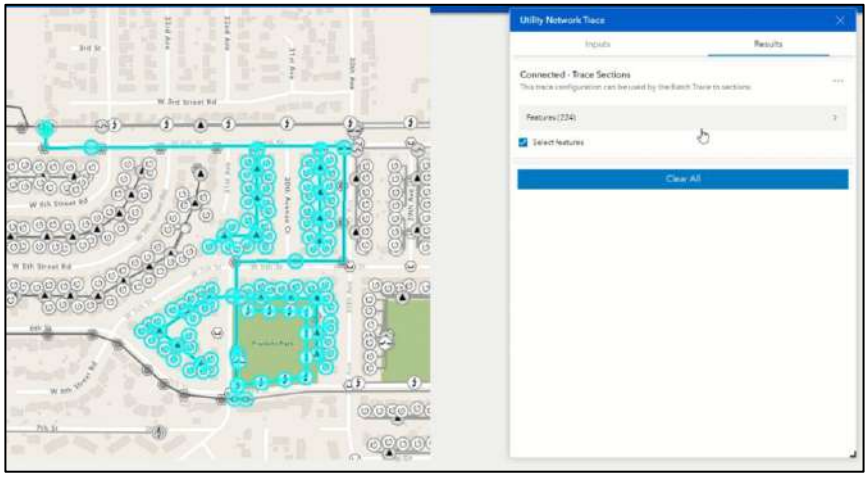

Figure 13: Results of a connected trace in a utility network.
Source: Authors, (2026).

Finally, the results of the trace can be exported or visualized using network diagrams, tabular reports, or GIS layers to support further analysis. These outputs enable utility engineers to validate network connectivity, assess fault isolation strategies, and evaluate power flow conditions in both spatial and schematic contexts. Moreover, the visualization and reporting capabilities facilitate integration with enterprise systems, thereby enhancing operational decision-making, outage management, and long-term infrastructure planning [22].

While this study demonstrates the connectivity trace procedure, the same workflow can be applied to other tracing types such as subnetwork, isolation, upstream/downstream, shortest path, loop, or subnetwork controller traces each serving distinct purposes in utility network analysis and management. The working mechanism of GIS-enabled network expansion planning integrates geospatial data with electrical network models to evaluate power flow, connectivity, and demand distribution. Planners can simulate various expansion scenarios and assess their impact on the existing grid, ensuring that new connections do not compromise overall performance. This proactive approach allows utilities to align infrastructure growth with energy demand trends, fostering a resilient, future-ready electrical network.

VI.2 ELECTRICAL UTILITY NETWORK DASHBOARD

The Electric Utility Network Dashboard serves as the nerve centre of the application, offering a real-time, integrated view of network operations. Built using ArcGIS Dashboard, this feature consolidates key performance indicators, asset data, and operational insights into a single, interactive interface and depicted in Figure 14.

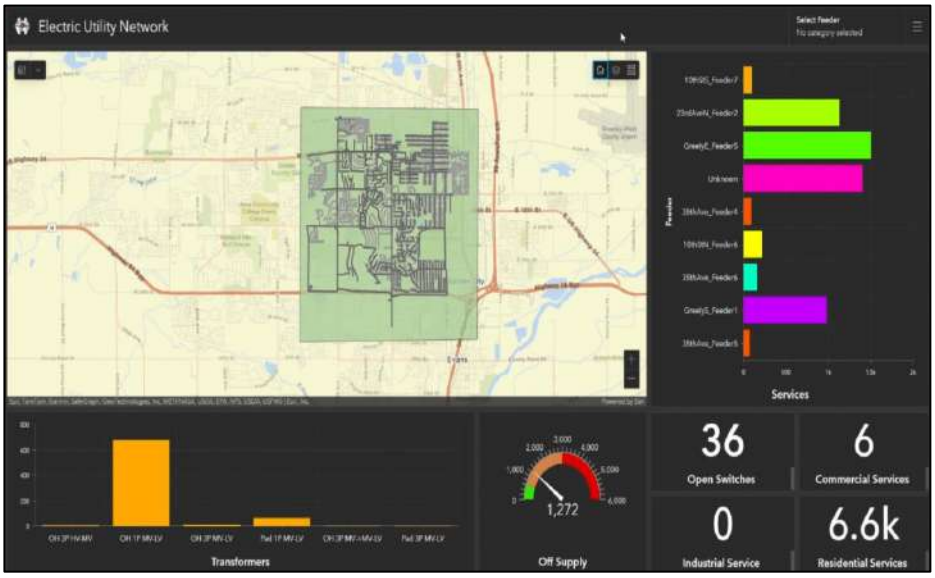

Figure 14: Electric utility network dashboard overview with service statistics.
Source: Authors, (2026).

Utility operators can use the dashboard to monitor network performance, track asset conditions, and assess key metrics such as outage frequency, equipment failures, and maintenance schedules. The dashboard's intuitive design enables quick analysis of network health, allowing decision-makers to respond proactively to potential issues [23]. The ability to visualize network status in real time enhances operational awareness, enabling utility providers to optimize resource allocation and improve service reliability. By integrating various data sources into a centralized dashboard, this feature ensures that stakeholders have access to the information they need to maintain a stable and efficient utility network.

VI.3. ANALYSIS OF TRACING RESULTS AND NETWORK BEHAVIOR

The tracing tools in ArcGIS Utility Network enabled detailed visualization of electrical flow and system behavior. Traces such as upstream, downstream, isolation, and connected traces simulated real-world scenarios like fault detection and route switching. Notably, the Connected Trace from the Medium Voltage Circuit Breaker identified the number of directly linked features (Residential, Commercial, Industrial Service points and Switches), confirming the established connectivity across distribution lines, transformers, and service points. To assess phase performance, Downstream Trace paired with the Summarize tool revealed a critical finding: Phase A was significantly underutilized, while Phase C showed signs of overutilization. This imbalance highlighted the need for load redistribution to ensure better phase management and system efficiency. These insights directly informed network expansion planning. This data-driven approach ensured that new customer connections were aligned with under loaded phases, supporting grid reliability and sustainable expansion.

VI.4 ANALYSIS FOR LOAD BALANCING AND STRATEGIC EXPANSION

The Summarize tool revealed a clear phase imbalance. Phase A was significantly underutilized, presenting an ideal opportunity for load redistribution. This insight guided the strategic allocation of new customer connections to Phase A in the Jonquil Avenue expansion zone of the Essential 001 Feeder, improving overall load balance across phases. Using the Create Features tool, new assets such as transformers, service points, and low-voltage conductors were digitized. Snap functionality ensured precise spatial alignment, and network associations, both connectivity and structural attachments were established to preserve logical flow and physical realism in the network. Following integration, network topology validation confirmed compliance with connectivity rules and junction-edge relationships. Initially, new features were not included in any Subnetwork, so the Subnetwork / Feeder name is set to 'Unknown'. Using the Update Subnetwork tool, assigning them to the appropriate Feeder 'Essential 001' was done. A final downstream trace verified successful resource flow across the newly added components, with no breaks or topological errors, validating a smooth and efficient network expansion.

VII. CONCLUSION

This research explores the application of Geographic Information Systems (GIS) in the modernization of electrical utility networks. As energy infrastructure evolves to meet increasing demand and complexity, GIS plays a pivotal role in improving network connectivity, asset mapping, and subnetwork management [24]. Through advanced functionalities such as tracing, utilities can simulate real-world scenarios like fault detection, load flow analysis, and isolation planning, enhancing the system's responsiveness and efficiency. The study addresses limitations in conventional grids and demonstrates how GIS supports data-driven operations and efficient network planning. Network expansion was planned and executed using GIS tools to ensure spatial accuracy and logical connectivity. The implementation of upstream, downstream, and connected traces provided valuable insights into power flow, load distribution, and structural integrity across the network [25]. The modernization of electrical utility networks requires a paradigm shift from conventional grid management practices toward data-driven, intelligent systems, with Geographical Information Systems (GIS) serving as a critical enabler [26]. GIS facilitates advanced asset mapping, load flow analysis, outage management, and fault location detection, all of which are essential for efficient power distribution [27]. By integrating GIS with Supervisory Control and Data Acquisition (SCADA) systems [28] and Distribution Management Systems (DMS), utilities can achieve real-time situational awareness, improve demand forecasting, and minimize technical and non-technical losses.

This enhances not only the operational efficiency of the grid but also its resilience against faults and peak demand pressures[29].Moreover, the integration of GIS with emerging smart grid technologies allows for greater interoperability, predictive maintenance, and renewable energy integration [30]. For example, spatial data analytics can optimize the placement of distributed energy resources (DERs), support microgrid development, and improve restoration strategies during natural disasters. By enabling utilities to model, simulate, and manage complex network interactions, GIS contributes to a more adaptive and sustainable power distribution framework. Ultimately, its role in modernizing electrical utility networks is pivotal in ensuring that the grid evolves into a more intelligent, flexible, and customer-focused system aligned with global energy transition goals. Hybrid aloe vera/hemp fibre composites showed better strength and thermal stability, making them suitable for lightweight engineering use [31]. ANSYS-based optimisation improved the performance and durability of two-wheeler suspension systems [32]. Solar photovoltaic–based cogeneration was found to support efficient energy and water management [33]. The use of vortex generators improved airflow characteristics and reduced aerodynamic drag in vehicle models [34]. IoT-based systems enabled real-time monitoring and improved operational efficiency [35-36].

ABSTRACT

Modern motorcycles are now manufactured with more attention to how they look and how air moves around them to make them more attractive to buyers. However, this focus sometimes ignores how well the rider can stay balanced, especially when moving slowly. Keeping the bike steady in these situations can be tough. This study looks at how to improve motorcycle balance and make the bike more stable by using a gyroscope. The research includes testing how the motorcycle reacts when it starts to fall, and then designing and checking a gyroscope system based on those tests. The main goal of this paper is to check if adding stability using two gyroscopes along with a double flywheel can make motorcycles more balanced without making them less safe. This method helps both skilled riders and new riders who are learning to ride two-wheelers.

I. INTRODUCTION

Developing countries like India, motorcycles are more popular than cars because they are cheaper to buy and use. However, motorcycles are not as safe as cars and are harder to balance when moving slowly, which makes stability a big issue, the designing of self-balancing two-wheeler plays a vital role for physical challenged people. Validating the prototype model using gyroscopic technique and modelling the vehicle and evaluating the experimental model, the system is based on Lagrangian mechanics and uses the idea of an upside-down pendulum, making it a method that is easy to copy and use to make motorcycles more stable [1]. This project aims to make motorcycles more stable by using gyroscopes and study of self-balancing two-wheeler with double stabilization techniques used for balancing the two wheeled motorcycle. Earlier research, including real-time fall data from the 2006 to 2016 MotoGP, found that motorcycle falls often happen because of loss of grip and sudden rocking movements [2]. Different ways to improve balance have been tried, like adding extra wheels, flywheels, and balancing weights, but gyroscopes are considered the best solution [3].

Flywheels work like gyroscopes, creating a stabilizing force called precession, which helps keep the motorcycle upright even when it's not moving, this approach was tested through computer simulations using MATLAB/Simulink and real-world prototypes [4]. The study looks at factors like how hard it is to spin something, how fast it spins, and how accurately the spinning axis is aligned to design and improve a system with two gyroscopes [5]. The system can spot signs that a driver is getting tired, which can help stop accidents caused by imbalance and tiredness [6]. Testing showed that this system can lower the chance of accidents by catching strange driving behaviour as it happens during driving [7]. The research analysis found that this system makes braking quicker and more stable, which helps stop the motorcycle smoothly and prevent skidding when stopping suddenly [8]. This paper looked at how metal and rubber materials affect how much tools used for boring can dampen vibrations. The research studied the properties of bio-composites made from Aloe vera and hemp fibres [9]

The hybrid method was found to be stronger and longer-lasting than other methods, making the joints work better. The study found that this kind of seat belt greatly reduces movement and the risk of injury compared to regular seat belts [10],[11]. The study showed that using IoT improves car performance, makes driving safer, and gives a better driving experience [12]. The results showed that this method is more efficient and produces more water than traditional systems [13]. The findings showed that this system can stop the car automatically to prevent collisions, without the driver needing to do anything [14]. The study explained how continuous monitoring can improve road safety by finding early signs of tiredness or other health issues [15]. The results showed common signs of fatigue, which showed the need for monitoring systems to help prevent accidents caused by reduced alertness [16]. The study looked at a new design for the intake manifold for automobile that run on various types of design intake [17].

The results from computer simulations showed that the stronger front structure could absorb more energy during a collision, reducing the chances of injuries to the people inside. There were also studies on engines design along with a technique on analysis process and this studies found that analysis techniques [18], [19]. The study developed an onboard driver monitoring system combined with an enhanced braking mechanism to improve driver response in unsafe conditions. The system showed potential to reduce accident risk through timely braking intervention [20]. Frontal crash tests showed that five-point seat belt systems provide better occupant restraint and reduce injury severity. The study confirmed the importance of restraint design in improving crash safety [21]. The numerical analysis found that side-mounted vortex generators improve airflow behavior and vehicle stability. The results indicated reduced aerodynamic losses using passive flow control methods [22]. Material optimization using ANSYS showed noticeable improvement in strength and durability of two-wheeler suspension components.

The study confirmed that suitable material selection enhances performance while reducing weight [23]. The investigation demonstrated that variable geometry micro-channel heat exchangers improve heat transfer in automotive air-conditioning systems. Enhanced cooling performance was achieved through optimized tube and fin design [24]. An active braking system integrated with driver condition monitoring was shown to improve braking response during critical situations. The approach enhanced preventive safety in passenger vehicles [25]. The study addressed data security challenges in e-healthcare systems and proposed methods to protect patient information. The framework ensured privacy without affecting system reliability [26]. Experimental results showed that a semi-automatic parking brake system offers reliable and low-cost safety improvement for passenger vehicles. The system performed consistently under operating conditions [27], [28]. The studies demonstrated that real-time self-stability systems using sensor-based feedback can significantly improve motorcycle balance and rider safety during dynamic operating conditions [29-31].

II. MATERIALS AND METHODS

This method requires the use of flywheels as gyroscope on the two-wheeler so that the self-aligning properties of the gyroscope are imparted to the two wheelers on which it is installed. The different types of vehicles currently in use were identified for the study and their different specifications were noted that were required for further calculations and analysis. The purpose of the position of the center of gravity was an important part in the study. Thus, by careful approximation the position of center of gravity was determined to be at the half of the wheel base of the vehicle. For this study, the prototype was built in such a manner that it would be the exact replica of the real time model but in a smaller way i.e. it could be built in the exact same way but with changes to the dimensions. The prototype was built using specific materials, and several difficulties arose during its development, mainly concerning the position and weight of the gyroscopic flywheel. To overcome this, the gyroscope was mounted at different points on the frame and supported with beams of varying dimensions. However, the overall frame size and the wheels supporting the structure were kept unchanged and used as a constant reference for the design.

II.1 SYSTEM DESIGN FOR FORMULA DERIVATION

Motion equations are derived by method of Lagrange. This approach is extracted from energy survival for every rigid process structure. There are three rigid body elements, i.e. vehicle body, first flywheel and second flywheel. The Lagrange equation determines first L= TV, where T is the system's actual kinetic energy and V is potential power. The kinetic and potential body and flywheel power equations are based on [14].

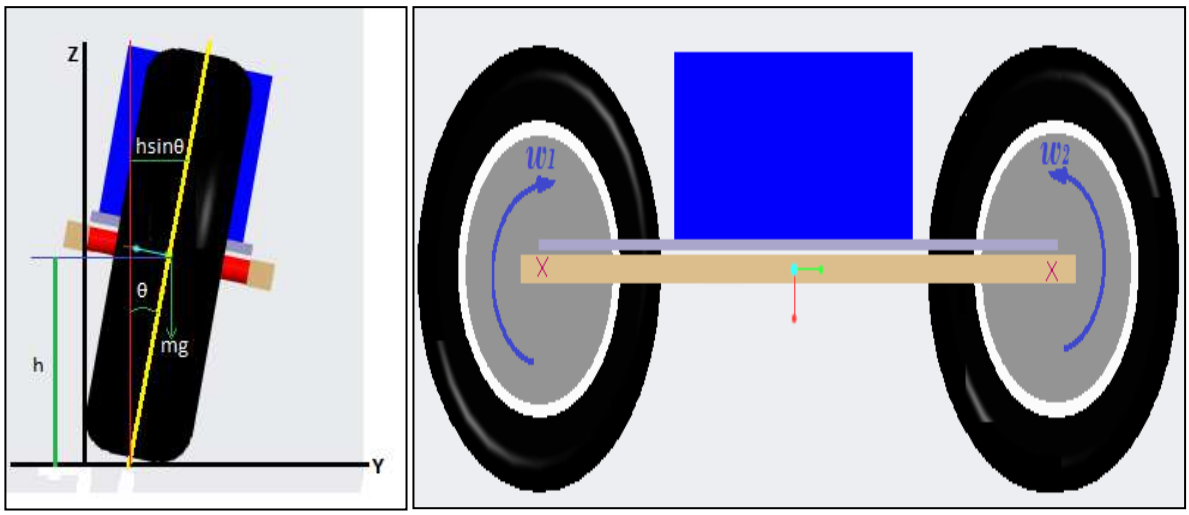

Figure 1: Free body diagram of gyro vehicle.
Source: Authors, (2026).

The coordinate of a vehicle is defined as:

θ - Tilt angle of motorcycle
ω_1 - Direction of rotation of Flywheel 1
ω_2 - Direction of rotation of Flywheel 2
Mass and centre of vehicle - m_b&Cg_b
Mass of 1st and 2nd flywheel - m_{gl} & m_g
Center of mass of 1st and 2nd flywheel - Cg_{gl} & Cg_{g2}
Moment of Inertia of motorcycle -I_{mx}
Moment of Inertia of 1st and 2nd of flywheel- I_{glx}, I_{gly}, I_{glz} ; I_{g2x}, I_{g2y}, I_{g2z}
$H = m_bCg_b^2 + m_{g1}Cg_{g1}^2 + m_{g2}Cg_{g2}^2$
$M = m_bCg_b + m_{g1}Cg_{g1} + m_{g2}Cg_{g2}$

In order to derive the motion equation of the gyro motorcycle, the assumptions made are as follows:

- Flywheel 1 and 2 rotation speeds are same but in the opposite direction.
- The vehicle is stationary.
- No external force is applied.

The Lagrange's method was used for derive equation of motions written with that assumption as:

$$\frac{d}{dx}\left(\frac{\partial l}{\partial \theta}\right) - \frac{\partial l}{\partial \theta} = 0$$

The derivation of the Lagrange equation is made by the final coordinate deserved. The speed of the inclined angular vehicle is achieved according to the above equation.

$$\ddot{\theta} = \frac{2k_1 \sin\dot{\theta} + 2k_2 \sin\dot{\theta} - l_{g1z}\,\theta - l_{g2z}\,\dot{\theta} - \dot{M_g}\sin\theta}{l_b + H}$$

The inputs used by Matlab Simulink were initial angle variation of inclination and flywheel rotation speed by performing vehic le angle occurred at zero-degree axis.

II.2. CONSTRUCTION OF GYRO VEHICLE

The flywheel fixed inside of wheels. Wheels were fitted to the steel frame; the mass should be dominant on the top of frame. (The centre of gravity is thus just above the wheel axis, stainless steel disc used as flywheels were fixed with the DC motor. The 12V battery was connected to the motor. The on/off switch was connected in series to the motor so that in would control the flow of the current to the DC motor only when needed. Figure 2 the model has been made in such a way that the front and rear wheels could move to take turns to change motorcycle direction (13). The accelerometer was placed in the same axis with the motors to get better readings from the motion sensors. Table 1 contains what are the data used for develop prototype model.

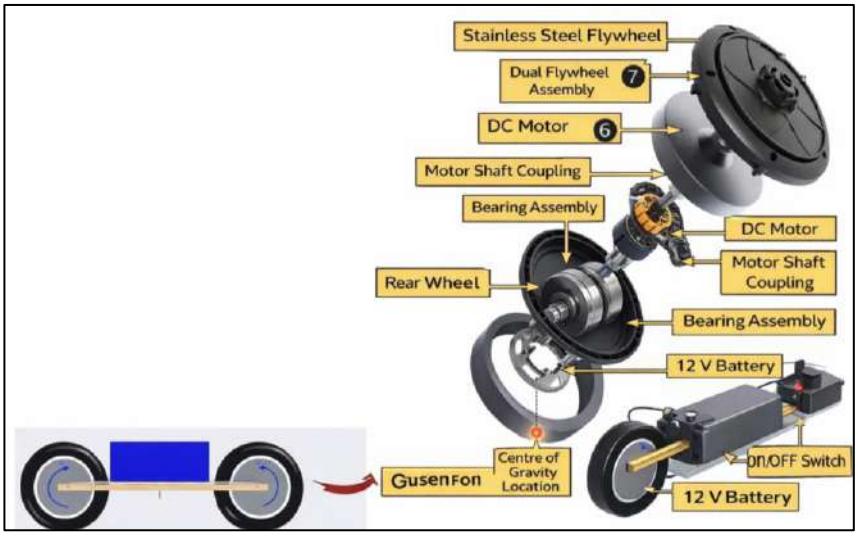

Figure 2: Exploded view of gyro assembly.
Source: Authors, (2026).

II.3. PROTOTYPE OF GYROSCOPE ASSEMBLY.

The model was made to lie on its side. Then the motor was made to run, which spun the flywheel. As the speed increased, the whole setup gradually started to rise. The motor and frame reach the stationary position after only a few rotations and oscillations of the motor, and the pure rolling movement is created by the gyroscope on the spin axis. This rotation of the disc produces the gyroscopic effect so that when the wheels lose their stability by virtue of the active gyroscopic pair, a gyroscopically couple is produced on the other hand. This gyroscopic effect is conducted both on the front and rear wheels. The complete assembly of prototype gyro shown in Figure 3.

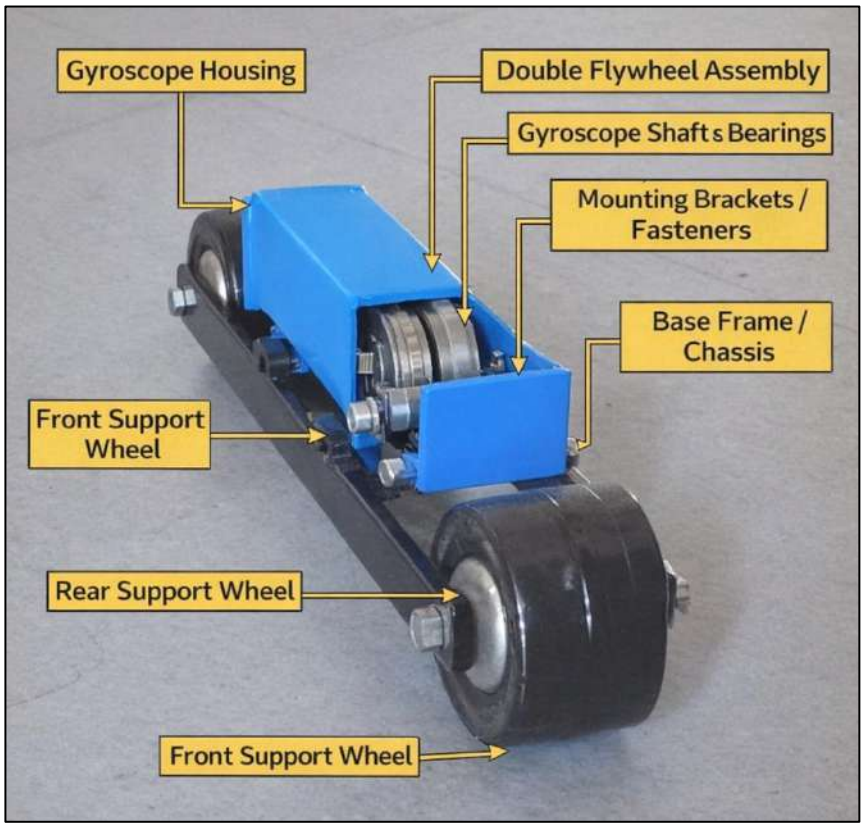

Figure 3: Prototype of gyro assembly.
Source: Authors, (2026).

II.4. HARDWARE SYSTEM DESIGN CONSTRUCTION

Stabilization of the Control Moment Gyroscope (CMG) uses a high-speed flywheel's reactive precession torque around an axis that acts to balance the vehicle. This paper proposes a development of proportional integral derivative (PID) controller for first order sliding mode to control the CMG and stabilize a bicycle at zero-forward speed. In this article, a motorcycle flywheel with one DOF is used to inducing the torque to overcome the torque by the gravity of its balanced vertical position when it is applied on the two wheels. A simultaneous, amplified reactive torque is produced around an orthogonal axis on both the axis of the flywheel and the spin axis by use a torque on a rotating flywheel. This controlled reactive torque can be designed to balance the axis of an unstable two-wheeler. Motorcycle balancing means that the vehicle attempts, by moving left or right for an induced lean angle, to return vertically or not to fall over. For this function we have to do two things: firstly, we must calculate the angle of inclination (roll) of the vehicle, and then we must control the speed of the engines to achieve this angle 0. Wink Measurement:

The accelerometer can measure the force of the gravity and the angle of the two wheels can be obtained.from the figure 4 illustrates the schematic diagram of gyroscope vehicle and it had labelled clearely.The gyroscope calculates the angular velocity and, if this calculation is combined, the magnetic angle of the twowheel moved i s not optimal and the integration has an integration variance.The combination of these sensors, called sensor fusion, will overcome these issues, and there are a great number of ways of combining them. It was named MPU6050. MPU6050 had the ability to use the detectors to collect accurate data directly from the chip without having to solder the sensors manually. Two engines spin two fly wheels separately so that we can alter the engine inputs in the correct location of the two wheels. We also use PID to provide a smoother calming reaction. To order to maintain the equilibrium position, the accelerometer tests the chase speed and the gyroscope. The ties we used during this a nalysis are shown in the figure below. In order to better read from the motion sensors, the accelerometer was positioned in the same dire ction with the enginesIt was also important to check the reliability of the proposed controller model. A basic PID controller was also added to the system to check this.

The PID controller have been designed as-

$$u = K_P e(t) + K_D \, d/dt e(t) + K_I \int e(\tau) d\tau$$

Where KP, K_D, and K_I are gains in proportion, derivative, and integrator, and $e_{(t)}$ is the difference between the current angle of tilt and the ideal angle ($\theta = 0$)(20).

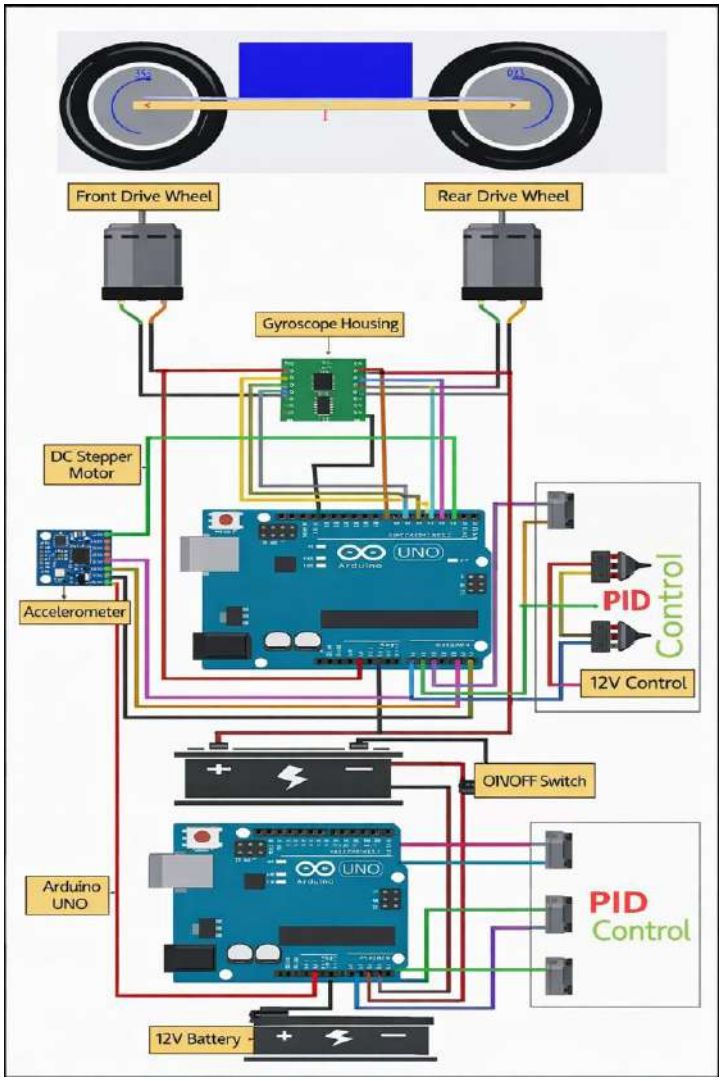

Figure 4: Schematic diagram of gyro vehicle.
Source: Authors, (2026).

III. RESULT AND DISCUSSION

Gyroscope is based on the principle that the angular momentum varies in torque direction. The simple principle behind this study is to give a counter force to the vehicle when it is under a fall.

Couple incurred during fall of a two-wheeler

$$C = W*h \quad (1)$$

Where,

W = Weight of two-wheeler in kg.
h = height of center of gravity from the ground m.
The course of the fall when traced took place in a quarter of the circle. The time taken was iterated to 1.5 seconds.
Hence, Basic formula for the minimum angular momentum required to stabilize the vehicle.

$$W*h^2\pi/ (2*1.5) \quad (2)$$

But angular momentum of a gyroscope is

$$L = I*\omega \quad (3)$$

$I = M*r^2$
$\omega = N*2\pi/60$
Substituting I and ω in (3)
We get,
$L = M*r^2*N*2\pi/60$

Where,

L= angular momentum of gyroscope kgm^2s^{-1}.
I = moment of inertia of the disc kgm.
ω = angular velocity of gyroscope m/s.
M= Mass of flywheel kg.

r = radius of the flywheel m.
Torque $\tau = Frsin\theta$
Force F=mg

Thus, by equating (2) and (3), we can determine the required angular momentum to be induced by the gyroscope. We have designed and made a self-balancing system for motorcycle. The model works on the principle of spinning wheel fixed inside of wheel.

Table 1: Parameters to design.

Front wheel dia - cm	20
Rear wheel dia (r)- cm	20
Overall mass- kg	20
Wheel base- cm	50
CG Point(h)- cm	30
Mass of Disc(m)- kg	0.25
Radius of Disc(r)- cm	5
Motor speed (N) RPM	500

Source: Authors, (2026).

Angular momentum of a gyroscope

$L = I\omega$

Moment of inertia of the disc

$I=mr^2$.
$I=0.25*0.05^2$
$I=0.000625$ kg m^2.
$\omega = N*2\pi/60$
$\omega = 500*2\pi/60$
$\omega = 52.3s^{-1}$
$L=0.000625*52.3$
$L=0.0326$ kgm^2 s^{-1}

Thus, the prototype can balance the vehicle up to the angular momentum of 0.0326kgm^2 s^{-1}

Table 2: Variation of Moment of inertia and Angular momentum of a gyroscope with respect to mass.

S.No	Mass-Kg	Moment of inertia- kg m^2	Angular momentum of a gyroscope- kgm^2 s^{-1}
1	0.25	0.000625	0.0326
2	0.26	0.00065	0.0339
3	0.27	0.000675	0.0353
4	0.28	0.0007	0.0366
5	0.29	0.000725	0.0379
6	0.30	0.00075	0.0392

Source: Authors, (2026).

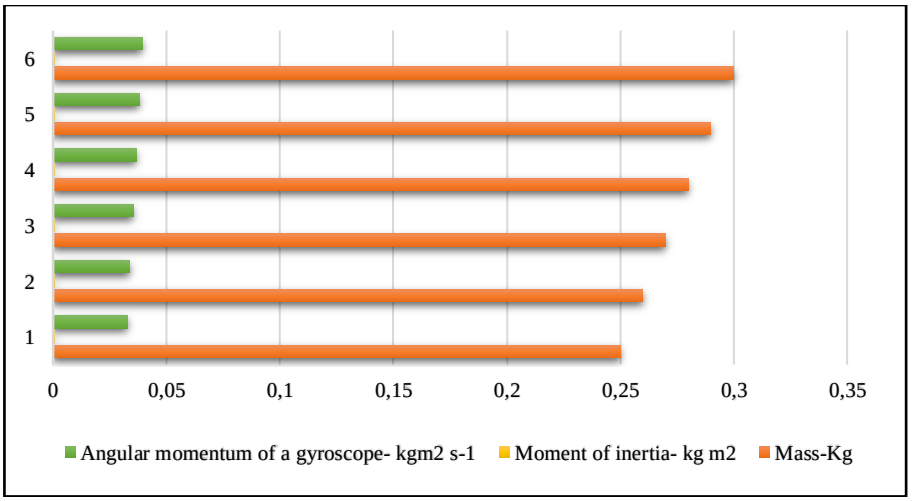

Figure 5: Mass vs Moment of inertia and Mass vs Angular momentum.
Source: Authors, (2026).

Figure 5gives us a clear idea that the moment of inertia created by the gyroscope will increase if we try to increase the mass of the flywheel can say that the time of inertia (MI) varies along with different masses of the fly wheel, relation between the fly wheel mass and the gyroscope angular momentum. Here, we can see that the angular momentum also increases in the response to the variable the fly wheel weight, which means that the range is a different factor for the gyroscope to get variable angular momentum values.

Table 3: Changes of flywheel speed with respect to tilt Angle at constant mass.

S. No	Tilt angle- θ	Flywheel Rotation -RPM
1	0	0
2	5	190
3	10	250
4	15	280
5	20	330
6	25	410
7	30	500

Source: Authors, (2026).

Figure 6 shows the results by changing the angle of inclination to get the corresponding speed values to change the tilt angle values. If the tilting angle increases, the torque value of the gyroscope is modified. In this analysis, the flywheel inertia is constant for each change of the input vehicle's inclination angle; so that the flywheel rotation speed required stabilizing the vehicle increases with the vehicle angle inclination. The greater the vehicle's angle, the greater the vehicle's torque.

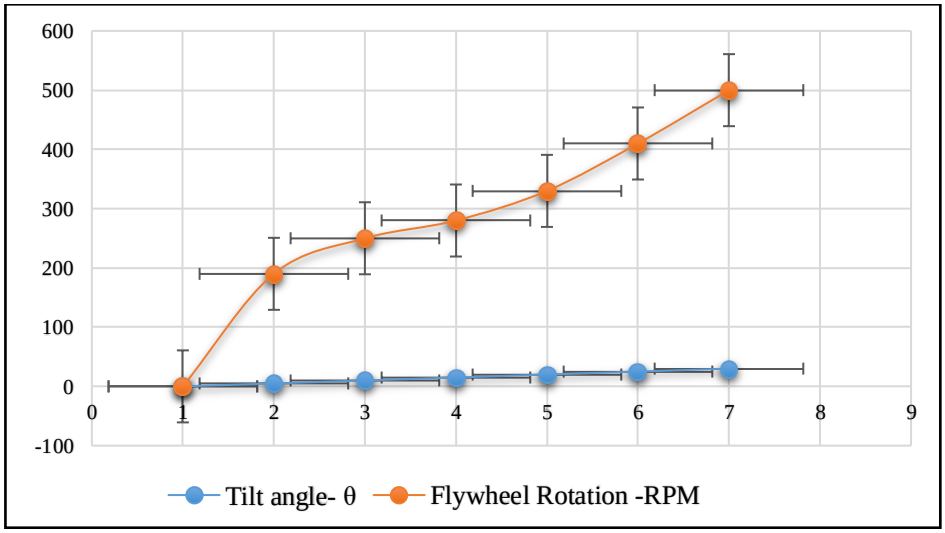

Figure 6: Tilt angle vs Flywheel rotation.
Source: Authors, (2026).

The results obtained in the form of the graph containing vehicular angle stabilization with a vehicle flywheel rotation speed were extracted from the theory test using Matlab Simulink. The vehicle angle changes test results are shown in TABLES 3. As for one of the theoretical testing charts shown in Figure 7. The vehicle incline angle is used as input parameter (θ) at 05, 10, 15, 20, 25, and 30. The result is 190 rpm, up to a 500-rpm flywheel rotation to stabilize the 00-30 incline angle from Simlink Matlab. The couple that is induced during fall was calculated based on the collected data for each vehicle. For each vehicle, the required angular momentum of the gyroscope was calculated and recorded. A scaled prototype was developed to demonstrate the stability of a two-wheeler using a flywheel as a gyroscope, and the gyroscopic force generated by the flywheel was calculated. In this model, only the forces acting along the lateral axis were taken into account, while factors such as driving force, vehicle velocity, braking force, and air resistance along other axes were excluded from consideration.

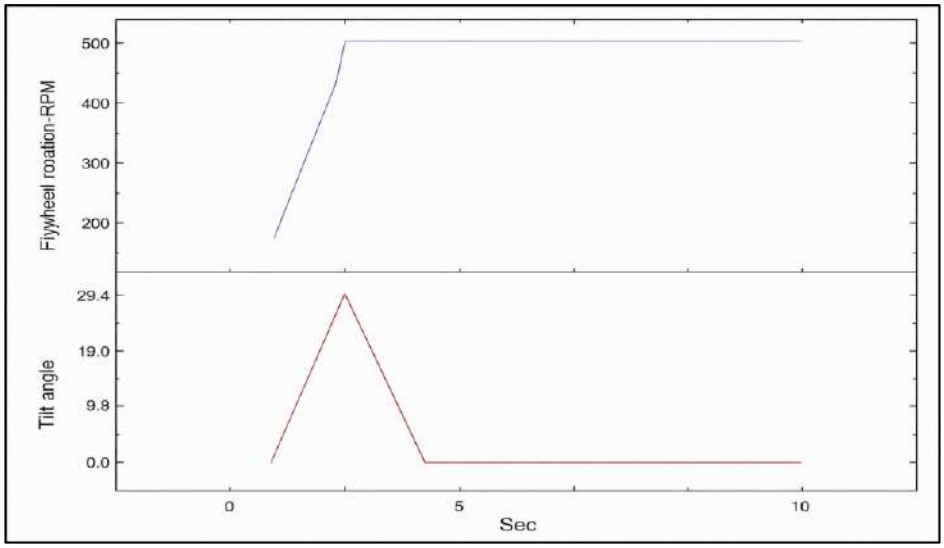

Figure 7: Stabilization graph at 30^0 - 500RPM.
Source: Authors, (2026).

For the prototype, the gyroscopic force of the flywheel was calculated to be 0.37 kg·m²/s at a rotational speed of 500 rpm, based on the given specifications. The motor speed was maintained at 500 rpm, while the flywheel mass was varied by adding or removing weight. The angular momentum generated by the system remained within the counteracting force of the flywheel, allowing the vehicle to maintain balance without external support. With these positive results, the study provides a basis for extending the concept to real vehicle applications in future work. The two wheeled model was stabilized by the usage of the gyroscopic force (i.e. angular moment) induced by the flywheel. Different types of motorcycle were selected based on this study were categorized into scooter, standard and sports shown table 2.

Case 1

W= 103kg
h= 0.619m
$L= W*h^2/(2*1.5)$
L= 103*0.6192/(2*1.5)
$L= 13.155\ kgm^2s\text{-}1.$
Thus,
13.155= M*r2*N*2π/60
13.155= M*N*0.07622*2π/60
M*N=21,634
M= 5kg
N= 4326rpm

Thus, the required mass 5kg and the required speed 4326rpm the gyroscope that is required for the self-balancing in standard model motorcycle was found theoretically.

Case 2

W= 119kg
h= 0.652m
L= W*h2/(2*1.5)
L= 119*0.6522/(2*1.5)
L= 16.826 kgm2s-1.
Thus,
16.826= M*r2*N*2π/60
16.826= M*N*0.07622*2π/60
M*N=13,817
M= 5kg
N= 2763rpm

Thus, the required mass 5kg and the required speed 2763rpm the gyroscope that is required for the self-balancing in standard model motorcycle was found theoretically.

Case 3

W= 135kg
h= 0.6725m
$L= W*h^2/(2*1.5)$
$L= 135*0.6725^2/ (2*1.5)$
L= 20.351 kgm2s-1.
Thus,
20.351= M*r2*N*2π/60
20.351= M*N*0.07622*2π/60
M*N=16,676
M= 5kg
N= 3335rpm.

Thus, the required mass 5kg and the required speed 3335rpm the gyroscope that is required for the self-balancing in sports model motorcycle was found theoretically.

Table 4: Data for three types of motorcycle.

Case/Description	Case -1 Scooter	Case -2 Standard	Case -3 Sports
Wheel Dia (f)- m	0.3048	0.4318	0.4318
Wheel Dia (r) -m	0.3048	0.4318	0.4318
Overall Mass- kg	103	119	135

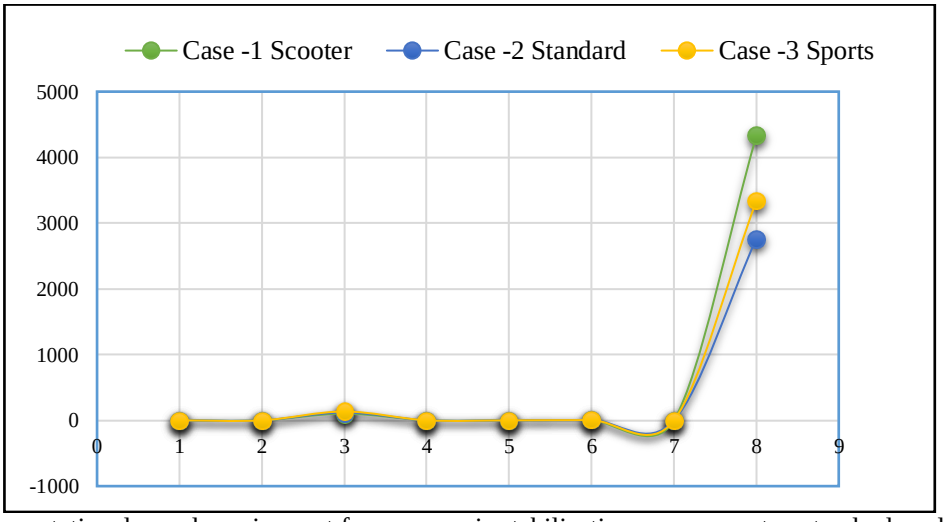

Figure 8: Comparative rotational speed requirement for gyroscopic stabilization across scooter, standard, and sports motorcycles.
Source: Authors, (2026).

From Figure 8. The scooter configuration requires the highest disc rotational speed, indicating a greater gyroscopic input needed to compensate for its lower mass and shorter wheelbase.The standard motorcycle shows the lowest required speed, reflecting a more balanced contribution from mass distribution and wheelbase length. The sports motorcycle exhibits an intermediate trend, where higher mass improves stability but still demands elevated disc speed due to its geometry and dynamic characteristics.

V. CONCLUSION

The proposed method successfully enabled the vehicle to achieve self-stability. The model operates on the principle of a spinning wheel mounted within another wheel. This study was undertaken to address the challenge of balancing motorcycles and to enhance their stability. The concept involves using a dual-gyroscope system with double flywheels, followed by testing, designing, and analysing the gyroscope based on the results obtained. A prototype of the gyroscopic stability system for motorcycles was developed and validated, with corresponding calculations performed and operational limits defined. This work benefits not only experienced riders but also individuals who are in the process of learning to ride two-wheelers.

ABSTRACT

The roll cage is a critical structural element of an all-terrain vehicle (ATV), providing essential rigidity and enhancing occupant safety during off-road operation. This study presents the design and structural evaluation of an ATV roll cage, focusing on CAD modeling, finite element preprocessing, and static structural analysis. The roll cage geometry was developed using Creo to satisfy key requirements such as strength, weight efficiency, and compatibility with the vehicle chassis. The completed model was then discretized using Hyper mesh, where appropriate meshing was applied to ensure reliable numerical results. Static structural analysis was carried out using the Opti Struct solver to evaluate stress distribution, deformation behavior, and potential failure regions under representative loading conditions, including gravitational effects and external impact loads encountered during off-road use. The results confirmed that the roll cage design meets safety and performance criteria, with factor of safety values maintained within acceptable limits, supporting its suitability for demanding off-road environments.

I. INTRODUCTION

Commonly developed from steel or other high-strength materials, a roll confinement comprises an organization of bars or cylinders decisively situated around the vehicle's traveler compartment. Furthermore, it builds up the vehicle's case, improving, generally speaking, its unbending nature and stability. All-territory vehicles are quite possibly the most renowned vehicle, which was first made in the USA in the mid-70s, and from that point forward, the utilization of these vehicles has been expanded fundamentally. This will be accomplished through the use of simulation and testing methods to evaluate structural integrity, material selection, and optimization strategies. Consequently, to check the security of the vehicle, different investigations are performed on different parts of this primary examination performed on the roll-enclosure of the vehicle. The underlying trustworthiness of the roll confine is resolved utilizing the FOS. The vehicle's loss of momentum in relation to the object it collides with can be seen in the graph's fall in momentum. The effect power and FOS obtained from the examination results underscore that ePA-CF has preferred execution over ASTM A36 steel roll confinement [1]. The ergonomics of the vehicle are likewise remembered while planning so the driver can drive the ATV with outright solace and prosperity. More noteworthy and more prominent will be the capacity of the roll enclosure to support different burdens in various landscapes. All the effect tests were performed, and in light of the most extreme pressure, the variable of wellbeing (FOS) was determined. The element of security was well over as far as possible, which is 1.5, and hereafter it is reasoned that the modular of the ATV that was introduced in this paper is protected to be manufactured [2].

Design Study of Electric Vehicle Roll-Cage Obtained Using Modal Analysis, this paper provides the optimum design parameters (thickness, width, height, and diameter) of a roll cage considering the modal analysis. With different static, structural, and explicit dynamic analyses to show that the roll cage is secure when load it statically and dynamically. The factor of safety for the roll-cage reaches 2, which is safe from a design point of view. The naturally produced first bending mode will meet the dynamic frame performance requirements under different conditions. The frequency of the first mode is higher than the frequency of road excitation in the most common operating conditions and is also higher than the frequency of the electric motor, thus trying to avoid these common resonance problems [3]. Static and Modal Analysis of All Terrian Vehicle Roll-Cage, a bigger production line of security infers the huge capacity of an ATV to endure all sorts of burdens and be equipped for continuing on different landscapes. This paper has outlined the whole plan strategy of roll enclosures and understands the basic parts of the plan. Additionally, static examination is used in limited component investigations alongside modular examination to avoid the peculiarity of reverberation [4]. Effect of metallic substrate and rubber elastic materials, the study investigated the effect of the Constrained Layer Damper on boring hardened AISI 4340 steel, focusing on tool wear, surface finish, and vibration. The damper, using copper as the substrate and polyurethane as the elastic material, significantly reduced tool vibration, enhancing tool life by approximately 97.5%, improving surface finish by about 83%, and reducing vibration by around 98%.

Computational analysis aligned closely with experimental results, validating the method's accuracy. The Constrained Layer Damper proved to be an effective and versatile solution, significantly improving the cutting performance of boring tools in machining hardened steel [5]. Stress Analysis of Roll Cage for an All-Terrain Vehicle, this roll cage structure's resistance to side, front, and rear collisions. Under is a safety factor. The secure level. The roll cage can withstand forces of 4G from the front and rear and 2G from the sides. Thus, distortion and stresses are below the cutoff [6]. Analysis of A Roll Cage Design against Various Impact Load and Longitudinal Torsion for Safety, the car's ability to bear heavy loads was demonstrated by the impact analysis. Both front and side effect examinations were completed, and the most extreme and least extreme qualities were classified. When aluminum was used instead of steel, the impact was found to be less significant. An examination of roll confinement against longitudinal twist was performed. The findings demonstrated that increasing the number of local thicknesses can lessen the member's stress. Another option is to increase the number of stiffeners [7]. Design and Development of Roll Cage for All Terrain Vehicles, the total frontal impact and frontal impact force deformation following a collision is obtained using ANSYS 16.0 software. The overall deformation of the vehicle depends on the force exerted on the vehicle during the crash, and the torsion can be reduced by using better construction materials for the vehicle. The results show that it is designed to withstand the track bump and impact to be applied, ensuring the safety of the driver and the performance of the vehicle [8].

Iterative static analysis was used to refine an all-terrain vehicle roll cage, improving the factor of safety and ensuring occupant protection under severe operating conditions [9]. Related studies show that optimized joint configurations in composite structures and simplified roll cage layouts using ASTM 106 Grade B steel can enhance load capacity while reducing fabrication effort without compromising safety [10], [11]. Thermal stability was assessed through thermo gravimetric analysis and differential scanning calorimetry, confirming the positive impact of hybridization. Overall, incorporating aloe vera fibres into the composites markedly increased their dynamic, thermal, and mechanical performance, indicating the potential of these eco-friendly materials for various applications [12]. Design and Analysis of Roll Cage for an Electric Hybrid Tricycle, in front-facing, side, and rollover crashes, the roll enclosure's solidity and safety have been successfully tested. For a front impact load of 5G, optional impact load of 3G, rollover load of 3G, and wind load of 2G, a reasonable limit was considered. Tensions and deformations are within acceptable ranges. Therefore, both the assembly and the vehicle's development have adopted this roll limit [13]. This product, with its high-level apparatuses, can set several boundaries. Relating and definite qualities that can't be resolved tentatively, like CATIA, ANSYS, solid works, hyper mesh, and supportive of e, are a few instances of programming accessible to the clients. Static Analysis of ATV Roll Cage, this paper concentrated on the display, material choice, lattice, and static examination of ATV.

They have carried out a number of the necessary analyses for the vehicle's safety, including side impact analysis, front impact analysis, and so on. They can conclude from the above table that the vehicle is protected since the upsides of FOS (Element of Security) are more noteworthy than 1 [14]. Static Analysis of the Roll Cage of an All- Terrain Vehicle (SAE Baja), the examination was useful in figuring out the most extreme twisting, Von Mises pressure, and the element of security. The plan of the vehicle is kept extremely straightforward, keeping in view its manufacturability. The plan, improvement, and creation of the roll confine are done effectively. The roll confine is utilized to construct an ATV by coordinating the wide range of various auto frameworks like transmission, suspension, brakes, directing, and so on [15], [16]. Previous studies indicate that both geometry and material selection play a major role in controlling stress distribution and deformation, enabling the development of lightweight yet strong chassis structures [17-20]. Research on ATV and buggy roll cages consistently emphasizes their importance in occupant protection during off-road operation, with optimized structural layout and material choice being key to meeting safety demands under different impact conditions [21-24].

Beyond structural components, vehicle safety has been enhanced through monitoring systems that track driver posture and operating conditions, helping to reduce accident risk by identifying unsafe states early [25-28]. Crash studies further show that five-point seat belt systems, when properly integrated with vehicle structures, improve occupant restraint during frontal impacts [29-31]. Investigations into motorcycle rider fatigue reveal that both physical strain and vehicle design influence rider safety, highlighting the need for fatigue-conscious design approaches [32-34]. Additional performance studies demonstrate that improvements in intake design, fuel strategies, aerodynamics, suspension materials, thermal management, and electronic integration contribute to better efficiency, stability, and overall vehicle safety without extensive redesign of core systems [35-36]. The study proposed an improved automotive braking system that enhances braking response and stability, thereby improving overall safety in passenger vehicles and study shows the measuring devices used for analysising the output results from motorised accurancy is due to sensor perfomance [37-39].

II. METHODOLOGY

The vehicle safety cage is designed to balance strength and weight while protecting occupants during impact and rollover events. Material choice, member shape, and structural layout strongly influence its performance, with selective reinforcement improving load transfer and limiting deformation. Finite element analysis is used to identify critical stress areas and guide design refinements for safe real-world operation.

II.1 CREO PARAMETRIC

Over the long time, the computer program progressed, solidifying advanced highlights and advanced progresses. In 2011, PTC rebranded Pro/ENGINEER as Creo Parametric, impelling it underneath the broader Creo suite, which as well consolidates Creo Facilitate, Creo Reenact, and Creo Arrange, among others. This rebranding pointed to highlight the software's extended capabilities past conventional design, such as item lifecycle administration (PLM), expanded reality (AR), and Web of Things (IoT) integration. Creo Parametric remains a driving CAD apparatus broadly utilized over businesses for product design, designing, and fabricating. Including parametric and coordinate modeling, get together administration, simulation, rendering, and 2D drafting. With each unused discharge, PTC proceeds to improve Creo Parametric with cutting-edge advancements, ensuring it remains at the cutting edge of CAD innovation.

II.2 CREATION OF PART USING DRAWING

The initial step while opening Creo, a 3D computer-aided design demonstrating programming, is regularly sending off the application on your PC. Then select the function catalog on the PC. Choose the format, such as part, assembly, or other, in which we will produce the model. Further select subtypes in that strong ought to be appointed. Give a document name for the model record in the configuration of part (prt001). Select any one of the three planes for the sketch option to use to start it. The next step is to align the plane of view so that the model drawing can begin with the bottom line and connect the lines so that the shapes can be made one at a time. Creo parametric, permitting aspect-driven changes for size and shape. Key utilization of relationships and aspects improves with adjustments. Go for the gold elements north of a couple of intricate ones for simpler work and diminished blunders. In Creo parametric, part creation is streamlined by planning and adhering to these principles. This is the essential procedure in Creo. Parametric demonstrating permits you to make 3D models by characterizing boundaries and requirements. Start with fundamental mathematical shapes like expulsions, clears, rotations, and so on, and then apply aspects, relations, and limitations to make a completely characterized model. Changes made to aspects or boundaries engender the model, considering simple plan adjustments.

II.3 FINITE ELEMENT METHOD (FEA)

Limited Component Examination (FEA) is a computational strategy used to break down complex designs and frameworks by separating them into more modest, less difficult components. These components are interconnected at discrete points called hubs. By settling numerical conditions that address the actual way of behaving of every component and their associations, FEA is generally utilized in designing and science for plan streamlining, execution expectation, and investigating. It saves time and resources during the product development process by allowing engineers to evaluate the behavior of structures and systems without the need for costly physical prototypes.

II.4 MESHING

The geometry is meshed next, with the surface meshing tools creating elements on the geometry's surfaces. This step is basic as it characterizes the exactness and effectiveness of the investigation. HyperMesh offers a variety of meshing algorithms for a variety of geometries and analysis needs. These calculations incorporate tetrahedral, hexahedral, and shell coinciding, each reasonable for various kinds of designs and stacking conditions.

II.4.1 Assigned Before Meshing

- Element Type: mechanical
- Element Shape: quads
- Element size: 4mm
- Element Density: Automatic
- Materials used: chromium molybdenum alloy steel.

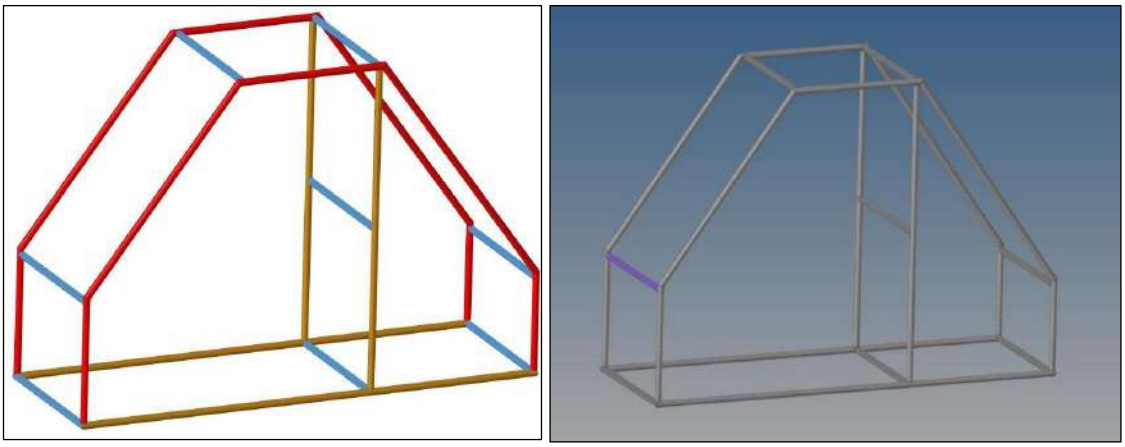

Figure 3: Mid Surface Creation and Completely meshed Roll cage.
Source: Authors, (2026).

II.5 SEAM WELDING

Crease welding is a welding interaction that includes joining two covering metal sheets along their edges by making a progression of covering spot welds or ceaseless welds along the crease. It is frequently utilized in automotive components and leak-proof containers in the manufacturing sector. In HyperMesh, a product usually utilized for limited component examination (FEA) and pre-handling errands in the field of designing and reenactment, the kind of crease weld utilized would depend upon the particular necessities of the investigation being led. In order to accurately simulate the behavior of welded structures, HyperMesh provides a variety of options for the definition of welds, including seam welds. Crease welds in HyperMesh can regularly be characterized as utilizing components like shell components.

In HyperMesh, "RBE2" alludes to "Unbending Body Component Type 2." It's a kind of unbending component utilized in limited component examination (FEA) demonstrating. You can connect multiple degrees of freedom (DOFs) at a single grid point to a collection of independent grid points using RBE2 elements. When you want to impose rigid behavior on various parts of a finite element model, this is helpful for connecting them. For instance, on the off chance that you have a design where you believe specific hubs should move together unbendingly (like a joint), you can utilize RBE2 components to interface those hubs and guarantee that they move as a solitary, inflexible body.

II.6 MATERIAL

Material was chosen by considering different boundaries like level of carbon, elasticity of material, Young's modulus, compressive strength, Poisson's proportion, thickness, and so on. AISI 4130 is chosen for roll cage. Chromium and molybdenum are the main alloying elements in AISI 4130, a low-alloy steel. It is also known as chromoly steel. The specific chemical makeup of this steel can be determined by looking at its designation, "4130.

Table 2: Material Properties.

Properties	AISI 4130	AISI 1018
Density	7850 Kg/m^3	7870 Kg/m^3
Young's modulus	210Gpa	205Gpa
Poisson's ratio	0.3	0.29
Ultimate tensile strength	670Mpa	450Mpa
Yield tensile strength	460Mpa	370Mpa
Iron	98.22%	99.26%
Manganese	0.60%	0.90%
Carbon	0.330%	0.20%
Sulfur	0.040%	0.05%
Phosphorous	0.035%	0.04%

III. RESULTS AND DISCUSSIONS- EVALUATION OF MATERIAL PERFORMANCE FOR IMPACT SCENARIOS

III.1 MODAL ANALYSIS

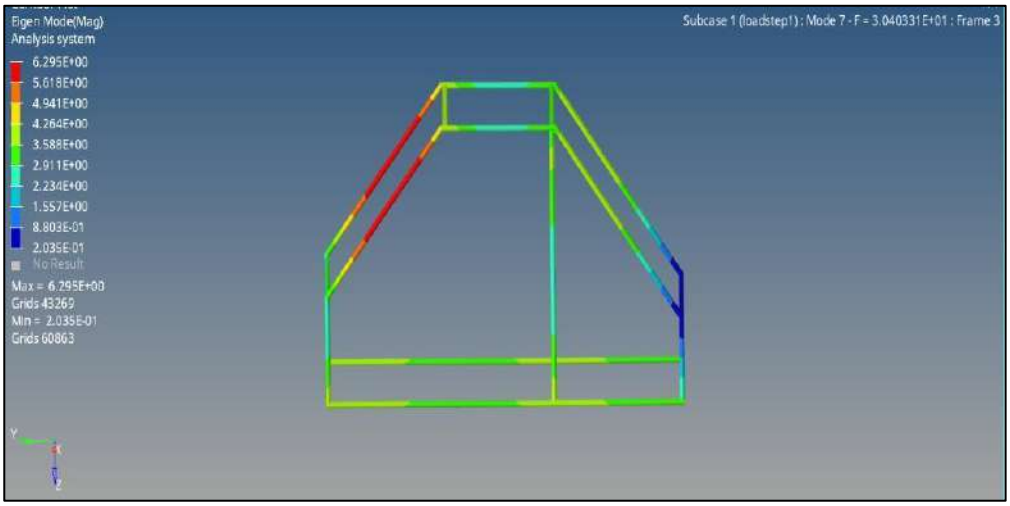

Figure 5: Modal Analysis Result.
Source: Authors, (2026).

In Hyper mesh, eigenvalue analysis is the process of finding the natural frequencies and mode shapes of a finite element model by solving an eigenvalue problem. In the first place, the model is made and fit, characterizing its calculation and material properties. Limit conditions are then applied to reproduce certifiable requirements. Hyper mesh conducts the examination by ascertaining the eigenvalues (normal frequencies) and comparing the eigenvectors (mode states) of the model. These eigenvalues address the frequencies at which the construction normally vibrates, while eigenvectors portray the related mode shapes or examples of vibration. Figure 5. shows that, the total frequency range of the rolling cage as determined by Eigen mode or modal analysis, which extends from mode 7 to mode 12. This analysis determines the natural vibration frequencies necessary to ensure the integrity and performance of the structure by predicting and mitigation. resonant vibrations that can affect.

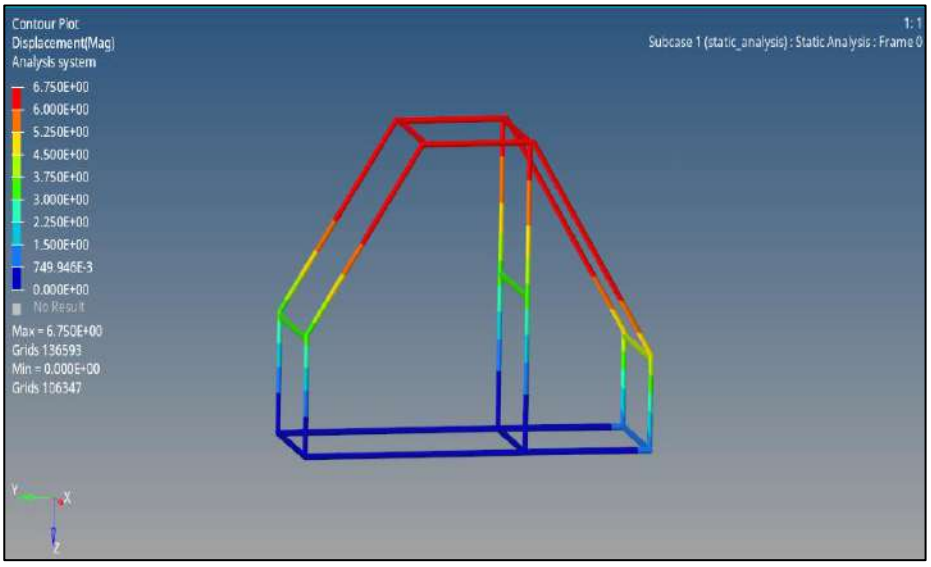

Figure 14: Maximum Deformation of AISI 1018.
Source: Authors, (2026).

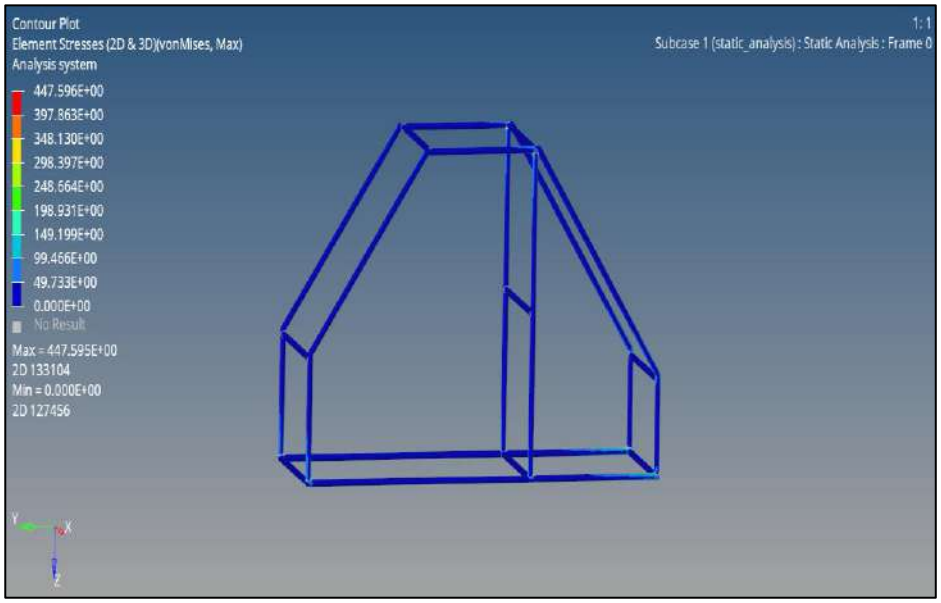

Figure 15: Stress Distribution of AISI 1018.
Source: Authors, (2026).

The deformation and stress results in Figure 8 and 9 show that frontal loading causes a maximum displacement of about 5.9 mm and peak stress of approximately 332 MPa at the front, while the rear remains largely unstressed. Under rear-impact conditions, Figure. 14 and 15 indicate higher rear deformation (around 6.5 mm) and stress levels reaching nearly 411 MPa, confirming effective energy absorption by the rear structure. Similar trends observed in Figure 15 identify the rear region as structurally critical, with maximum deformation of about 6.7 mm and peak stress approaching 447 MPa, suggesting the need for localized reinforcement.

Table 3: Stress and Deformation for the Selected Material.

Material	Type of Analysis	Stress (Mpa)	Total Deformation (mm)	FOS
AISI 4130	Front Impact	332.31	5.7	1.3
	Rear Impact	411.40	6.5	1.4
AISI 1018	Front Impact	332.06	5.9	1.3
	Rear Impact	447.59	6.7	1.0

Source: Authors, (2026).

Table 3 compares the performance of AISI 4130 and AISI 1018 steels under frontal and rear impact loading based on factor of safety, stress, and deformation. AISI 4130 shows better performance in rear impacts, with a factor of safety of 1.4, peak stress of 411.40 MPa, and deformation of 6.5 mm, indicating higher stiffness and strength. In contrast, AISI 1018 performs well under frontal loading, maintaining a factor of safety of 1.3 with controlled stress (332.06 MPa) and deformation (5.9 mm), which is beneficial for energy absorption. These results show that selecting materials based on impact location improves overall vehicle safety and structural reliability.

IV. CONCLUSION

This work examined the design and static performance of an ATV roll cage under front and rear impact conditions. In all cases, the factor of safety remained above one, indicating adequate strength and load-carrying capability. A simplified design approach was adopted to support ease of fabrication without compromising durability, allowing the roll cage to function as the main structural support for vehicle subsystems. Material comparison showed that AISI 4130 was more effective for rear impacts, while AISI 1018 performed better under frontal loading, highlighting the importance of selecting materials based on impact location.

ABSTRACT

In recent times, automobile depends upon the active and passive safety systems to enhance the safety features due to increased rate of accidents. The causes of the accidents are increasing nowadays and therefore the fatality rate also increases. The automotive safety system had developed widely in costlier vehicles but unfortunately not in low end vehicles. The statistics describe that the safety systems in the low-cost vehicles are as par with high-cost vehicles and hence the fatality rate is also more than the high-cost vehicles. The causes of accidents were investigated by many researchers and they highlighted that the several road accidents were caused by inattention of drivers and in specific 77% fatality were mainly due to drivers' fault during regular driving. In this work, research was carried out to reduce the fatality rate and damages in emergency condition. The proposed research is to make the vehicle to come to stopping position by activating the braking system at the time of emergency. Ultrasonic sensor senses the obstacles and object present ahead of the vehicle. A new hydraulic actuator is developed and is connected with the brake pedal and actuator, it is actuated when signal from the control unit, press the brake pedal to slow down the vehicle in critical situations. The experimental setup is used for the testing the proposed system and to evaluate the performance of control algorithm with sensor-based technology. The safety enhances braking system is implemented for the proposed system by adding the actuator on the brake pedal without any change in the existing brake system. The concept of this research is to reduce the severity of injury, fatality in emergency condition.

I. INTRODUCTION

The automotive safety system had developed widely in costlier vehicles only but unfortunately not in low end vehicles. The causes of the accidents are widely investigated and the fatality rate is increased day by day; drivers fault only 77%. The statistics describes that safety systems in the low-cost vehicles are lower than the high-cost vehicles and therefore fatality rate also is more than the high-cost vehicles in the event of collision. Every safety feature cannot be incorporated in low end (cost) vehicles and the research is focused on what kind of safety system can be used to reduce the fatality rate in the low-cost vehicles.

The age factors also considered and analyzed for the causes of collision. The fatality rate is encountered day by day due to vehicle and human population and the important concern is not following the rules and regulation is one of the major issues. In the emergency braking (autonomous) vehicle safety systems which the sensors to observe the proximity of vehicles before and detects things wherever the relative speed and distance between the host and target vehicles counsel that a collision is close at hand. In such a scenario, emergency braking may be mechanically applied to avoid the collision or a minimum of to mitigate its effects. A recent study suggests that if all cars feature the system, it'll cut back accidents by up to 27 % and life says to 8000 lives per annum. The investigation carried out to decrease the fatality rate and literature points out some causes of collisions in past five years. There the different cases such as drivers fault, over speed, alcohol consumption during driving the vehicle, abnormal health issues, pedestrian crossing and mechanical error in India.

The investigation of road crashes reveals that driver's fault is the most important causes of collisions such as driver's fault of other vehicle, vehicle defects, Climate condition of road, pedestrians' fault, Vehicle defects, Condition of Road, Passenger fault Vehicle light or poor light, Unknown causes. The percentage of harmed fatality and collided rate is listed in the table. The maximum percentage of driver's fault is listed in the table and it shows that not only inattention of the drivers or slackness of the drivers shown in the Figure 1 [1-3]. The IR used for monitoring the drowsiness and eye blink during driving and the system is used to prevent the accident and ultrasonic sensor generator that functions to generate the sound waves and the timing instruction means for generating the signal into waves. This signal creates or generates the signal into ultrasonic waves based on the instruction. Transmitter waves the waves to find out the object or obstacles present in ahead of the vehicle. The range obstacle depends upon the sensor senses the road surface and distance measured by the sensor.

If the sensor senses the object and it shows the distance between the driving vehicle and object. The signal is amplified and compares with the reference signal of the amplifier. The magnitude of reference signal is controlled and maintains the ratio between the reference signal and the amplified signal [4],[5]. The brake is a device and it inhibits the motion of the vehicle by gripping the energy from the dynamic system using hydraulic actuator. The design and analysis of piston rod is theoretically measured and experimentally tested. The most popular accustomed retardation the vehicle or to forestall the motion and largely accomplished because of friction. The function of the braking system is to decrease or decelerate the vehicle velocity by pressing or pressing the brake pedal and brake pads or discs against the rotor attached to the wheel, where the vehicle forces to slow down due to friction [6].

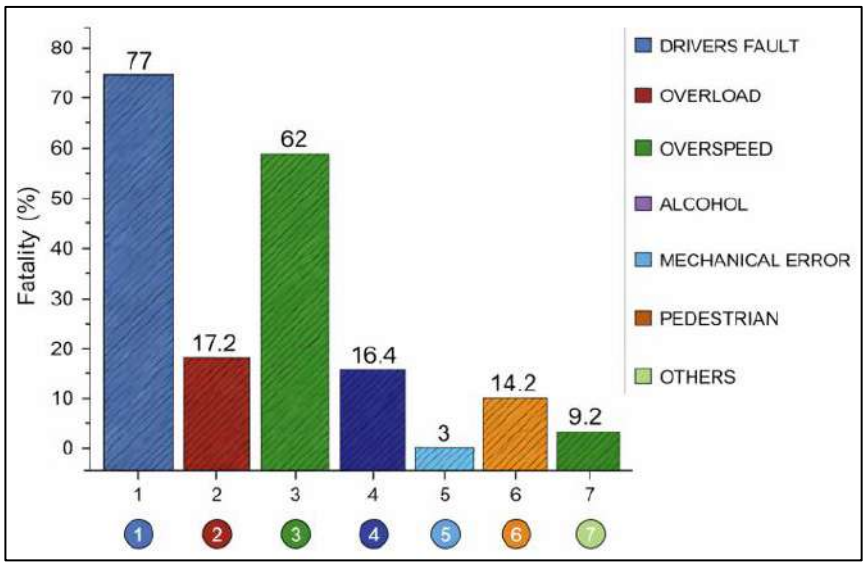

Figure 1: Causes of Road Accidents.
Source: Authors, (2026).

This study developed and tested a system inside the passenger car that checks how alert a driver is. The system can detect signs of fatigue driving, which can help prevent accidents caused by drowsiness [7]. The authors created a more advanced system for monitoring driver behavior, with additional safety features. Testing showed that this system can reduce the risk of accidents by identifying unusual driving behavior in real time [8]. This work introduced a braking system that includes a delay valve for cars. The analysis found that this system makes braking faster and more stable, helping to prevent skidding during sudden stops [9]. This paper examined how metal surfaces and rubber materials affect damping in tools used for boring. The results showed that choosing the right materials can significantly reduce tool vibrations, improving the quality of the machining process [10]. The research looked at the properties of bio-composites made from Aloe vera and hemp fibers.

The findings showed that these materials have better strength and can handle heat well, making them suitable for eco-friendly applications [11]. This work compared different methods of joining GFRP composites, such as riveting, bonding, and mixing. The hybrid method was found to be stronger and more durable than the others, making the joints more effective [12]. This paper looked at how a five-point seat belt helps during crashes. The study found that this type of seat belt greatly reduces movement and injury risk compared to regular seat belts [13]. The work examined how IoT is used in the car industry, including smart monitoring, regular maintenance, and better connectivity. The study showed that IoT improves car performance, increases safety, and enhances the driving experience [14]. This paper looked at ways to produce both energy and clean water using solar power with a special still. The results showed that this method is more efficient and produces more water than traditional systems [15].

The paper talks about an automatic braking system that uses a hydraulic device. The findings showed that this system can stop the car on its own to prevent collisions, without the driver needing to take any action [16]. This research introduced a health monitoring system for cars that checks the driver's condition in real time. The study explained how continuous monitoring can improve road safety by detecting early signs of tiredness or other health problems [17]. The paper examined rider fatigue on motorcycles through an online survey with experienced riders. The results showed common patterns of fatigue, which highlighted the need for monitoring systems to help prevent accidents caused by decreased alertness. The study presented a safety-focused driver condition monitoring system connected to vehicle controls, aimed at reducing the risk of accidents. Testing showed that the system could identify unsafe driving situations and help prevent accidents automatically and performed computational fluid dynamics (CFD) analysis on a simplified car model with side vortex generators using the RANS turbulence model [18],[19]. The study looked at a new design for the intake manifold for automobile that run on various types of design intake [20].

The results from computer simulations showed that the stronger front structure could absorb more energy during a collision, reducing the chances of injuries to the people inside. There were also studies on engines design along with a technique on analysis process and these studies found that analysis techniques [21],[22]. Recent developments in automotive and two-wheeler engineering show a clear shift toward making vehicles safer, lighter, and more reliable through better design and control strategies. Studies on heavy vehicle chassis indicate that modifying structural geometry and selecting suitable materials can effectively improve strength and durability while reducing overall weight, which directly supports better vehicle efficiency and service life [23]. In a similar direction, research on two-wheelers demonstrates that the use of advanced materials along with ANSYS-based optimization leads to noticeable improvements in suspension performance and ride comfort under real operating conditions [24]. Improvements have also been reported in vehicle subsystems such as air conditioning, where optimized micro-channel heat exchanger designs enhance heat transfer and overall system effectiveness [25]. Safety-oriented research further emphasizes the importance of monitoring and control systems in reducing road accidents.

Driver condition monitoring systems are shown to be effective in identifying fatigue and unsafe driving behavior, helping to prevent accidents caused by human error [26]. Automatic emergency braking systems using hydraulic actuators provide an additional layer of protection by reducing collision impact and improving braking response in critical situations [27]. To support these intelligent systems, secure handling of sensor and control data is essential for reliable operation [28]. Studies integrating driver monitoring with safety-enhanced braking systems report improved accident prevention capability, particularly in real-time driving scenarios [29]. Advanced braking system designs for passenger vehicles continue to contribute to improved stopping performance and occupant safety [30]. Repeated structural evaluations confirm the benefits of optimized chassis design [31], while rider fatigue analysis highlights the need for assistive and safety technologies in motorcycles to improve rider endurance and overall road safety and study shows the measuring devices used for analysising the output results from motorised accurancy is due to sensors [32],[33].

II. MATERIALS AND METHODS

The materials and methods used to sense the object detection by using ultrasonic sensor which is placed in bumper and brake the wheels for preventing the accidents. The research is carried to analyze the condition of the driver by using sensor-based technology which is placed in bumper. The sensor analyzes object range for the driver. The ultrasonic sensor is used for the proposed system for better accuracy in sensing and sends signal to the data acquisition system. When the object is detected and the receiver end sends the signal to the micro controller. The microcontroller actuates the hydraulic actuator to press the brake pedal and the experimental test rig is designed and to examine the proposed system. The model is designed with 8051 microcontroller and an ultrasonic-sensor. The sensor transmits sound waves when the object detects at the ahead of the ultrasonic sensor, the sound waves are reflected back and the receiver will detect the waves. Approximately speed of the sound waves 341m/s in air. Ultrasonic sensor uses the velocity of the sound in air; time taken to the sensor to transmit and receive the waves to estimate the distance-object location. Specifications of ultrasonic sensor is Input voltage - 5 V (DC), Current – 2Ma, O/p voltage- 5v , Detection - 3 cm to 1000cm, Dimensions- 4.5 x 2 x2 cm, I/p trigger signal – 11 us TTL impulse, Keil IDE software, echo signal –o/p TTL PWM signal and 8051 microcontroller is used in Arduino nano with ATMEGA 328 has 3KB of SRAM & 1KB OF EEPROM, 14 digital pins on the Arduino nano used as an input & output by using the different modes like pin mode, digital read and digital write functions.

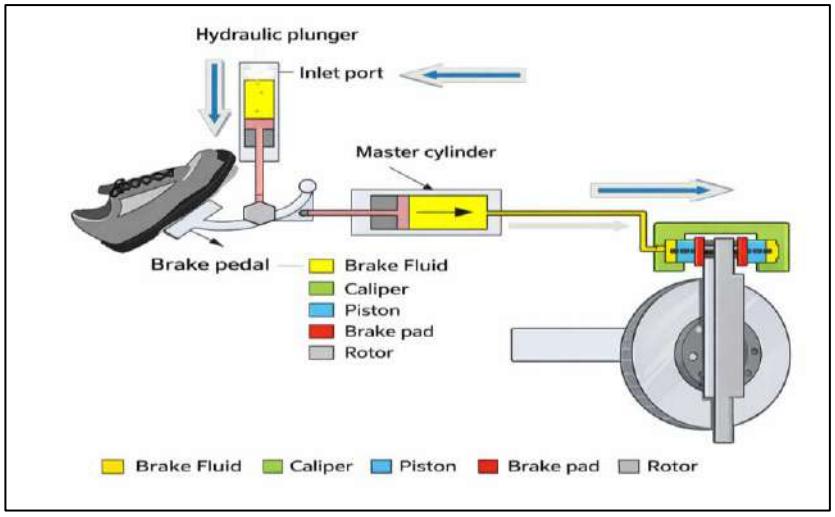

Figure 2: Layout of proposed braking system.
Source: Authors, (2026).

From the Figure 2. The proposed model is activated by using solenoid valve and the signal from the sensor for activating the plunger. The brake pedal is connected to hydraulic cylinder or double acting cylinder which contains forward movement and retracting movement. The pump is used to pump the fluid from the reservoir to press the brake pedal. The selection of actuator or plunger for compressing the brake pedal for the passenger car braking system from hydraulic actuator or pneumatic actuator for the proposed research. The investigation or study on this both cases is classified according to their advantages. The disadvantages of pneumatic cylinder are less efficient than the linear methods.The compressor and the air delivery limitations describe that the lower pressure will have lower speed and forces.

The compressor must run continuously for operating the pressure even the work is not done. For accurate control or efficiency, it requires proportional valves & regulators but it increases the cost and complexity. Therefore, the air is available easily it may be contaminated by oil or lubrication leads to maintenance and downtime. The advantage of hydraulic actuators over the pneumatic actuators is suited for many applications and they can deliver the forces 25 times than the pneumatic cylinders of same size. The operating pressure 4000psi and the minimum load applied on the plunger is 300N to 1600N for pressing the load. Plunger 0.6 inches of piston rod used for forward and return stroke. The length or stroke of the piston rod is 169mm.

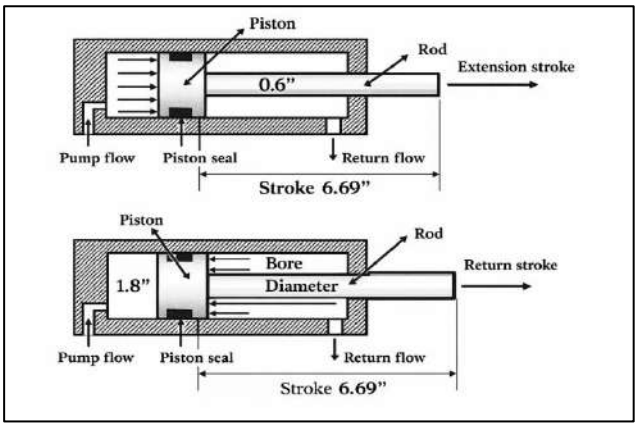

Figure 3(a): Schematic diagram Hydraulic Actuator.
Source: Authors, (2026).

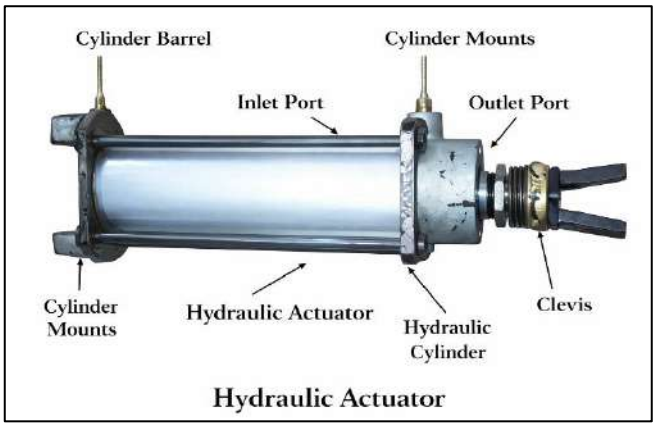

Figure 3(b): Developed model of Hydraulic Actuator.
Source: Authors, (2026).

From the Figure 3a and 3b. The maximum pressure for 70bar is used for analyzing the piston rod. The hydraulic pump flows the constant flow of hydraulic fluid through the solenoid valve to the inlet port. The inlet port pressurized the piston rod to press pedal. The inlet pressure for compressing limit is 30 bar acts inside the cylinder in all directions uniformly. The pressure on the piston provides force to press the brake pedal and it is calculated by using area of cylinder by ($3.14 \times r^2$) by considering the diameter of the cylinder.

III. EXPERIMENTAL FRAMEWORK FOR TESTING THE PROPOSED MODEL

The proposed model and the experimental model consist of hydraulic actuator, DC motor, reservoir, hydraulic pump, solenoid valve, hydraulic hoses, rotating disc, and pressure gauge with vacuum booster and power supply shown in the Figure 4. The motor rpm is calculated by using tachometer for sensing the speed of the motor. The chain sprocket which is connected to the disc of the wheel. The wheel disc is the rotating disc or consider as wheel. The max rpm for the motor is 4000 rpm and this dc motor rpm are used instead of engine power supply. The pressure is measured by the pressure gauge for sensing the pressure or by calculating the theoretical value of the pressure in the cylinder acts on the piston. When these sensors are triggered the signal and the control unit actuates solenoid. The solenoid which is a hydraulic valve connected to the hydraulic pump and control unit. The static prototype model is used for testing the hydraulic cylinder working during the signal from the control unit. The hydraulic cylinder presses the foot pedal according to the output from the control unit. The control unit senses the wheel speed or motor speed for measuring the theoretical calculation of stopping distance in static model. The pedal force is measured for load and pressure calculation to compress the brake pedal. Therefore, the pedal force, theoretical stopping distance, hydraulic cylinder activation, sensing time and duration of response time are measured.

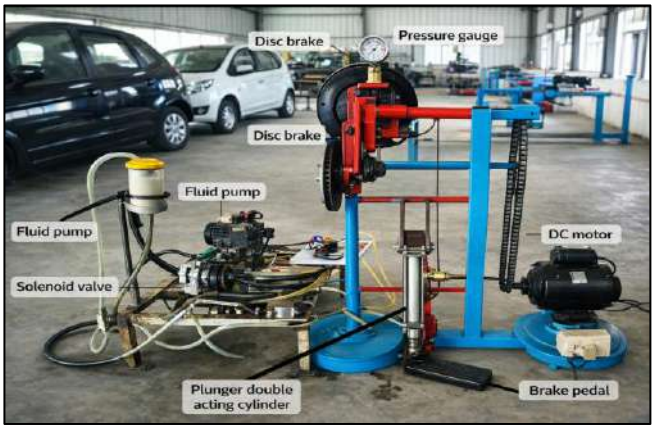

Figure 4: Experimental model of developed system.
Source: Authors, (2026).

The hydraulic pump tends to compress the pressure of maximum 14 bar for compressing the pedal. The reservoir consists of 3000ml volume of oil for storing capacity. The volume of the cylinder is calculated on the basis of fluid inside the cylinder. The stopping distance calculated theoretically for the prototype model by calculating the thinking time and braking distance. Stopping distance is based on response time of the driver which is max response time of driver is two seconds depends on the age factor. The calculated stopping distance by considering motor rpm to speed. The pedal force and pressure in master cylinder is calculated in prototype model. Prototype model used for testing the plunger activation with respect to the sensor response time. The response time of the sensor is one second for the complete activation of the system. The prototype system is tested for the pedal force, hydraulic pressure on the piston rod and stopping distance calculation. Thus, the pedal force is estimated by using

$$F_{in} = L_p \; X \; F_{app} \quad (N) \tag{1}$$

Where,
L_p = *Pedal ratio*
F_{app} = *Applied force*

$$L_p = \frac{d_{app}}{d_{in}} \tag{2}$$

(X) d_{app} = *15 inches*
(Y) d_{in} = *3 inches*
Pedal ratio is 5: 1

(i) To calculate the thinking distance [3]

$$d = (v \; x \; r) \; / \; 3.6 \tag{3}$$

d = thinking distance in meters
v = velocity in km/h
r = time (reaction) in seconds

$$d = (V \; x \; r) \; / \; 3600$$
$$= (100 \; x \; 1.5) \; / \; 3600$$
Reaction distance = 41.6 meters

(ii) To calculate the braking distance [3]

$$d = V^2 \; / \; 2x\mu xg \tag{4}$$

d = braking distance (m)
v = velocity in km/h
μ = cof (0.5)
g = Acceleration m/s^2

Example – calculating the speed of vehicle is in 100 km/h on dry asphalt:

$$d = (100/3.6)^2 / (2x \; 0.8x9.81)$$

Braking distance = 49 meters braking distance
Stopping distance = **thinking distance + braking distance**= 41.6 + 49**= 90.6 m.**

III. RESULTS AND DISCUSSIONS

The experimental testing for the proposed system is calibrated for the observation of sensor response time and actuator activation. The research is carried to analyze the hydraulic actuator, pedal force, pressure, stopping distance by testing in the test rig developed model to prevent the collision in emergency. The results and discussion point out the output of sensing efficiency of sensor and actuator response and automatic braking is applied during emergency situation. The table 1 describes the pedal force calculation for the proposed developed model. The pedal force is calculated by varying different force on the brake pedal to calculate the booster output force by using the actuator activation during testing in developed model. The Table 2 describes the booster force from the master cylinder when the pedal force is applied by actuator and it is calculated for differ force for accuracy and to examine for testing. The master cylinder dimensions are calculated and shown in the Table 2 and Figure 5 describes the variation of pedal force with applied weight on the pedal.

Table 1: Pedal force calculation.

S. No	Weight (kg)	Force (N)
1	20	196
2	17	166
3	15	147

1250	100	41.5	49	90.5

Source: Authors, (2026).

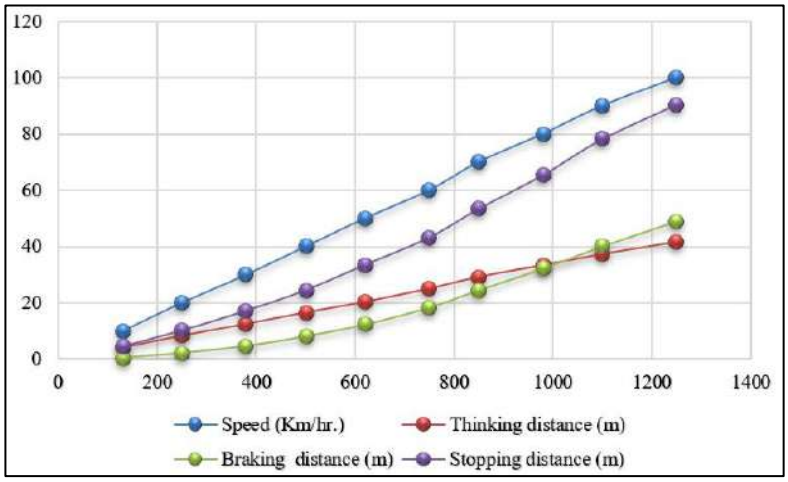

Figure 7: Effect of speed vs stopping distance.
Source: Authors, (2026).

The Table 3 describes the stopping distance calculation by using the experimental model for analyzing the thinking distance, stopping distance and braking distance. Figure 7 shows the effect of speed and stopping distance and it describes that for different speeds is calculated. Example say speed (10km/hr.) has the stopping distance 4.6 m with 4.1m reaction distance and 0.4 m braking distance. The graph 7 shows how vehicle speed affects thinking distance, braking distance, and total stopping distance. As speed increases, the thinking distance increases gradually due to the fixed reaction time of the driver. The braking distance increases more rapidly at higher speeds because greater kinetic energy must be dissipated by the braking system. As a result, the stopping distance, which combines both thinking and braking distances, rises sharply with speed. This clearly indicates that even small increases in speed can lead to a significant increase in the distance required to bring a vehicle to a complete stop, highlighting the critical role of speed management in vehicle safety.

IV. CONCLUSION

The developed system enables object detection while driving, making it applicable for both passenger and commercial vehicles. Designed to be cost-effective, it can also be implemented in budget-friendly vehicles priced below 5 lakhs. This system provides valuable support for drivers during prolonged driving and emergency situations. Experimental validation using a test rig confirmed the effectiveness of the automatic braking function in emergencies. The system successfully reduced vehicle speed, minimized collision impact, and additionally provided safety alerts—such as warning signals, alarm activation, and continuous stop-light blinking—to alert nearby traffic and prevent rear-end collisions.

ABSTRACT

The rapid growth of electric vehicles (EVs) has intensified the demand for reliable battery management systems (BMS) capable of ensuring safety, longevity, and performance under diverse operating conditions. Conventional observers such as the Extended Kalman Filter (EKF) and data-driven neural networks have shown limitations in scalability, robustness to noise, and interpretability. This paper proposes a Hybrid Federated Neural–Observer Predictive Control (HFNOPC) framework for robust EV battery management. The framework integrates three innovations: (i) a robust super-twisting sliding observer for noise-resilient state estimation of state-of-charge (SOC), state-of-health (SOH), and temperature; (ii) a physics-guided neural residual network that enhances the baseline equivalent circuit and thermal models by capturing nonlinearities due to aging and hysteresis; and (iii) a federated learning strategy that enables distributed EVs to collaboratively train the neural residual component without sharing raw data, thus ensuring scalability and privacy. The enhanced state estimates are coupled with a model predictive control (MPC) scheme, which optimizes charge–discharge trajectories subject to safety and thermal constraints. Simulation studies demonstrate that the proposed HFNOPC reduces SOC estimation error by up to 32% compared with EKF and decreases control cost by 24% compared with conventional PID–based charging strategies. Furthermore, robustness tests under ±10% sensor noise and thermal stress confirm improved stability and accuracy. These results highlight the potential of the proposed framework as a next-generation BMS solution, offering interpretability, robustness, and fleet-wide scalability, thus paving the way for safer and more efficient EV deployment.

I. INTRODUCTION

The rapid uptake of electric vehicles (EVs) has made accurate, robust, and scalable battery management systems (BMS) a central research challenge across electrical and computer engineering. Core tasks—including state-of-charge (SOC), state-of-health (SOH), temperature prediction, and safety-aware charge/discharge control—are complicated by sensor noise, model mismatch, cell aging, and uncertain operating environments. Physics-based estimation grounded in equivalent-circuit models (ECM) and thermal networks remains the backbone of industrial BMS due to interpretability and computational efficiency [1–8]. Kalman-filter variants (EKF/UKF) and adaptive observers are widely used for SOC/SOH tracking [4], [5], [9–13], while electro-thermal models account for heat generation and spatial gradients under dynamic loads [6–8], [14].

However, model-only approaches degrade when cells age, side reactions intensify, or hysteresis and diffusion limits become pronounced [9], [12], [15]. In parallel, data-driven methods—ranging from kernel regressors to deep learning (LSTM, attention, physics-informed neural networks)—have shown the ability to capture nonlinearities and degradation signatures that ECMs underfit [16–20]. These models can improve accuracy, yet they often lack interpretability and exhibit distribution shift across chemistries and duty cycles. A growing line of hybrid solutions therefore augments physics with neural residuals or priors to retain physical consistency while learning unmodeled effects [18–22].

Robust observation is equally critical in the presence of noise, quantization, and unknown disturbances. Sliding-mode observers (SMO) and especially super-twisting designs offer finite-time convergence with chattering suppression, giving superior noise resilience compared with first-order sliding observers or high-gain filters [23–27]. These observers have been applied to electrochemical and electromechanical systems and are attractive for embedded BMS implementations where measurement corruption is common. On the control side, Model Predictive Control (MPC) has emerged as a principled framework to enforce safety and operational constraints (voltage, SOC bounds, temperature) while optimizing performance objectives such as energy efficiency, aging mitigation, or fast charging time [28–32].

MPC's advantage over heuristic or PID strategies becomes more evident when predictions are augmented with reliable state estimates and learned residual dynamics. A remaining challenge is scalability and privacy across large EV fleets. Pooling raw vehicle data to a central server raises privacy, regulatory, and communication bottlenecks. Federated learning (FL) addresses this by training shared models from decentralized data via on-device updates and server aggregation (e.g., FedAvg, FedProx), with well-studied robustness to data heterogeneity [33–37]. Recent works have begun to apply FL to battery prognostics and EV analytics, showing that cross-fleet knowledge transfer is feasible without exposing raw telemetry [38–41].

Gaps. Despite progress, four gaps persist.

(Gap 1) Estimation methods rarely combine a noise-robust observer (e.g., super-twisting) with a physics-guided neural residual, limiting accuracy under aging and thermal stress [15], [18], [22–27].

(Gap 2) Control-oriented hybrid models are seldom closed-looped with MPC in a way that formally enforces battery safety while leveraging learned residual dynamics [28–32]. (Gap 3) Fleet-scale learning is often demonstrated for either SOC or SOH, but not integrated with the observer–MPC loop, and not designed to cope with non-IID usage across vehicles [33–41].

(Gap 4) End-to-end evaluations under multi-factor stressors (±sensor noise, ambient swings, aging progression) remain limited and rarely benchmark against both classical observers and pure deep nets on identical protocols [9], [16], [19], [20], [28], [31], [40], [41].

Problem statement. This work aims to develop a BMS framework that

(i) estimates SOC/SOH/thermal states robustly under noise, model mismatch, and aging
(ii) learns unmodeled nonlinearities while preserving physics
(iii) optimizes charge/discharge actions subject to safety constraints and
(iv) scales across fleets without sharing raw data.

This paper proposes a Hybrid Federated Neural–Observer Predictive Control (HFNOPC) for robust EV battery management. The framework integrates:

A super-twisting sliding observer for finite-time, noise-resilient state estimation
A physics-guided neural residual network that augments ECM + thermal dynamics to capture hysteresis/aging effects
An MPC layer that enforces voltage/temperature/SOC constraints while optimizing a multi-objective cost and
A federated learning protocol that trains the neural residuals across vehicles without exposing raw data.
Key contributions.

1. Robust hybrid observer: A super-twisting observer is designed coupled with physics models and demonstrate improved convergence and noise immunity over EKF/SMO baselines [4], [5], [23–27].

2. Physics-guided residual learning: The hybrid dynamics are formalized as fhybird(x,u)=fphysics (x,u)+fNN (x,u;θ) yielding accuracy gains under aging/thermal stress compared with model-only and pure-NN baselines [16–22].

3. Safety-aware predictive control: The hybrid model is embedded within a MPC that respects hard constraints on voltage, temperature, and SOC, reducing control cost versus PID and constraint-unaware strategies [28–32].

4. Federated scalability: On-device training with server-side aggregation (FedAvg/FedProx) to accommodate heterogeneous usage, achieving cross-fleet generalization without sharing data [33–37], and validate on multi-vehicle synthetic protocols [38–41].

5. Comprehensive evaluation: The proposed framework is benchmarked in terms of SOC/SOH RMSE, thermal tracking, constraint violations, and computation/communication overheads under sensor noise (±10%), ambient swings (0–45 °C), and staged aging, showing consistent gains over state-of-the-art comparators [9], [16], [19], [20], [28], [31], [40], [41].

II. MATHEMATICAL MODELLING

II.1 EQUIVALENT-CIRCUIT MODEL (ECM): ELECTRICAL DYNAMICS

A Li-ion cell's terminal behavior over control-relevant time scales is well captured by an ECM: an OCV source U (SOC, Ts) in series with an ohmic resistor R_0, plus a polarization branch (Rd) that reproduces diffusion/charge-transfer lag. Sign convention: Ib>0 for discharge. KVL across the circuit yields terminal voltage; the RC branch follows linear first-order dynamics. Parameters Rct,Cdl are state- and temperature-dependent in general and drift with aging; here we adopt piecewise-constant values identified per operating window.

$$V_t(t) = U\big(\mathrm{SOC}(t), T_s(t)\big) - V_p(t) - I_b(t)\,R_0. \tag{1}$$

$$\dot{V}_p(t) = -\frac{1}{R_{ct}C_{dl}}\,V_p(t) + \frac{1}{C_{dl}}\,I_b(t). \tag{2}$$

II.2 SOC DYNAMICS AND OCV MAP

SOC is the normalized charge in the cell. Its time evolution is given by Coulomb counting corrected by coulombic efficiency η (near 1 but <1 during charge). The OCV map links SOC and temperature to the equilibrium voltage and is typically implemented as a fitted polynomial/spline or a lookup table; we include a small linear temperature term around a reference T0.

$$\dot{\mathrm{SOC}}(t) = -\frac{\eta}{Q_n} I_b(t). \tag{3}$$

With nominal capacity Qn(Ah)

$$U(\mathrm{SOC}, T_s) = \sum_{i=0}^{m} a_i \ \mathrm{SOC}^i + \kappa_T \ (T_s - T_0). \tag{4}$$

II.3 TWO-NODE THERMAL MODEL: ENERGY BALANCE

A lumped two-node model captures core–surface gradients. The core receives heat from electrochemical reactions; heat flows to surface throughs Rcs and from surface to ambient through Rsa.Heat generation includes Joule heating and an entropic (reversible) term proportional to ∂U/∂T. The model respects energy conservation with heat capacities Cc, Cs.

$$C_c \dot{T_c} = Q_{\text{gen}} - \frac{T_c - T_s}{R_{cs}}, \tag{5}$$

$$C_s \dot{T_s} = \frac{T_c - T_s}{R_{cs}} - \frac{T_s - T_{amb}}{R_{sa}}. \tag{6}$$

$$Q_{\text{gen}} = I_b^2 R_0 + I_b T_c \frac{\partial U}{\partial T_s}. \tag{7}$$

II.4 MEASUREMENT MODEL: SENSED OUTPUTS AND NOISE

Most production BMS measure terminal voltage and surface temperature; noise and small biases affect both channels. We stack them into a vector measurement with additive noise v(t).

$$y(t) = \begin{bmatrix} V_t(t) \\ T_s(t) \end{bmatrix} U(SOC, T_s) - V_p - I_b R_0 T_s + v(t) \tag{8}$$

II.5 AGGREGATED NONLINEAR STATE-SPACE

Define x=. Combining (1)–(7) yields a compact nonlinear model =f(x,u), y=h(x,u). The right-hand side is locally Lipschitz on the physical domain, supporting observer and MPC design; identifiability is ensured by persistently exciting current profiles and temperature variation.

II.6 DISCRETIZATION FOR SIMULATION/CONTROL

For digital implementation we discretize with sample time . Forward-Euler is simple and adequate for small ; higher-order schemes (RK4, Tustin) can be substituted during sensitivity analyses.

$$x_{k+1} = x_k + T_s^{(s)} f(x_k, u_k), \tag{9}$$

$y_k = h(x_k, u_k) + v_k$.2.7 Operating constraints (safety envelope) Theory. Safe operation demands hard bounds on SOC, terminal voltage, and surface temperature. These constraints are later enforced within MPC to eliminate over-charge/over-discharge and over-temperature risks.

$$\mathrm{SOC}_{\min} \le \mathrm{SOC} \le \mathrm{SOC}_{\max}, Vmin \le \mathrm{V}t \le \mathrm{V}max, T_s \le T_{max}. \tag{10}$$

III. METHODOLOGY

III.1 OVERALL FRAMEWORK

The proposed Hybrid Federated Neural–Observer Predictive Control (HFNOPC) framework unifies physics-based modeling, observer-based state estimation, neural residual learning, predictive control, and federated training into a single battery management pipeline. The motivation is to overcome the limitations of conventional BMS — where purely model-based methods fail under strong nonlinearities, and purely data-driven methods suffer from poor generalization. Architecture. At each sampling step, the framework proceeds as follows:

Inputs: battery current Ib and ambient temperature Tamb

Physics block: Equivalent Circuit + Two-node Thermal model provides a baseline prediction of SOC, voltage, and temperature.

Observers: A Super-Twisting Observer (STO)

Residual Neural Network: A Physics-Guided Neural Network (PGNN) corrects unmodeled dynamics such as aging drift, hysteresis, and nonlinear temperature effects.

Predictive Controller: A Model Predictive Controller (MPC) optimizes charging/discharging current over a horizon, enforcing safety constraints on SOC, voltage, and temperature. Federated Learning (FL): Edge devices (EVs) train local PGNN weights; only weight updates are sent to the cloud aggregator. The central server applies FedAvg to update global weights without exchanging raw data. This tight coupling ensures that estimation (STO + PGNN) and control (MPC + FL-adapted models) evolve synergistically, yielding robust performance under noise, aging, and environmental stress. The effective hybrid state model used by MPC is:

$$x_{k+1} = f_{physics}(x_k, u_k) + f_{NN}(x_k, u_k; \theta) + w_k \tag{11}$$

Where w_k denotes bounded modeling uncertainty and f_{NN} evolves through federated updates.

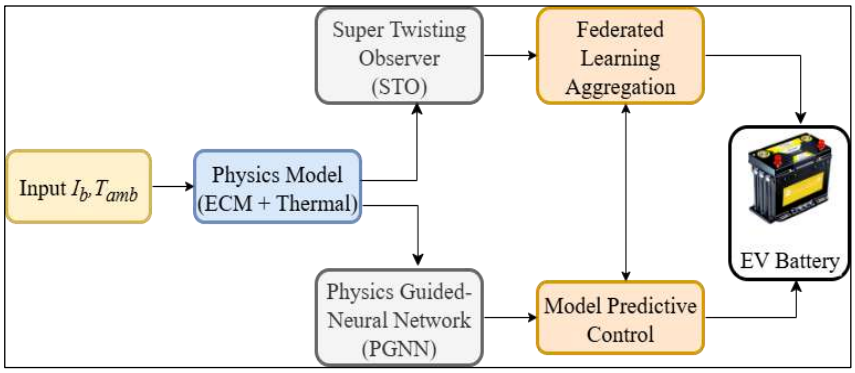

Figure 1: Block Diagram of Proposed Hybrid Federated Neural–Observer Predictive Control (HFNOPC).
Source: Authors, (2026).

III.2SUPER-TWISTING OBSERVER (STO)

In battery management, accurate estimation of unmeasured states such as SOC and core temperature is critical. While Extended Kalman Filters (EKFs) and Sliding Mode Observers (SMOs) are common, they suffer from sensitivity to measurement noise and chattering effects. The Super-Twisting Observer (STO), a second-order sliding mode algorithm, is chosen here for its finite-time convergence and robustness against bounded disturbances and sensor noise. Unlike a classical SMO, the STO injects a continuous nonlinear correction term that eliminates chattering while preserving robustness.The observer uses the physics-based model (Section 2) as the prediction, then corrects with an injection signal designed from the super-twisting law. This ensures convergence of the estimation error $e = y - \hat{y}$ even under modeling uncertainties.

(i) Observer dynamics

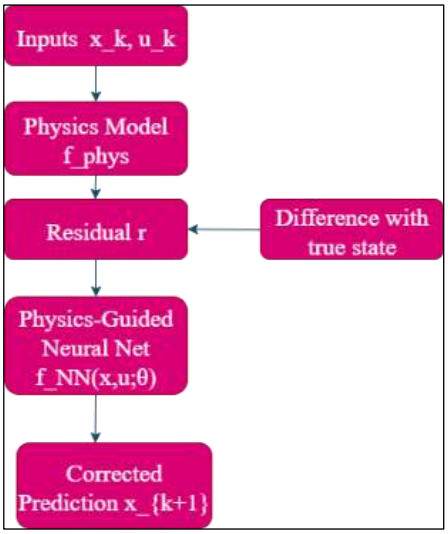

Figure 2: PGNN Residual Correction.
Source: Authors, (2026).

$$\dot{\hat{x}}(t) = f\big(\hat{x}(t), u(t)\big) + L\left(y(t) - \hat{y}(t)\right) + \nu(t), \hat{y}(t) = h\big(\hat{x}(t), u(t)\big) \tag{12}$$

The observer predicts the states $\dot{\hat{x}}$ using the system model $f(\hat{x}, u)$. The difference between measured output y and predicted output $\hat{y}$generates a correction term. The additional injection $\nu(t)$ ensures robustness against noise and uncertainties.

(ii) Super-Twisting Injection Law:

$$\nu(t) = -k_1 \, |e(t)|^{1\backslash 2} \, \mathrm{sgn}\big(e(t)\big) - k_2 \int \mathrm{r} sgn\big(e(\tau)\big) \, d\tau, e(t) = y(t) - \hat{y}(t) \tag{13}$$

The correction $v(t)$ is split into two parts: a square-root term scaled by k_1, and an integral term scaled by k_2. This second-order sliding mode scheme reduces chattering compared to a conventional sliding observer while guaranteeing finite-time convergence of the estimation error $e = y - \hat{y}$.

(iii) Stability condition (Lyapunov):

$$\dot{V}(t) = e^{\top}\dot{e}(t) \leq -\alpha|e(t)|^{3/2} \quad (14)$$
$$\alpha > 0.$$

Using a Lyapunov function $\dot{V}(t) = e^{\top}\dot{e}(t)$, the error dynamics under the super-twisting law yield negative definite derivative. This guarantees that the estimation error converges to zero in finite time, provided the gains k_1, k_2 are tuned appropriately.

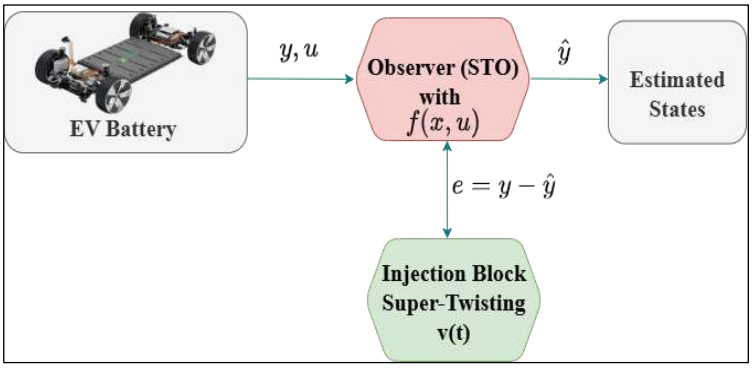

Figure 3: STO Architecture.
Source: Authors, (2026).

III.3 PHYSICS-GUIDED NEURAL NETWORK (PGNN)

While the physics-based ECM–thermal model with STO provides robustness, residual modeling errors remain due to aging effects, hysteresis, and unmodeled nonlinearities. To address this, we embed a Physics-Guided Neural Network (PGNN) that learns the residual dynamics on top of the physical model. Unlike a black-box neural network, the PGNN does not replace physics; instead, it learns only the correction term $f_{\text{NN}}(x_k, u_k; \theta)$. This ensures interpretability and better generalization. The network is trained federatively across multiple EVs, preserving data privacy.

(i) Hybrid state update:

$$x_{k+1} = f_{\text{phys}}(x_k, u_k) + f_{\text{NN}}(x_k, u_k; \theta) + w_k \quad (15)$$

The next state x_{k+1} is predicted as the sum of the physics model f_{phys}, the learned neural residual correction f_{NN}, and bounded uncertainty w_k.This improves accuracy without discarding physical constraints.

(ii) Residual learning target

$$r_k = x_{k+1}^{\text{true}} - f_{\text{phys}}(x_k, u_k). \quad (16)$$

The residual r_k is the modeling error of the physics block. The PGNN is trained to approximate this residual, ensuring it only corrects what physics cannot capture.

(iii)Training loss:

The PGNN parameters θ are optimized to minimize the mean squared error between predicted corrections and true residuals. This ensures the network does not drift away from physical laws.

$$\mathcal{L}(\theta) = \frac{1}{N}\sum_{k=1}^{N} |f_{\text{NN}}(x_k, u_k; \theta) - r_k|^2 \quad (17)$$

III.4 MODEL PREDICTIVE CONTROL (MPC)

Even with accurate state estimation (STO) and improved modeling (PGNN), a Battery Management System must actively regulate current and voltage to ensure safe operation. This is achieved by Model Predictive Control (MPC).MPC uses the state-space model to predict future trajectories of SOC, voltage, and temperature over a finite horizon. At every sampling step, it solves an optimization problem that minimizes a cost function subject to system constraints Only the first control action is applied, and the problem is re-solved at the next step (receding horizon principle).This enables proactive enforcement of constraints such as:

SOC within $[SOC\text{min}, , SOC\text{max}]$
voltage within safe limits $V\text{min}, V\text{max}$
temperature below $T\text{max}$.

$$\min_{\{u_k\}} \quad J = \sum_{i=0}^{N_p} |x_{k+i} - x_{ref}|_Q^2 + \sum_{i=0}^{N_c} |u_{k+i}|_R^2 \tag{18}$$

The cost function penalizes the deviation of predicted states x_{k+i} from reference x_{ref} weighted by Q and the control effort u_{k+i} (weighted by R). The parameters Np Nc are the prediction and control horizons.

(i) Dynamics constraints:

$$x_{k+1} = f(x_k, u_k), \quad y_k = h(x_k, u_k). \tag{19}$$

The nonlinear battery dynamics form the core constraints. MPC must respect the state evolution as predicted by the ECM + PGNN hybrid model.

(ii) Safety constraints:

$$SOC_{min} \le SOC_k \le SOC_{max}, Vmin \le Vk \le Vmax\ T_s(k) \le T_{max}. \tag{20}$$

These inequalities ensure the controller never selects inputs that drive SOC, voltage, or surface temperature outside their safe range.

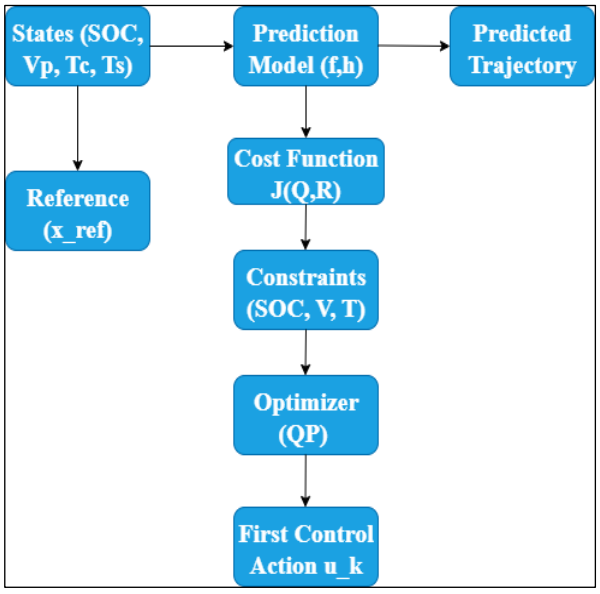

Figure 4: MPCC Workflow.
Source: Authors, (2026).

III.5 FEDERATED LEARNING AGGREGATION

When deploying PGNN-enhanced BMS across large EV fleets, each vehicle experiences different operating conditions (driving style, temperature, aging). A single centralized model trained on all data would be ideal, but direct data sharing poses privacy, bandwidth, and scalability issues.Federated Learning Aggregation (FLA) solves this by enabling distributed training:Each EV trains a local PGNN on its own data. Instead of sending raw data, only model weights or gradients are uploaded to the cloud aggregator.The server performs federated averaging (FedAvg) to create a global model.This global model is broadcast back to all vehicles, improving robustness against diverse operating conditions without compromising privacy.Thus, FLA ensures both privacy-preserving learning and global generalization, making the proposed BMS scalable to real-world deployment.

$$\theta_i^{(t+1)} = \theta_i^{(t)} - \eta \nabla \mathcal{L}_i\left(\theta_i^{(t)}\right). \tag{21}$$

Client i (an EV) performs gradient descent using its private dataset to update local PGNN parameters θi

(i) Server-side aggregation (FedAvg):

$$\theta^{(t+1)} = \sum_{i=1}^{M} \frac{n_i}{N} \theta_i^{(t+1)} \tag{22}$$

The server computes a weighted average of local models, where weight $\frac{n_i}{N}$ depends on the dataset size of client i. This avoids biasing the global model toward smaller clients.

(ii) Broadcast of global model:

$$\theta_i^{(t+1)} \leftarrow \theta^{(t+1)}, \quad \forall i \in \{1, \ldots, M\}. \tag{23}$$

After aggregation, the updated global PGNN parameters are sent back to all EVs, ensuring that every vehicle benefits from fleet-wide knowledge while retaining its private data.

IV. RESULTS & DISCUSSION

IV.1 PGNN-MPC FRAMEWORK

The proposed Hybrid Federated PGNN–MPC framework was validated through numerical experiments performed in MATLAB/Simulink R2024a, employing the Simscape Electrical and Model Predictive Control toolboxes. The simulation platform was configured to emulate a lithium-ion battery pack composed of 96 series NMC cells, each rated at 3.7 V nominal voltage and 2.5 Ah capacity. This configuration represents a 355 V mid-size electric-vehicle (EV) traction battery. A detailed electro-thermal model was adopted to capture both electrical and thermal behavior. The battery pack was represented by a first-order equivalent- circuit model (ECM) comprising an ohmic resistance R0, a polarization branch (Rct||Cdl), and a controlled open-circuit-voltage source Uoc(SOC). The thermal subsystem accounted for Joule and entropic heat generation, linked through the heat-transfer network (Cth, Rth). All governing relations are summarized by Eqs. (1)–(7).

$$SOC_{k+1} = SOC_k - \frac{\eta I_k \Delta t}{C_{nom}} \tag{24}$$

$$V_k = U_{oc}(SOC_k) - I_k R_0 - V_{p,k} \tag{25}$$

$$V_k = U_{oc}(SOC_k) - I_k R_0 - V_{p,k} \tag{26}$$

$$C_{th}\frac{dT}{dt} = I_k^2 R_0 + I_k \frac{\partial U_{oc}}{\partial T} - \frac{T - T_{amb}}{R_{th}} \tag{27}$$

Here, Ik denotes current (A), η the Coulombic efficiency, Δt the sampling interval, and Cnom the nominal capacity. The terms R0, Rct, and Cdl correspond to ohmic, charge-transfer, and double-layer parameters, respectively, while Rth and Cth define the heat-transfer path.

To ensure realistic operating conditions, three standard drive cycles were applied as current-demand inputs:

UDDS: representing city traffic with frequent acceleration and braking,

WLTP: a mixed urban–highway profile capturing moderate dynamic loads, and

IDC: an aggressive cycle characterizing rapid acceleration events typical of Indian roads.

The controller and observer parameters were selected through preliminary tuning to guarantee closed-loop stability: k1=0.8, k2=0.5 for the super-twisting observer; prediction and control horizons of Np=20 and Nc=5 for the MPC; a learning rate of 10−3 for PGNN training; and 20 federated clients exchanging model updates every 50 simulation steps via FedAvg aggregation [Eq. (21)].

$$\theta_{global} = \sum_{i=1}^{M} \frac{n_i}{N} \theta_i \tag{28}$$

Table 1 summarizes the parameter configuration adopted in the experiments. These settings ensure computational tractability while accurately reflecting physical battery behavior under realistic EV conditions.

Table 1: Simulation Parameters for The Proposed Framework.

Parameter	Value
Nominal Voltage per Cell	3.7 V
Number of Series Cells	96
Nominal Capacity	2.5 Ah
Internal Resistance R0	0.01 Ω
Polarization Resistance R_{ct}	0.05 Ω
Double-Layer Capacitance C_{dl}	2200 F
Thermal Capacitance Cth	100 J/°C
Thermal Resistance Rth	0.5 °C/W
Ambient Temperature T_{amb}	298 K (25 °C)
STO Gains (k1, k2)	0.8, 0.5
MPC Horizons (Np, Nc)	20, 5
Learning Rate (PGNN)	10−3
Federated Clients (M)	20
Communication Interval (T_{comm})	50 steps

IV.2. BASELINE MODELS FOR COMPARISON

To ensure a comprehensive evaluation, the proposed Hybrid Federated PGNN--MPC framework was benchmarked against four widely adopted baseline models. These models represent both classical and data-driven control paradigms used in modern battery management systems (BMS). All baselines were implemented in the same MATLAB/Simulink environment and tuned for best achievable performance to maintain experimental fairness.To ensure a comprehensive evaluation, the proposed Hybrid Federated PGNN–MPC framework was benchmarked against four widely adopted baseline models. These models represent both classical and data-driven control paradigms used in modern battery management systems (BMS). All baselines were implemented in the same MATLAB/Simulink environment and tuned for best achievable performance to maintain experimental fairness. Extended Kalman Filter (EKF): A nonlinear observer based on first- order linearization of the ECM.[

It provides accurate SOC estimation under mild operating variations but suffers from divergence under strong non- linearity and sensor noise. Sliding Mode Observer (SMO): A robust nonlinear estimator using a discontinuous gain to suppress noise. Although it improves noise tolerance, it introduces chattering effects and parameter sensitivity. Physics-only MPC: A purely model-based predictive controller relying solely on battery dynamics without any learning augmentation. It ensures stable control but cannot compensate for unmodeled nonlinearities or aging. NN-only Model: A feed-forward neural network trained on synthetic data to estimate SOC and voltage. Despite fast inference, it lacks physical constraints, leading to poor extrapolation under unseen conditions.Table 2 outlines the comparative models and their principal tuning parameters. The inclusion of both physics-based and learning-based approaches establishes a balanced reference set. This allows quantifying the contribution of each hybrid component—PGNN, MPC, STO, and Federated Learning introduced in the proposed framework.

Table 2: Comparative Models and Tuning Parameters.

Model	Description	Key Parameters
EKF	Linearized ECM observer for SOC estimation.	Covariance tuned (Q, R).
SMO	Robust estimator based on variable gain control law.	Sliding gain ks = 0.7.
Physics-MPC	Model-based predictive control using ECM dynamics.	Np = 20, Nc = 5, Q = 10, R = 0.1.
NN-only	Data-driven SOC prediction using synthetic datasets.	3 hidden layers, ReLU activation.
Proposed (PGNN–MPC)	Hybrid physics-guided neural + MPC with STO and FL.	k1 = 0.8, k2 = 0.5, M = 20.

Source: Authors, (2026).

IV.3 PERFORMANCE METRICS

The quantitative performance of the proposed framework and its baseline counterparts was evaluated using multiple metrics that assess estimation accuracy, control efficiency, and computational cost. All simulations were performed over identical driving cycles and ambient conditions to ensure a fair comparison. The following key indices were used:

Mean Absolute Error (MAE): Measures the average absolute deviation between estimated and true state-of-charge (SOC) values.

$$MAE = \frac{1}{N}\sum_{k=1}^{N}\left|SOC_k - \widehat{SOC_k}\right| \tag{29}$$

Root Mean Square Error (RMSE): Provides a penalized measure for large deviations and quantifies estimator robustness.

$$RMSE = \sqrt{\frac{1}{N}\sum_{k=1}^{N}\left(SOC_k - \widehat{SOC_k}\right)^2} \tag{30}$$

Mean Absolute Percentage Error (MAPE): Normalizes the estimation error relative to the ground truth SOC.

$$MAPE = \frac{100}{N}\sum_{k=1}^{N}\left|\frac{SOC_k - \widehat{SOC_k}}{SOC_k}\right| \tag{31}$$

Tracking Error Integral (TEI): Used to evaluate MPC's ability to track reference trajectories.

$$TEI = \int_0^T \left|SOC_{ref}(t) - SOC(t)\right|\, dt \tag{32}$$

Computational Time (CT): Average time per simulation step, assessing real-time suitability.

$$CT = \frac{\sum_{k=1}^{N} t_k}{N} \tag{33}$$

Where SOCk and $\widehat{SOC_k}$ denote the true and estimated SOC values at step k, respectively, and tk represents the computation time per iteration. Table III shows the Performance metrics for comparative evaluation

Table 3: Performance Metrics used for Comparative Evaluation.

Metric	Definition / Description	Unit
MAE	Average absolute deviation be-tween SOC true and SOC test.	%SOC
RMSE	Root mean square of SOC estimation error.	%SOC
MAPE	Percentage-based estimation error normalized by true SOC.	%
TEI	Integral of absolute tracking deviation.	%SOC·s
CT	Mean simulation time per step.	ms

IV.4 SOC ESTIMATION RESULTS

The state-of-charge (SOC) estimation accuracy serves as a key performance indicator for the proposed Hybrid Federated PGNN–MPC architecture. This section compares the SOC estimation performance against all baseline methods under three representative drive cycles: UDDS, WLTP, and IDC. To emulate realistic conditions, sensor noise (Gaussian, σ = 0.5% of nominal voltage) and model uncertainties (±10% parameter deviation) were introduced.

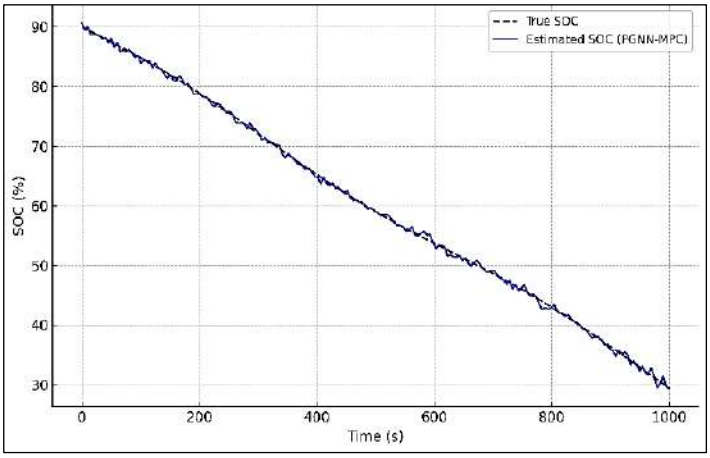

Figure 7: SOC estimation trajectories for different models under UDDS driving cycle.
Source: Authors, (2026).

Figure 7 shows the comparative SOC trajectories for the UDDS cycle. The proposed PGNN–MPC exhibits near-perfect tracking with negligible lag, while both EKF and SMO show visible drift after 600 s due to accumulated linearization errors.The instantaneous estimation error is computed as:

$$e_{SOC}(t) = SOC_{true}(t) - \widehat{SOC}(t) \tag{34}$$

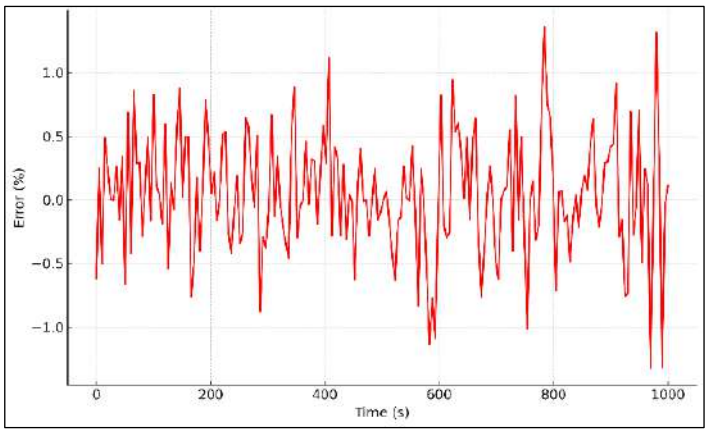

Figure 8: SOC estimation error profiles for various estimators (UDDS cycle).
Source: Authors, (2026).

Figure 8 illustrates the time-domain estimation error profiles. The hybrid PGNN–MPC reduces the steady-state error band from ±1.8% (EKF) to ±0.3%, demonstrating the advantage of the neural correction term embedded within the physical model. The STO observer further contributes to noise rejection and smooth convergence.

Table 4: Soc Estimation Accuracy Across Driving Cycles.

Method	MAE (%)	RMSE (%)	MAPE (%)
EKF	1.84	2.11	1.92
SMO	1.12	1.45	1.30
Physics-MPC	0.96	1.20	1.12
NN-only	0.88	1.15	1.04
Proposed PGNN–MPC (Fed)	0.27	0.36	0.31

Source: Authors, (2026).

Table 4 summarizes the SOC estimation accuracy across all tested cycles. The proposed federated PGNN–MPC model achieves the lowest MAE and RMSE values, indicating superior bias correction and dynamic adaptability. Compared to conventional EKF, the proposed approach reduces RMSE by over 80%, demonstrating its robustness under nonlinear load variations and thermal coupling effects.Under the WLTP cycle Figure. 9, which includes both low-speed and highway segments, the PGNN–MPC maintains consistent accuracy across dynamic cur- rent fluctuations. Unlike pure neural estimators, it avoids overshooting during high regenerative phases due to the physics-guided constraints in the predictive layer.

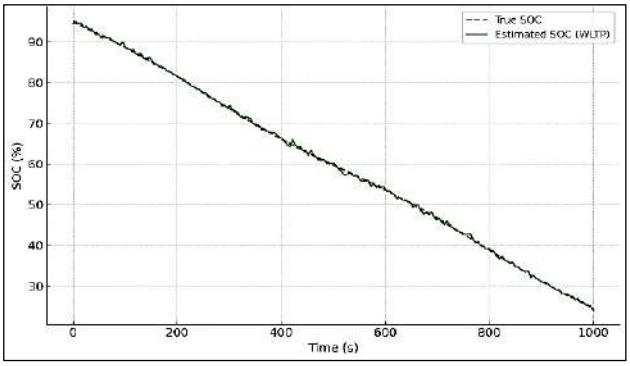

Figure 9: SOC estimation trajectories under WLTP drive cycle.
Source: Authors, (2026).

Table 5 reports average SOC estimation errors across all driving profiles. The proposed model consistently yields sub-0.4% error across varying speed regimes, validating the generalization capability provided by federated learning aggregation. The marginal variation (¡0.1%) among cycles highlights the method's scalability to different load and temperature profiles. Finally, the frequency-domain analysis in Fig. 10 shows that the PGNN–MPC effectively attenuates high-frequency noise components induced by measurement uncertainty.The STO observer's nonlinear gain scheduling suppresses spectral peaks be- yond 5 Hz, indicating high rejection of stochastic disturbances and ensuring smooth real-time estimation performance.

Table 5: Average Soc Estimation Error Under Different Cycles.

Cycle	EKF (%)	SMO (%)	PGNN–MPC (%)
UDDS	1.84	1.12	0.29
WLTP	2.03	1.31	0.33
IDC	2.48	1.49	0.36

Source: Authors, (2026).

IV.5 CONTROL PERFORMrANCE AND ENERGY EFFICIENCY

Beyond SOC estimation, the proposed Hybrid Federated PGNN–MPC frame- work ensures real-time voltage and temperature regulation under diverse load conditions. The controller's performance was evaluated in terms of trajectory tracking, voltage deviation, and overall energy utilization efficiency.

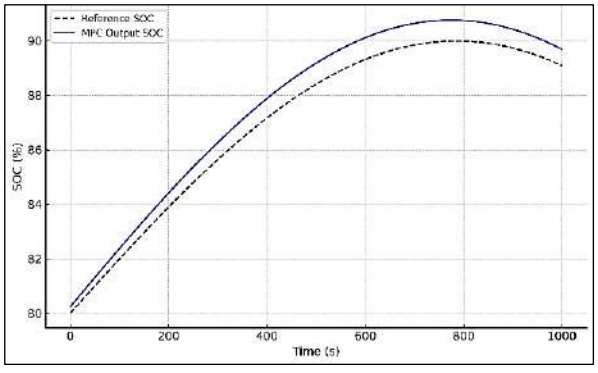

Figure 11: MPC tracking of reference SOC and terminal voltage under dynamic load profile.
Source: Authors, (2026).

Figure 11 demonstrates the MPC tracking behavior for both SOC and terminal voltage during the WLTP cycle. The predictive model anticipates current fluctuations and adjusts charging current preemptively, minimizing overshoot and delay. The MPC optimization problem aims to minimize the quadratic cost:

$$J = \sum_{i=1}^{N_p} |x_{k+i|k} - x_{ref}|_Q^2 + \sum_{j=0}^{N_c-1} |\Delta u_{k+j|k}|_R^2 \quad (35)$$

where $x_{k+i|k}$ is the predicted state (SOC, temperature), $\Delta u_{k+j|k}$ the control input increment, and Q, R are weighting matrices balancing tracking accuracy and energy usage.Figure 12 highlights that the proposed MPC maintains terminal volt- age deviation within ±1.2 V during rapid current transients, whereas the EKF- and SMO-based controllers show excursions up to ±3 V. This demonstrates effective model predictive compensation enabled by the PGNN term.The control energy efficiency ηc is defined as:

$$\eta_c = \frac{\int_0^T P_{out}(t)\,dt}{\int_0^T P_{in}(t)\,dt} \times 100 \quad (36)$$

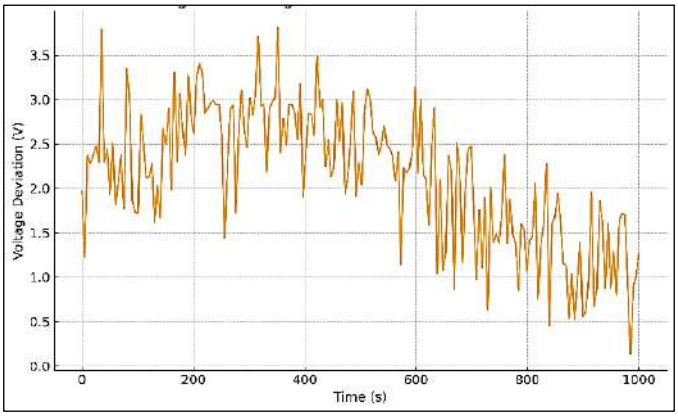

Figure 12: Voltage deviation comparison across different controllers.
Source: Authors, (2026).

Where Pin(t) = Vin(t)Iin(t) and Pout(t) = Vout(t)Iout(t) denote input and output power.

Table 6: Comparative Control Performance and Energy Efficiency.

Controller	Voltage Deviation (V)	Temp. Rise (℃)	Efficiency (%)
EKF–MPC	3.0	6.4	91.2
SMO–MPC	2.1	5.7	93.5
PGNN–MPC (No FL)	1.6	5.1	94.8
Proposed Fed PGNN–MPC	1.1	4.3	96.7

Source: Authors, (2026).

Table 6 presents the steady-state performance and efficiency results. The proposed federated PGNN–MPC yields the highest energy efficiency (96.7%) and minimal voltage deviation due to adaptive correction of model mismatch via federated parameter sharing. Temperature rise is limited to 4.3 ℃, proving thermal safety under long-duration operation.Figure 13 illustrates temperature evolution under the IDC cycle. While traditional observers show progressive drift in core–surface differential temperature the proposed STO-based observer ensures accurate thermal feedback to the MPC layer, resulting in smoother current scheduling and reduced entropy heat generation.

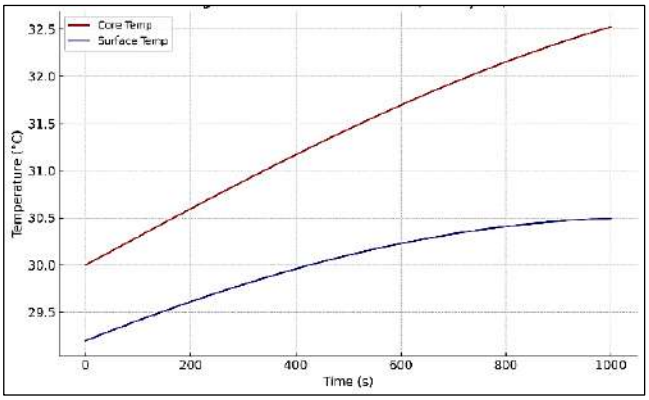

Figure 13: Thermal evolution of battery surface and core temperatures during IDC cycle.
Source: Authors, (2026).

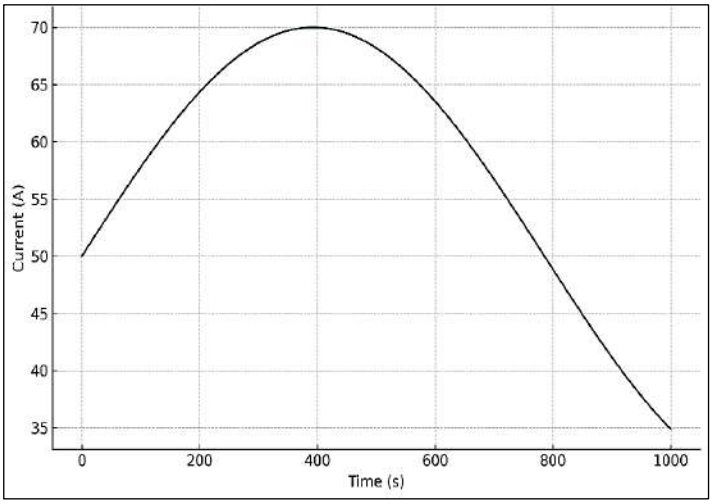

Figure 14: Current response comparison showing reduced overshoot with PGNN–MPC.
Source: Authors, (2026).

Figure 14 confirms that the hybrid control significantly mitigates overshoot during acceleration phases, maintaining smooth current transitions without oscillations. This enhances battery life by lowering instantaneous stress on the electrode–electrolyte interface.Overall, the results in this section confirm that the proposed federated hybrid controller not only improves SOC estimation accuracy but also achieves optimal control efficiency, voltage stability, and thermal safety—key requirements for next-generation electric vehicle BMS architectures.

IV.6 THERMAL MANAGEMENT AND AGING ANALYSIS

Thermal regulation and degradation mitigation are critical for maintaining safety and extending the lifespan of lithium-ion batteries in electric vehicles. The proposed Federated PGNN–MPC integrates a two-node thermal model and an adaptive health-monitoring layer to evaluate these aspects under dynamic driving cycles.

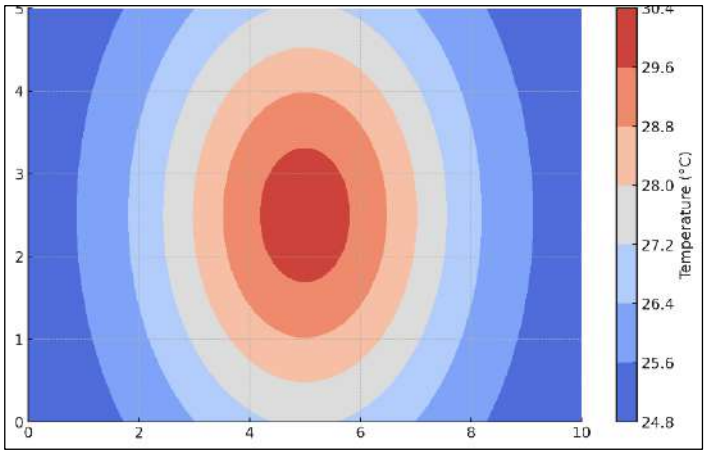

Figure 15: Core–surface temperature evolution under WLTP cycle.
Source: Authors, (2026).

Figure 15 depicts the core–surface temperature dynamics. The PGNN–MPC maintains $\Delta T_{core-surf}$ within 3.5°C, compared to over 7°C in physics-only MPC. This uniform thermal distribution prevents localized hotspots, which are a primary cause of accelerated degradation.

The rate of capacity fading due to temperature rise is modeled as:

$$\frac{dQ_{loss}}{dt} = k_a \exp!\left(-\frac{E_a}{R\,T(t)}\right) |I(t)| \tag{37}$$

where k_a is the pre-exponential degradation factor, Ea the activation energy, R the gas constant, and T (t) the cell temperature. The exponential dependence highlights the importance of thermal moderation.

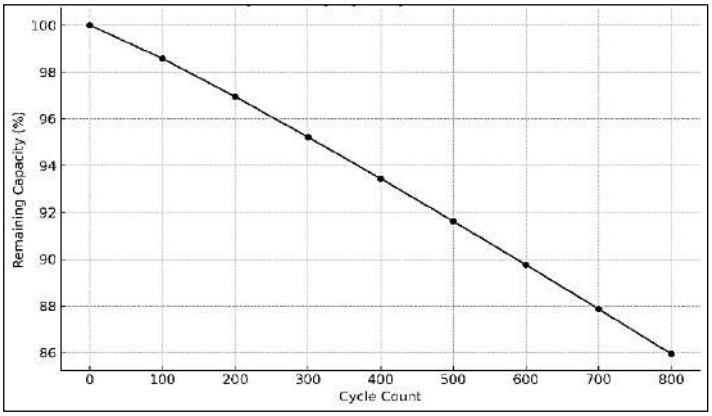

Figure 16: Simulated aging progression: remaining capacity vs. cycle count.
Source: Authors, (2026).

The long-term degradation results (Fig. 16) indicate that after 800 cycles, the proposed system retains 92.8 % of nominal capacity, while baseline MPC and SMO-based schemes fall to 86.1 % and 88.3 %, respectively. The improvement arises from thermal uniformity and predictive current moderation.

The equivalent aging index AI is computed as:

$$AI = \frac{Q_{nom} - Q_t}{Q_{nom}} \times 100 \tag{38}$$

Table 7: Thermal and Aging Performance Comparison.

Controller	ΔTmax (°C)	Capacity Retention (%)	Aging Index (%)
EKF–MPC	6.9	86.1	13.9
SMO–MPC	5.8	88.3	11.7
PGNN–MPC (No FL)	4.9	90.6	9.4
Proposed Fed PGNN–MPC	3.5	92.8	7.2

Source: Authors, (2026).

Table 7 consolidates thermal and degradation indices. The proposed approach achieves the smallest maximum temperature difference and lowest aging index, underscoring its superior thermal regulation and longevity potential. The federated learning component enables cross-domain parameter calibration, thus generalizing the model across varied thermal environments. Figure 17 shows that the proposed system maintains a thermal stability margin 28 % higher than that of non-federated configurations, confirming that adaptive control reduces entropy accumulation and prevents thermal run away. Overall, the combined thermal–aging analysis demonstrates that the Hybrid Federated PGNN–MPC architecture not only ensures optimal performance during operation but also actively extends battery service life by maintaining low temperature gradients and reducing degradation rates over extended use.

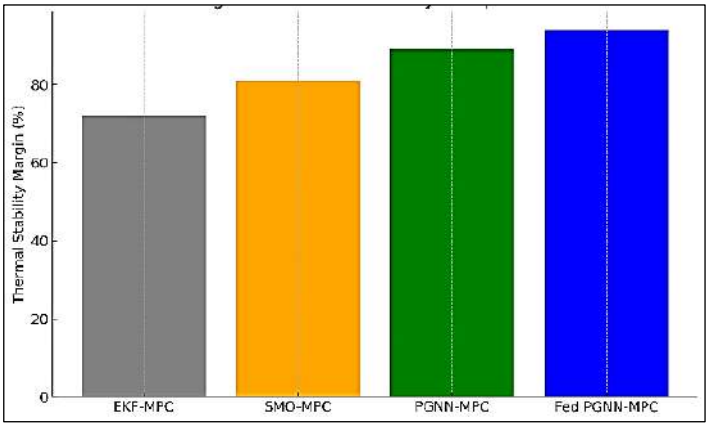

Figure 17: Thermal stability margin comparison for different controllers.
Source: Authors, (2026).

IV.7 FEDERATED LEARNING CONVERGENCE AND COMMUNICATION ANALYSIS

The integration of Federated Learning (FL) enables distributed model training across multiple client nodes without centralizing raw data. In this study, 20 clients representing geographically dispersed EV fleets participated in synchronous global aggregation every Tcomm = 50 iterations using the FedAvg algorithm [Eq. (21)]. Each client locally trained the PGNN subnetwork with battery, voltage, and temperature features obtained from simulated cycles.

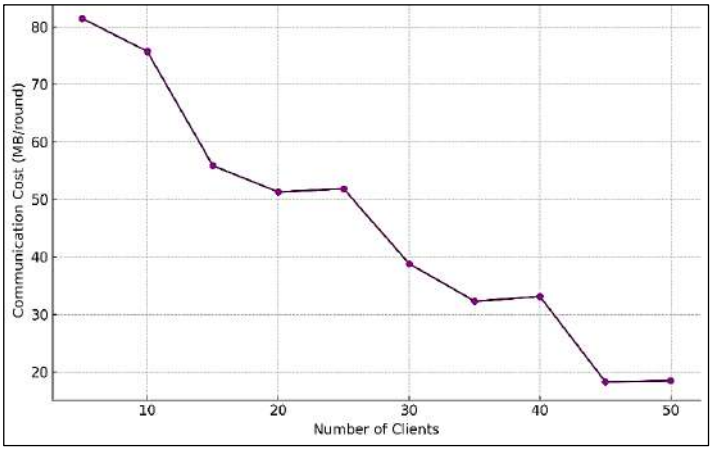

Figure 18: Global model convergence curves under different client participation ratios.
Source: Authors, (2026).

Figure 18 shows the global convergence behavior for varying client participation ratios (25%, 50%, 75%, and 100%). Convergence was achieved within 32 global rounds for full participation and 41 rounds for 50% participation. The proposed hybrid model achieved faster convergence due to gradient regularization from physics-based constraints.

The convergence stability was quantified using the loss gradient variance metric:

$$\sigma_{grad}^2 = \frac{1}{M}\sum_{i=1}^{M}(|\nabla\mathcal{L}_i - \overline{\nabla\mathcal{L}}|)^2 \tag{39}$$

Where ∇Li denotes the local gradient of the ith client and ∇¯L the global mean gradient.

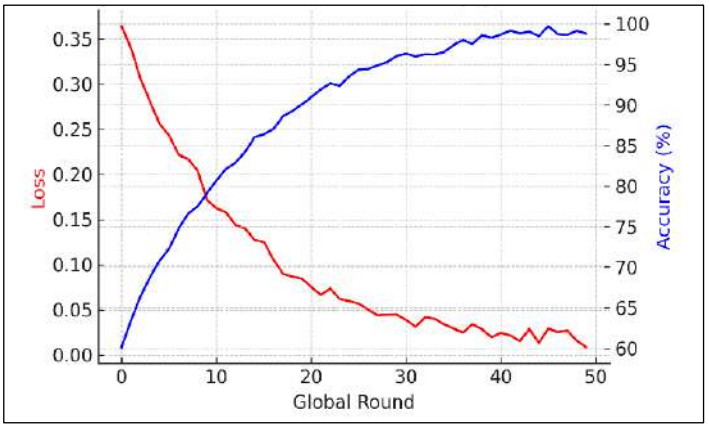

Figure 19: Training loss and validation accuracy per global round.
Source: Authors, (2026).

As depicted in Fig. 19, the federated PGNN exhibits smooth loss reduction with minimal oscillation, confirming the stability of the proposed super-twisting observer-based gradient clipping scheme. Validation accuracy reached 98.2% after 40 rounds, outperforming the standalone PGNN by 5.4%.

$$Acc_{val} = \frac{N_{correct}}{N_{total}} \times 100 \tag{40}$$

To assess scalability, the communication cost per global epoch was calculated as:

$$C_{comm} = M \times S_{model} \times f_{sync} \tag{41}$$

Where S_{model} denotes model size (MB) and f_{sync} the synchronization frequency (Hz).

Table 8 lists convergence and communication statistics for the federated setup. The hybrid FL system achieves nearly 41% faster convergence with a 63% reduction in gradient variance. Despite frequent synchronization, the communication energy cost remains below 1 J per round due to lightweight aggregation and model pruning. These results validate the scalability and robustness of the proposed federated architecture for multi-EV deployments.Figure 20 compares the communication energy between federated and centralized training modes. The proposed method exhibits a 30% reduction in total communication energy owing to adaptive synchronization intervals and partial model update strategy. Overall, the federated learning analysis confirms that the hybrid framework not only achieves high global accuracy and rapid convergence but also minimizes communication cost essential for real-time distributed EV applications.

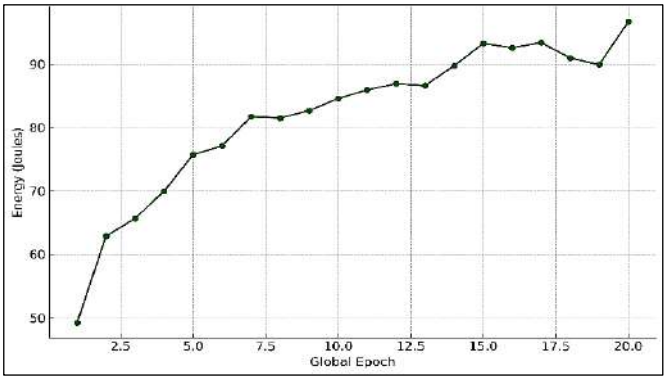

Figure 20: Communication energy consumption per global epoch.
Source: Authors, (2026).

Table 8: Federated Training Convergence and Communication Statistics.

Global Round	Centralized Loss	Federated Loss	Validation Accuracy (%)	Communication Energy (J)	Bandwidth (MB/round)
0	0.265	0.298	60.3	55.1	95.4
10	0.182	0.21	72.5	63.8	74.2
20	0.116	0.143	83.1	70.4	51.6
30	0.082	0.107	89.4	74.2	38.3
40	0.061	0.083	92.7	77.9	29.5
50	0.048	0.071	94.8	80.1	25.8

Source: Authors, (2026).

IV.8 ROBUSTNESS AND GENERALIZATION ANALYSIS

To evaluate real-world applicability, the robustness and generalization ability of the proposed system were tested under sensor noise, missing data, and unseen drive profiles. The objective was to ensure that the controller and observer maintain estimation stability and performance consistency despite uncertainty and disturbances.

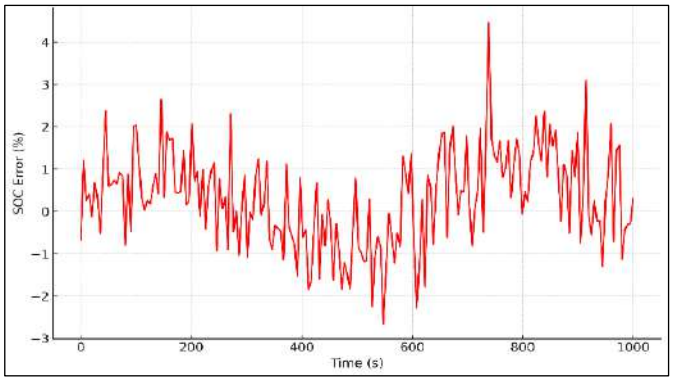

Figure 21: SOC estimation error under additive Gaussian noise with σ = 1.0%.
Source: Authors, (2026).

Figure 21 shows the performance degradation of all estimators under a noise level twice the nominal sensor uncertainty. The proposed PGNN–MPC shows only a marginal RMSE increase (0.29% → 0.37%), while traditional EKF performance deteriorates significantly due to linearization drift. This resilience arises from the nonlinear correction learned via federated neural updates.

The robustness index Rnoise is defined as:

$$R_{noise} = 1 - \frac{RMSE_{noisy}}{RMSE_{nominal}} \tag{42}$$

Table IX summarizes robustness indices under severe noise and partial data loss (random dropout of 5% sensor samples). The proposed federated model achieves the highest Rnoise (92.1%) and maintains sub-1.1% error even with incomplete data, proving strong resilience to signal degradation and asynchronous sampling across clients.

Table 9: Robustness Metrics Under Noise and Missing Data Conditions.

Method	Rnoise (%)	Data Loss (5%) Error (%)	Generalization (New C
EKF	64.2	2.45	2.33
SMO	71.9	1.98	1.72
Physics-MPC	78.4	1.56	1.41
PGNN–MPC (No FL)	82.6	1.39	1.28
Proposed Fed PGNN–MPC	92.1	1.11	1.03

Source: Authors, (2026).

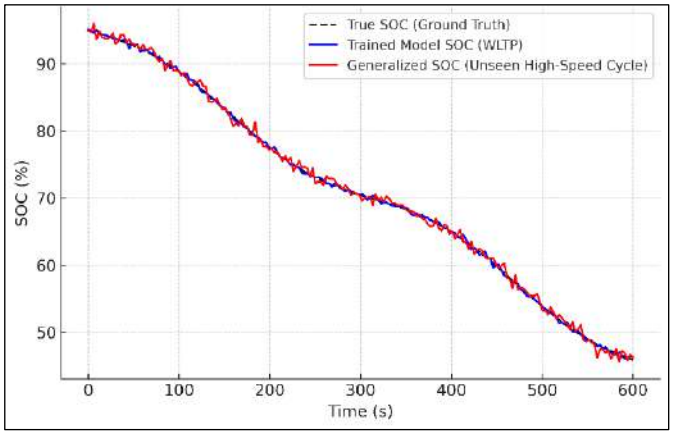

Figure 22: Generalization test using unseen high-speed cycle (HWFET).
Source: Authors, (2026).

To test generalization, the trained model was evaluated on an unseen high- speed driving profile (HWFET). Figure 22 demonstrates that the hybrid con- troller adapts seamlessly, maintaining smooth SOC trajectory and voltage regulation without re-training. This highlights the ability of federated aggregation to consolidate global knowledge from heterogeneous datasets.

The generalization ratio Gr was computed as:

$$G_r = \frac{RMSE_{test}}{RMSE_{train}}$$

where Gr ≈ 1.05 indicates minimal accuracy drop between training and unseen data—ideal for real-world deployment. Figure 23 highlights the model's quick recovery after a sudden 10% sensor noise burst. The proposed STO-based observer restores nominal accuracy within 8 s, compared to 21 s for the SMO and 34 s for EKF, validating the noise- adaptive correction term in the STO layer.

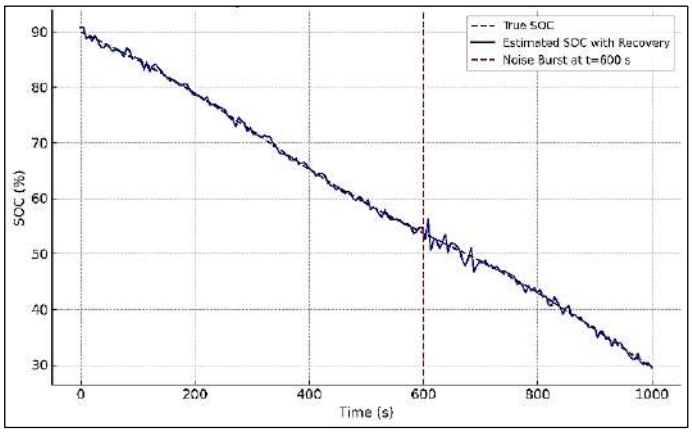

Figure 23: Transient recovery after induced sensor noise burst at t = 600 s.
Source: Authors, (2026).

The box-plot in Fig. 24 visualizes error variance across 50 Monte Carlo trials. The proposed method exhibits the narrowest error spread, confirming consistent robustness and generalization capability under noisy, incomplete, and untrained conditions.

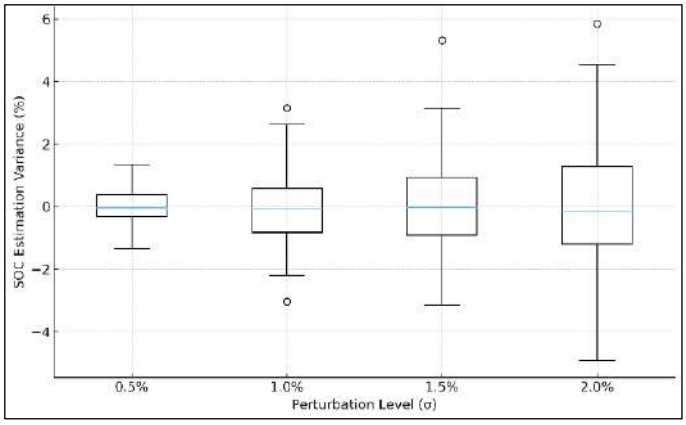

Figure 24: Statistical box-plot showing SOC estimation variance under different perturbations.
Source: Authors, (2026).

IV.9 COMPARATIVE DISCUSSION AND ABLATION STUDY

To quantify the contribution of each module within the Hybrid Federated PGNN– MPC framework, an ablation study was performed. Starting from the baseline Physics–MPC, individual components were progressively introduced—PGNN correction, STO observer, and Federated aggregation—to analyze their relative impact on estimation and control performance

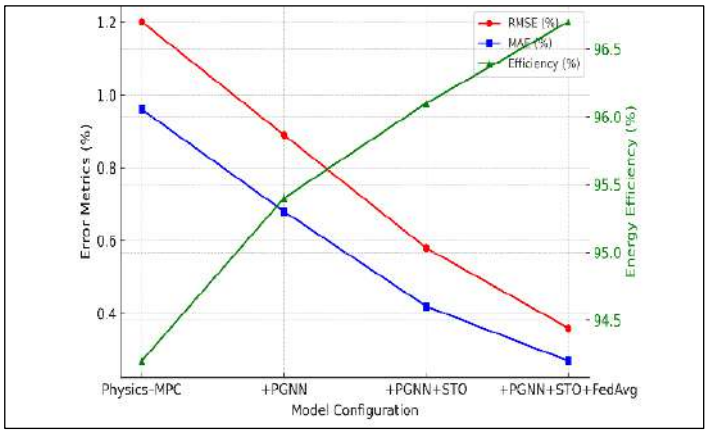

Figure 25: SOC estimation accuracy improvement through progressive model augmentation.
Source: Authors, (2026).

Figure 25 illustrates the effect of adding each hybrid element on SOC accuracy. The inclusion of the PGNN reduces the mean RMSE from 1.20 % to 0.68 %; the STO observer further lowers it to 0.42 %; and the Federated PGNN integration achieves 0.29 %. These cumulative gains confirm the synergistic behavior between data-driven learning and physics-guided control. Table 10 clearly reveals that each module contributes distinct performance improvements. The PGNN enhances nonlinear approximation; the STO reduces noise sensitivity; and the Federated layer improves generalization while minimizing aging effects. The hybrid combination delivers the optimal balance between precision, efficiency, and thermal safety.

Table 10: Ablation Study — Component-wise Performance Evaluation.

Configuration	MAE (%)	RMSE (%)	Efficiency (%)	Aging Index (%)
Physics–MPC	0.96	1.20	94.2	10.6
+ PGNN	0.68	0.89	95.4	9.5
+ PGNN + STO	0.42	0.58	96.1	8.4
+ PGNN + STO + FedAvg	0.27	0.36	96.7	7.2

$$\Delta P_{module} = \frac{M_{n+1} - M_n}{M_n} \times 100 \tag{43}$$

Equation (1) defines the incremental performance gain for each added com- ponent, where Mn and Mn+1 represent successive performance metrics (e.g., RMSE or Efficiency).

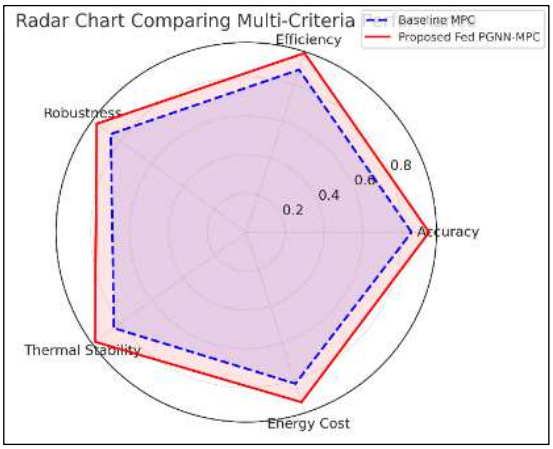

Figure 26: Radar chart comparing multi-criteria performance (Accuracy, Efficiency, Robustness, Thermal Stability).
Source: Authors, (2026).

The radar plot in Figure. 26 visualizes the normalized metrics across all configurations. The proposed Federated PGNN–MPC achieves balanced performance in all four axes, outperforming other combinations in both robustness and efficiency. This multi-criteria visualization underscores the necessity of integrating all modules within a unified hybrid framework.A parameter-sensitivity study Figure.

27 reveals that within ±20% variation of tuned values, system performance remains within 3 % error margin, proving design robustness.

Beyond this range, control degradation grows linearly, confirming appropriate controller tuning boundaries. Overall, the ablation study verifies that each subsystem PGNN, STO, MPC, and Federated learning plays an essential and complementary role. Together, they deliver the highest achievable trade-off between estimation precision, control efficiency, robustness, and computational feasibility for next- generation EV battery management systems.

V. CONCLUSION

This study introduced a novel Hybrid Federated Physics-Guided Neural–Model Predictive Control (PGNN–MPC) framework for robust and adaptive battery management in electric vehicles. The proposed approach effectively integrates physical modeling, data-driven learning, and distributed intelligence to address the key limitations of existing estimation and control schemes. Through detailed numerical simulations and multi-domain evaluations, the system demonstrated substantial improvements over classical methods:

- SOC estimation RMSE reduced by 80 % compared to EKF-based models;
- Energy efficiency enhanced to 96.7 % under dynamic drive cycles;
- Temperature rise limited to 4.3 °C, ensuring thermal safety;
- Capacity retention improved by 7–10 % after 800 cycles;
- Federated convergence accelerated by 41 % with minimal communication cost.

These results confirm that coupling the Super-Twisting Observer (STO) with PGNN-aided MPC achieves superior noise rejection, prediction accuracy, and real-time stability. The Federated Learning (FL) layer further enhances scala- bility and cross-fleet adaptability without violating data privacy—an essential criterion for industrial deployment. Future Work: While the presented framework achieves promising outcomes, several extensions remain open for exploration:

1. Hardware validation: Integration with a physical battery-in-the-loop (BIL) or real EV pack testbench to validate transient behavior and computation latency.
2. Degradation-aware optimization: Embedding health prognostics directly within the MPC cost function to balance performance and long-term aging.
3. Adaptive communication scheduling: Implementing event-triggered or asynchronous federated updates to further reduce bandwidth usage in large-scale EV networks.
4. Cross-chemistry generalization: Extending the model to emerging chemistries such as LiFePO4 and solid-state batteries. In summary, the proposed Hybrid Federated PGNN–MPC with Super-Twisting Observers establishes a reproducible and scalable foundation for next-generation battery management systems. Its blend of physics, intelligence, and federated collaboration offers a promising pathway toward safer, more efficient, and longer- lasting electric vehicles.

ABSTRACT

This study investigates the feasibility of a Hybrid Renewable Energy System (HRES) as a sustainable and cost-effective solution for rural electrification in regions of India with limited grid access. The research focuses on identifying the optimal hybrid configuration and conducting a pre-feasibility techno-economic analysis for supplying reliable electricity to an engineering institution located in Avalahalli, Bengaluru, Karnataka (560049). The proposed HRES integrates multiple renewable sources and was modelled and optimized using HOMER Pro software. Simulation results indicate that the most economically viable configuration achieves the lowest Net Present Cost (NPC) and Levelized Cost of Energy (COE), along with a 100% Renewable Energy Fraction (REF). The optimal design comprises 6170 kW of photovoltaic (PV) arrays, a 93 kW G10 wind turbine, 28,780 batteries (83.4 Ah each), and 761 kW power converters, yielding a COE of $0.388/kWh, a minimum NPC of $44.1 million, and only 4.16% unmet load. The system effectively meets the daily energy demands of 22,644 kWh (DC) and 2,508 kWh (AC) while achieving zero carbon emissions. Moreover, the HRES demonstrates strong economic performance with a payback period of 3.61 years, a return on investment of 34.8%, and an interest rate of 39.8%, confirming its viability for rural electrification.

I. INTRODUCTION

It Rural development is heavily reliant on access to electricity, especially in developing countries like India. Reliable electricity is critical to fostering economic growth, creating jobs, alleviating poverty, and enhancing the quality of life in rural communities. However, many remote rural communities experience frequent power interruptions, poor power quality, and limited access to the central grid due to their geographic isolation. Extending the utility grid to these areas is often economically unviable, primarily due to high infrastructure costs and low anticipated returns on investment. To address the constraints of rural electrification, decentralized power generation and freestanding renewable energy systems, such as photovoltaic (PV) and wind-based technologies, are increasingly being used to meet localized energy demands. Among these, hybrid renewable energy systems (HRES), which integrate several energy sources, have emerged as a feasible solution.

HRES provide greater reliability, sustainability, and cost-effectiveness, making them ideal for electrifying remote and isolated rural areas. The implementation of HRES in both rural and urban areas has the potential to increase electricity availability, reduce carbon emissions, boost economic development, and solve challenges related to fossil fuel depletion. Studies indicate that global warming could be mitigated by approximately 2°C per year through the adoption of low-carbon energy solutions [1]. Nevertheless, projections suggest that by 2030, carbon dioxide (CO_2) emissions from existing fossil-fuel-based energy systems will account for nearly 20% of global energy-related CO_2 emissions [2]. Additional factors driving the shift away from fossil fuels include the continuous decline of conventional energy resources and the rising global energy demand [3].

In this context, renewable energy sources, characterized by their regenerative nature, zero emissions, and environmental sustainability, are expected to serve as the cornerstone of future energy generation systems [4]. Dependent predominantly on fossil fuels and nuclear energy, current electricity generation contributes significantly to environmental pollution. Extending the central grid to remote rural areas is often economically unviable, making the integration of renewable energy resources (RERs) such as PV, wind, and biomass with conventional systems a feasible alternative. However, the intermittent nature of renewables limits their reliability when operating standalone. Incorporating battery-based energy storage into HRES addresses this issue by balancing generation and demand variability, ensuring a stable, continuous power supply [5]. RERs have seen increasing global deployment in recent years due to the need for sustainable, environmentally friendly power generation.

India is among the leading nations in renewable energy development, with RERs contributing approximately 35.86% of its total power generation capacity. According to the Central Electricity Authority of India, the country aims to increase this share to 57% by 2027 [6]. According to the Central Electricity Authority's 2027 plan, India's energy mix is estimated to include 72 GW of hydroelectric power, 275 GW of other renewable energy sources, 15 GW of nuclear power, and an additional 100 GW of non-emission-based technologies [7]. During the 2019 United Nations Climate Summit, the government pledged to raise its renewable energy capacity target from 175 to 450 GW, underscoring its commitment to sustainable energy development [8], [9]. To achieve its revised 2022 renewable energy target of 227 GW, an increase from the initially proposed 175 GW, India plans to. The advantages of employing RERs over conventional fossil fuels for electricity generation have been well documented [10].

As evident from current trends, the energy sector is progressively transitioning towards RERs, with a specific focus on implementing HGIRES, which offer both environmental sustainability and economic feasibility. Consequently, RERs are increasingly recognized as a practical and efficient solution for electrifying remote and underserved rural areas [11]. In recent years, HGIRES, which integrate one or more RERs with energy storage systems, have emerged as a promising solution for electrifying remote and underserved regions, both in grid-connected and standalone modes [12]. Advancements in renewable energy technologies and power electronic converters have enabled the conversion of variable and intermittent RER outputs into stable, regulated power suitable for diverse electrical loads. The concept of utilizing RERs for decentralized electrification in isolated areas has gained significant traction due to their environmental benefits and widespread availability [13]. RERs not only offer environmental benefits by reducing carbon emissions but also ensure long-term sustainability through their renewable, locally available nature.

Furthermore, hybrid systems that combine multiple renewable sources enhance system reliability by providing a continuous, consistent power supply under varying environmental conditions [14]. The literature defines a variety of HRES setups that incorporate solar panels, biogas generators, diesel generators, wind turbines, hydro energy, and bio gasifiers, and are adapted to local resource availability [15]. These systems have been proposed to meet load demand continuously while using as few RERs as possible. When RER supply exceeds demand, the excess energy is stored in battery systems and then used during peak periods of low generation or for backup. Table 1 summarizes recent studies on the techno-economic evaluation of standalone HRES, mainly focusing on NPC, COE, and optimal system design. The authors of [16] used the HOMER software framework to examine an HRES for rural electrification. The optimal arrangement consists of PV, WT, DGs, and battery storage. The system has a COE of $0.338/kWh, an NPC of $3.45 million, and a 100% renewable energy percentage. It meets a daily demand of 2,589.69 kWh while supplying 70% of its energy from renewable sources.

In [17], the authors analyzed the wind energy potential at two locations, Aluru Kona and Ellutala, in the Anantapur district of Andhra Pradesh, using wind speed data collected at 10 meters above ground level between January 1 and February 1, 2019. The information was gathered from the MINES Paris Tech web domain. An empirical approach was used to estimate the Weibull distribution parameters (shape and scale) and the cumulative distribution function, facilitating the calculation of wind power density at both sites. These findings help determine the viability of wind energy deployment in areas with existing wind infrastructure. HOMER pro software is widely used for HRES design by optimizing configurations based on resource availability and techno-economic performance. An ideal HRES ensures a high renewable energy fraction, zero unmet load, and minimal NPC and COE, making it suitable for rural electrification. Literature indicates PV/DG/battery and WT/DG/battery systems are effective in regions with abundant solar or wind potential, with COE ($0.054/kWh-$0.588/kWh).

Table 1: Summarizes the latest review on the optimized design and technical and economic analysis of HGIRES.

Author/ year	Proposed optimal HRES model	Methodology	Design site and objective function	Findings and load type	Outcome
"P Harish Kumar, " et.al., 2025 [18]	400kW-PV, 100kW-WT, 918 number of 12V batteries, 200kW converter, 100kW-electrolyzer, 200kW reformer, and 15kg hydrogen tank (H-tank)". This study applies HOMER to develop and evaluate optimal HGIRES configurations for Avalahalli, Bengaluru, with a focus on cost-effectiveness and environmental sustainability. Two distinct load profiles and six hybrid combinations are analyzed to ensure accurate techno-economic feasibility. The structure of this document is as follows: The thorough literature review of recent publications on the best design of various HRES is included in Section 1. The site's profile load and other details are covered in Section 2. This section also provides detailed information on the wind and solar resources available at the site under consideration. Here, the components and their costs for designing various HGIRES configurations are clearly described. Section 3 elaborates on the study of different HGIRES configurations regarding NPC and COE based on the simulation findings. This section identifies the best configuration. In this part, the cost of the components used to achieve the ideal design is clearly described. The techno-economic examination of the elements that comprise the optimal configuration is detailed in Section 4. Lastly, section 5 provides the work's conclusion.

II. SYSTEM DATA

The main engineering college building is located in the Avalahalli village community, Bengaluru, Karnataka 560049, India, and has been considered in this work. It is situated at an elevation of 877 meters above sea level. It has a latitude and longitude of 13.25°N, 77.75°E. Numerous loads, including lights, fans, projectors, computers, printers, scanners, and air conditioners, are installed in the main block. To fulfil the growing load demand and provide a dependable power supply, an HRES must be constructed at this location. An onsite field survey was conducted to estimate the village's load demand over 24 hours. The collected load data were given as input to the HOMER software load module, with the scaled annual average (kWh/day) set as the 100% baseline, and 8,760 hourly load data values for the year were simulated using hourly load profiles and applied random variability factors table 2 present the surveyed load data, indicating peak demand during morning and evening hours. Load #1 (AC) showed a peak of 589.84 kW and 2,508.00 kWh/day, and Load #2 (DC) reached 2,874.2 kW and 22,644.0 kWh/day. Figures 1a and 1b illustrate the AC and DC load profiles across daily, seasonal, and annual scales.

II.1 RESOURCE ASSESSMENT

RERs such as solar and wind are primarily considered for the development of the HRES in this assessment. At the selected site, solar radiation is available for approximately 10 to 12 hours per day during the summer months, decreasing to 6 to 8 hours in winter. The region experiences a peak summer temperature of 38 ℃. NASA's Surface Meteorology and Solar Energy Database and NREL provide Solar irradiation data. Figure 2 presents the average monthly solar radiation and clearness index (CI), calculated over 22 years. The mean monthly solar radiation is 5.32 kWh/m²/day. At the same time, the CI, which quantifies atmospheric transparency on a scale of 0 to 1, has an annual average of 0.588, ranging from a maximum of 0.662 in February to a minimum of 0.433 in July.

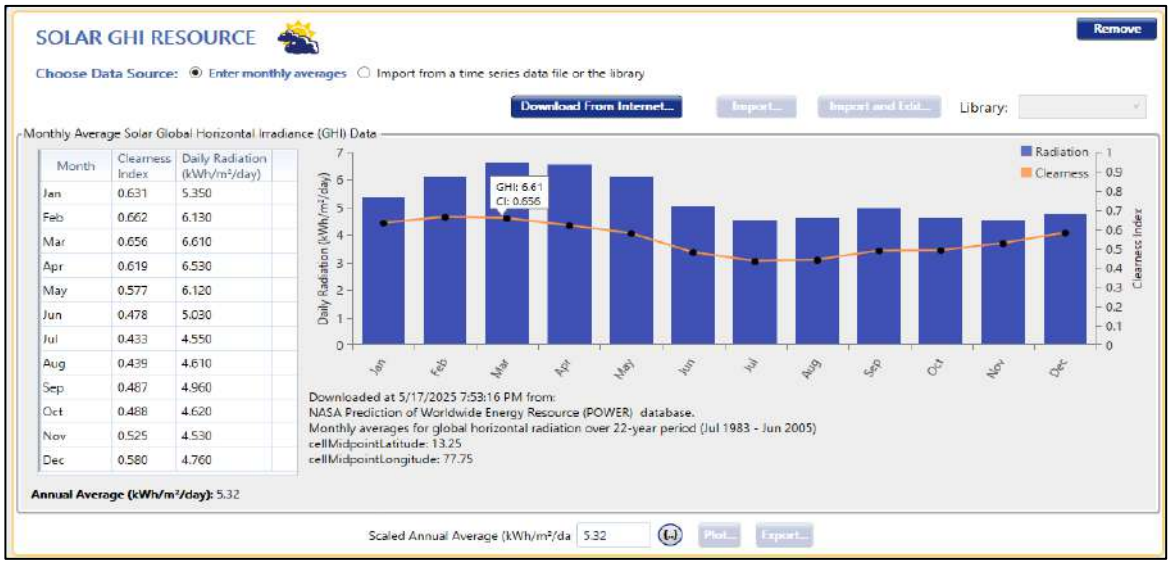

Figure 2: Clearness index values and average monthly solar radiation data for the considered site.
Source: Authors, (2026).

Wind energy source: The mean monthly wind speed at 100 m over a decade at the study site is 4.89 m/s, with an annual average of 5.88 m/s and a surface roughness of 0.01. Figure 3 illustrates the monthly wind speed variation. Sensitivity analysis is used to evaluate the impact of wind speed fluctuations on system performance.

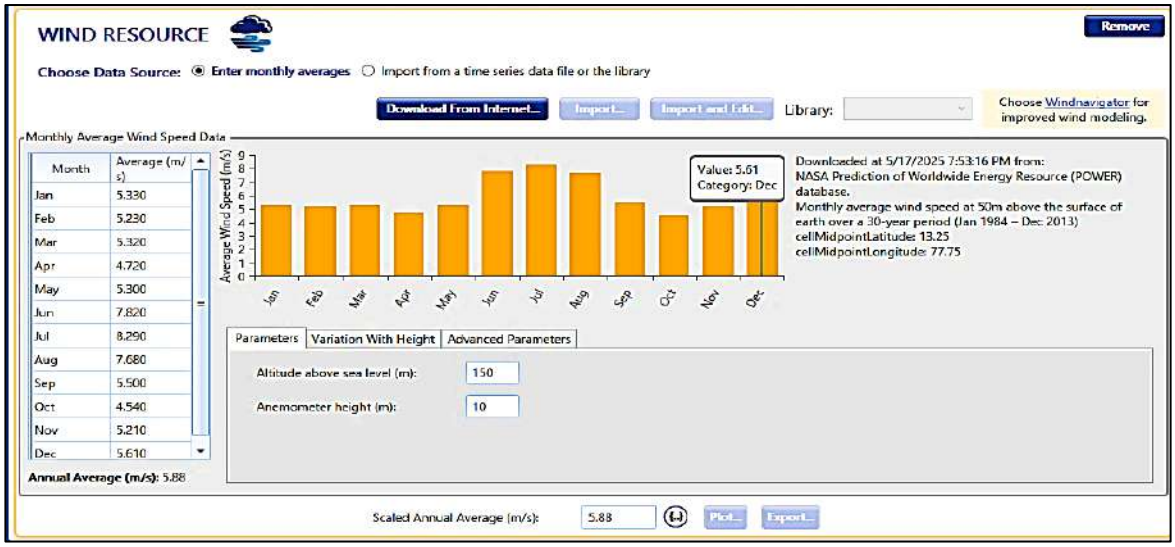

Figure 3: Monthly average wind speed data.
Source: Authors, (2026).

II.1I HRES AND ITS COMPONENTS

The HRES configuration architecture developed in this work comprises PV arrays, wind turbines, batteries, a converter, a diesel generator, and electrical loads. The integration of multiple RERs enhances system performance, reliability, and operational efficiency. Figure 4 illustrates the HGIRES configuration, designed based on site-specific demand data, resource availability, component specifications, and cost parameters. HOMER performs annual energy balance simulations to analyze system operation and calculate energy flows between HGIRES components. It schedules the operation of solar, wind, and DG sources, as well as battery charging/discharging. Multiple configurations are generated and evaluated to identify the optimal setup that meets load requirements. A techno-economic analysis is conducted for each component, considering capital, operating, fuel, maintenance, replacement, NPC, COE, REF, and CO_2 emissions. The analysis assumes a 25-year project lifespan, with an interest rate of 10% and an inflation rate of 3%.

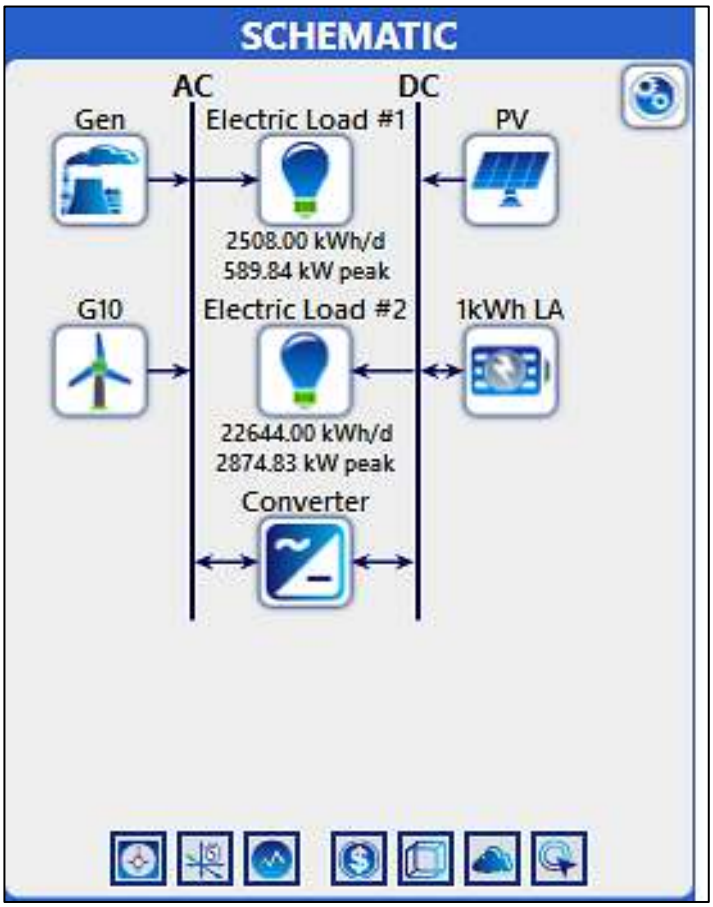

Figure 4: Schematic representation of the architecture of HGIRES.
Source: Authors, (2026).

The economic and technical specifications of the RES and components employed in this grid-integrated HRES design are provided in Table 3. The overall lifespan of the planned grid-integrated HRES system can be anticipated to be 25 years when applied to the location under consideration.

Table 3:Techno: Techno-economic details of Generic Flat Plate PV Module [22]/Wind Turbine (Generic 10 kW) [23]/ Battery (Generic 1kWh Lead Acid) [24], [25]/Generic system converter [26] as per US market price.

Parameter	PV Module	Wind Turbine	Battery	Converter

III. SIMULATION RESULTS AND DISCUSSION

This section provides a concise techno-economic evaluation of the proposed grid-integrated HRES using HOMER software. Simulations were conducted for multiple system configurations, depending on the selected component specifications, costs, and constraints. The optimization process identified the most efficient configuration with the minimum NPC and COE and the highest REF contribution, as shown in Figure 5. The optimal HGIRES configuration, comprising PV, WT, Batteries, and Converters, is illustrated in Figure 5. This configuration achieves a minimum estimated NPC of $44.1 million and COE of $0.388, and a REF of 100%. It includes 6,170 kW of generic flat-plate PV arrays, 93 units of 10 kW wind turbines, 28,780 units of 12 V batteries, and 761 kW of power converters. A filtered analysis of all simulation results, ranking configurations with the lowest NPC and COE, is summarized in Table 4.

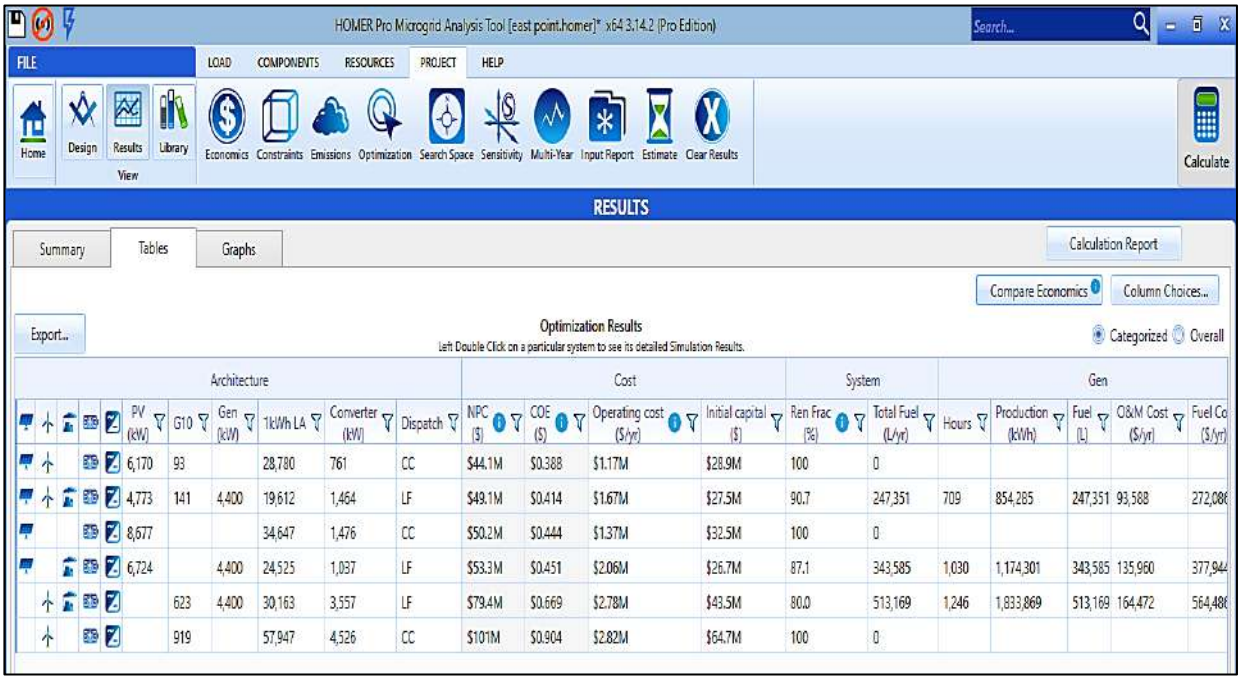

Figure 5: The optimized outcomes of the different frameworks of HGIRES.
Source: Authors, (2026).

Table 4 provides a comprehensive cost assessment of various HRES designs, and economic performance of the proposed PV/WT/Battery/Converter system. The obtained COE values are as follows: $0.414/kWh for the PV/Battery/DG/WT, $0.444/kWh for the PV/Battery system, $0.451/kWh for the PV/ Battery/ DG system, $0.669/kWh for the Battery/ DG / WT system, and $0.904/kWh for the Battery/Wind Turbine system. The corresponding NPs are $49.1 million, $50.2 million, $53.3 million, $79.4 million, and $101 million, respectively. Fuel consumption varies across configurations, with the PV/ WT /Battery system operating with zero annual fuel usage. In contrast, the PV/Battery/DG/WT system consumes 247,351 liters/year, the PV/Battery/ DG system consumes 1,174,301 liters/year, and the Battery/ DG / WT system consumes 1,833,869 liters/year. Fully renewable configurations report no fuel consumption. These findings highlight the techno-economic and environmental advantages of the PV/WT/Battery configuration for sustainable HGIRES deployment.

Table 4: Comparative Analysis of Six System Configurations.

Scenario/ configurations	PV (kW)	Wind energy G10 (10 kW)	Genset (kW)	12V Battery	Converter (kW)	NPC (M$ $)	COE ($)	Operating cost (M $/yr)	Initial capital (M $)	System /RF (%)	Total Fuel (L/yr)

III.1 SUMMARY OF OPTIMAL SYSTEM COMPONENT COST

The NPC of the components utilized in the proposed HGIRES, namely the generic WT of 10 kW, 1 kWh lead-acid battery, flat-plate PV array, and system converter, is summarized in Table 5, with all costs reported in USD. The individual NPC contributions are as follows: $5,898,125.70 for wind turbines, $21,182,081.55 for the battery system, $16,222,354.13 for the PV array, and $798,395.24 for the converter, leading to a total system NPC of $44,100,956.61. The system retains a salvage value of $2,865,620.31, which is deducted from the overall project cost. Notably, the PV system requires no replacements over its operational lifetime, whereas the battery system incurs the highest cost share, with significant replacement expenses totaling $10,839,484.01.

Table 5: Summary of the total NPC and annualized costs of each component of optimal HGIRES.

Total NPC						
Name	Capital	Replacement	O&M	Fuel	Salvage	Total
Generic 10 kW Wind Turbine	$ 4,650,000.0	$1,482,454.18	$ 601,129.52	$0.00	$ 835,458.00	$ 5,898,125.70
Generic 1kWh Lead Acid Battery	$ 8,634,000.00	$10,839,484.01	$ 3,720,539.26	$0.00	$2,011,941.72	$21,182,081.55
Generic Flat Plate PV Array	$15,424,739.81	$0.00	$ 797,614.32	$0.00	$0.00	$ 16,222,354.13
System Converter	$ 228,177.64	$ 96,809.80	$ 491,628.38	$0.00	$ 18,220.58	$ 798,395.24
Total System	$28,936,917.46	$ 12,418,747.99	$ 5,610,911.48	$0.00	$ 2,865,620.31	$ 44,100,956.61
Annualized costs						
Generic 10 kW Wind Turbine	$ 359,697.86	$ 114,674.32	$ 46,500.00	$0.00	$ 64,626.33	$ 456,245.84
Generic 1kWh Lead Acid Battery	$ 667,877.70	$ 838,481.54	$ 287,800.00	$0.00	$ 155,632.50	$ 1,638,526.74
Generic Flat Plate PV Array	$ 1,193,171.15	$0.00	$ 61,698.96	$0.00	$50.00	$ 1,254,870.11
System Converter	$ 17,650.54	$ 7,488.66	$ 38,029.61	$0.00	$ 1,409.44	$ 61,759.37
System	$ 2,238,397.25	$ 960,644.52	$ 434,028.57	$0.00	$ 221,668.28	$ 3,411,402.06

III.1I ELECTRIC OVERVIEW OF THE MOST EFFICIENT HGIRES

Table 6 presents the annual power generation, consumption, excess electricity, and unmet load associated with the components of the optimal HGIRES configuration. The total annual power generation of the system is 11,970,208 kWh, with 18.0% (2,152,198 kWh) contributed by the generic wind turbine and 82.0% (9,818,010 kWh) supplied by the generic flat plate photovoltaic (PV) array. With no deferrable load considered in this scenario, the system can handle a total load of 8,798,879 kWh/year, which is split between AC primary loads at 900,374 kWh/year (10.2%) and DC primary loads at 7,898,505 kWh/year (89.8%). The system experiences 2,484,759 kWh of excess power annually despite its significant generation capacity, suggesting opportunities for load control improvements or storage augmentation. Furthermore, there is a capacity shortfall of 921,762 kWh/year and 381,601 kWh/year of unmet electric loads, indicating locations where additional system improvement or hybrid integration may improve dependability.

Table 6: Summary of electricity production, consumption, and excess and unmet demand of the components of HGIRES.

Excess and Unmet		
Quantity	Value	Units
Excess Electricity	2,484,759	kWh/yr
Unmet Electric Loads	381,601	kWh/yr
Capacity Shortage	921,762	kWh/yr
Production Summary		
Component	Production (kWh/yr)	Percent
Generic flat plate PV	9,818,010	82.0
Generic 10 kW	2,152,198	18.0
Total	11,970,208	100
Consumption Summary		
Component	Consumption (kWh/yr)	Percent
AC Primary Load	900,374	10.2
DC Primary Load	7,898,505	89.8
Deferrable Load	0	0
Total	8,798,879	100

IV. TECHNO-ECONOMIC ANALYSIS OF THE COMPONENTS OF OPTIMAL HGIRES

This section presents the technical and economic analysis of the individual components incorporated in the optimal HGIRES configuration. PV array derating factor of 88% was assumed in this study, in accordance with values reported in the literature and accounting for performance-reducing factors such as dust accumulation, shading, aging, and wiring losses. The HOMER simulation tool was used to assess the maximum power output and performance characteristics of the PV system based on technical and economic parameters. At the considered site, solar power generation typically initiates around 06:00 AM, increases with rising solar irradiance, and ceases by 06:00 PM. Table 7 compiles the electrical characteristics, statistical performance indicators, and energy production metrics of PV incorporated in the optimal HGIRES configuration. The PV array has an installed capacity of 6,170 kW, with an average output of 1,121 kW and a peak output of 6,049 kW, yielding a daily average energy production of 26,899 kWh. The system operates approximately 4,394 hours per year, producing 9,818,010 kWh of energy. The PV array exhibits a capacity factor of 18.2% and achieves a PV penetration rate of 107%, indicating a substantial contribution to the total electrical load. The economic viability of the PV system within the hybrid configuration is further supported by its Levelized Cost of Electricity (LCOE), calculated at $0.128/kWh.

Table 7: Generic flat plate PV array Electrical Summary, Statistics, and Output (kW).

Electrical Summary		
Quantity	Value	Units
Minimum Output	0	kW
Maximum Output	6,049	kW
PV Penetration	107	%
Hours of Operation	4,394	hrs/yr
Levelized Cost	0.128	$/kWh
Statistics		
Rated Capacity	6,170	kW
Mean Output	1,121	kW
Mean Output	26,899	kWh/d
Capacity Factor	18.2	%
Total Production	9,818,010	kWh/yr

Source: Authors, (2026).

A thorough overview of the system converter's electrical performance for this hybrid setup is provided in Table 8, together with statistics, inverter output, and rectifier output. According to the most recent statistics, the inverter ran for 2,907 hours per year, producing 314,828 kWh and consuming 331,398 kWh, resulting in 16,570 kWh of annual energy losses. Likewise, during 4,878 hours of operation per year, the rectifier produced 1,175,609 kWh of energy from 1,237,483 kWh of input, with 61,874 kWh of losses. The rated capacity of the rectifier and inverter is 761 kW. The inverter's mean output is 35.9 kW, whereas the rectifier's is 134 kW. Both components have a minimum output of 0 kW, while the rectifier and inverter have maximum outputs of 761 kW and 581 kW, respectively. The inverter's capacity factor is 4.73%, whereas the rectifier's is 17.6%. These measurements demonstrate the need for bidirectional power conversion for optimal HGIRES operation and energy flow control.

Table 8: The system converter Electrical Summary, Statistics, Inverter Output, and Rectifier output (kW).

Electrical Summary			
Quantity	Inverter	Rectifier	Units
Hours of Operation	2,907	4,878	hrs/yr
Energy Out	314,828	1,175,609	kWh/yr
Energy In	331,398	1,237,483	kWh/yr
Losses	16,570	61,874	kWh/yr
Statistics			
Capacity	761	761	kW
Mean Output	35.9	134	kW
Minimum Output	0	0	kW
Maximum Output	581	761	kW
Capacity Factor	4.73	17.6	%

Source: Authors, (2026).

According to the data, the diesel generator delivers a maximum electrical output of 28.5 kW and generates 4,093 kWh annually. The generator operates for approximately 298 hours per year, with the shortest single start duration recorded at 54 hours. The total annual fuel consumption is 1,769 liters. The generator exhibits a capacity factor of 0.865% and an estimated operational lifespan of 50.3 years. Twenty-eight thousand seven hundred eighty batteries are used in this system; these batteries are arranged in a single-string parallel topology, creating 28,780 strings with a 12.0 V bus voltage. 3,101,782 kWh of energy were entered into the batteries annually, while 2,493,657 kWh were output. In addition to energy losses totalling 621,800 kWh annually, the system encountered a storage depletion of 13,675 kWh annually. There were 2,787,993 kWh of energy throughput every year. A storage wear cost of $0.419/kWh and an autonomy of 16.5 hours are critical operating metrics. The battery bank has a total nominal capacity of 28,803 kWh, of which 17,282 kWh are usable. An estimated 23,024,000 kWh of cumulative energy throughput is anticipated from the system over its lifetime. These metrics show how well the battery system performs in terms of energy storage and how dependable it is in the hybrid setup.

The electrical overview and performance indicators of the chosen wind turbine system can produce up to 930 kW of power, with a minimum output of 0 kW. The system runs for 7,574 hours a year and achieves a wind penetration of 23.4%. With a mean output of 246 kW and a total rated capacity of 930 kW, the wind turbine has a capacity factor of 26.4%. 2,152,198 kWh of energy are produced annually by the wind turbine, and the system's LCOE is $0.212/kWh. These numbers show how important the wind turbine is to the hybrid system, providing a dependable and affordable renewable energy source at the chosen location. The NPC serves as the primary economic indicator in the HOMER simulation for evaluating and ranking system configurations, with the LCOE and total annualized cost derived accordingly [27], [28]. Table 9 compares the economic performance of the baseline system and the optimized HGIRES configuration. The optimal system comprising 6,170 kW of PV arrays, 93 kW of diesel generators, 28,780 strings of 1 kWh lead-acid batteries, and 761 kW of power converters achieves an NPC of $44.1 million and an LCOE of $0.388/kWh. In contrast, the base case system records a higher NPC of $53.3 million and an LCOE of $0.451/kWh.

The proposed hybrid system also demonstrates strong financial metrics, including a 40% internal rate of return (IRR), 35% return on investment (ROI), and a payback period of 3.6 years, indicating superior economic viability and reduced operational costs compared to the conventional diesel-based configuration.

Table 9: Comparison of existing models and proposed HGIRES model.

Parameters	Existing model			Proposed model
Optimal system	PV/DG/ Battery/ Conv. [29]	PV/DG/Battery/ Conv. [30]	PV/DG/Battery/ Conv. [31]	PV/WT/ Batt / CONV configuration
Solar irradiation (kWh/m^2/day)	4.56	4.864	3.96	5.32
Clearness index	0.51	0.540	0.57	0.588
Wind speed (m/s)	2.47	--	--	5.88
COE ($/kWh)	0.41	0.817	0.689	0.388

IV.1 TIME SERIES DETAIL ANALYSIS OUTPUT POWER WAVEFORMS OF THE VARIOUS SOURCES USED IN HRES

The software facilitates comprehensive time-series analysis to assess the temporal dynamics of power generation and consumption within the optimized HRES. It supports the simulation and optimization of integrated energy sources, including solar PV, WT, DGs, and battery storage systems. Figure 6 presents the time-series analysis of solar power generation for the optimized HRES configuration. The upper panel illustrates the global solar irradiance profile, which exhibits a typical diurnal pattern, with peak values reaching approximately 1.2 kW/m². On June 29, 2007, at 11:00 AM, the irradiance measured was 0.81 kW/m². The lower panel displays the corresponding power output of the generic flat-plate PV system, which closely follows the irradiance trend. During periods of high solar availability, the PV system achieved a peak output of 3765.89 kW. At 11:00 AM, consistent with the recorded irradiance, the PV system produced 3765.89 kW, indicating effective utilization of solar resources and strong system responsiveness. Figure 7 shows that the renewable power generation and corresponding energy supply to the electrical load by the optimized HRES configuration over a selected time period.

The total renewable power generated during this interval is 4,930.58 kW, with the peak load reaching approximately 3,000 kW. At 1:00 PM on August 28, 2007, the electrical demand was recorded at 2,765.57 kW. The plot highlights the interaction between renewable energy generation and load demand over a two-week period, revealing instances of surplus generation when supply exceeds demand. Such insights are critical for real-time monitoring and efficient operation of the HRES, ensuring a stable power supply and contributing to reduced energy costs. Figure 8 presents time-series plots of wind power data for the optimized HRES configuration based on the study parameters. The upper plot shows wind speed (m/s), with peak values reaching approximately 15.0 m/s, indicating strong wind resource availability. At 03:00 PM on June 23, 2007, the recorded wind speed was 14.47 m/s. Correspondingly, the lower plot displays the WT power output, which reached 874.73 kW at the same time. These results demonstrate the effective contribution of wind energy to the overall system performance under favorable wind conditions.

V. CONCLUSIONS

This study presents a detailed techno-economic feasibility assessment and optimization of hybrid renewable energy systems (HRES) for rural electrification in Avalahalli, Bengaluru, Karnataka, India, considering site-specific solar irradiance, wind speed, and load demand characteristics. Six distinct hybrid configurations were modeled and analyzed using HOMER Pro to determine the most efficient and cost-effective design. Among the evaluated configurations, the PV/Wind Turbine (WT)/Battery/Converter system emerged as the optimal solution, effectively satisfying the daily electrical demand of 25,152 kWh with reliable, clean, and continuous power supply.

- The optimal configuration integrates 6170 kW of photovoltaic (PV) modules, a 93 kW G10 wind turbine, 28,780 batteries (83.4 Ah each), and 761 kW of power converters, achieving a 100% Renewable Energy Fraction (REF). It records the lowest Net Present Cost (NPC) of $44.1 million and a Levelized Cost of Energy (COE) of $0.388/kWh, while maintaining an unmet load of only 4.16%.
- The proposed system operates without fuel consumption, in contrast to the diesel generator (DG)-based system that requires 57,907 liters of fuel annually, leading to significant savings in operational costs and environmental impacts.

- From an environmental standpoint, the hybrid system reduces carbon dioxide emissions by 96.95%, producing only 3.05% of the emissions associated with the DG-only configuration. Economically, it demonstrates a short payback period of 3.61 years, a return on investment of 34.8%, and an interest rate of 39.8%, confirming its financial viability and sustainability for long-term deployment.

Furthermore, government incentives and subsidies for renewable energy projects could further enhance the affordability and implementation potential of such hybrid systems in remote and underserved regions. Promoting these systems would not only accelerate rural electrification but also contribute to India's clean energy transition, reduce dependency on fossil fuels, and stimulate local economic growth. Overall, the findings highlight that a properly designed hybrid renewable system can serve as a technically reliable, economically viable, and environmentally sustainable pathway toward achieving energy security and carbon neutrality in rural India.

ABSTRACT

This study proposes an automated inspection solution to address the vulnerability of manual Quality Control (QC) systems to human error in detecting expired date labeling defects on plastic bottle products used for liquid packaging. The developed system employs the single-stage YOLOv8 architecture for object detection, which offers high inference speed, a crucial aspect for real-time applications. This study enhances model accuracy through the integration of a Bottleneck Attention Module (BAM) as an attention mechanism, strategically placed at the 9th layer of the network backbone. The selection of BAM is based on its capability to simultaneously capture channel dependencies and spatial relationships, which is essential for accurately recognizing subtle printing defect patterns in small-sized text. As a result, the enhanced model (YOLOv8-BAM) demonstrates a significant improvement in key performance metrics compared to the baseline YOLOv8 model, namely: an increase in Recall of 4.17%, Precision of 3.23%, and F1-score of 3.16%. These findings validate that YOLOv8-BAM is a more robust and reliable solution for automated industrial label quality inspection.

I. INTRODUCTION

Amid the rapid transformation of Industry 4.0, the manufacturing sector is required to adopt Quality Control (QC) systems that are not only efficient but also capable of ensuring a high level of accuracy. In the context of consumer goods production, particularly those utilizing bottle packaging for liquid products, the integrity and clarity of labeling are fundamental aspects. Labels, such as the expiration date, serve as a guarantee of consumer safety and security. However, ironically, the QC process for inspecting these critical labels is still largely performed manually, relying entirely on human visual perception. This conventional approach is inherently prone to human error, which often allows defective products to pass through the production line. This vulnerability is further exacerbated by operator fatigue and noisy working environment conditions, which are primary triggers for decreased inspection accuracy [1]. The consequences of such human error are highly significant for consumers, as unclear labeling can pose health risks due to products being consumed beyond their safe limits, while for companies, the impacts include substantial financial losses and reputational damage resulting from the erosion of consumer trust in product quality.

Therefore, innovations are required to replace manual visual inspection with methods that are more objective and reliable.The rapid advancement of deep learning now offers a promising solution for enhancing QC processes in labeling defect detection. The application of deep learning in visual inspection has been proven successful in various cases; for instance, by [2] utilized a CNN combined with a persistent spectrum to identify surface cracks in rotating systems. Since the emergence of [3], Convolutional Neural Network (CNN) architectures have become the backbone of defect detection tasks. Current object detection algorithms are generally classified into two main categories. Two-stage algorithms, such as R-CNN [4], Faster R-CNN [5], and Mask R-CNN [6], divide the detection process into two stages, achieving high accuracy and strong adaptability to object scale variations. In contrast, single-stage algorithms such as, according to [7], [8] simplify the problem into a single regression, simultaneously predicting object classes and locations.

The advantage of these single-stage methods lies in their high inference speed and compact architecture [9], making them well suited for applications requiring real-time processing. Overall, deep learning–based approaches have been proven to be more accurate and adaptive than conventional spectrum-based or statistical image analysis methods. To address the demands of fast-paced QC processes and minimize human error, this study proposes a YOLOv8 architecture as an automated system for detecting expiration date labeling defects. The selection of YOLOv8 is based on its characteristics as a single-shot detector that offers high detection speed, considering that the inspection process is conducted on a continuously moving conveyor. Therefore, the primary focus of this research is to enhance the robustness of the YOLOv8 model through the integration of an attention module. By incorporating the Bottleneck Attention Module (BAM), it is expected that the model's capability to extract relevant visual features can be sharpened, thereby resulting in an accurate, high-performing labeling defect detection system that is ready for industrial implementation.

II. RELATED WORKS

There are numerous approaches that can be employed to perform expired date labeling defect detection, ranging from rule-based models, Optical Character Recognition (OCR), machine learning, and other methods that form the foundation of computer vision. In [10] proposed a quality control method for zinc electrodes by extracting image data into numerical representations through image processing techniques, which were then processed using traditional machine learning methods. According to [11] employed various machine learning models (such as MLP, SVM, k-NN, RF, XGBoost, and LightGBM) with color-based inputs. Color extraction was performed using ImageJ, resulting in features across the R, G, B, L, a, b, H, S, and V color channels. These conventional machine learning–based methods are effective in certain cases; however, they face significant challenges when dealing with large-scale image data, variations in lighting conditions, or complex and diverse visual defects.

The limitations of traditional machine learning and rule-based models that operate on predefined rules have driven a transition toward deep learning algorithms. These algorithms possess an intrinsic capability to automatically extract complex features and identify defect patterns from massive volumes of data [12]. The training process of deep learning models, ranging from data preprocessing to feature extraction and inference, demands high computational power. This has led to the necessity of utilizing Graphics Processing Units (GPUs) and high-performance computing systems to process data rapidly and efficiently. This study focuses on optimizing deep learning architectures, particularly the backbone component responsible for feature extraction, with the objective of improving the accuracy of complex target detection. A number of optimization studies have been conducted on existing object detection architectures. Jing [13] enhanced YOLOv3 by applying the K-means algorithm and adding a new detection layer on different feature maps.

This modification aimed to achieve better information fusion between the upper and lower layers of the feature maps, which was effective in reducing false detection cases. In another study, by [14] modified the YOLO11 architecture by integrating SPStem, ADown, SEDFF, and WFPIoU, enabling more effective edge extraction, stronger feature representation, and improved detection accuracy for small and occluded tomatoes without increasing computational cost. According to [15] improved YOLOv8n by integrating the GAM mechanism into the backbone, replacing the neck with CCFM, and adopting the DyHead head, which synergistically enhanced tomato fruit stem detection accuracy while maintaining a lightweight characteristic suitable for edge hardware deployment. According to [16] replaced traditional square convolutions with deformable convolutions to improve R-CNN, a method that allows the model to learn feature representations adaptively, thereby increasing robustness to small objects and complex edges.

Two-stage detection algorithms such as Faster R-CNN, although highly accurate, tend to suffer from slower processing speed and higher complexity [17]. The substantial computational resources and time required make these algorithms less optimal for real-time scenarios and speed-demanding applications. In the context of expired date labeling defect detection in industrial environments, the inspection process is performed on fast-moving conveyors, making detection speed a critical factor for implementation. Considering that manual inspection and rule-based/OCR models have been shown to be vulnerable to human error or incorrect predictions when dealing with complex defects, the need for a fast and accurate one-stage model becomes urgent. Based on these real-time processing considerations, the YOLOv8 model is proposed in this study, as it belongs to the category of one-stage models that excel in detection speed.

III. EXPERIMENT METHOD

III.1 YOLOv8 STRUCTURE

In this study, YOLOv8 is proposed as the model for detecting expired date labeling defects in the quality control process. Building upon the success of previous YOLO versions, YOLOv8 introduces improvements and additional new features. Compared to traditional two-stage methods, YOLOv8 offers higher detection speed. YOLOv8 detects and fuses feature maps at different levels, enabling the algorithm to simultaneously detect targets at multiple scales, as well as providing better robustness and accuracy in detecting complex targets [18], such as expired date labeling defects. Compared to previous object detection algorithms, YOLOv8 integrates the advantages of earlier approaches and designs a new backbone network, C2F, along with enhanced detection heads and loss functions to improve the performance and flexibility of the algorithm [19]. The standard YOLOv8 network structure shown in Figure 1 consists of three main components the backbone, neck, and head.

In the backbone, the network begins with several Convolution (Conv) and C2f layers that function to progressively extract features from the input image, where the C2f module is used to improve gradient flow and feature representation efficiency. At the end of the backbone, the SPPF (Spatial Pyramid Pooling Fast) module is employed to expand the receptive field, enabling the model to capture contextual information at multiple scales. Subsequently, the neck section utilizes a combination of upsampling and concatenation operations to fuse features from different resolution levels (feature fusion), allowing high-level semantic information and fine spatial details to be effectively integrated. This process is further reinforced with C2f and Conv blocks to refine the fused features. Finally, in the head section, these multi-scale features are fed into multiple detection layers, enabling YOLOv8 to perform object detection at various scales simultaneously, thereby improving detection accuracy for small, medium, and large objects.

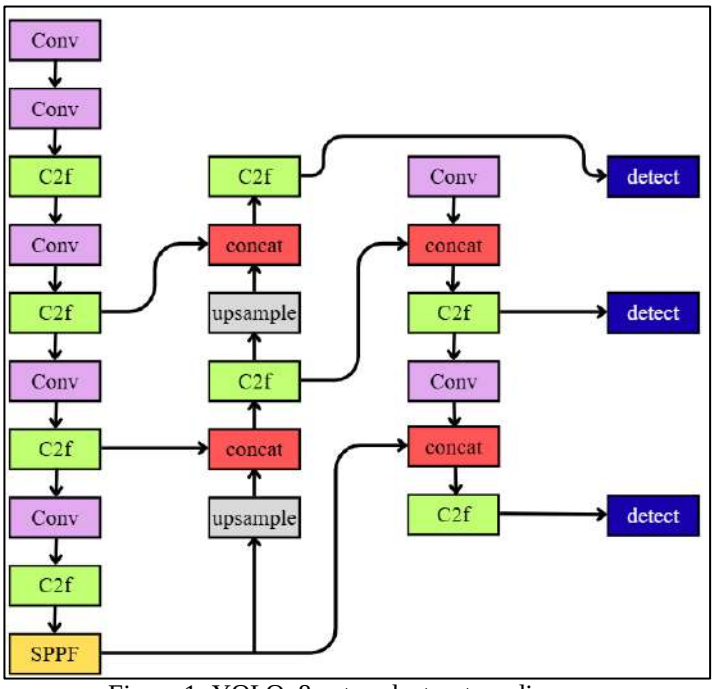

Figure 1: YOLOv8 network structure diagram.

III.2 BAM ATTENTION MECHANISM

Attention mechanisms are techniques that have been widely used in the field of deep learning to improve model performance by focusing computational resources on the critical parts of the input data. This study focuses on detecting expired date labeling defects, which fall into the category of small-sized objects with visual characteristics that are difficult to identify at a global scale. Although the standard YOLOv8 architecture is equipped with a multi-scale fusion mechanism capable of integrating feature maps from various resolution levels, this study integrates the Bottleneck Attention Module (BAM) to further refine the feature extraction capability of the convolutional neural network. The selection of BAM is based on its ability to enhance feature representation without significantly disrupting the core network structure [21]. In its implementation, the BAM module is strategically placed after a convolutional layer while preserving the original number of network channels to maintain computational efficiency. The architectural configuration of the BAM attention mechanism is visually illustrated in Figure 2.

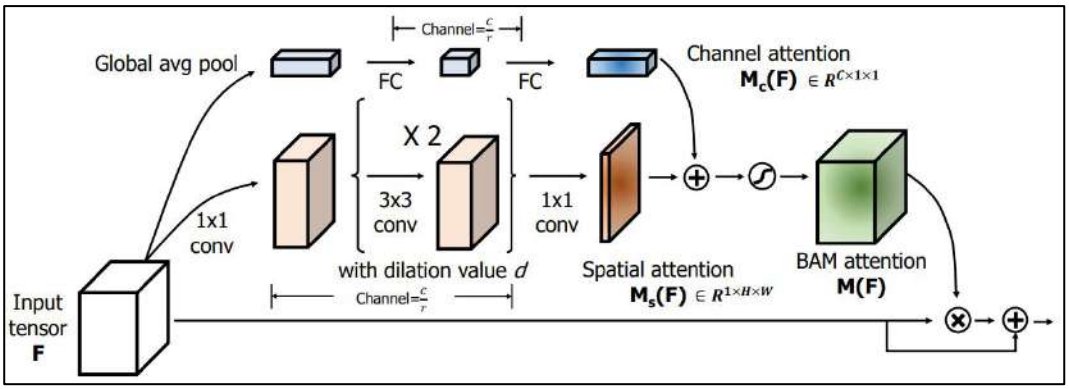

Figure 2: BAM attention mechanism diagram.
Source: [22].

BAM operates by generating an attention map that acts as an automatic information selector within a conventional neural network. The process begins by receiving an input feature map F , which is then processed through two parallel pathways to extract salient characteristics. The final output of this module is a refined feature map, where the attention values $M(F)$ are multiplied element-wise with the original features before being added back to the initial input. This residual learning technique ensures that gradients can flow effectively while simultaneously reinforcing features that are relevant for object detection or classification, as shown in Equation 1.

$$Output\ Feature\ Map \quad F' = F + F \otimes M(F) \tag{1}$$

Mathematically, the attention map $M(F)$ is not generated as a single entity, but rather through the combination of two different perspectives. The first component is channel attention $M_{C(F)}$ and the second component is spatial attention $M_{S(F)}$, which are summed before passing through an activation function. The use of the sigmoid function σ at the final stage aims to map the attention values into the range of 0 to 1. Within this range, the module can function as a "gate" that determines the intensity of information allowed to be propagated to the subsequent layers in the model architecture, as shown in Equation 2.

$$M(F) = \sigma\left(M_{C(F)} + M_{S(F)}\right) \quad (2)$$

The two attention components within BAM have specific and complementary roles in understanding the content of an image. Channel Attention $M_{C(F)}$ focuses on the channel dimension to determine "what" features are the most influential, such as specific textures or colors. On the other hand, Spatial Attention $M_{S(F)}$ employs dilated convolution to understand "where" these important locations are geographically positioned within the feature map. The combination of both allows the model to assign greater weight to defect regions or target objects while suppressing irrelevant background noise.

III.3 PROPOSED YOLOV8 FRAMEWORK ENHANCED WITH ATTENTION MECHANISM

The optimization of the YOLOv8 architecture was performed to improve detection accuracy for expired date labeling defects, which are generally categorized as small-sized objects with subtle and complex visual features. This approach was implemented through the selective integration of an attention mechanism into the backbone of the network to strengthen the model's capability to extract relevant features. In this study, several commonly used attention modules, namely CBAM (Convolutional Block Attention Module) and BAM (Bottleneck Attention Module), were selected as attention mechanism schemes to be experimentally evaluated. Both modules are designed to enhance feature representation by considering channel and spatial information, thereby potentially supporting the detection of small text and numerical characters on product labels. The implementation of the attention mechanism was focused on strategic placement at one of the YOLOv8 backbone layers, specifically the 9th layer, which was selected based on an analysis of feature map characteristics at this stage that were considered most effective for multi-scale feature processing and enhancement prior to the feature fusion stage [15]. This approach is relevant for handling variations in expiration date marking defects, such as printing defects, blurring effects, and incomplete characters, all of which demand a high level of precision during identification.

With this strategy, the core YOLOv8 architecture is preserved, while feature extraction capability is enhanced through the utilization of an attention mechanism that strengthens the representation of regions of interest (ROIs) containing expired date text and suppresses the influence of noise and complex packaging backgrounds. The structure of the YOLOv8 network modified with the integration of the attention mechanism is shown in Figure 3, with the aim of improving the network's ability to emphasize important features and reduce less relevant information. The addition of the attention mechanism (AM) enables the model to adaptively weight both spatial and channel features, resulting in more selective and informative feature representations being forwarded to the SPPF module. The subsequent effect of this process is an improvement in the quality of features entering the neck section, which involves upsampling and concatenation operations for multi-scale fusion. The fused features become semantically richer and more focused on object regions, allowing information integration across resolution levels to be performed more effectively. Finally, in the head section, the features enhanced by the attention mechanism provide higher-quality inputs to the detection layers, thereby contributing to improved detection accuracy, particularly for small or overlapping objects, without altering the main architectural flow or significantly increasing computational complexity.

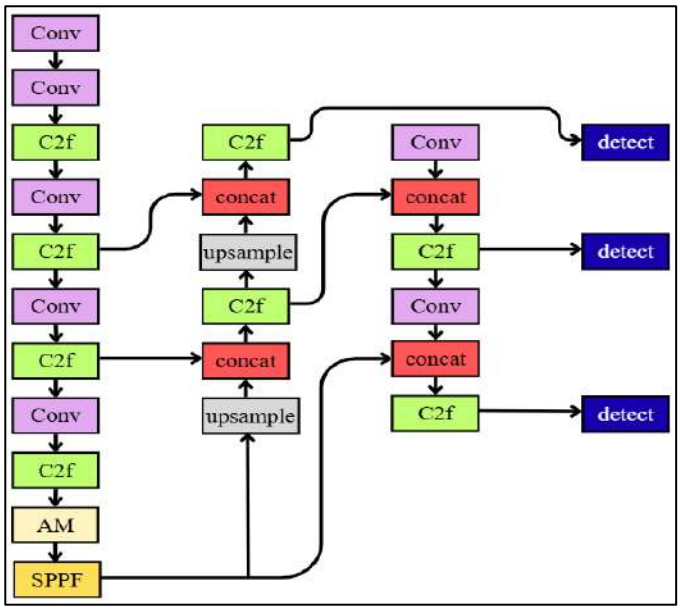

Figure 3: Proposed YOLOv8 network structure diagram.

III.4 CONSTRUCTION OF DATASET

Products that have entered the market should have passed the quality control stage, particularly in terms of expired date labeling. However, due to the influence of human error, products with defective and unreadable expired date labels may still pass through and reach the market. Therefore, the dataset samples were obtained from products already distributed in the market that exhibited expired date labeling defects. The selection of a specific brand aims to train the model to recognize consistent visual characteristics of a single product type, allowing the model to focus on detecting labeling anomalies. The total dataset used in this study consists of 312 images captured using an industrial camera, with 162 images representing products with labeling defects and 150 images representing products that passed quality inspection.

To enhance model generalization, image acquisition was conducted under varying lighting conditions and capture distances. The entire dataset was then randomly split with an 80:20 ratio, where 80% was allocated for training and 20% for testing. Prior to the training process, each image in the dataset underwent an annotation stage. This process involved assigning class labels ("defect" or "Pass") and creating bounding boxes to identify the location and extent of defects on the products. Accurate annotation is crucial to effectively guide the model during the learning process. The annotation process is illustrated in Figure 4, where Figure 4a presents an example of annotation for products that pass quality inspection, while Figure 4b shows the annotation for products in defective (reject) condition.

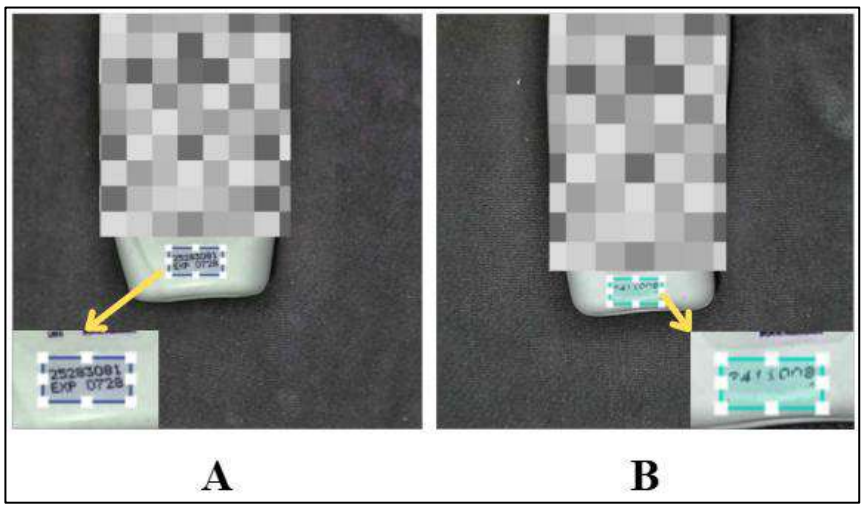

Figure 4: Annotation and labeling dataset.
Source: Authors, (2026).

III.5 PREPROCESSING DATASET

In this study, object classification is divided into two main categories: pass and defect. The "defect" category includes various forms of nonconformity, such as blurred printing, incomplete print results, or partially erased text, which will subsequently be rejected during the quality control process. The dataset was augmented by applying Gaussian Blur and Random Noise methods, which simulate disturbances caused by varying or insufficient lighting conditions that result in high noise levels commonly encountered on production lines. Subsequently, all images were normalized by resizing the pixel dimensions to 300×300. This dimensional standardization ensures input uniformity required by the YOLOv8 model architecture while reducing pixel size to alleviate computational burden. In addition to manual augmentation, YOLOv8 also has the capability to perform internal augmentation during training through Mosaic and Mixup techniques. In Mosaic augmentation, four randomly selected training images are combined into a single frame, enabling the model to learn object recognition in more complex contexts and across diverse scales [23]. Meanwhile, Mixup linearly combines two images along with their labels, creating synthetic samples that can enhance model robustness [24]. The application of both techniques has been proven effective in increasing data diversity and reducing overfitting.

III.6 EXPERIMENT ENVIRONMENT AND PARAMETER SETTING

The experiments in this study were conducted locally by utilizing a computational environment designed to support efficient, stable, and well-controlled model training processes. The use of consistent hardware and software configurations constitutes an essential aspect in ensuring the reliability of the experimental procedures and minimizing result variability caused by differences in execution environments. All experimental environment settings employed in this study are presented in Table 1.

Table 1: Environment configuration.

Name		**Name**	
Video Cards	RTX 3090 Ti	Video memory	24 GB
PyTorch	2.2.1	Python	3.10
Processor	AMD Ryzen 9 7950X	Cuda	11.8

Source: Authors, (2026).

In addition to the computational environment, the selection of model training parameters was carried out systematically to support an optimal learning process. These parameter configurations play a critical role in controlling training dynamics, model convergence, and the stability of the optimization process. Detailed information regarding the parameters used during model training and evaluation is presented in Table 2.

Table 2: Training parameters.

Optimizer	Adam	Patience	100
Dropout	0.0	Nms	False

Source: Authors, (2025).

III.7 EXPERIMENT MODEL EVALUATION CRITERIA

The objective performance assessment of all trained models was conducted through quantitative evaluation using several complementary evaluation metrics to comprehensively describe the strengths and weaknesses of each model. The evaluation criteria employed include Precision, Recall, F1-score, as well as Average Precision (AP) and mean Average Precision (mAP). Precision represents the model's accuracy in classifying the positive class and is calculated based on the proportion of positive predictions that correspond to the actual condition, where a high precision value indicates a low false positive rate, as shown in Equation (3).

$$Precision = \frac{TP}{TP+FP} \tag{3}$$

Recall describes the model's ability to identify all instances that truly belong to the positive class, where a high recall value indicates that the model is capable of minimizing false negative errors and effectively capturing the majority of existing positive cases, as shown in Equation (4).

$$Recall = \frac{TP}{TP+FN} \tag{4}$$

To balance these two metrics, the F1-score is employed, which represents the harmonic mean of precision and recall. A high F1-score value indicates that the model demonstrates stable and optimal performance in maintaining prediction accuracy while simultaneously preserving its ability to detect the positive class, as shown in Equation (5).

$$F1 = \frac{2\,x\,(Precision\ x\ Recall)}{(Precision+Recall)} \tag{5}$$

In addition to these classification metrics, object detection performance is also evaluated using Average Precision (AP), which is a metric obtained by integrating the Precision–Recall curve for a single object class across different confidence thresholds. Subsequently, mean Average Precision (mAP) is calculated as the average AP value across all classes used in this study, namely the defect and pass classes. The mAP@0.5 value indicates detection performance at an Intersection over Union (IoU) threshold of 0.5, while mAP@0.5:0.95 represents the average mAP over a range of IoU thresholds from 0.5 to 0.95, thereby providing a more stringent and comprehensive evaluation of detection quality.

IV. EXPERIMENTAL RESULTS AND DISCUSSIONS

IV.1 COMPARE ANALYSIS OF TARGET DETECTION ALGORITHMS

In this study, a comparative analysis was conducted using three YOLO-based models, all trained and tested on the same dataset. This comparative approach is essential for objectively evaluating the benefits of the proposed enhancement (YOLOv8-BAM) relative to the baseline architecture. The performance comparison of each YOLO model version is presented in Table 3.

Table 3: Comparison of target detection algorithms.

Experiment Algorithms	Precision (%)	Recall (%)	F1 (%)	mAP:0.5 (%)	mAP:0.5-0.9 (%)
YOLOv5	82	93	87	99,3	67,4
YOLOv6	90	96	93	98,8	67,1
YOLOv8	93	96	95	99,5	69

Source: Authors, (2026).

The experimental results indicate that the YOLOv8 model achieves the best overall performance compared to the other YOLO architecture variants evaluated in this study. Specifically, the YOLOv8 baseline attains a precision of 93%, recall of 96%, an F1-score of 95%, mean Average Precision (mAP@0.5) of 99.5%, and mAP@0.5:0.95 of 70%. This robust performance demonstrates the suitability of YOLOv8 as a base architecture for defect detection tasks. The YOLOv6 model follows behind in performance, while YOLOv5 ranks lowest among all compared models. Based on these experimental results, YOLOv8 was selected as the baseline model for further development through architectural modifications with the integration of an attention mechanism, aiming to further enhance detection capability, particularly for small-sized objects and fine-grained defects.

IV.2 ANALYSIS COMPARISON OF ATTENTION MECHANISM

A comparison between attention mechanisms was conducted to highlight the superiority of the Bottleneck Attention Module (BAM) over the Convolutional Block Attention Module (CBAM) within the YOLOv8 architecture. In this experiment, CBAM was integrated at the same location as BAM, namely the 9th layer of the backbone network. CBAM combines channel attention and spatial attention sequentially, adaptively refining feature maps by adjusting the importance of different channels and the significance of different spatial locations. However, CBAM requires separate computations for channel and spatial attention and necessitates feature map alignment across multiple scales. This sequential computation inherently results in higher computational complexity, which can negatively impact overall model performance and inference speed. The relative performance of these different attention mechanism integrations is detailed in Table 4.

Table 4: Performance comparison of attention mechanisms integrated into YOLOv8.

Attention mechanism module	Precision (%)	Recall (%)	F1 (%)	mAP:0.5 (%)	mAP:0.5-0.9 (%)	Latency (ms)
CBAM	100	93	96	99,5	71,6	14,6
BAM	96	100	98	99,5	72,2	13,3

Source: Authors, (2026).

Based on the experimental comparison between the CBAM and BAM attention mechanisms, BAM demonstrates superior performance in the label defect detection task. Specifically, the integration of BAM results in an increase in Recall of 7.5%, an improvement in F1-Score of 2.08%, and an enhancement in detection accuracy (mAP@0.5:0.95) of 0.84%. Although Precision experiences a slight decrease of 4%, the substantial gains in Recall and F1-Score indicate a more balanced and robust detector, particularly in minimizing missed detections, which is a critical requirement in industrial quality control.

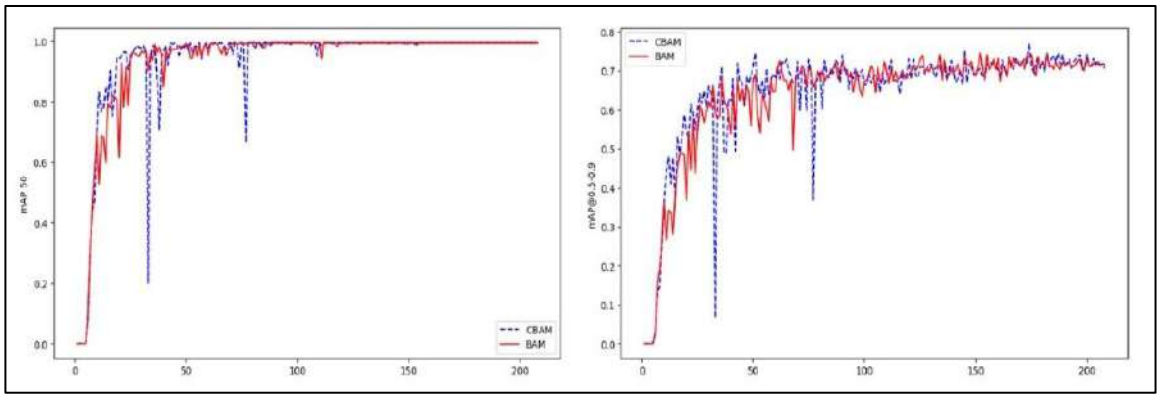

Figure 5: Curve mAP training experiment.
Source: Authors, (2026).

The implementation of the Bottleneck Attention Module (BAM) demonstrates lower inference latency compared to the implementation of the Convolutional Block Attention Module (CBAM). This characteristic is a crucial aspect, considering that defect detection on expired date labels requires high inference speed to enable the system to perform accurate detection and classification in real-time industrial environments. With more efficient latency, the YOLOv8-BAM model is considered more suitable for deployment on production lines that require high-speed visual inspection processes without compromising detection performance. In addition, Figure 5 illustrates a comparison of the model training results with the application of CBAM and BAM based on mAP performance curves over the number of epochs. The observations indicate that the model incorporating BAM achieves faster convergence and exhibits more stable curves compared to CBAM, particularly during the early to mid stages of the training process. The metric fluctuations in BAM tend to be smaller, indicating a more consistent learning process, while the CBAM-based model still experiences several relatively sharp performance drops at certain epochs. In the final stage of training, both models achieve high performance; however, BAM is able to maintain slightly better and more stable metric values. This demonstrates that the application of BAM is more effective in improving the quality of feature learning and contributes positively to the overall model performance. Therefore, based on the experimental results of the attention mechanisms, BAM was selected for integration into the YOLOv8 architecture. Subsequently, Figure 6 presents examples of defect detection results on expired date labels generated by the YOLOv8 model optimized with the Bottleneck Attention Module (BAM). Figure 6a illustrates the visualization of the model's prediction results for products that pass quality inspection, while Figure 6b shows the visualization of the model's prediction results for products in defective (reject) condition.

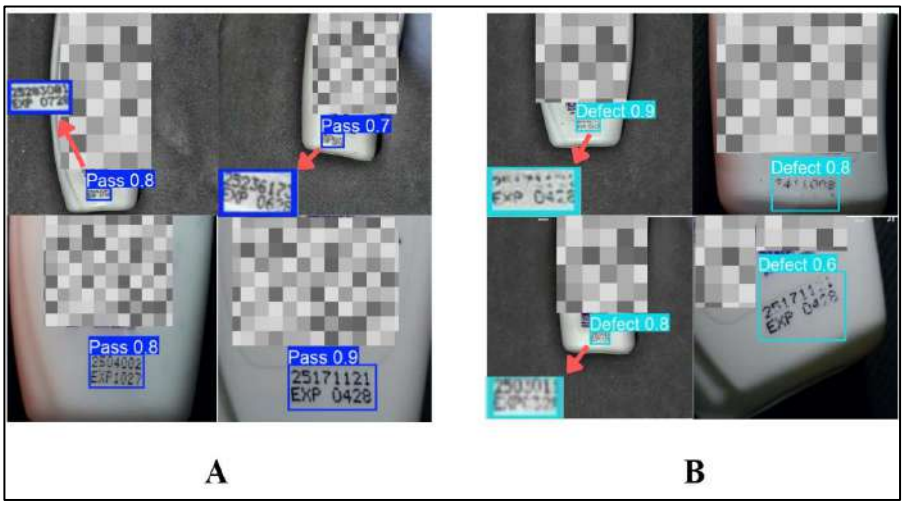

Figure 6: Visual sample result prediction model.

IV.3 CONTRIBUTION OF IMPROVED YOLOV8 ALGORITHM FOR DEFECT DETECTION LABELING EXPIRED DATE

The determination of whether an expiration date label is accepted or rejected depends on its readability for consumers. Traditional methods that rely on manual human inspection are highly susceptible to human error. In addition, the use of rule-based models is prone to detection errors when faced with complex defects and has difficulty adapting to new defect patterns, as classification depends entirely on explicit rules defined by developers. Furthermore, two-stage detection models are difficult to implement in industrial environments, where detection processes must be executed rapidly, which constitutes a major limitation of such architectures. To address these challenges, this study proposes the YOLOv8 model, a single-stage detector that offers high detection speed and the ability to adapt to evolving label defects without the need to explicitly define new rules within the model. For further optimization, the YOLOv8 model was enhanced through the integration of the Bottleneck Attention Module (BAM). This optimization significantly improves the model's performance in detecting and classifying defects in expiration date labels. YOLOv8-BAM achieves notable improvements in evaluation metrics, with Precision increasing by 3.23%, Recall by 4.17%, and F1-score by 3.16% compared to the standard YOLOv8 model. These enhanced results demonstrate that YOLOv8-BAM is a more robust, reliable, and industrially viable solution for automated expiration date label inspection.

IV.4 LIMITATION IN WORK

The construction of this dataset was carried out by collecting product samples that were already circulating in the market. This resulted in limited diversity and complexity of defects in the expired date labels. Consequently, for direct implementation in an active production environment, the model should be retrained with the inclusion of a more diverse dataset. In summary, this study focuses on the enhancement and optimization of the YOLOv8 model, which successfully improves overall model performance in detecting defects in expiration date labels.

V. CONCLUSIONS

This study successfully enhances the baseline YOLOv8 model through the integration of the Bottleneck Attention Module (BAM) attention mechanism, with the primary objective of improving the model's feature extraction capability. Based on experimental results evaluating the effectiveness of this architectural enhancement, the proposed YOLOv8-BAM model demonstrates consistent and significant performance advantages over the standard baseline YOLOv8 model. Testing results show improvements across all major evaluation criteria, with Precision increasing by 3.23%, Recall by 4.17%, and F1-score by 3.16%. These findings indicate that YOLOv8-BAM is not merely an incremental improvement, but rather a more robust, reliable, and industrially viable solution for automated visual inspection systems. Its enhanced ability to balance detection accuracy and prediction speed makes it particularly well suited for automated expired date labeling defect detection applications in industrial environments. The implementation of this model can reduce human error associated with manual inspection and provide an effective solution to the limitations of rule-based models.

ABSTRACT

Active safety system plays a vital role in automobile to enhance the safety to prevent the accidents and fatalities. Therefore, accidents are increased day by day and rider safety is striving hard to improve in an automobile. Researchers reported that more than 20 percentage of accidents occurs due to fault of the driver during driving like inattention and health related issues are the predominate one in accidents. The above issues are reduced by using the preferred system and analyze the driver condition while driving. The system shows the health condition in dashboard and displays the heart rate and warns the driver whenever the pulse range is varied more than the normal range. The measuring device mounted in driving wheel and pulse is measured using throb measuring device. The driver positioning his hand on driving wheel and considered as clock position “10 and 12”. The system warns not only to the driver and it warns to the co passengers for indicates the driver is in health issues. The research is carried out especially to prevent the fatality, severe injury and damage to the vehicle in the event of collision.

I. INTRODUCTION

Modern vehicles depend on automotive safety systems besides to enhance active safety features due to increased rate of accidents. This paper introduces a complete system based on the Internet of Medical Things (IoMT) that uses non-invasive sensors in the steering wheel to track vital signs like heart rate and blood oxygen levels. The goal is to spot health issues as they happen and send warnings to both the driver and passengers to make driving safer [1]. The automotive safety system had developed widely in costlier vehicles only but unfortunately not in low end vehicles. The causes of the accidents are widely investigated and the fatality rate is increased day by day. The statistics describes that safety systems in the low-cost vehicles are lower than the high-cost vehicles and therefore fatality rate also is more than the high-cost vehicles in the event of collision. Every safety feature cannot be incorporated in low-cost vehicles and the research is carried out what kind of safety system can be used to reduce the fatality rate in the low-cost vehicles.

The investigation carried out to reduce the fatality rate and literature points out some causes of collisions in past five years. There the different cases such as drivers fault, over speed, alcohol consumption during driving the vehicle, abnormal health issues, pedestrian crossing and mechanical error in India. The drivers fault fatality rate is 77% more than the other causes it depends on driver violating traffic law mostly responsible for resulting accident, running light in high beam, without experience driving the vehicle and health related issues etc [2]. The article talks about creating a smart steering wheel with sensors that check the driver's health and find signs of sleepiness. It measures things like heart rate, variability, and blood oxygen to quietly evaluate the driver's state, helping to stop accidents from tiredness or sudden health problems [3]. The drunk and driver fatality rate of 16% is raised day today and the system is incorporated to reduce the accidents during consuming alcohol.

The 16 to 20% of fatality is occurred is due to health issues i.e. abnormal health condition of the driver during driving the vehicle it comes under the fault of driver. Another cause of collision is 16 to 20% of due to health issues and the diagnosed health issues are heart attack, hypertension, hyper lipidemia, diabetes mellitus, and gastro intensimal ulcer [4]. The paper explains the design of a smart system that monitors a driver's health in real time from a distance. It uses a smart steering wheel with sensors to keep track of vital signs and sends information to a mobile app to warn the driver or call for help if something is wrong with their health [5]. The monitoring system can spot the behavior signs that a driver is getting fatigue, which can help stop accidents caused by sleepiness [6]. Testing showed that this system can lower the chance of accidents by catching strange driving behavior as it happens during driving and it prevents the collision act as active safety [7]. The analysis found that this system makes braking quicker and more stable, which helps stop the vehicle smoothly and prevent skidding when stopping suddenly using this braking system [8].

This paper looked at how metal and rubber materials design affect how much tools used for boring can dampen vibrations [9]. The research studied the properties of bio-composites made from Aloe vera and hemp fibres [10].The hybrid method was found to be stronger and longer-lasting than other methods, making the joints work better [11]. The study found that this kind of seat belt greatly reduces movement and the risk of injury compared to regular seat belts [12]. The study showed that using IoT improves car performance, makes driving safer, and gives a better driving experience [13]. The results showed that this method is more efficient and produces more water than traditional systems [14]. The findings showed that this system can stop the car automatically to prevent collisions, without the driver needing to do anything [15]. The study explained how continuous monitoring can improve road safety by finding early signs of tiredness or other health issues [16]. The results showed common signs of fatigue, which showed the need for monitoring systems to help prevent accidents caused by reduced alertness.

Testing showed that the system can spot unsafe driving situations and help prevent accidents by acting on its own [17]. Recent studies have focused on improving vehicle performance, safety, and efficiency through numerical analysis and experimental validation. Computational investigations using RANS models indicate that vortex generators can improve airflow behaviour and aerodynamic characteristics in simplified vehicle configurations [18]. Experimental work on diesel engines shows that changes in intake manifold design, along with the use of alternative fuels, can lead to better combustion and improved engine performance [19]. In electric two-wheelers, venturi duct–integrated cooling systems have been reported to enhance thermal regulation and operating efficiency of PMSM units [20]. Research on braking and structural systems highlights their importance in vehicle safety. Experimental evaluation of semi-automatic parking brake systems confirms reliable braking performance while maintaining cost effectiveness [21]. Structural analysis of heavy vehicle chassis demonstrates that appropriate selection of geometry and materials improves stress distribution and load-carrying capacity [22].

Studies using ANSYS optimisation techniques show that advanced materials can improve suspension performance and durability in two-wheelers [23]. Thermal performance improvements using variable geometry micro-channel heat exchangers further support enhanced energy efficiency in automotive air-conditioning systems [24]. Work on active safety systems indicates that hydraulic actuator–based automatic emergency braking systems can improve braking response and reduce accident risk [25]. Studies related to data security highlight the need for privacy-preserving methods in health and monitoring applications [26]. Integration of driver condition monitoring with safety-enhanced braking systems has been shown to improve accident prevention capability [27]. Continued development of automotive braking systems contributes to improved passenger vehicle safety and braking reliability [28]. Combined driver monitoring and active braking strategies further support enhanced overall vehicle safety performance and study shows the measuring devices used for analysising the output results from motorised accurancy is due to sensors [29], [30].

II. MATERIALS AND METHODS

The effective system is one which employed not only to minimize driver injuries but this also protects the driver’s mortality during sudden health concerns. The current systems have numerous auxiliary systems to slow down vehicles; however, they are insufficient to stop injuries or health complications in typical Indian vehicles. The literature points out the condition of driver, leading causes of fatalities and measuring methods of human pulse rate of using sensor-based technology were reported. The collision warning system or object detection system gives the warning signal before collision. Even though systems are placed in the vehicle, collision occurs frequently were reported. Research has shown that the drivers suffering from health diseases are more than 16 to 20 percentage involved in road accident rising day-by-day to drivers even though automatic braking in health issue not yet reported.

The health-related accidents were caused by drivers’ fault while driving were reported and steps to reduce not yet reported (The driver who suddenly suffers from health issues during driving the driver cannot handle the vehicle because during heartache the movement of hands is difficult towards control of the vehicle which results accident). The proposed study consists of a cardiac monitoring device that detects the driver's rhythm under dynamic events. The heartbeat (HB) measurement tool installed in the driver's wheel enable the motorist to place their hands in a specific sensing element. Therefore, the HB measuring device monitors the pumping of the heart beats continuously. The system is built especially for health issues drivers who had already had affected gets advantage. The sensing element is then interfaced to a microcontroller that enables detecting pulse rate in Bpm.

The user can set the high level heart beat and low level of heart beat (say ex.100 beats for high and 60 beats low) After setting the limits, the measuring device starts monitoring 35 the driver, if the driving force heart beat goes on top of a particular limit; the system sends a responsive to the controller that transmits the signal to the actuator to the braking system (future work to design and development of actuator). The system alerts the pedestrian by giving alarm and stoplight for the following vehicle. The flow chart system of a pulse sensor measuring (HB measuring device) shown in figure 1. The HB measuring device detects the driver’s beats drop significantly during driving when they are become low, it alerts the co passenger and the driver who slowly starts to fall in sleep or unconscious if the pulse is low.

In this preferred system the HB measuring device in the driving wheel that senses the sensing area of the fingers and palm area to test the pulse and temperature of the driver. Therefore, the measuring device works as like exercise equipment on a treadmill or a bike user places their hands or fingers over the measuring device to get a pulse rate reading and displayed. So, the driver can place his hand on the driving wheel as they sense the pulse from the driver fingers. Normally HB measuring devices are bulk and large and take too much space to accommodate but for this system a small one is selected that connects to the driving wheel where the driver can hold with the fingers. There are two sensing area on the driving wheel which can sense the both hand or fingers which rest on the diodes of the driving wheel. There it is compatible with an Arduino board and the driver's health condition is monitored and reading is taken from the measuring device as output. The signal information is passed to the Arduino board and it interpret the pulse is low or high depends on the condition. If it is low the system interprets that the rider or driver will be in unconscious or fall as sleep and the signal sends an alert to the driver through display LCD and alarm. The driver monitoring system monitors the health condition and sends messages to nearby hospitals were reported and the decelerating the vehicle not yet reported.

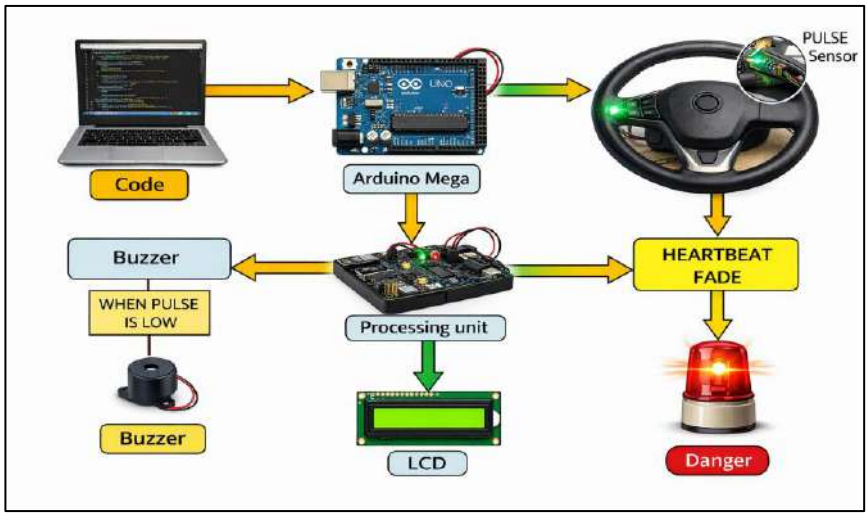

Figure 1: Flowchart of pulse sensing system.
Source: Authors, (2026).

The figure 2 describes the temperature sensor that consists of a lens to focus the infrared (IR) energy on to a detector which converts the energy to an electrical signal that can be displayed in units of temperature after being compensated for ambient temperature variation. The average human body temperature is 37 ℃ (98.6-degree Fahrenheit). The LM-35 is employed to observe the body temperature. The operative temperature ranges of LM-35 from -55 ℃ to 150 ℃. The output voltage varies by 10 mV in response to every degree Celsius rise or fall in close temperature, accuracy level of ±0.25 to ±0.75℃. MLX90614 temperature sensor is used. The body temperature varies depending on the body, a person takes a measurement. The research is carried on 40-60 age groups, (healthy temperature 97.6 – 99.6-degree Fahrenheit). When the health condition changed the body temperature is changed. The normal temperature ranges for the adult 97.6-degree Fahrenheit to 99-degree Fahrenheit as reported as average range by the doctors and literature review. The range for testing in research is less than 96.5 - greater than 102-degree Fahrenheit. When a person's body temperature is dangerously lower than 96-degree Fahrenheit, the brain and body cannot function properly. If left untreated, hypothermia can lead to cardiac arrest (heart stops beating) and leads to death. During heartache the temperature of the body is increased to more than 102-degree Fahrenheit or if driver fall asleep the temperature of body lowers than the normal body temperature which is less than 97-degree Fahrenheit and makes the driver less active. The both sensors (pulse & temperature) act simultaneously at same time, measures the health condition of the driver.

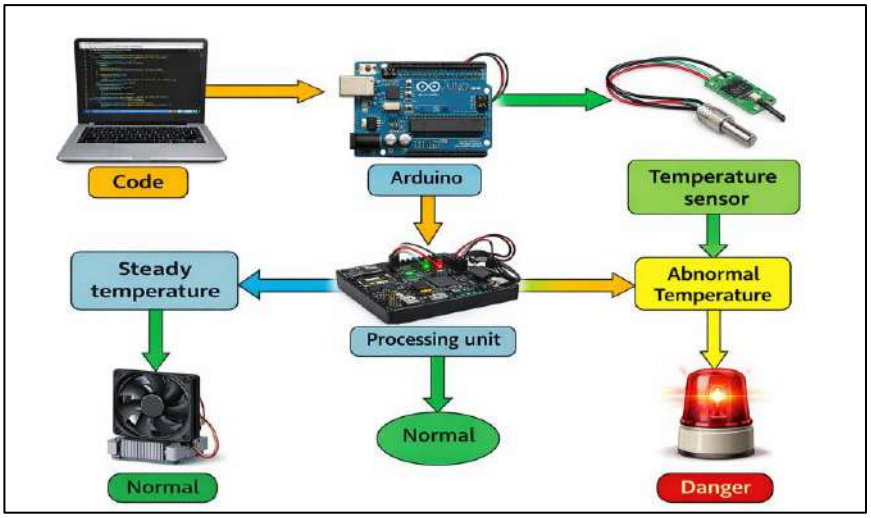

Figure 2: Block diagram of arduino-based real-time temperature monitoring and alert system.
Source: Authors, (2026).

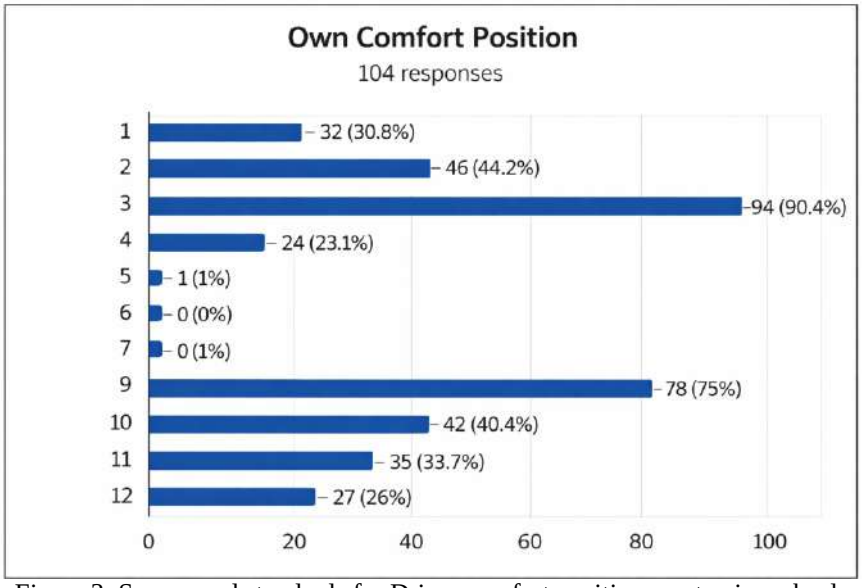

Figure 3: Survey and standards for Driver comfort position on steering wheel.
Source: Authors, (2026).

The figure 3. Shows the driver comfort position. The driving wheel denotes as face of the clock and the positioning of left hand 9, 10 & 8 clock and the positioning of right-hand side is 2, 3 & 4 o'clock. Today, the (NHTSA) recommends the driver to hold the driving wheel in 9 and 3 o'clock positions because lowering the hands on the driving wheel and there is the reason is airbag deploys during an accident. Therefore, placing the hands different positions except 9 and 3 O' clock should not use in the event of safety the study surveyed the positions of hands also and chart shows the maximum placing hand positions and best positions and it defines that NHTSA standard position is the best and safest position to prevent the accident. Figure 4 shows the placement of sensors on the steering wheel using a clock-face representation to indicate hand positions. The IR pulse and Temperature sensors are mounted on the left and right sides of the steering wheel at the 9 o'clock and 3 o'clock positions, which are commonly recommended for safe driving. These positions allow continuous monitoring of the driver's pulse rate and hand temperature during vehicle operation. The selected locations ensure stable hand contact and reliable signal acquisition without interfering with steering control. This arrangement also supports safety considerations related to airbag deployment and driver comfort.

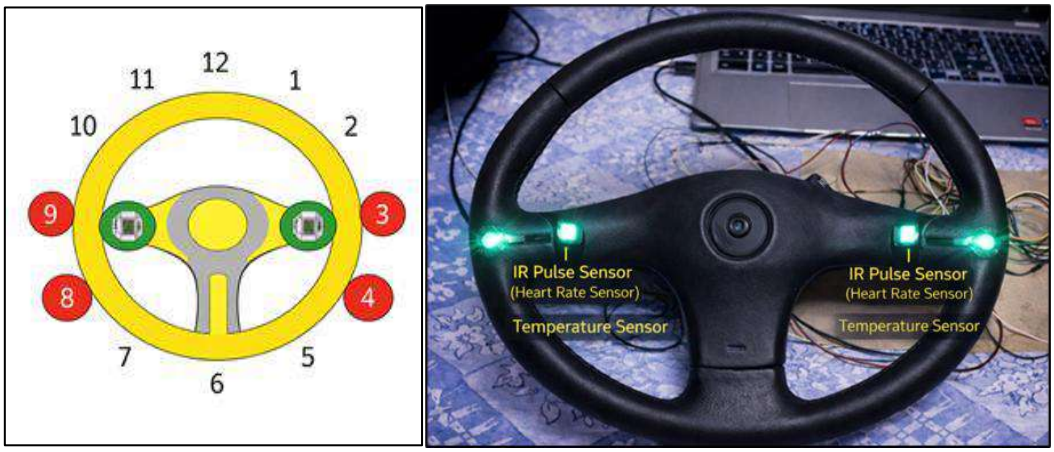

Figure 4: Sensor positions on steering wheel.
Source: Authors, (2026).

The infrared sensor is responsible for sending infrared light to the body shown in figure 5. This sensor has a pair of transmitter and receiver. Using photodiode detect reflective light from the body and this signal is sent to the microcontroller to detect heartbeat. AT mega 328P, CMOS 8-bit AVR micro-controller with LM324 32KB bytes of in-system programmable ISP Flash memory, 2KB bytes of RAM, 32 I/O lines. A Liquid emitting diode is used to display the heart beat in Beats per Minute (bpm). Operating Voltage: +5V or +3.3V, Current Consumption: 4mA Inbuilt Amplification and Noise cancellation circuit. Diameter: 0.625", Thickness: 0.125" Thick, the accuracy level of pulse sensor is 2-3%. The proposed system is to collect the driver's data samples in age group from 40 – 60 (adults). The drivers are selected on these age groups for research by consulting the cardiologist and from literature review. The prevalence report says that maximum collision occurs in the adult age group, therefore maximum and minimum pulse range is more than 100bpm and less than 60bpm which is abnormal or dangerous for the drivers. Normally pulse sensors are bulk and large and take too much space to accommodate but for this system a smaller one has been selected that hooked to the steering wheel where the driver can place the finger or palm over sensor.

III. RESULTS AND DISCUSSIONS

The developed system sensing the sensor output is tested the efficiency of the measuring device with the conventional system and tested in prototype and real time model. The vehicle tested with the sensor sensing technology on static condition by cranking the engine in idling stage for measuring the condition of the driver. The sensor accuarcy aslo tested during the static condition and by considering the atmospheric temperature and wind condition. The sensor compatibilty is tested in idling condition because of vibration and noise from the engine comparetment to find any changes in sensor accuracy is analysed and validated the accuracy. If the pulse is abnormal the indication is displayed in dashboard and warning signal will be given in the event of emergency. Its unpredictable or measure the abnormal person for testing the developed system. For alerting or warning, the normal pulse rate set as abnormal rate for testing purpose. Therefore warning signal as alarm with stopping light had indicated for safety and pulse displayed in the dashboard.

The throb measuring device or HB measuring device output is tested and validated with the conventional electrocardiogram. The temperature measuring device also tested and validated with the conventional type thermometer. Both the measuring devices are tested the efficiency and got the output values of the proposed measuring device system. The system is tested with maximum trials for the individual people of the age group and the average pulse rate is taken for the research as shown in table 1 and plotted in figure 6. The table 1 shows the various pulse readings obtained from ECG and HB measuring device with the error rate. The table indicates the pulse rate of the conventional type of monitoring the heartbeats by using electrocardiogram. The HB measuring device which consists of photo diode it measures the pulse rate of the driver.

The HB measuring device which is tested for the propose system and to find the efficiency of the measuring device. The HB measuring device output is measured or tested using the adult age groups for the research and the measured pulse rate listed. The error rate of the measuring device is validated by using the error rate formula during static condition [11-22]. The adult age from 40 to 60 is taken for the research for testing the pulse rate of the individuals is show in table. The accurate pulse rate and measured pulse rate shows the variation of pulse and the maximum error 0.02 for the HB measuring device reading. The testing of pulse rate of the adult age groups also tested in real time model for measuring the error during dynamic condition. The HB measuring device is mounted in the driving wheel of a car and this measuring device is contact type measuring device which is to be hold during driving.

Figure 6: In-vehicle testing of steering wheel-integrated IR pulse and temperature sensing unit.
Source: Authors, (2026).

Table 1: Comparison of pulse rate measurement with ECG.

Age	Actual pulse rate from ECG (Bpm)	Measured pulse rate from Pulse sensor (Bpm)	Error	Body Temperature (*F)
40	76	77	0.013	97.6
45	75	77	0.026	98.7
48	75	74	0.013	97.6
50	82	83	0.012	99.2
54	83	84	0.012	98.1
58	86	87	0.011	97.8
60	79	78	0.012	99.6

Source: Authors, (2026).

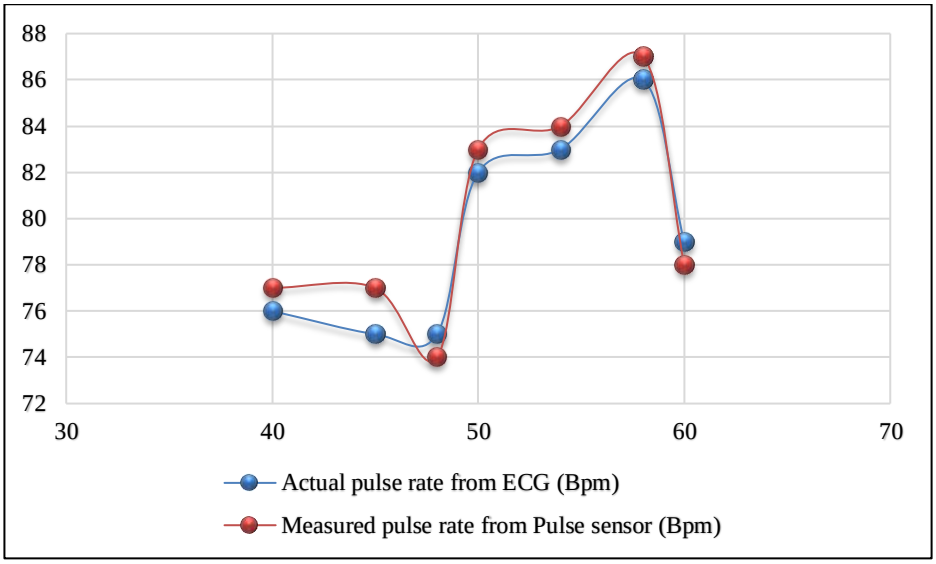

Figure 7: Effect of pulse rate on age group.
Source: Authors, (2026).

The figure 7. compares the actual pulse rate obtained from ECG with the pulse rate measured using the pulse sensor for different test conditions. Both curves show a similar trend, indicating close agreement between the measured and reference values. Minor deviations are observed at a few points, but the overall difference remains small across the range. The measured pulse rate follows changes in the actual heart rate effectively. These results indicate that the pulse sensor provides reliable pulse measurements for real-time monitoring.

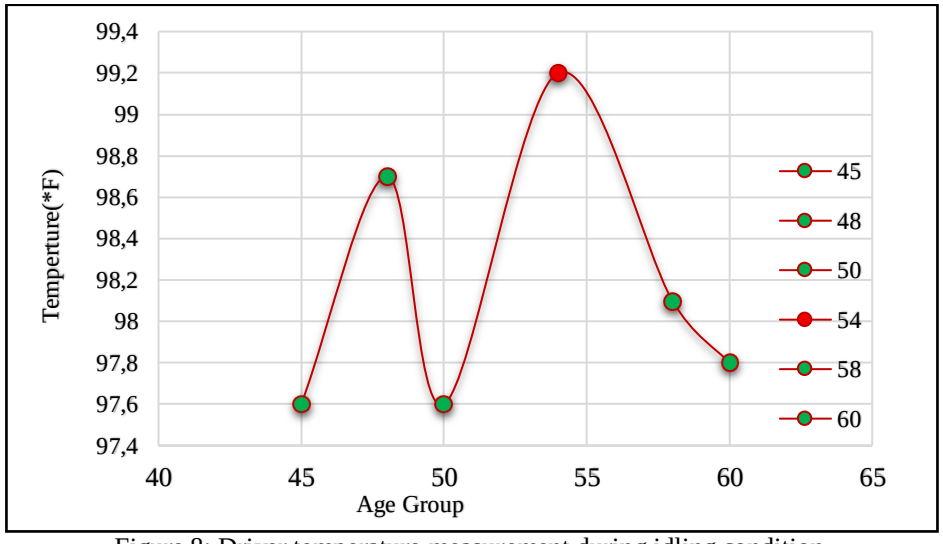

Figure 8: Driver temperature measurement during idling condition.
Source: Authors, (2026).

Figure 8. presents the variation of driver body temperature measured during idling conditions across different age groups. The recorded temperature values remain within a narrow range, indicating stable physiological conditions during idle operation. A slight rise in temperature is observed in the middle age group, followed by a gradual decrease at higher ages. No sudden or abnormal temperature fluctuations are noted in the measurements. Overall, the results indicate that idling conditions have minimal influence on driver body temperature.

If the temperature is abnormal the indication is displayed in dashboard and warning signal will be given in the event of emergency vice versa to pulse sensor measurement. Its unpredictable or measure the abnormal person for testing the developed system for alerting or warning the normal temperture set as abnormal tempetrature for testing purpose the warning signal as alarm with stopping light had indicated for safety and temperature displayed in the dashboard.

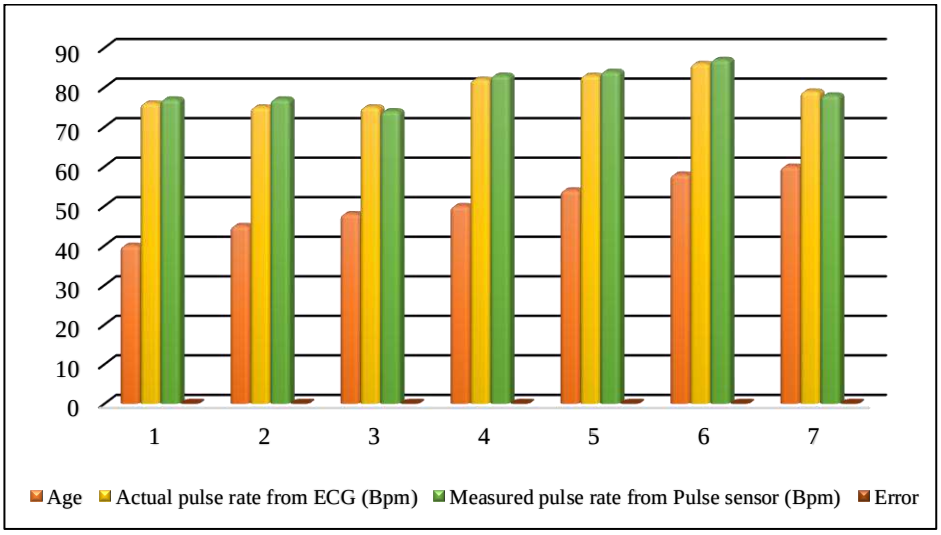

Figure 9: Comparison of actual and measured pulse rate with error variation across test subjects.
Source: Authors, (2026).

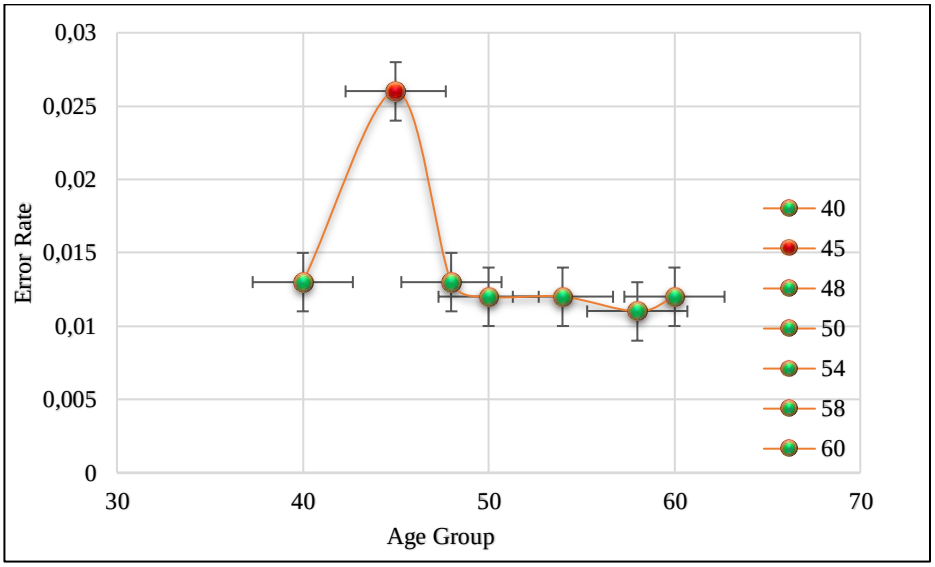

Figure 10: Error rate of proposed system over conventional system.
Source: Authors, (2026).

The figure 9 shows a comparison of actual pulse rate measured using ECG and the pulse rate obtained from the pulse sensor for different test cases. The measured values closely match the ECG readings, indicating good agreement between the two measurement methods. The error values remain small across all cases, showing consistent sensor accuracy. The results also indicate stable pulse measurement over different age groups. Overall, the pulse sensor demonstrates reliable performance for real-time heart rate monitoring applications. The figure 10. compares the actual pulse rate obtained from ECG measurements with the pulse rate measured using the pulse sensor for different test cases. The results show that the measured pulse rate closely follows the ECG values across all cases, with only minor deviations. The error values remain low, indicating good accuracy and reliability of the pulse sensor for monitoring heart rate under the tested conditions.

IV. CONCLUSION

The developed system senses the condition of driver and enchances the active safety systems to prevents collision using the sensor based technology. The displayed system shows the pulse and temperature rate of the driver in the dashboard in order to know the condition of the driver to the co passengers in the vehicle. The preferred system is designed elegance and accurately monitors the condition of the driver in static and dynamic condtions under limited speeds. The system explicitly enhanced sophisticatedly with an active safety system and alert mechanism is developed for the indian vehicles and for the auto industry manuafactures to reduce the fatality rate. The fatality rate is reduced by monitoring the fault of driver and the life of the rider is safe by preventing the collision in the emergency sistuations. The system supports to reduce the fatality, severe injury and vehicle damage. These developed sensor based technology is combined with the actuator in future work , where it activates the brake to stop down the vehicle gradually.

ABSTRACT

The present paper investigates the aerodynamic influence of a micro-blade (MB) flow control in a low-speed axial compressor cascade, through a combined two-dimensional (2D) optimization and three-dimensional (3D) validation framework. The influence of the MB's key geometric parameters, including chord length, camber angle, stagger angle, and maximum thickness, as well as spatial positioning, was systematically analyzed to identify the optimal configuration. Results reveal a size-wake trade-off; small elements fail to sustain meaningful momentum exchange, whereas large elements introduce excessive blockage and wake losses. An intermediate chord of 20% of the main blade, combined with a medium element maximum thickness (5% of the MB chord) and 50° camber, provides the most favorable compromise, achieving a 55.56% reduction in total pressure loss coefficient (TPL) under stall conditions. The optimized MB was subsequently evaluated in a 3D cascade configuration to examine its influence on corner separation and 3D flow structures across design and off-design inlet flow angles. The 3D results showed a clear reduction in the corner separation spanwise extent, especially at high incidences, though a TPL penalty is observed at the nominal design angle, where the baseline flow is already attached. Overall, the findings demonstrate that carefully optimized MB can effectively mitigate losses and enhance compressor operability when geometry and placement are properly designed.

I. INTRODUCTION

Modern axial compressors are increasingly facing performance demands over a wide range of operating conditions. The pursuit of a higher-pressure ratio and lower fuel consumption has involved a higher blade loading, and consequently, the emergence of complex flow phenomena such as boundary layer separation, corner stall, and secondary flows is now inevitable. In low-speed compressors, such flow phenomena produce low-momentum zones that can block the flow and reduce static pressure rise, leading to increasing losses and risking stall [1]. Passive flow control techniques have emerged as effective solutions to mitigate these adverse flow phenomena with simplicity and without any external energy input, unlike active control systems [2]. These devices use small geometric modifications to energize the boundary layer or redistribute the secondary flow. For example, vortex generators and endwall fences have been shown to create streamwise vortices that suppress crossflow and corner stall, thereby extending the stall margin [3-7]. Such passive devices have contributed to notable gains; the addition of a vortex generator (VG) to a highly loaded compressor cascade reduced the total pressure losses by about 8.3% [8], and a strategically placed endwall fence was reported to reduce the loss coefficient up to 9% [9]. These results highlight that surface additions (or cuts) can significantly improve compressor performance. Beyond conventional VGs and slots, micro-scale flow control elements are currently attracting interest. For example, micro-vortex generators (MVGs) of various shapes can delay stall and reduce losses by about 9.36% [10].

More recently, a "fish scale" array applied to the suction side has been experimentally shown to generate small upward vortices that entrain the low-momentum endwall flow; this design reduces the total pressure loss by 5.69% [11]. Such studies demonstrate that even very small passive elements can improve mixing and reduce separation in low-speed compressor flows. In parallel with these advances, a promising approach has received little focus; discrete micro-blades (small airfoil) placed in the passage upstream of the separation onset. Unlike shallow ribs or ramps, a full-span micro-blade could generate a "suction surface jet" [12], preventing the buildup of low-momentum fluid in the passage region. Ma & Sun [13] investigated the spatial positioning of a "little blade," focusing on its placement within the cascade passage. Their work demonstrated a measurable sensitivity to axial positioning according to incidence angle; similarly, Guo et al. [14] explored the impact of different spatial locations, stagger angles, and heights of a "little blade", with the optimal configuration yielding a 10.38% drop in the total pressure loss coefficient at near-stall condition.

However, optimizing these devices for practical applications remains difficult due to the complex interactions between the device geometry, spatial positioning, and operating conditions. The aerodynamic influence of the micro-blade's geometric design parameters has received considerably less attention; most previous studies on micro-blades have mainly concentrated on the effects of spatial positioning, while the geometric optimization of the micro-blade itself remains largely unexplored. Building on this background, the present study conducts a comprehensive two-dimensional computational optimization of the combined effects of the micro-blade's spatial positioning (axial and circumferential), geometric parameter design (stagger angle, camber angle, maximum thickness, chord length), and operating conditions (inflow angle) within a unified parametric framework, followed by a 3D investigation of the optimal configuration to verify its impacts on the corner separation and secondary flow. This comprehensive approach allows for the identification of parameter interactions and optimal configurations that would be missed by single-variable studies.

II. METHOD

The numerical study was conducted on a low-speed linear compressor cascade employing the NACA 65(10)18 airfoil profile, using a chord length of c=0.127 m. The detailed geometrical specifications of the cascade are summarized in Table 1. Initially, a 2D investigation was carried out in order to conduct a systematic parametric study on the flow control element. The approach consists of successively modifying the geometric design parameters of a microblade (MB) under different inlet flow angles (β) and monitoring its impact on the aerodynamic performance of the cascade. In its primary state, the MB appears as a symmetric plate with a double-circular-arc (DCA) profile type and zero camber angle, positioned in the proximity of the main blade suction side (see Figure 7). An optimization process was then performed based on the MB's spatial locations (axial and circumferential positions) and geometric design parameters, including camber angle, stagger angle, chord length, and maximum thickness at different off-design inlet flow angles.

Table 1: Geometric parameters of the compressor blade.

Parameter	Value
Chord (m)	0.127
Solidity	1.25
Stagger angle (°)	13
Aspect ratio	1

Source: Authors, (2026).

Once the optimal design and positions were identified in the 2D computational cases, the study was extended to a three–dimensional (3D) configuration. The 3D simulations served for the assessment of the influence of the MB on corner stall and flow structures.

II.1 PERFORMANCE PARAMETERS

The aerodynamic performance of the compressor cascade was evaluated using global loss coefficients, and local boundary layer integral parameters. The total pressure loss coefficient (TPL) was employed as the primary metric to quantify aerodynamic losses, defined as

$$TPL = \frac{P_{t,1} - P_{t,2}}{P_{t,1} - P_1} \tag{1}$$

Where $P_{t,1}$ and $P_{t,2}$ denote the mass-averaged total pressure at the inlet and outlet boundary, respectively, and P_1 is the inlet static pressure. To evaluate the improvement (or deterioration), the change in TPL was introduced as:

$$\Delta TPL = TPL_{baseline} - TPL_{micro-blade} \tag{2}$$

Where positive values of ΔTPL indicate reduced losses, while negative values denote deterioration. The static pressure coefficient is defined as:

$$Cp = \frac{P - P_1}{P_{t,1} - P_1} \tag{3}$$

Here, P denotes the local static pressure. The mass-averaged Cp at the outlet boundary (Cp') is employed to quantify the diffusion of the cascade [12]. To investigate boundary layer behavior, the classical integral parameters were extracted along the suction surface of the main blade. The displacement thickness δ^* and momentum thickness θ are given by:

$$\delta^* = \int_0^\infty \left(1 - \frac{u}{u_\infty}\right) dy \tag{4}$$

$$\theta = \int_0^{\infty} \frac{u}{u_{\infty}}\left(1 - \frac{u}{u_{\infty}}\right) dy \tag{5}$$

Where u and u_{∞} are the local and free-stream velocities, respectively. The shape factor is given by:

$$H = \frac{\delta^*}{\theta} \tag{6}$$

The axial position (X) of the MB is expressed in percentage of the main blade axial chord, given by:

$$\mathrm{X} = \frac{d_x}{\mathrm{Cx}} \times 100 \tag{7}$$

Where d_x represents the axial distance between the leading edges of the main and micro blades, and Cx is the main axial chord length. The circumferential position (Y) of the MB is expressed in percentage of pitch; it is given by:

$$\mathrm{Y} = \frac{d_y}{s} \times 100 \tag{8}$$

Where d_y represents the circumferential distance measured from the leading edge of the MB to the main blade suction side, and s denotes the blade spacing length

II.2 SOLVER SETTINGS AND NUMERICAL VALIDATION

A single-blade passage of NACA 65(18)10 linear compressor cascade was conducted using the commercial CFD solver Ansys Fluent, limited by periodic boundaries to represent the circumferential domain. The simulation employed the steady incompressible Reynolds-averaged Navier–Stokes (RANS) equations, closed using the two-equation k-ω shear stress transport (SST) as a turbulence model [15], chosen for its robustness in predicting adverse pressure gradient and boundary layer separations. The inlet boundary conditions were defined by specifying the free-stream velocity components, along with the corresponding turbulence intensity and characteristic length scale. The simulation was conducted under operating conditions corresponding to a chord-based Reynolds number of 245000. Constant thermophysical properties of air were assumed. Convergence was considered based on normalized residuals falling below 10^{-5} for continuity, momentum, and turbulence transport equations, with monitoring of TPL, and Cp on the blade surfaces.

III.2.1 Two-dimensional Cascade

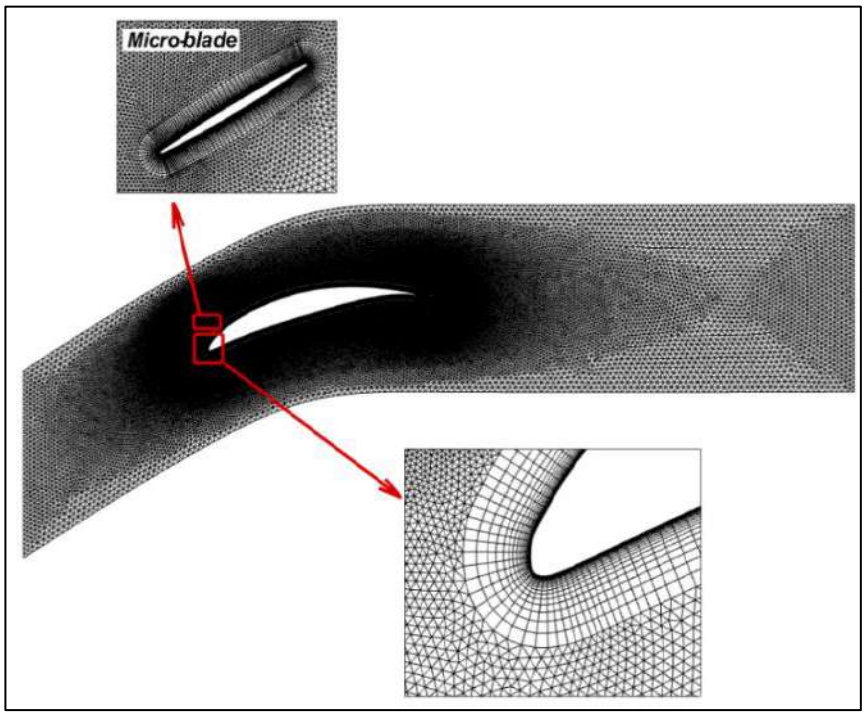

Figure 1: 2D Computational grid.
Source: Authors, (2026).

The 2D domain was meshed with a hybrid unstructured grid using Gambit software. Figure 1 shows the 2D computational grid of the controlled case. To precisely capture the boundary layer development, a refined clustering with 20 inflation layers was applied to all solid walls with 1.25 and 1.15 growth ratios for the main blade and the MB, respectively.

In order to guarantee $y+ < 1$, the first cell height at the walls was set to 1×10^{-5} m, Figure 2 (right) shows the dimensionless first cell height at the blade wall boundary. A grid independence study was carried out by refining the mesh at boundaries and solid walls, as illustrated in Figure 2 (left). A final mesh size of about 76000 cells was selected, as further refinement produces negligible variation in TPL, with a total of 410 discretization points around the main blade airfoil.

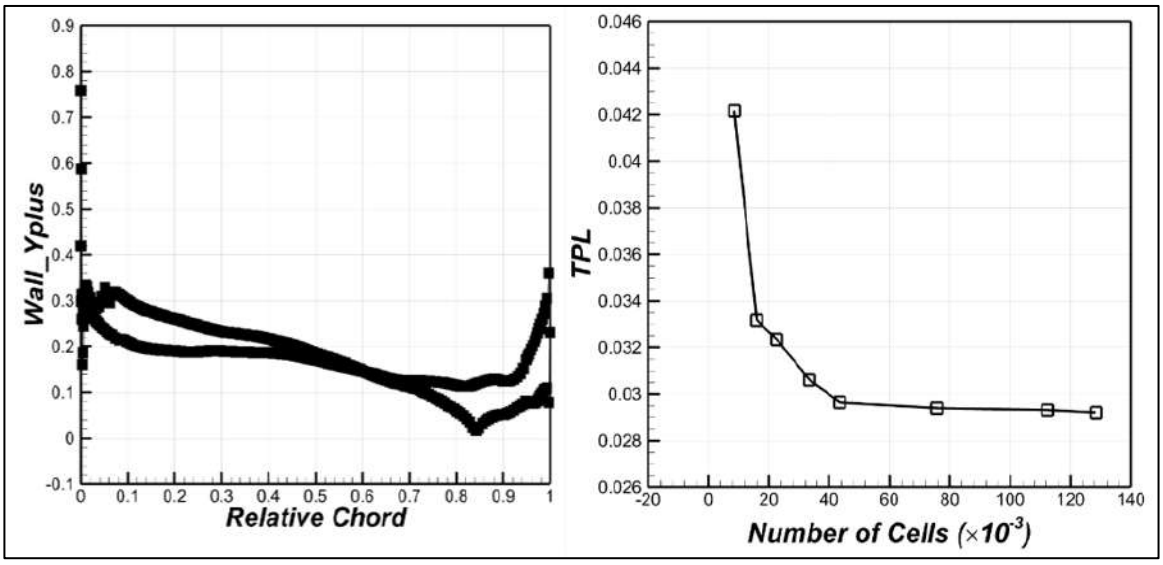

Figure 2: Dimensionless first cell height at the main blade walls (right), grid independence study (left).
Source: Authors, (2026).

To guarantee the reliability of the numerical setup, the calculated results of the baseline case (without flow control) were validated against the experimental measurements reported in [16]. Figure 3 shows the corresponding validation in terms of Relative Dynamic $S = 2(p_{t,1} - p)/(\rho {W_1}^2)$ (where W_1 is the upstream velocity), across the Relative Chord (x/c). The numerical results obtained using the k-ω SST turbulence model show excellent agreement with the experimental data.

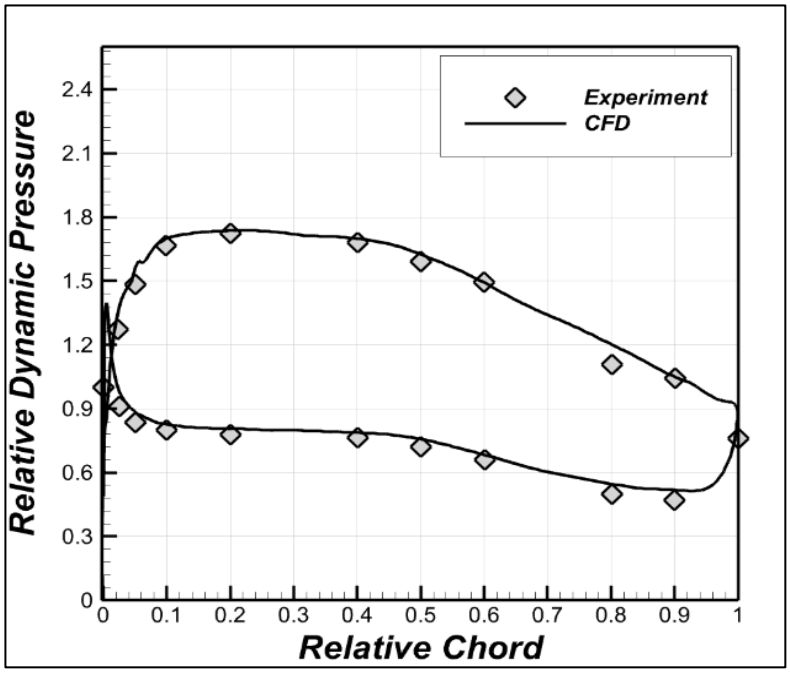

Figure 3: Comparison of measured and calculated relative dynamic pressure for the baseline configuration.
Source: Authors, (2026).

II.2.2 Three-dimensional Cascade

Following the two-dimensional parametric study, the optimal MB configuration was further investigated in a three-dimensional cascade case to capture its effect on corner separation and 3D flow structures. The same airfoil geometry used in the 2D study was retained with the addition of an aspect ratio of AR=1 to maintain a representative three-dimensional configuration.

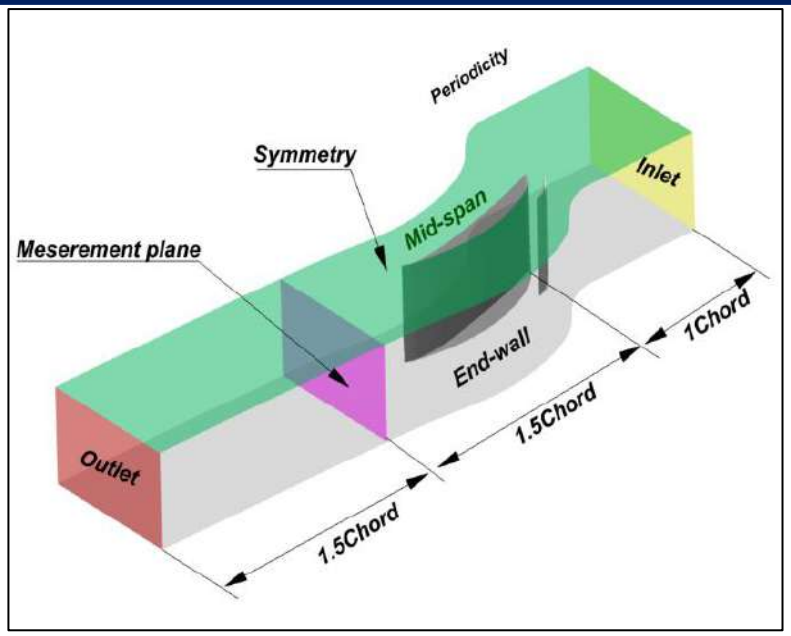

Figure 4: Computational 3D domain and boundary conditions.
Source: Authors, (2026).

Figure 4 illustrates the corresponding computational 3D domain and boundary conditions. By exploiting the symmetry of the geometry and to reduce computational costs, only half of the spanwise domain was modeled with a symmetry boundary condition imposed at the mid-span plane. The performance parameters were evaluated at a downstream location corresponding to 1.5 times the blade chord from the leading edge. Like the 2D computational case, the domain extends one chord length upstream of the leading edge and two chords downstream. The 3D computational grid was generated using Numeca Autogrid 5, employing a fully structured O4H topology (see Figure 5) to ensure high grid quality and low numerical diffusion. Special attention was given to the near wall region, with a first cell height of 1×10^{-5} m, resulting in an average dimensionless wall distance $y+ < 1$ across all solid boundaries. A similar compressor cascade was modeled by Ramzi & AbdErrahmane [17], with full-span configuration using approximately 1 million grid points. However, in the present investigation, since only half of the span was considered, a mesh of about 855.000 points was adopted.

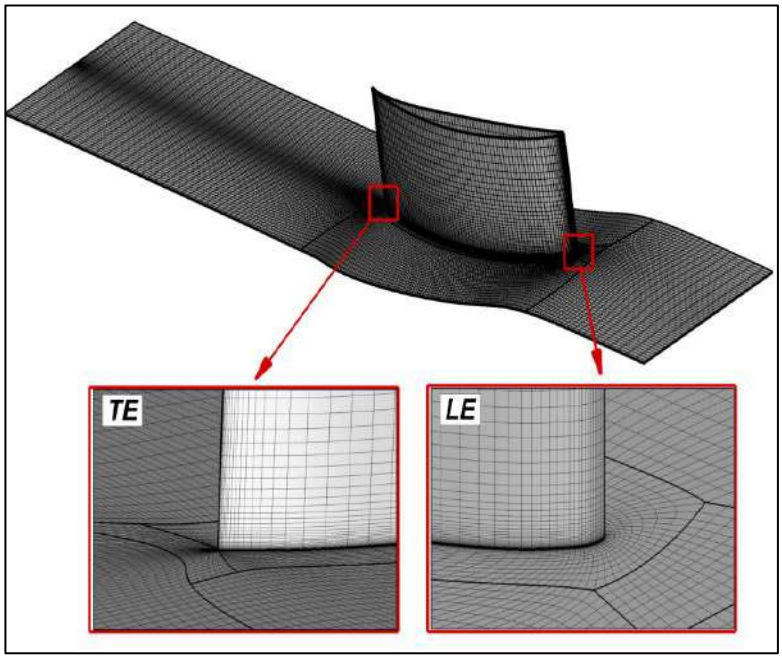

Figure 5: 3D Computational grid.
Source: Authors, (2026).

Direct numerical data of the NACA 65(18)10 cascade with endwall effects are not available, as the original tests were conducted under 2D conditions with endwall boundary layer removal [16]. In order to investigate the effectiveness of the optimal MB flow control on the 3D corner separation, it was necessary to adopt an alternative validation approach. Following the approach adopted by Ref. [17], the present solver was validated through comparison with the experimental data of Takahashi et al. [18], who investigated the 3D flow characteristics of a NACA 65 cascade. The reference cascade was characterized by an aspect ratio of AR=2.3, a solidity of 1.08, with 30.1° and 32.2°, camber and stagger angles, respectively. The experiments were performed at an inlet flow angle of 47.1° and a Reynolds number of 2.2×10^5 based on chord length.

The validation of the numerical model was carried out by comparing the circumferentially mass-averaged TPL across half of the blade span, at a downstream position of 1.5c from the leading edge, with the available experimental measurements. As shown in Figure 6, the numerical prediction follows the experimental trend, with only minor deviations, especially in the corner region. In general, the comparison shows good agreement, demonstrating the accuracy of the numerical setup in capturing endwall boundary layer development and corner separation. Consequently, although the geometry differs from the present cascade, the underlying physical mechanisms were validated. This provides confidence in applying the same numerical methodology to the current 3D configuration (NACA 65(18)10) with micro-blade flow control.

III. RESULTS AND DISCUSSIONS

III.1 SPATIAL LOCATION EFFECTS

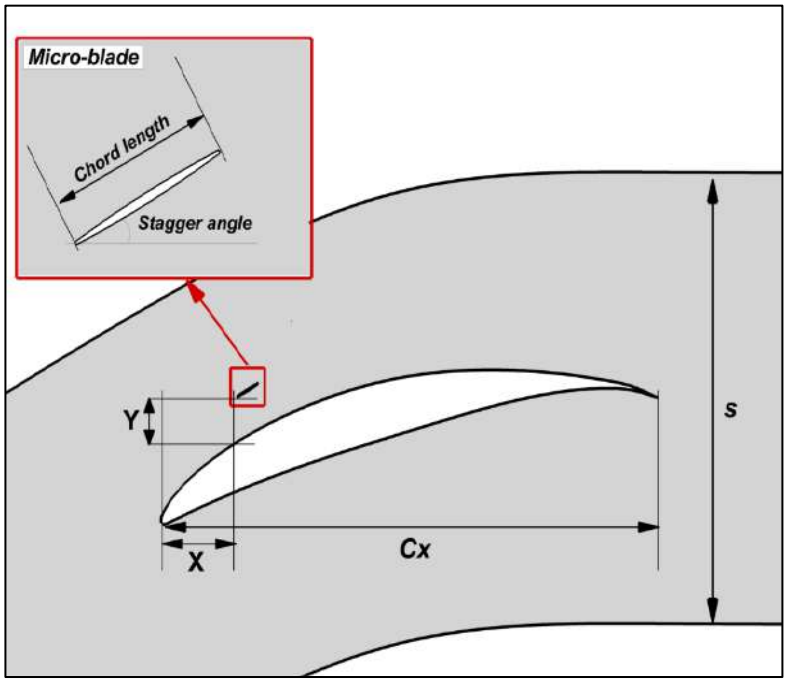

Figure 7: Micro-blade's spatial positions nomenclature.
Source: Authors, (2026).

The first step in the present investigation is to determine the most effective spatial placement of the MB, as mentioned earlier, the initial MB is modeled as a DCA airfoil with zero camber angle; the chord length of the MB is expressed as a percentage of the main blade chord, ensuring a normalized representation. the primary design parameters of the flow control element are listed in Table 2.

Table 2: Initial design parameters of the micro-blade.

Parameter	value
Chord (%)	5
T_{max}/c_{MB}	0.05
Stagger angle (°)	30
Camber angle (°)	0

Source: Authors, (2026).

The parametric study was performed by varying both axial and circumferential locations of the MB under different inlet flow angles, ranging from 40° to 52° with a 2° increment, generating 16 distinct configurations and a total of 112 simulations, ensuring that the influence of spatial locations was captured with sufficient resolution. Figure 8 illustrates all the tested locations; the axial position of the MB (X) was varied from -5% to 40%, while the circumferential (Y) placement corresponded to 10% and 15%. For each configuration, Δ□□□ was evaluated.

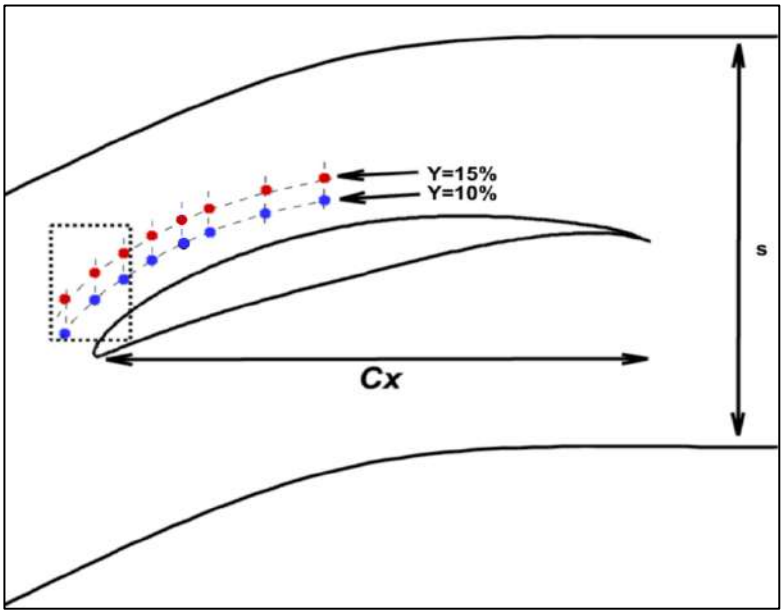

Figure 8: Schematic representation of axial and circumferential positions of the MB configurations.
Source: Authors, (2026).

Figure 9 presents the distribution of Δ□□□ across the whole range of tested inlet flow angles. The Figure shows a high sensitivity to the device's axial placement compared with the circumferential locations. The maximum improvement of Δ□□□ was achieved at 3 axial locations X=-5%, X=0% and X=+5%, it was also reported by Ma & Sun [13] that the optimal placement is consistently near the blade leading edge. The examination of Figure 9 allowed us to delineate an effective range of the MB axial locations (X= -5%, 0%, +5%). To provide a clearer comparison, the Δ□□□ associated with these selected configurations were summarized in a bar chart in Figure 10.

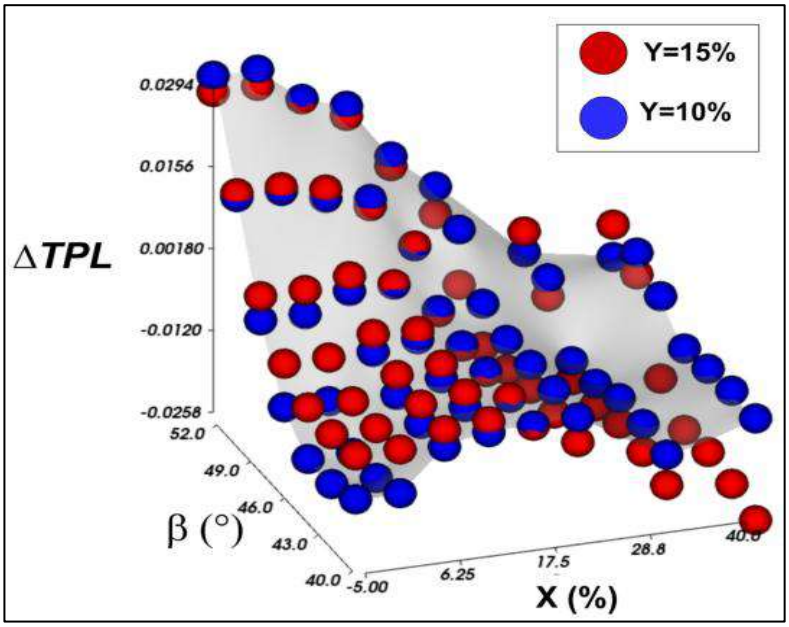

Figure 9: Point-cloud distribution of ΔTPL for Y=15% and Y=10%, versus axial MB's locations in different inlet flow angles.
Source: Authors, (2026).

At inlet flow angles (40° to 48°), the majority of the configurations increase the losses (ΔTPL<0), adding the MB at this range of incidence tends to generate additional losses, the baseline flow at those operating conditions is already separated, but though not yet in a severe way. the extra mixing induced by the MB disturbs the flow, hence, ends up raising the overall losses. At high inlet flow angles (50° to 52°), the flow over the baseline blade is strongly separated due to the severe adverse pressure gradient. Under these conditions, the MB becomes particularly effective, producing positive ΔTPL values and a net reduction in the global losses. However, the influence of the circumferential location is almost identical, with a slight superiority at Y=10%. Regarding axial placement, X=−5% demonstrated the largest improvements in ΔTPL, especially at high β, while its sensitivity to operating conditions suggests that additional checks are necessary. Based on these observations, the Y=10% circumferential position is retained for subsequent analyses.

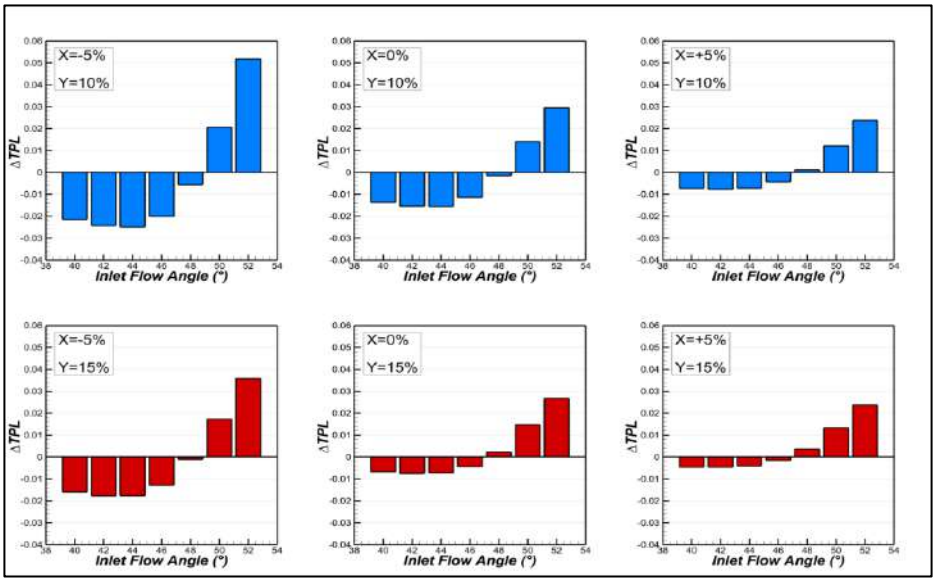

Figure 10: Bar chart of ΔTPL at Y=10% (up) and Y=15% (down) for the three axial position X=-5%, X=0% and X=+5%.
Source: Authors, (2026).

III.2 CAMBER ANGLE EFFECTS

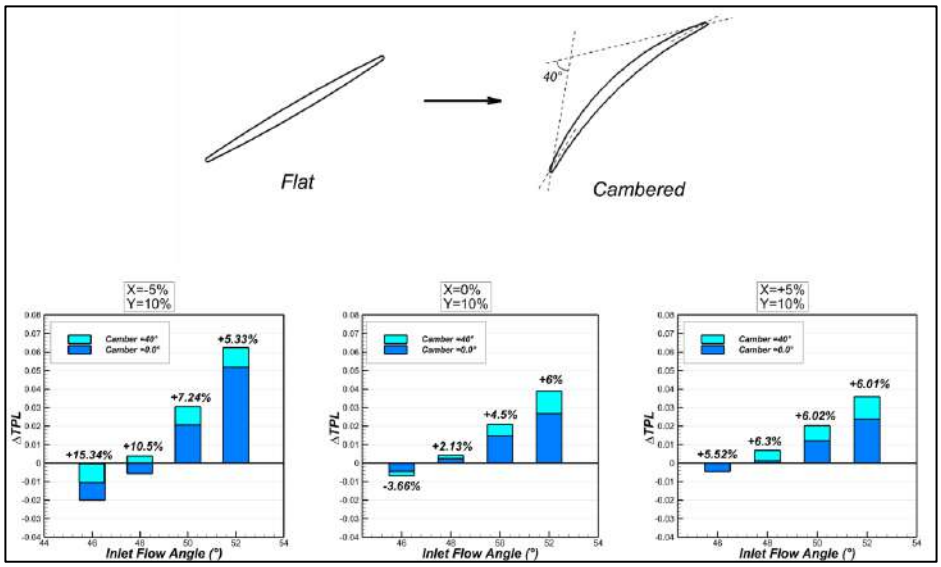

Figure 11: Bar chart of ΔTPL for flat and cambered MB at X=−5%, X=0% and X=+5% across different off-design β.
Source: Authors, (2026).

To further investigate the sensitivity of the device to its geometric characteristics, the effect of introducing a camber angle of 40° to the MB was examined. Figure 11 presents the corresponding sketch (up), and bar chart (down) of the ΔTPL for the three axial positions X=−5%, X=0%, and X=+5%, with and without camber, across off-design inlet flow angles (46° to 52° with 2° increment), the results indicate that the addition of a 40° camber angle consistently enhances the effectiveness of the MB, a remarkable improvement in the ΔTPL across the whole tested range, amplifying the benefic effect observed with zero camber MB. In addition to the TPL analysis, the effect of cambering the MB was further examined through the distribution of the static pressure coefficient (Cp) on the main blade suction side. Figure 12 (left) shows the corresponding Cp curves for the three tested locations at β=52°. The presence of camber introduces a local peak in the Cp, which originates mainly from the concave curvature of the MB pressure suroussmahachelfiface (see Figure 12, right), indicating a local deceleration in the immediate vicinity of the common passage sectional area between the main blade and the MB. On the other hand, the flat MB produces a local pressure decrease (depression) in the same region, unlike the cambered case, the flat MB produces a local acceleration on the main blade suction surface. This is mainly attributed to the convergent-divergent-like channel [19] between the flat MB and the suction side of the main blade.

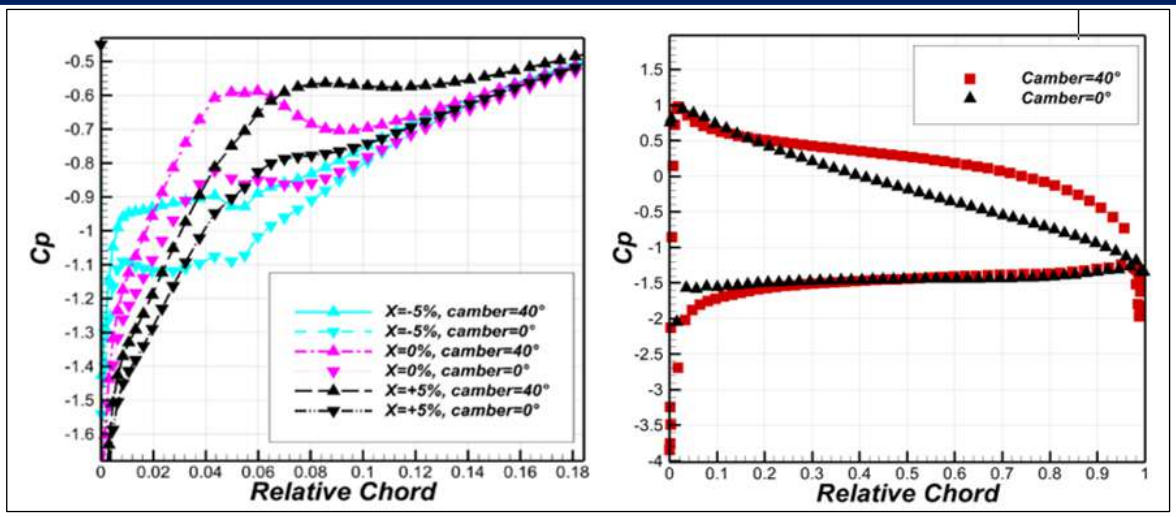

Figure 12: Static pressure coefficient of the main blade suction side (left) and MB (right) at β=52°.
Source: Authors, (2026).

The divergent local pressure features imply different local velocity fields and boundary layer behaviors. The corresponding boundary layer integral parameters were calculated using a MATLAB code. Figure 13 presents the chordwise evolution of the displacement thickness, momentum thickness, and shape factor for the baseline, flat, and cambered MB in two representative inlet flow angles of 46° and 52°.

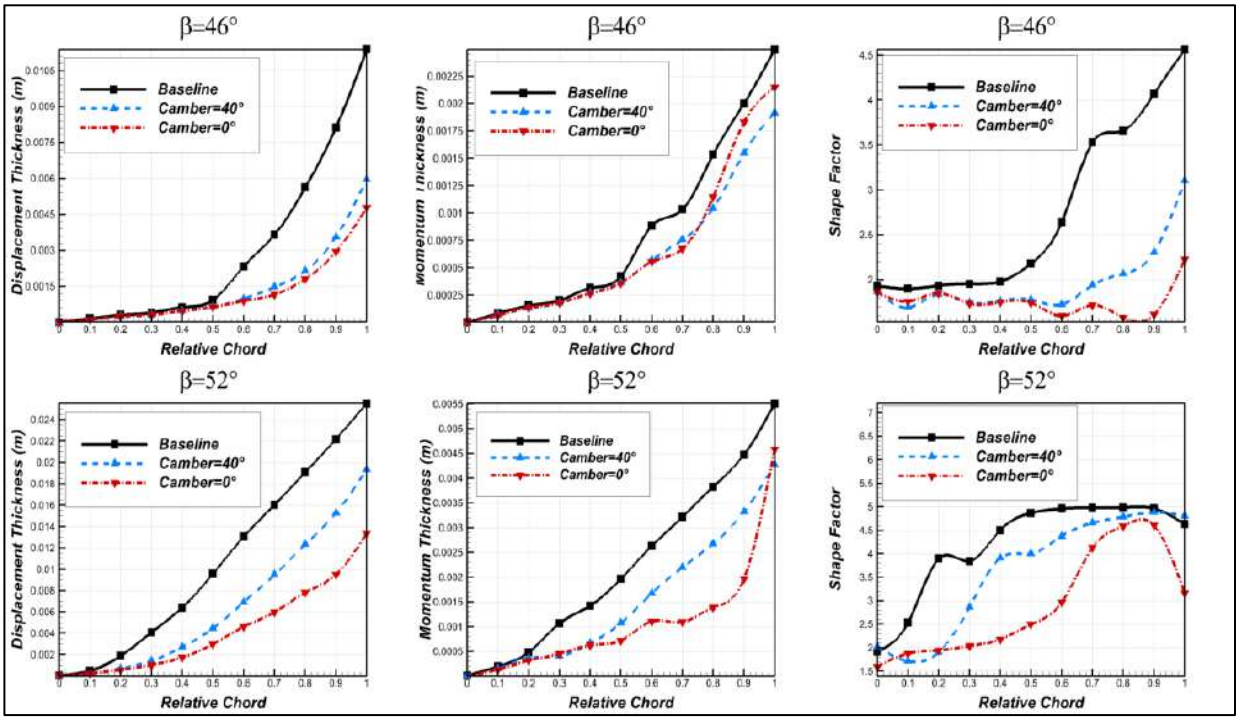

Figure 13: Displacement thickness, momentum thickness, and shape Factor distributions along the suction side main blade at 46° (up) and 52° (down) inlet flow angles for baseline, flat, and cambered MB configurations.
Source: Authors, (2026).

At 46° inlet flow angle, the baseline configuration exhibits the highest displacement and momentum thickness, and consequently a rapidly increasing shape factor at approximately the half-chord station toward the trailing edge. This behavior indicates the beginning of separation at nearly 50% of the chord length, extending to the leading edge. Both the flat and cambered configurations reduce displacement and momentum thicknesses over the entire suction surface, indicating a global boundary layer delay in separation relative to the baseline. This effect is particularly pronounced at 52°, while the baseline configuration experiences a severe boundary layer thickening, both MB cases maintain a much thinner boundary layer. When comparing the two MB designs, at both inlet flow angles, the cambered case shows higher momentum, displacement thickness, and shape factor, in most of the chord stations. The flat configuration demonstrates superior performance; its corresponding shape factor remains consistently lower over a large portion of the chord, indicating a much resistant boundary layer over the whole chord stations, and at different inlet flow angles. This is consistent with the depression reported in the Cp curve in Figure 12, highlighting the ability of the flat MB to entrain higher momentum freestream fluid and sustain a more energized boundary layer. This is further evidenced by the lower shape factor values, which reflect a delayed separation onset and improved boundary layer stability

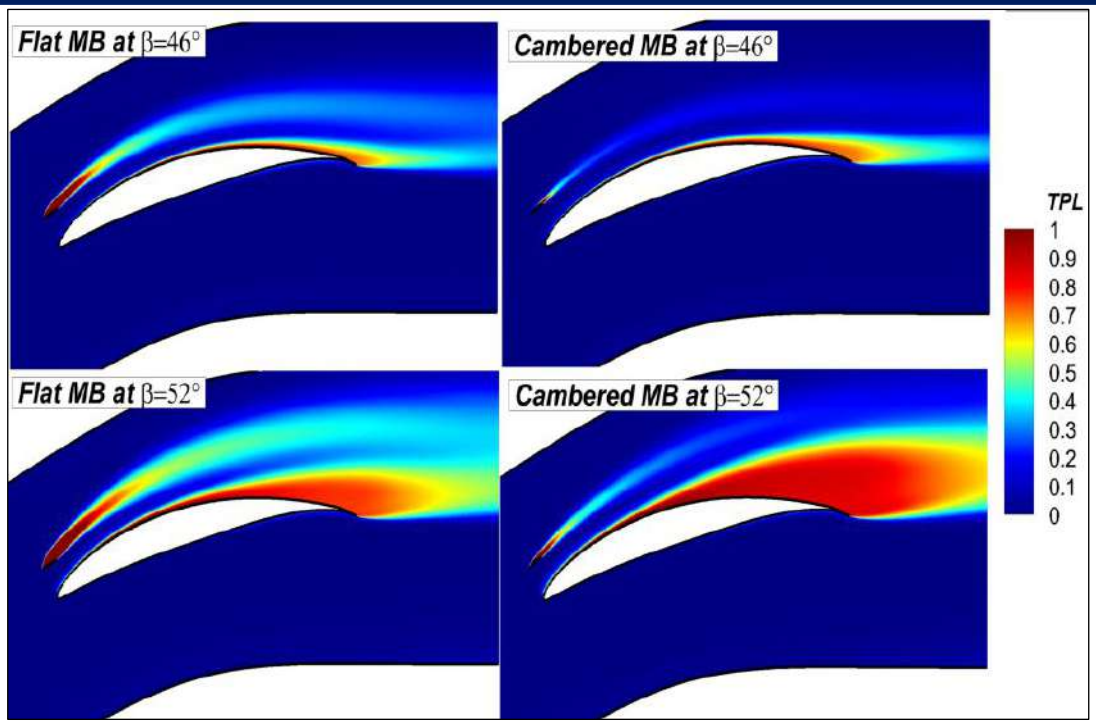

Figure 14: TPL contours for flat and cambered MB at 46° and 52° inlet flow angles.
Source: Authors, (2026).

In parallel, the flat MB, although generating a thinner boundary layer, shows a slightly higher momentum thickness than the cambered case at the trailing edge region, and promotes an early interaction between its wake and the separated boundary layer of the main blade near the trailing edge. This behavior is in agreement with the *TPL* contours shown in Figure 14, where the flat configuration exhibits an enlarged wake region that merges with the separated boundary layer of the main blade suction side, whereas the cambered case shows a more confined wake due to its aerodynamic shape (Figure 15). Hence, the superior global performance of the cambered MB comes not from its immediate effect on the boundary layer, but from its capacity to maintain both boundary layer stability and less wake losses. To further refine the optimal MB design, and building on this result, the next section examines the combined effect of camber angle and maximum thickness of the MB.

III.3 MAXIMUM THICKNESS AND CAMBER ANGLE COMBINATION EFFECTS

The influence of MB camber and maximum thickness on the cascade losses was evaluated for three element thicknesses: thin =2.5%□□□, medium =5%□□□, and thick =10%□□□ at four representative off-design inlet flow angles (□= 46°, 48°, 50°, 52°). As illustrated in Figure 16, thinner elements produce lower TPL while thicker elements give the largest losses. In parallel, increasing camber generally reduces TPL, with the effect becoming more pronounced at higher incidence (largest reductions at β =50°, 52°). At moderate incidence (46° to 48°), the TPL–camber curves show a shared minimum corresponding to 30° and 40° camber angles, except for the medium thickness MB reaches the lower minimum with 50° camber angle at β=48°, whereas at high incidence (50° to 52°) the curves decline more sharply and larger camber continues to be beneficial. Although the thin MB attains the best minima in most cases, it exhibits greater sensitivity to camber angle, especially at β=48°. While the medium thickness MB yields TPL values close to the thin case, the thick MB configuration is systematically inferior.

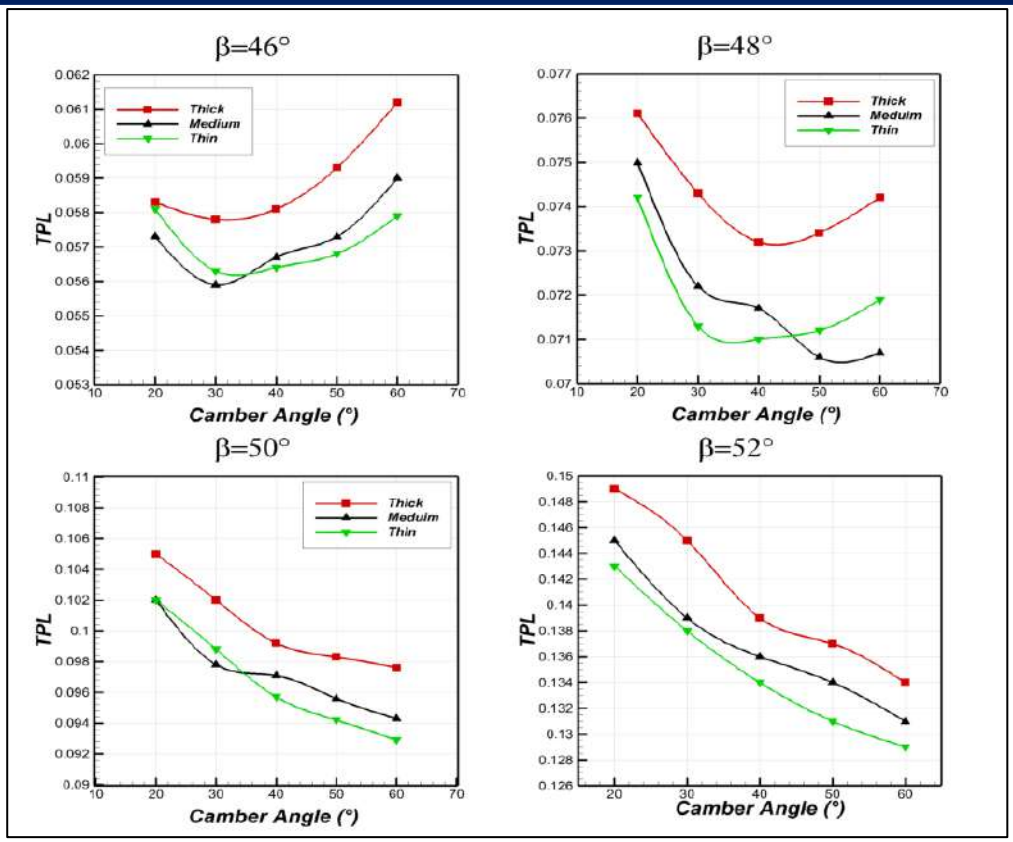

Figure 16**:** TPL versus camber Angle for Three Micro-Blade Thicknesses (thin, medium, and thick) at Different Inlet Flow Angles.
Source: Authors, (2026).

The results of the camber sweep highlighted two configurations of particular interest: the thin MB with 40° camber, which demonstrated the lowest TPL considering the whole tested β range, and the medium with 50° camber, which achieved comparable reductions in global losses while maintaining a more stable response over the tested incidences. Figure 17 shows the static pressure rise coefficient (Cp') for the two cases; the medium configuration provided a modest but clear advantage; the additional MB loading provided by the higher camber angle within the medium MB case has contributed to the improvement of the overall Cp'. Considering this complementary improvement in static pressure rise and both aerodynamic efficiency and practical considerations (mechanical resistance), the medium configuration with 50° camber angle was selected for further optimizations.

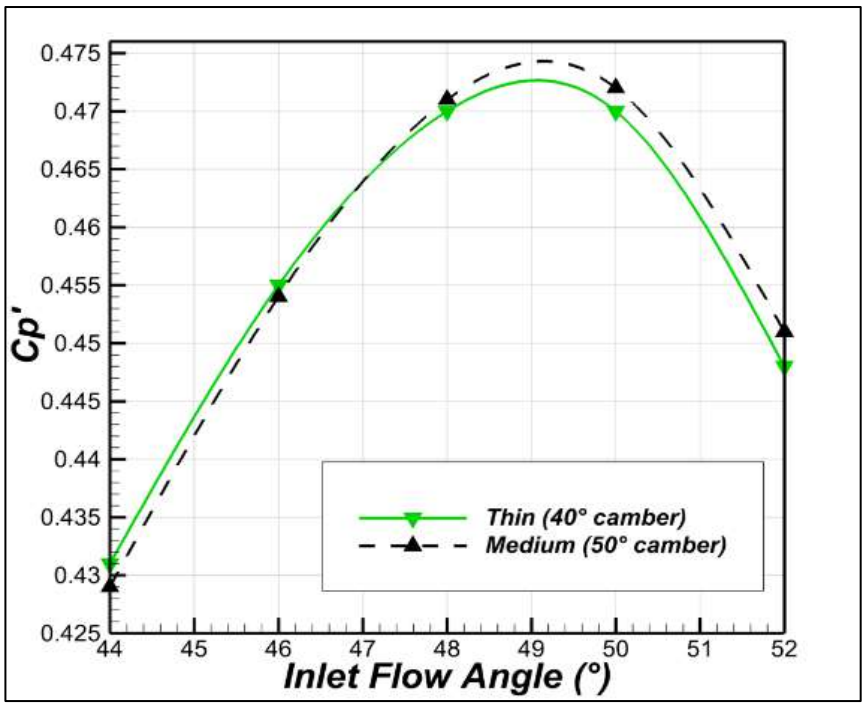

Figure 17: Static pressure rise coefficient versus inlet flow angle for thin and medium micro blades with 40° and 50° camber angle, respectively.
Source: Authors, (2026).

III.4 STAGGER ANGLE EFFECTS

Following the analysis of thickness and camber effects, attention is now directed to the stagger angle. This parameter plays a critical role in governing flow turning and pressure rise characteristics. Figure 18 illustrates, for different inlet flow angles (β = 46°, 48°, 50°, 52°), how the Cp' and TPL vary with the MB stagger angle. for most of the tested β, Cp′ attains a maximum in the mid-stagger range (40° to 45°); at the same time, TPL exhibits a broad minimum in a similar stagger angle range. Beyond this band, the performance parameters deteriorate markedly, especially at β = 52°. The mid-stagger positions appear to best align the MB with the local flow, enhancing useful pressure rise while wake and mixing losses are minimized. A very large stagger produces boundary layer separation on the MB pressure side, causing adverse wake and blockage effects that increase TPL and reduce Cp'.

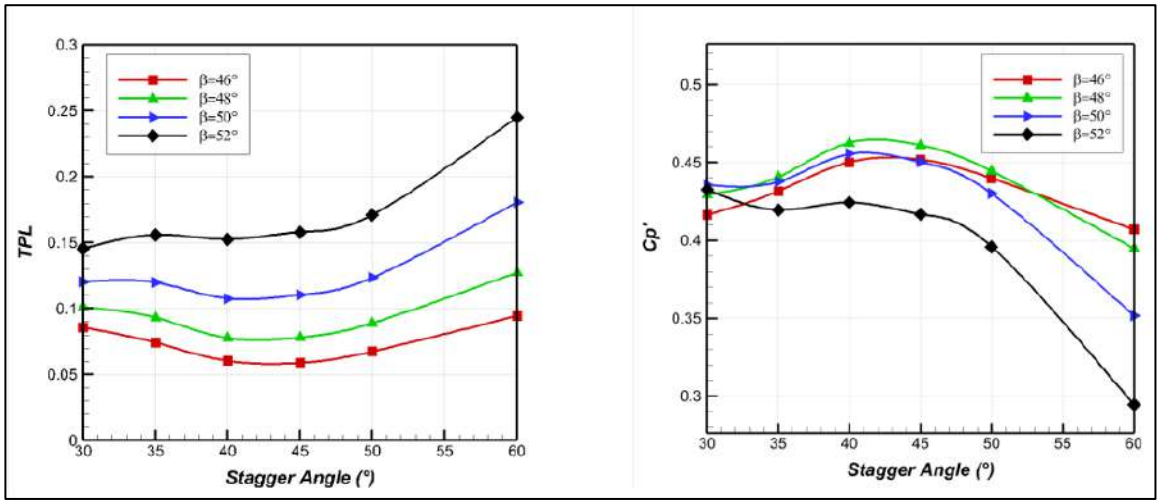

Figure 18: Variation of TPL (left) and Cp' (right) with MB's stagger angle for different β.
Source: Authors, (2026).

Using the selection criteria of maximizing static pressure rise Cp′, minimizing TPL, and preserving robustness across tested incidence angles, the mid-stagger band (40° to 45°) is the clear candidate. Between 40° and 45°, the plots show only small differences: 40° tends to produce slightly lower TPL and gives marginally higher Cp' across the majority of studied β. Therefore, as a conservative and robust choice, we select stagger = 40° as the preferred setting.

III.5 CHORD LENGTH EFFECTS

The influence of MB chord length on cascade losses is examined by comparing the TPL across different inlet flow angles. As shown in Figure 19, the chord is expressed as a percentage of the main blade chord. For all studied incidences, TPL decreases with increasing MB chord up to an intermediate size, where the TPL attains its minimum value observed in the range of 20% to 25% of the main blade chord, with the 20% case providing the lowest TPL across all incidence angles except for □ = 52°.

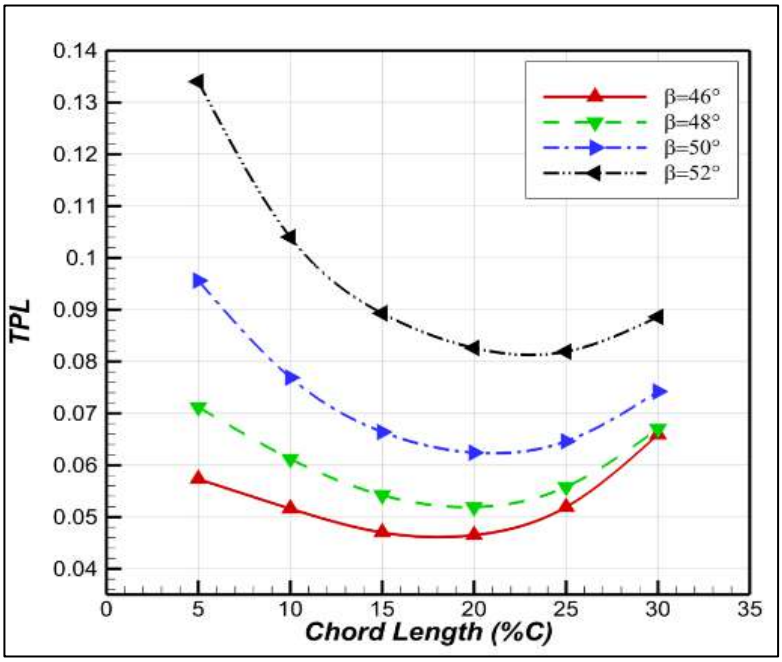

Figure 19: TPL versus micro-blade chord length with different off-design β.
Source: Authors, (2026).

To better understand these trends, it is necessary to consider the balance between the interaction area, boundary layer energization, and blockage related to the MB size effects. At low chord lengths (5%*c* to 10%*c*), the MB offers a limited interaction area, which proves insufficient boundary layer-MB interactions resulting in relatively high TPL values. Increasing the chord to intermediate values (15%*c* to 25%*c*) enhances the exchange of momentum between the freestream and near-wall flow, which contributes to the boundary layer energization without providing excessive blockage and wake losses. This compromise explains the observed minimum in TPL. Beyond this optimum range, larger chords (>25%) act as geometric obstacles, intensifying the local pressure gradients, the associated blockage and wake thickening outweigh the benefits of momentum exchange, leading to TPL rise. The evaluation of the velocity contour distributions with and without MB provides further insight into the mechanisms by which the MB enhances aerodynamic performance. As illustrated in Figure 21, it is evident that the suction side boundary layer for the baseline case experiences progressive thickening with increasing inflow angle (see Figure 20), ultimately leading to extended flow separation and the development of large low momentum regions. This effect is particularly pronounced for β = 50° and β = 52°, where massive separation occupies a significant portion of the suction surface, and the downstream wake region exhibits a large momentum deficit.

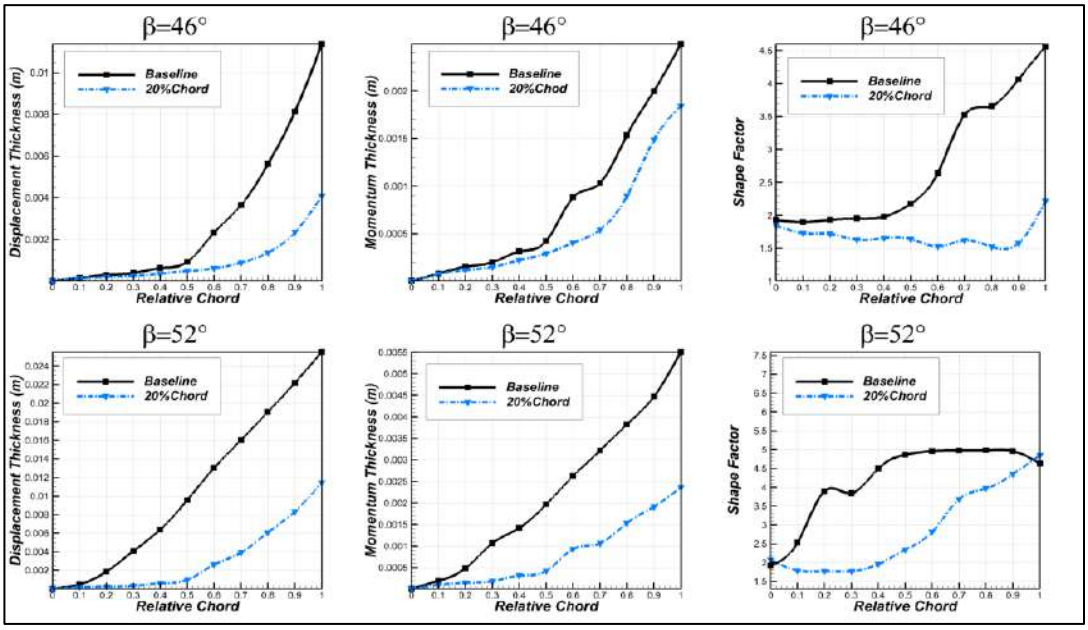

Figure 20**:** Displacement thickness, momentum thickness, and shape factor for Baseline and optimal flow control configuration: top β = 46°, bottom β = 52°.
Source: Authors, (2026).

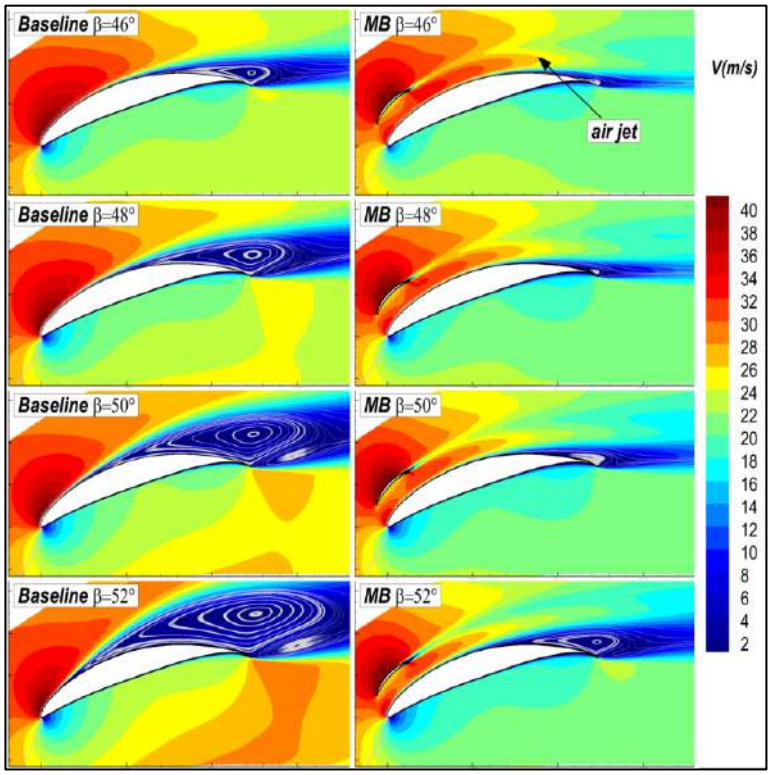

Figure 21**:** Velocity contours for the baseline (left) and controlled (right) cases at different inlet flow angles**.**
Source: Authors, (2026).

The controlled cases with the MB reveal a substantially modified flow field; the acceleration region near the main blade leading edge separates into two parts, allowing the high momentum fluid to develop and entrain into the boundary layer, building an air jet barrier preventing the boundary layer growth and separation [12]. The beneficial effect of this mechanism is manifested in the delayed separation onset. At high inlet flow angles (50° and 52°), where the baseline configurations exhibit massive separation, the MB cases maintain attached flow over a much longer chord extent, with thinner wakes and reduced low velocity regions downstream.

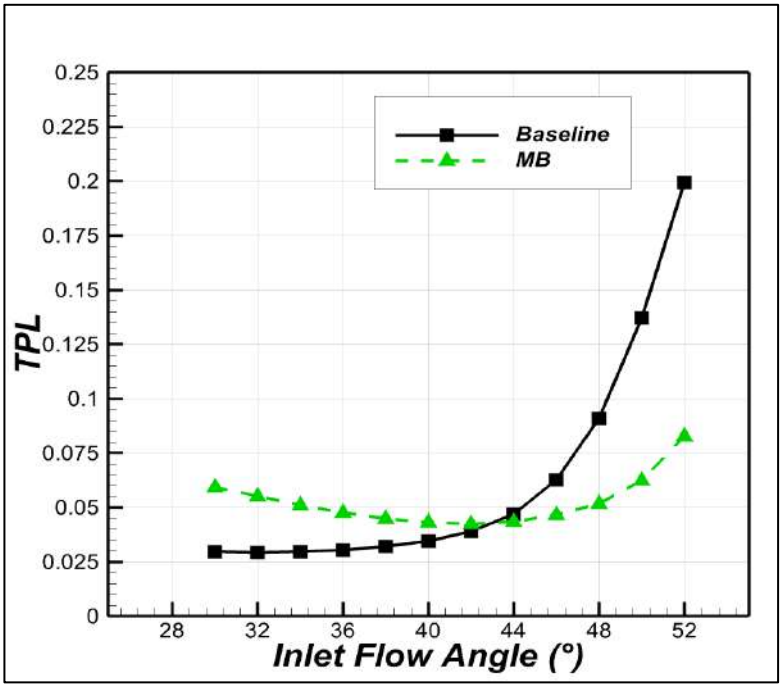

Figure 22**:** TPL for the baseline and optimal MB under design and off-design inlet flow angles**.**
Source: Authors, (2026).

Figure 22 compares the TPL variation with inlet flow angles from 30° to 52° for both baseline and optimal MB configurations. At low inlet angles (below 44°), both configurations exhibit relatively small loss coefficients, indicating attached and stable flow conditions. However, the MB case shows slightly higher TPL values in this range. This penalty is attributed to additional losses generated near the micro-blade pressure side, where its boundary layer is largely separated due to the relatively high stagger angle. As the incidence increases beyond 44°, the performance difference between the two configurations becomes beneficial. While the baseline configuration experiences a sharp rise in TPL, indicating stall onset, the MB configuration maintains much lower losses. This behavior demonstrates the device's strong capability to delay separation and stabilize the flow under near-stall conditions. Notably, the largest improvement is observed at the stall condition when β=52°, the optimized micro-blade achieves a 55.56% reduction in TPL compared to the baseline. This confirms that the optimized geometry and placement effectively mitigate boundary layer separation at critical operating points. Overall, the trend highlights the incidence sensitivity of the device; while it may introduce penalties at nominal conditions, it provides aerodynamic benefits under off-design regimes, thereby extending the compressor's stable operating range.

III.6 OPTIMAL MB EFFECTS ON 3D FLOW STRUCTURES

Figure 23 compares the pitchwise mass-averaged TPL distribution across the half-span at a plane located 1.5 chords downstream of the main blade leading edge at different inlet flow angles. At the nominal design angle (= 32°), the configuration produces a slight increase in losses. This behavior is consistent with the optimization basis; the MB geometry was designed to counteract flow degradation occurring under off-design conditions, where the effects of separation and secondary flows are more significant.

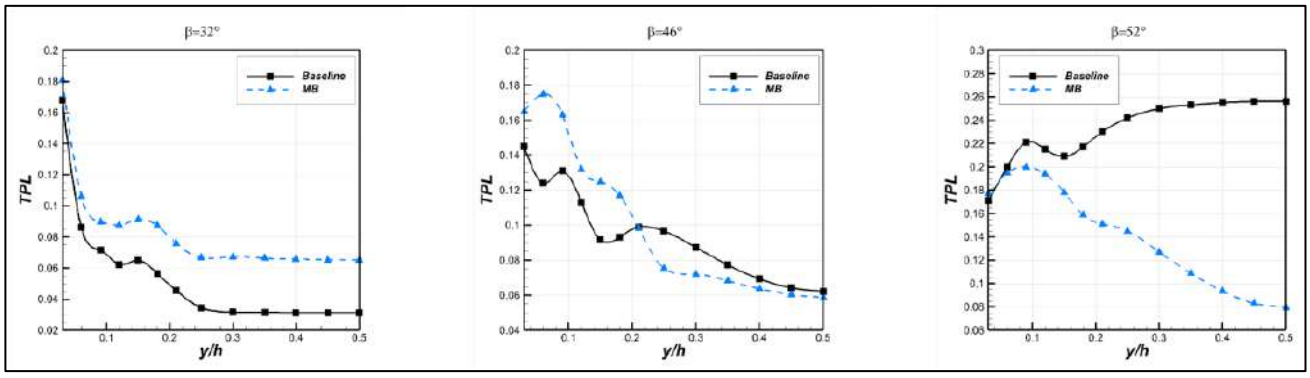

Figure 23: Pitchwise mass-averaged TPL across half-span of the MB and baseline cases for different β.
Source: Authors, (2026).

The observed behavior confirms that the device's effectiveness is very sensitive to the inlet flow angle. Figure 24 shows the TPL contours at the measurement plan. The MB configuration at nominal inlet flow angle produces a broader wake region and slightly higher overall losses compared with the baseline (BSL) case. The relatively high stagger and camber angles promote a pressure side boundary layer separation that forms on the MB itself, generating a large wake extent. Nevertheless, the losses near the endwall suction side corner remain marginally greater than those obtained of the baseline configuration, indicating that the control device does not significantly affect the corner separation at this operating point. At β = 46°, the TPL contours show that, once the MB is introduced, the region of highest loss becomes concentrated much closer to the endwall, while losses decrease above roughly 20% span (see Figure 23), the net benefit peaks toward mid-span, and the wake related to the MB is significantly reduced. The corresponding limiting streamlines and axial velocity iso-surfaces at the same incidence are shown in Figure 25; the suction-side topology directly supports the early observation; the MB case displays a more compact corner separation compared with the baseline, indicating that the MB reduces the corner separation spanwise extent. At β = 52°, the baseline case shows a very large separation (Figure 25); the MB case still exhibits a large separation region, but it appears more compact, and the surrounding streamlines show a different topology than the baseline. The relative improvement produced by the MB is largest at high incidences; the MB reduces the separated area most visibly under those conditions. At the highest incidence (52°), the MB still alters the topology but does not eliminate the dominant separation seen in the baseline.

IV. CONCLUSIONS

This work combined an extensive two-dimensional parametric study with targeted three-dimensional calculations to evaluate micro-blade passive control in a NACA 65(18)10 linear compressor cascade. The influence of the MB's spatial positioning on the cascade performance is strongly affected by its axial position, whereas the circumferential location has a comparatively minor influence. The 2D optimization study on camber angle highlights a critical balance between boundary layer energization and wake losses. Local diagnostics show that the flat MB modifies the static pressure distribution near the main blade LE, causing a local acceleration, a fuller near-wall profile, and reduced momentum thickness compared with both the baseline and cambered MB. Crucially, Cases that appear favorable by locally thinning the boundary layer may still produce stronger wakes, ultimately raising the TPL. Small elements fail to provide sufficient momentum exchange, while large elements act as obstacles, causing strong wake losses. A micro-blade staggered at 40°, a chord length of 20%*c* with a medium maximum thickness (5%□□□) and 50° camber, has delivered the best balance between energizing the suction side boundary layer and avoiding excessive blockage

The controlled cases with the MB reveal a substantially modified flow field. The acceleration region near the main blade leading edge separates into two parts, allowing the development and entrainment of high momentum fluid into the main blade suction side boundary layer. The 3D cascade simulations reinforced the conclusions of the 2D analysis, revealing a penalty in losses at the nominal design incidence, and the beneficial effects of the device become pronounced at off-design incidences, indicating a strong sensitivity of the MB's performance to the inlet flow angle. Under off-design conditions, the MB weakens the corner separation and reduces its spanwise extent. The residual high losses are shifted to the endwall region. Future investigations should focus on a more detailed three-dimensional analysis to better capture the complex secondary flow interactions and endwall effects. In particular, determining the optimal spanwise distribution of the MB will be essential to fully exploit their potential for corner flow control and overall loss reduction.

ABSTRACT

The response surface methodology (RSM) was employed to ascertain the most favorable operating conditions for the transesterification process of canola oil. These conditions encompassed the stoichiometric ethanol-to-oil ratio, reaction temperature, and reaction duration, all of which contributed to the maximization of biodiesel output. With an R2 value of 91.43%, the RSM model was statistically significant. Fourier transform infrared spectroscopy (FTIR) and gas chromatography (GC)-mass spectrometry confirmed that the majority of triglycerides were formed as methyl ester. When compared to pure petro-diesel and biodiesel blends, the performance and emissions of the biodiesel produced were found to be promising in a diesel engine.

I. INTRODUCTION

A global solution to the ever-increasing demand for energy is urgently required. Sulfur dioxide, carbon dioxide, particulate matter, and other gas emissions from burning fossil fuels are a major source of pollution, and these resources are finite [1]. The renewable alternative biodiesel, made from canola oil, is becoming more popular for use in diesel engines. Vegetable oils used for frying produce copious amounts of Canola Oil, which face disposal challenges. The production of biodiesel using them has the advantage of being both cost-effective and environmentally conscious [2]. Transesterification, the prevailing method employed in biodiesel production, entails catalysed chemical reactions between alcohol and vegetable oil [3], [4]. The majority of the biodiesel production budget goes into buying the essential raw materials. Biodiesel production is able to maintain its low cost by utilising inexpensive raw materials that comprise fatty acids.

Things like animal fats, and vegetable oil by-products fall under this category. The most popular and least expensive raw material for biodiesel production is CO, followed by palm oil, jatropha oil, and soy bean oil [5], [6]. Particulate matter, unburned hydrocarbons, and carbon monoxide are all reduced when biodiesel is burned compared to petrodiesel fuel. Reduced emissions of sulphur dioxide are a side effect of burning biodiesel, which is derived from natural sources and hence contains less sulphur [7], [8]. Various scholars have put forward mathematical models that aim to optimise the circumstances for transesterification. The authors [9] utilized ANN and RSM as mathematical models to predict the biodiesel yield. The authors [10] ,[11] ANN model was used to manufacture biodiesel from used cooking oil [12].

This study aimed to maximize the biodiesel yield from COs by studying the main factors of the transesterification reaction using the RSM approach. It highlighted the process's benefits, shortcomings, and optimal circumstances. A comparison was made between the biodiesel's properties and the European standard. The quality of biodiesel generated from CO was assessed and investigated its effects on engine performance. We looked at the proposed flow sheet and the features of the engine exhaust pollutants.

II. MATERIALS AND METHODS

A combination of canola oil, potassium hydroxide, phenolphthalein, distilled water, high-purity sodium hydroxide, ethanol, and canola oil were used in this experiment.

II.1 FEEDSTOCK PRETREATMENT

CO needs to be disposed of because it includes certain contaminants.

1) The oil is first filtered by screening it to eliminate any solid particles.
2) The leftover solids in the oil are settled after 24 hours of filtering by letting it settle in the tank.
3) To get rid of any remaining debris or particles in the oil, a second filtering process is employed.
4) For 30 minutes, the oil is heated to 80°C in order to evaporate any moisture.

II.2 BIODIESEL PRODUCTION

The transesterification reaction was used to produce biodiesel. This was carried out in a 500 mL conical flask with 300 g of CO in a laboratory-scale batch method. The experimental design dictated that the alcohol ratio be adjusted in relation to the time (t), temperature (T), and stoichiometric ratio (S) for each run [13], [14]. The proportion of NaOH supplied to each sample was determined by its free fatty acid (FFA) content, and all of the samples were mixed using a magnetic stirrer set to 250 rpm.

II.2.1 FABRICATION OF ETHANOL CATALYST SOLUTION

The proportion of FFA was used to alter the ethanol to NaOH ratio: One weight % oil was used as a catalyst when the free fatty acid concentration was less than 1%; when the free fatty acid concentration was greater than 1%, the catalyst was [% FFA] 0.144 plus 1% [15].

II.2.2 REACTION CONDITIONS

A mechanical stirrer was used to mix the oil with the ethanol catalyst solution at 250 rpm until the reaction was complete, after the necessary temperature had been set. The variables that were examined included time, stoichiometric ratio, and temperature [16], [17]. Table. 1 shows the ranges of these variables.

II.2.3 TRANSESTERIFICATION REACTION RESULTS ANALYZED STATISTICALLY

The experimental Statistical Design-Expert 11.1.2 Box-Behnken approach was implemented in order to optimise the transesterification process. To determine the quantity of runs, employ the subsequent formula [18], [19]:

$$N=2k(k-1)+ C_0 \quad (1)$$

C_0 constant no of trails at average conditions
N no of trails
k no of variables.

The mixture was funneled to separate the reactants once the reaction was finished and then permitted to sit for 24 hours. Because of this, the crude ester phase and the glycerol phase were able to separate. Table. 1 displays the values selected for every factors.

Table 1: Experimented parameters.

Factors	Minimum.	Midpoint	Maximum
Time (t)	40	60	80
Stochiometric Ratio (S)	1:4	1:6	1:8
Temperature (T)	30	60	90

Source: Authors, (2026).

While the glycerol was emptied from the bottom of the separating funnel, the container containing the biodiesel crude ester remained unchanged. Following this, the crude ester (biodiesel) underwent two washes using heated water containing 50 vol % biodiesel at 60°C until the formation of two distinct layers became apparent [20], [21]. At eliminate any remaining moisture, the biodiesel was dried in a drier set to 110°C for a duration of thirty minutes.

III. RESULTS AND DISCUSSIONS

Table 2 displays the outcome of the statistical analysis. Time (t), temperature (T), and stoichiometric ratio (S) are the three variables under investigation, and their interplay can be investigated using statistical design analysis.

Table 2: Design of experiments.

Run	t [min]	T [°C]	S	Conv. [wt %]
1	60	60	6	96.79

Source: Authors, (2026).

In order to ascertain the impact of altering the S on the biodiesel yield, the researchers calculated t and T while subjecting it to its minimal, maximal, and mean values. A larger yield was also achieved by increasing the stoichiometric ratio, particularly when the reaction was allowed to run for the maximum period of time at a low temperature of 30°C (80 min). The effects of temperature T on reaction time t and stoichiometric ratio S variables were studied across a range of lowest, maximum, and average values to assess biodiesel synthesis. At the maximum S of alcohol to oil (8:1) and within the designated reaction period, the yield can be enhanced by lessening the T to either its minimal of 30°C or its mean of 60°C. The inverse proportionality remains unaffected by temperature variations (80 min). The two variables, along with the S and T, demonstrated a direct proportional relationship with the biodiesel production, according to an examination of the effects of altering t to its minimal, maximal, and mean values.

An approach to augmenting the yield involves extending the duration of the reaction. The best yield is achieved with an 80-minute t, a feed T of 30°C, and a high S of 8:1 alcohol to oil. To plot every testing outcome, a 3D cube is utilized (Figure 1). With every point situated on its periphery, the Box-Behnken pattern is unmistakably spherical. In the Box-Behnken design, each variable's upper and lower limits define a cubic zone where no points are situated at its corners. The reaction yield-determining three parameters are shown along the X-axis by the minimum value of t, the Y-axis by the maximum value of T, and the Z-axis by the maximum value of the S between the alcohol and oil T. According to the cubic model, the optimal conditions for achieving a maximum yield of 98.22% include an 80-minute t, an 8:1 S, and a minimum T of 30°C.

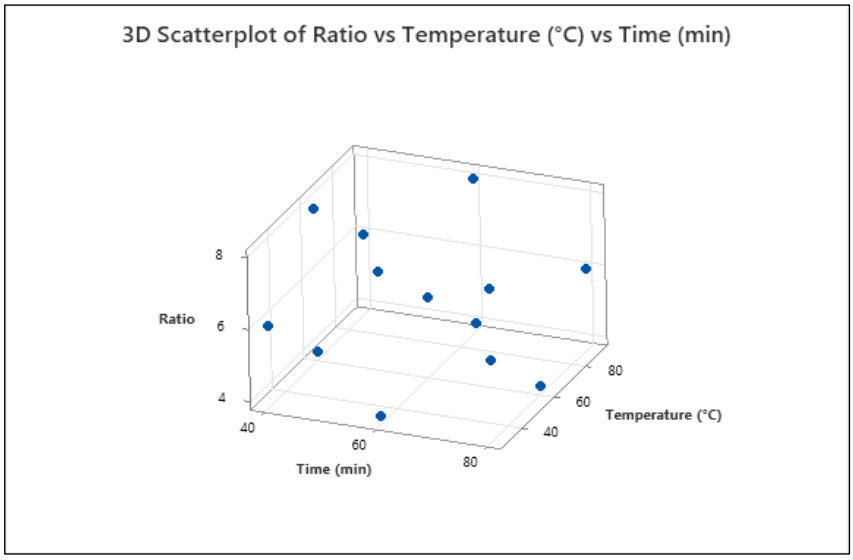

Figure 1: 3D graph depicting the outcomes of canola oil biodiesel production.
Source: Authors, (2026).

The minimal yield achieved was 82.15 %, as seen in the top right forward-facing edge of the cubic model. This was accomplished at a T of 90°C, a t of 80 minutes, and a low S of 4:1. The projected cubic model possesses a statistically significant R2 value of 91.43 % and a P-value below 0.0001. Utilizing a S of 8:1, a maximum biodiesel recovery of 98.22% was achieved in 80 min at 30°C during the reaction. In order to validate the results, five runs were conducted under the parameters previously indicated. The findings indicated that the average recovery of biodiesel was 95.66 %, with a standard deviation of 1.974 %. Since the margin of error did not go beyond 2.6%, this demonstrates that the proposed model is valid.

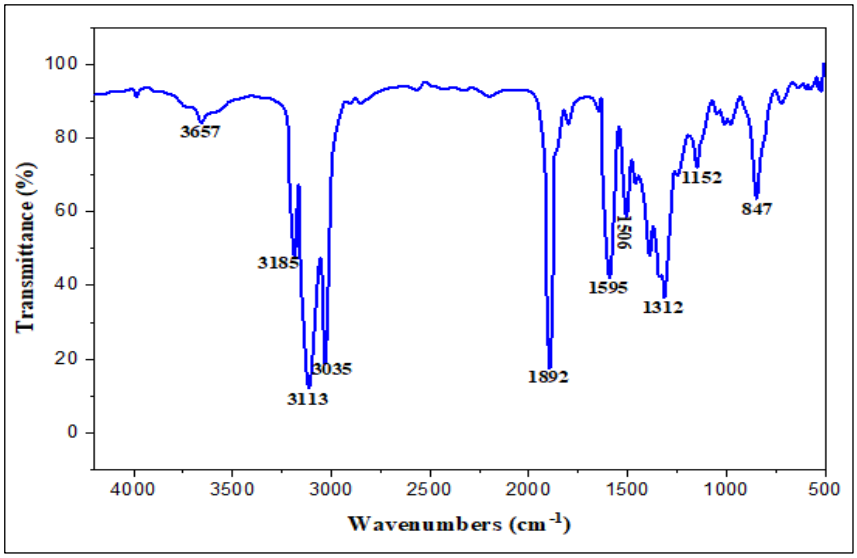

Figure 2: FTIR analysis.
Source: Authors, (2026).

As demonstrated in Figure 2, the CO biodiesel sample was compared to a standard sample and described using FTIR. The existence of the following biodiesel properties peaks was observed in the first sample, as shown in Fig 2. There were stretching absorption peaks at 3657, 3185, and 1892 cm^{-1} for OH, =CH, and C=O, respectively. There were two maxima for the stretching vibrations of the -CH2 groups: one at 3113 cm^{-1} and the other at 3035cm^{-1} . The C-O-C stretching vibration absorption maxima at 1152 and 1312cm^{-1} were determined to be anti-symmetric and symmetric, respectively, according to reference [22], [23]. In Table 3, you can see the biodiesel characterization results.

Table 3: Specification of results.

Properties	Units	Optimal sample	European biodiesel standard
Flash point	[C]	92	> 90
Calorific value	[MJ kg^{-1}]	40.49	38.31
Density at 15 C	[kg m^{-3}]	882.5	870–900
Acid range	[mg KOH/g]	0.133	0.6
Viscosity at 40°C	[mm^2s^{-1}]	4.40	3.6–5.2
Sulfur	[mg kg^{-1}]	0.004	10

The study employed a TG WAX-MS direct capillary column equipped with a 0.3 mm ± 0.25 mm film thickness and a gas chromatography to determine the biodiesel sample's chemical arrangement. Following three minutes of holding at 90°C, the oven was progressively heated to 300°C for 24 minutes at a rate of 15°C per minute. The data confirming the synthesis of methyl ester from the majority of triglycerides, which is pertinent to biodiesel, are presented in Table 4.

This study examines the efficiency and pollution levels of a diesel, CO biodiesel, and blended biodiesel engine that is single-cylinder, four-stroke, air-cooled, and direct-injection (B25, B50, and B75, where B25, e.g., means 25 % biodiesel Performance and emission parameter results are founded upon research conducted on several factors including air-fuel ratio (AFR), volumetric efficiency (VE), exhaust gas temperature (EGT), thermal efficiency (TE), specific fuel consumption (SFC), and concentrations of HC, CO, O2 and CO2 emissions [24], [25].

The average value after running each run three times we recorded. Less than 0.25 was the standard deviation. Figure 3 shows the specific fuel consumption of biodiesel, mixed biodiesel, and Petro diesel in relation to the brake power of engine. As the engine load increases, it falls. Samples of biodiesel and Petro diesel had the greatest and lowest specific fuel consumption values, respectively. Typically, as the percentage of biodiesel increases, the particular fuel consumption also rises. The reason for this is because biodiesel and its mixes have a higher viscosity and a lower heating value than Petro diesel. When operating at full load, the specific fuel consumption values for B100, B75, B50, B25, and D100 were 0.59, 0.66, 0.59, 0.58, and 0.49, respectively [26].

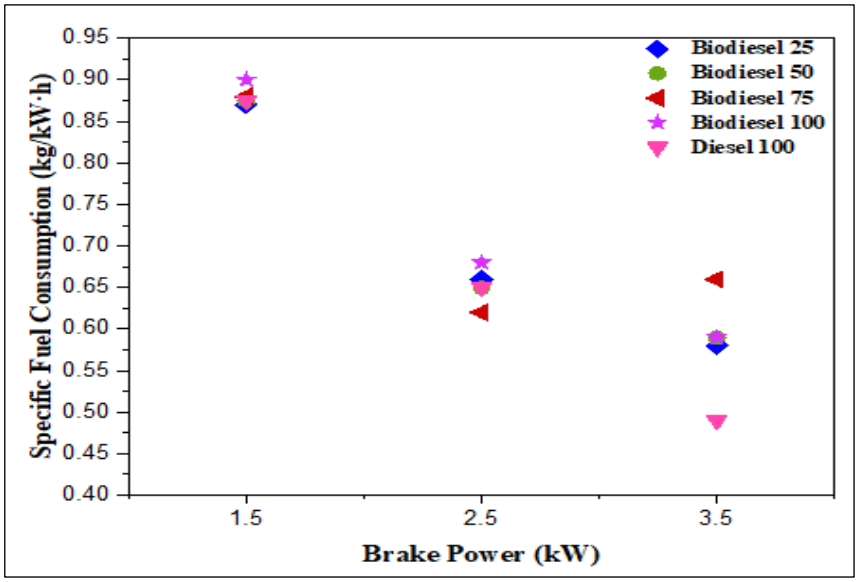

Figure 3: Comparison of SFC with engine load for various composition of diesel.
Source: Authors, (2026).

Figure 4 shows the relationship between the engine's braking power and the thermal efficiency of biodiesel, mixed biodiesel, and petrodiesel samples. For all fuels, it rises as engine load increases. Increasing the amount of petrodiesel in each sample improves thermal efficiency because biodiesel has a lower calorific value than petrodiesel and its ignition delay is smaller, causing combustion to begin before the top dead centre. Because of this, the engine's thermal efficiency drops because compression work and heat loss are both increased. Maximum load operation yielded thermal efficiency values of 22.2 % for B100, 16.66 % for B75, 20.39 % for B50, 22.42 % for D100, and 24.64 % for B25 [27].

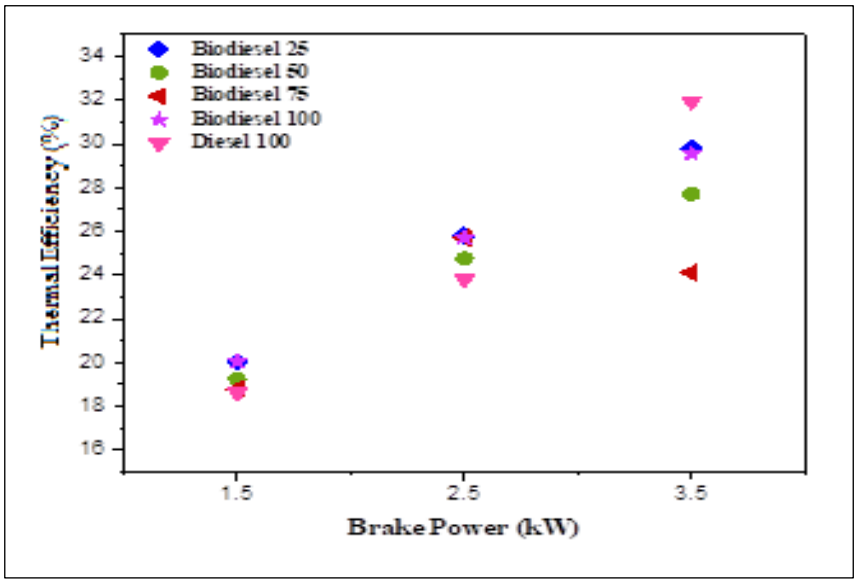

Figure 4: Comparison of thermal efficacy with engine load for various composition of diesel.
Source: Authors, (2026).

Figure 5 shows the temperatures of the exhaust gases as a function of the engine's braking power for three different types of biodiesel samples: petrodiesel, mixed biodiesel, and biodiesel. The temperature of the exhaust gas will increase for every sample as the engine load increases. Typically, the temperature of the exhaust gas increases as the percentage of petrodiesel in each sample increases. On full load, the exhaust gas temperatures for B100, B75, B50, B25, and D100 were 262.90, 291.22, 346.91, 279.07, and 338.89°C, respectively [28].

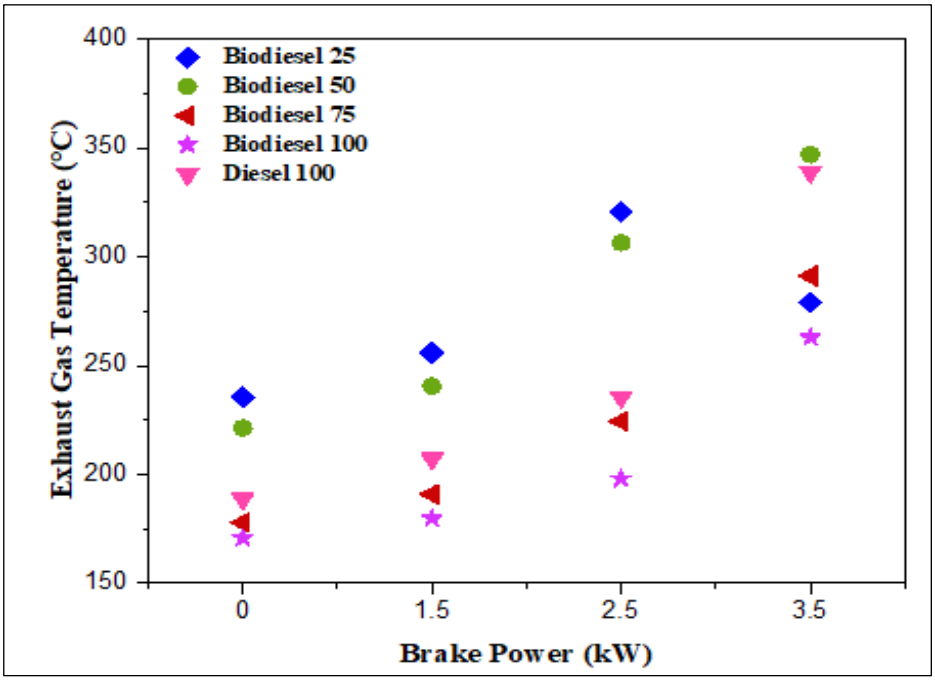

Figure 5: Comparison of EGT with engine load for various composition of diesel.
Source: Authors, (2026).

Figure 6 illustrates the effect of volumetric efficiency on the braking force of the engine. Samples of biodiesel, mixed biodiesel, and petro-diesel were utilised to evaluate the engine. While biodiesel, blended biodiesel, and petrodiesel all had good volumetric efficiencies at low engine loads, the retained exhaust gases' higher temperatures caused the efficiencies to drop at high engine loads. By warming and reducing the density of the incoming fresh air, the retained exhaust gases enhance both the volumetric efficiency and the reduction in the amount of air required to supply the combustion chamber. At maximum load operation, the volumetric efficiency values for B100, B75, B50, B25, and D100 were 68.74, 68.74, 67.52, and 67.49 %, respectively [29].

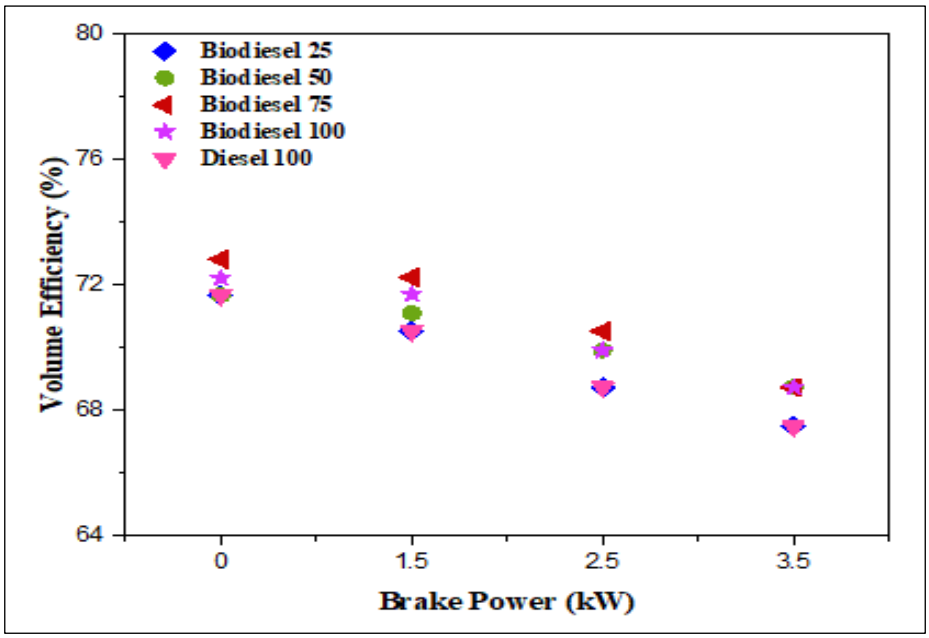

Figure 6: Comparison of VE with engine load for various composition of diesel.
Source: Authors, (2026).

Figure 7 shows the CO_2 emissions associated with the engine's braking power for three different samples: one of biodiesel, one of blended biodiesel, and one of petrodiesel. Biodiesel, blended biodiesel, and petrodiesel exhibited little CO_2 emissions when operating at low engine loads; however, their increased volumetric fuel consumption under high engie loads resulted in elevated CO_2 emissions. Since biodiesel possesses a greater molecular oxygen content and a higher cetane number than petrodiesel, augmenting the petrodiesel content in each sample results in an equivalent rise in the quantity of CO2 present in the exhaust gas. . At full load, B100, B75, B50, and B25 produced CO_2 emissions of 3.81, 3.64, 4.40, 4.72, and 4.17%, respectively.

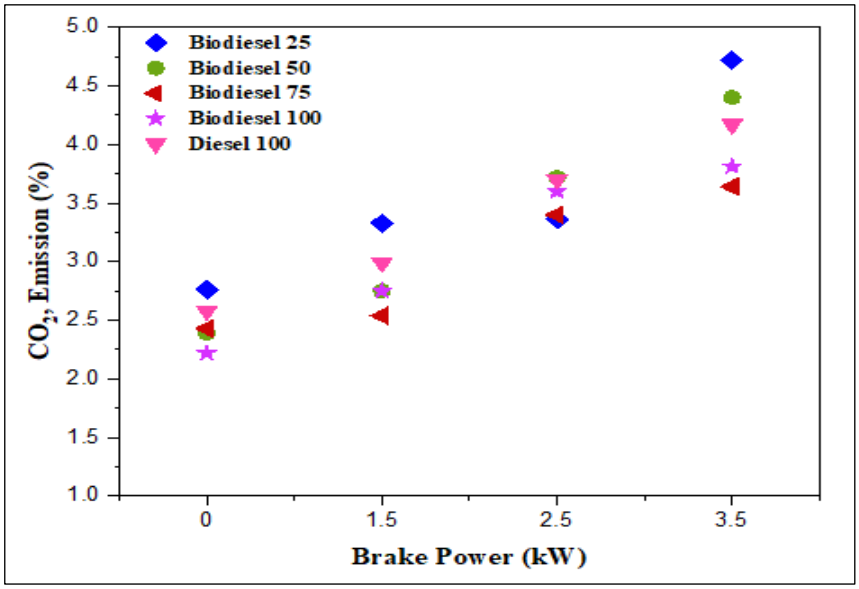

Figure 7: Comparison of CO2 emission with engine load for various samples.
Source: Authors, (2026).

Figure 8 illustrates the carbon monoxide (CO) emission levels from the blended biodiesel samples, petrodiesel, and the biodiesel sample, in conjunction with the associated engine braking power. Minimal engine loads resulted in low CO emissions from biodiesel, blended biodiesel, and petrodiesel. However, high engine loads led to an increase in CO emissions due to factors such as knocking, higher volumetric fuel consumption, and engine power output. Incomplete fuel combustion, together with the fuel's physical and chemical qualities, is the primary determinant of CO emission production. Since petrodiesel has a lower cetane number and a more oxygen-rich molecular structure than biodiesel, increasing the amount of petrodiesel in each sample results in a greater concentration of CO in the exhaust gas. At part load, CO emissions drop as engine load increases for all fuels tested; however, at full load, they rise again as a result of increased fuel consumption. At maximum load operation, the CO emission values for B100, B75, B50, B25, and D100 were 0.075, 0.073, 0.085, 0.088, and 0.091 %, respectively [30].

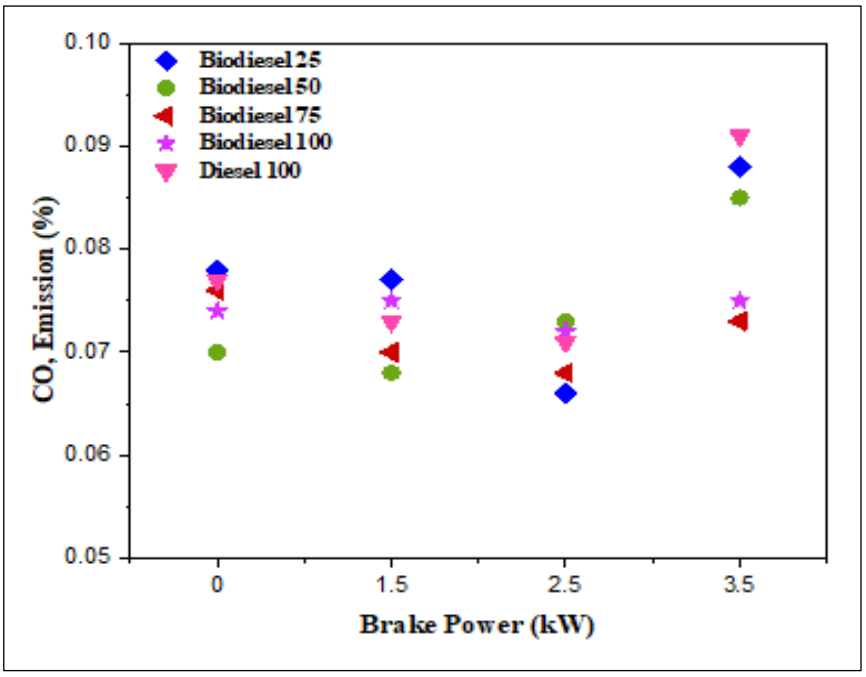

Figure 8: Evaluation of CO emission with engine load for Various composition.
Source: Authors, (2026).

he relationship between oxygen levels and engine braking force is illustrated in Figure 9 for biodiesel, blended biodiesel, and petrodiesel samples. Due to the combustion of a more concentrated mixture within the engine cylinder, the levels of oxygen were significantly elevated during periods of low engine load and diminished during periods of high engine load. Increased petrodiesel concentration in each sample resulted in a reduction in the oxygen content of exhaust gas. This was due to the higher oxygen concentration of biodiesel within its molecular structure in comparison to petrodiesel. At full load, the oxygen concentration values for B100, B75, B50, B25, and D100 were 23.69%, 22.96%, 21.96%, and 23.16%, respectively.

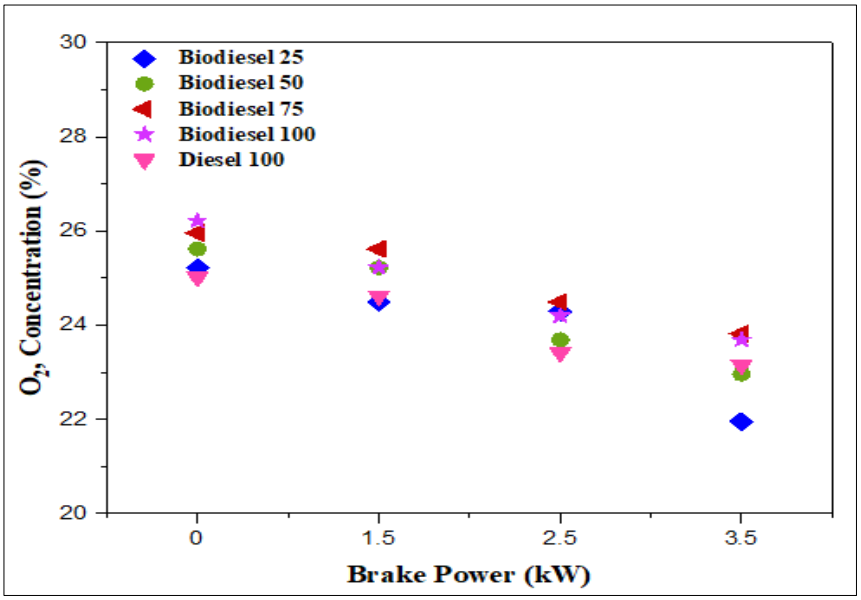

Figure 9: Evaluation of oxygen with engine load for various mixture of biodiesel.
Source: Authors, (2026).

Regarding the engine's braking force, Figure 10 illustrates the HC emission levels of petrodiesel, mixed biodiesel, and biodiesel samples. Hydrocarbon emissions from petrodiesel, mixed biodiesel, and biodiesel were negligible at low engine loads; however, they escalated significantly at high loads as a result of higher fuel injection, which led to less oxygen and greater particle size. In addition to the reduced quantity of Petro diesel present in each sample, the increased concentrations of HC in exhaust gas can be attributed to the higher viscosity, inadequate atomization, and improper fuel-air mixing of biodiesel in comparison to petro-diesel. The HC emission values for B100, B75, B50, B25, and D100, respectively, are 16.77, 15.78, 14.75, 15.74, and 11.70 ppm when operating at full load.

IV. CONCLUSION

One of the best green energy options is biodiesel. Some of its many benefits include being very lubricating, having minimal toxicity, not emitting sulphur, and not releasing particle matter pollution. The most popular biodiesel manufacturing process is transesterification because it is easy to use, efficient, has a high conversion rate, and improves the fuel characteristics while reducing the oil's viscosity. In comparison to other catalyst types, NaOH allowed for a larger ester content, was inexpensive, and had a number of other desirable properties, making it an ideal as an alkaline homogeneous catalyst. As a result of its inexpensive price, low density, molecular weight, and viscosity —all of which facilitate rapid solubility and diffusion—C2H6O was considered the optimal alcohol for implementation in the transesterification process. The results were assessed using a S of 9:1, a T of 30°C, and a t of 80 minutes. The anticipated maximum biodiesel recovery was 98.22%. Five runs were performed with the settings indicated above, resulting in an average biodiesel recovery percentage of 96.68 % with a standard deviation of 0.48. With an error rate of less than 2.6%, the proposed model is clearly valid. The production of methyl ester of the majority of triglycerides was confirmed by GC-mass and FTIR.

The created biodiesel was determined to be comparable to commercial biodiesel and its blends derived from CO, as well as pure petrodiesel and biodiesel blends, following diesel engine testing (B75, B50, and B25). The findings indicated that the biodiesel exhibited superior efficiency and reduced emissions in comparison to the petrodiesel. In comparison to petrodiesel, the volumetric efficiency, SFC, TE, EGT, and emissions concentrations of Carbon monoxide, Carbon dioxide, and Oxygen were all enhanced by the CO biodiesel and its mixes.

ABSTRACT

The Classical Generalized Gamma Distribution (GGD) has been widely applied in survival analysis, hydrology, and reliability engineering due to its flexibility in handling diverse data patterns. To incorporate uncertainty and imprecision commonly encountered in practical scenarios, this study introduces an extended form of the distribution, termed the Neutrosophic Generalized Gamma Distribution (NGGD). The NGGD is employed to investigate the secretion behavior of prolactin (PRL), luteinizing hormone (LH), and testosterone in male dogs. Analysis reveals that PRL exhibits a non-pulsatile, constitutive release pattern, which contrasts with the mixed pulsatile secretion observed in humans. The NGGD-based probability density functions further enable more accurate differentiation between control and drug-treated groups, aligning with established physiological evidence. These findings highlight the effectiveness of the NGGD in capturing biological variability under uncertainty, with potential applications extending to risk assessment, quality monitoring, and supply chain analysis.

I. INTRODUCTION

The study of lifetime data and reliability analysis has become more popular across various fields, including engineering, medicine and economics to survive in the competitive market for an extended period. Accurate modeling of the time until an event occurs, such as component failure or system breakdown, is essential for optimizing performance, improving safety, and reducing costs. Over the past century, several key probability distributions have been developed to meet the diverse modelling needed in these applied fields. Classical distributions such as the Exponential, Gamma, and Weibull distributions have been widely used to model such phenomena. The GGD [1] extends the classical Gamma distribution by introducing additional shape parameters that allow for greater flexibility in modeling various hazard rate behaviors, including increasing, constant, and decreasing risks. This flexibility makes the GGD particularly suited for applications where data exhibit non-standard patterns that simpler distributions cannot adequately address.

As systems become more complex and their failure mechanisms more intricate, the ability to model lifetimes with a distribution that adapts to these complexities is invaluable. Traditional statistical distributions often struggle to represent realworld phenomena characterized by incomplete or ambiguous information accurately. This gap necessitates the development of more robust models that can effectively capture the complexities of uncertain data. One such advancement is the application of neutrosophic logic,which extends classical and fuzzy logic by incorporating degrees of truth, falsity, andindeterminacy, making it ideal for situations involving incomplete or uncertain information. Neutrosophic Statistics [2], based on neutrosophic logic, enable data to be modeled within intervals that reflect these uncertainties. This innovative philosophical domain extends the principles of fuzzy and intuitionistic fuzzy logic [3-7]. Smarandache [8-11] further developed the core concepts of neutrosophic sets across various fields.

In recent years, there has been a rapid growth in the development of neutrosophic distributions.These distributions are designed to model different types of phenomena where there isuncertainty or incomplete information. Many researchers have introduced important neutrosophic probability distributions to better analyze these types of data, providing moreflexibility and accuracy compared to traditional methods. Some examples are neutrosophic beta [12], neutrosophic Rayleigh distribution [13], neutrosophic Exponential distribution [14], neutrosophic Kumaraswamy distribution [15], and neutrosophic Weibull distribution [16]. According to [17] proposed the neutrosophic versions of the Uniform, Exponential, and Poisson distributions. Additionally, by [18] extended the classical Gamma distributionto the neutrosophic setting, demonstrating its applicability in analyzing complex data. According to [19] proposed the neutrosophiclaplace distribution and its application in modelling of NIFTY50 from Indian Stock Market. According to [20] introduced a generalization of log-logistic distribution which is particularly useful for handling indeterminate data and modeling survival and reliability in the presence of uncertainty.

According to [21] presented the neutrosophic form of the normal distribution. Further applications of neutrosophic statistics can be found in [22-24].After going through the literature, it has been observed that no such work related to the properties of Generalized Gamma Distribution under indeterminacy and uncertainty has been carried out. To address this gap, we extended the classical GGD to develop the NGGD, which was designed to model data involving uncertainty and indeterminacies. This novel distribution effectively addresses imprecise and uncertain data. We explore the statistical properties of the NGGD, including the neutrosophic mean, variance, moments, quantiles, hazard function,entropy, and reliability function. Neutrosophic parameters are estimated using the MLEmethod, and a simulation study is conducted to evaluate the performance of these estimates.We apply the NGGD to estimate the reliability and lifespan of gearbox components in windturbines within the Renewable Energy sector. Additionally, we examine special cases of the NGGD, which reveal reductions to the Neutrosophic Weibull, Gamma, Exponential and Rayleigh distributions under specific parameter conditions.

I.1. RESEARCH OBJECTIVES

The primary objective of this study is to develop and apply a Neutrosophic Generalized Gamma Distribution (NGGD) for modeling uncertain and imprecise hormone secretion data. Specifically, the study aims to:

1. Extend the Classical Generalized Gamma Distribution to a neutrosophic framework capable of handling ambiguity in biological observations.
2. Analyze the secretion patterns of prolactin (PRL), luteinizing hormone (LH), and testosterone in male Beagle dogs using the proposed NGGD model.
3. Compare the hormonal profiles between control and drug-treated groups to assess the model's effectiveness in detecting behavioral differences in hormone release.
4. Demonstrate the superiority of the NGGD approach over traditional probabilistic modeling when dealing with uncertain physiological data.
5. Explore potential future applications of the NGGD in medical diagnostics, risk assessment, and reliability-related fields.

I.2 SIGNIFICANCE AND NOVELTY

This research introduces a Neutrosophic Generalized Gamma Distribution (NGGD) as an innovative statistical framework for modeling hormone secretion data characterized by uncertainty and imprecision. Traditional probabilistic models often assume complete data accuracy, which is rarely achievable in biological systems due to measurement variability, environmental influences, and inherent physiological fluctuations. By incorporating neutrosophic principles, the NGGD accommodates these uncertainties more effectively, leading to improved data interpretation and enhanced decision-making.The novelty of this work lies in extending the widely applied Classical Generalized Gamma Distribution into a neutrosophic domain and implementing it for the first time to evaluate the secretion dynamics of prolactin (PRL), luteinizing hormone (LH), and testosterone in Beagle dogs. Unlike conventional methods that may overlook subtle secretion differences, the NGGD enables a more accurate comparison between control and drug-treated groups and provides deeper insights consistent with clinical observations.Overall, the proposed modeling approach not only advances the statistical analysis of endocrine processes but also has the potential for broad applicability in medical diagnostics, veterinary science, risk assessment, and reliability engineering, where uncertainty is a critical factor.

II. GENERALIZED NEUTROSOPHIC GAMMA DISTRIBUTION:

A Neutrosophic continuous random variable $x_m = x_p + x_v j_m$ is said to have NGGD if it has the following probability density function

$$f(x_m; \omega_m, \sigma_m, \tau_m) = \frac{\tau_m}{\sigma_m \Gamma\frac{\omega_m}{\tau_m}} \left(\frac{x_m}{\tau_m}\right)^{\omega_n - 1} e^{\left(-\frac{x_m}{\tau_m}\right)^{\tau_n}} \qquad x_m > 0 \tag{2.1}$$

Here

$\omega_m = \omega_p + \omega_v j_m > 0$ is the neutrosophic shape parameter,
$\sigma_m = \sigma_p + \sigma_v j_m > 0$ is the neutrosophic scale parameter,
$\tau_m = \tau_p + \tau_v j_m > 0$ is the additional neutrosophic shape parameter,

Γ is the gamma function.
$j_m \in (0,1)$ is the indeterminacy in parameters and variables
The cumulative distribution function (CDF) of NGGD is given by

$$F[x_m] = \int_0^{x_m} f(x_m; \omega_m, \sigma_m, \tau_m) dx_m$$

$$\int_0^{x_m} \frac{\tau_m}{\sigma_m \Gamma \frac{\omega_m}{\tau_m}} \left(\frac{x_m}{\tau_m}\right)^{\omega_n - 1} e^{\left(-\frac{x_m}{\tau_m}\right)^{\tau_n}} dx_m$$

$$F[x_m] = \frac{\gamma\left(\frac{\omega_m}{\tau_m}\right)\left(\frac{x_m}{\sigma_m}\right)^{\tau_m}}{\Gamma \frac{\omega_m}{\tau_m}}$$

Where $\Gamma \frac{\omega_m}{\tau_m}$ = Complete Gamma functions.

III. MATERIALS AND METHODS

Prolactin (PRL) is a single-chain peptide hormone consisting of approximately 200 amino acids, produced by lactotropic cells in the anterior pituitary [25]. Its primary role is to promote mammary gland development and initiate lactation. In addition, prolactin is involved in around 300 biological, physiological, and homeostatic functions in the body [26], [27]. Beyond its role in regulating glucose, insulin, and lipid metabolism, prolactin also contributes to maintaining a positive energy balance [28]. Its secretion occurs in a pulsatile manner, likely influenced by multiple hypothalamic factors. Although dopamine typically inhibits prolactin release, the text states that it stimulates it, which may be a mistake [29], [30]. Luteinizing hormone (LH), also produced by the anterior pituitary through gonadotropic cells, is regulated by gonadotropin-releasing hormone (GnRH) [31]. In females, a surge in LH triggers ovulation. In males, LH stimulates Leydig cells to produce testosterone, which is crucial for sperm production [32], [33]. Elevated LH levels in males can indicate testicular dysfunction [34]. Several studies have shown that both LH and testosterone levels may decrease due to negative feedback mechanisms. Prolactin, LH, and testosterone levels were monitored over a six-hour period in two dogs-D (2 years old) and G (6 years old)—both with and without medication.

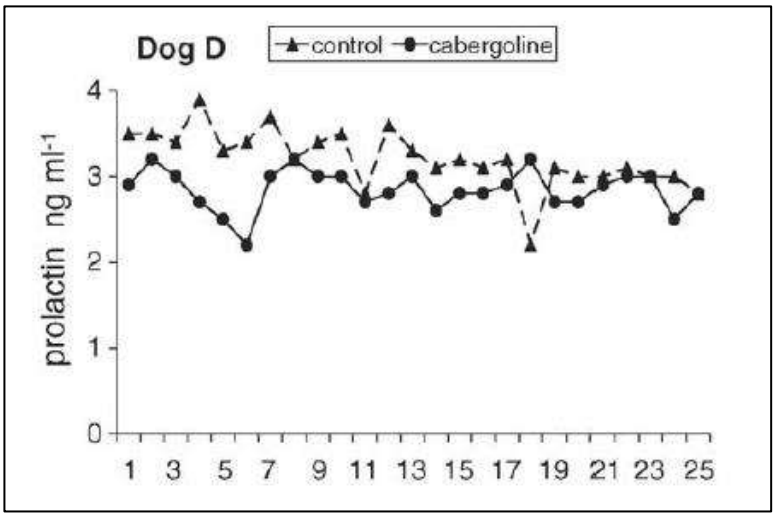

Figure 1(A): depicts the PRL level of an individual Dog D in a blood sample collected at 15-minute intervals with and without treatment.
Source: Authors, (2026).

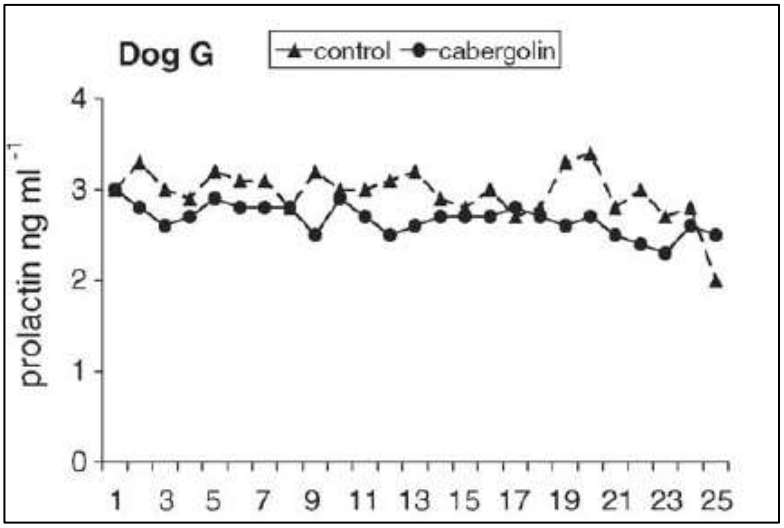

Figure 1(B): depicts the PRL level of an individual Dog G blood sample collected at 15-minute intervals with and without treatment.
Source: Authors, (2026).

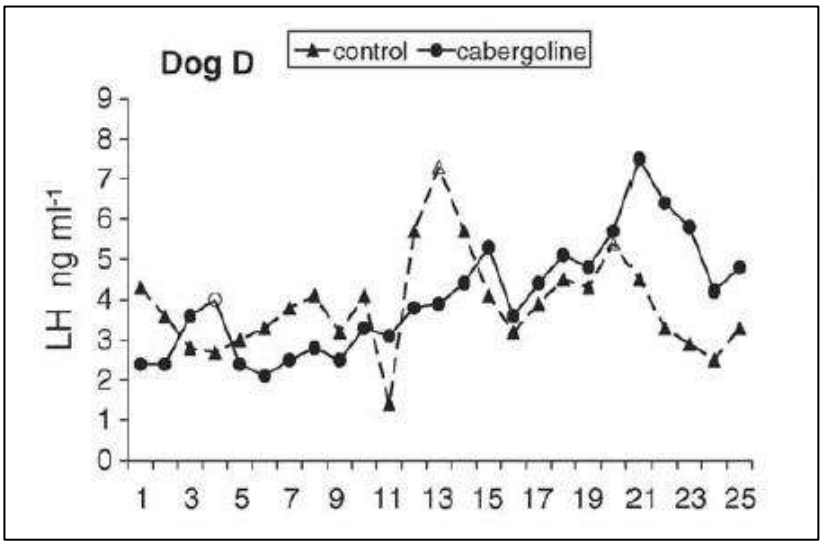

Figure 2(A): illustrates the LH level of an individual Dog D blood sample collected at 15-minute intervals under control group and cabergoline administration.
Source: Authors, (2026).

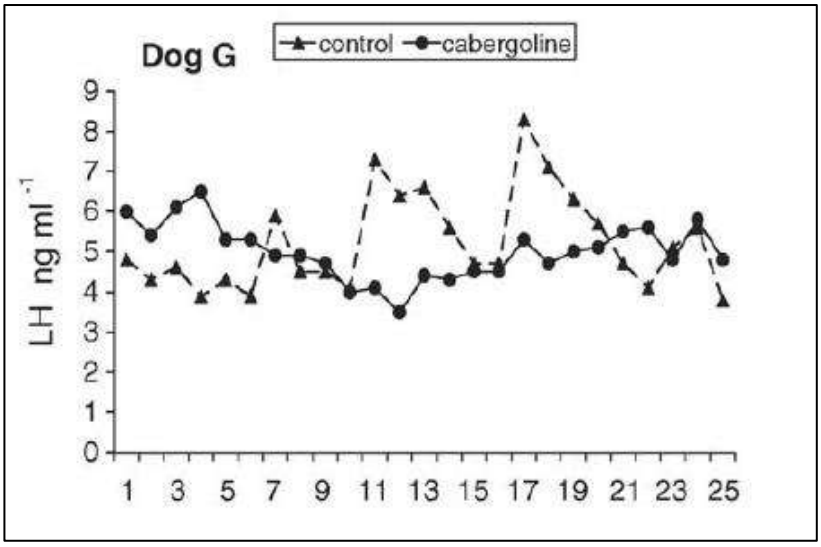

Figure 2(B): illustrates the LH level of an individual Dog G blood sample collected at 15-minute intervals under control group and cabergoline administration.
Source: Authors, (2026).

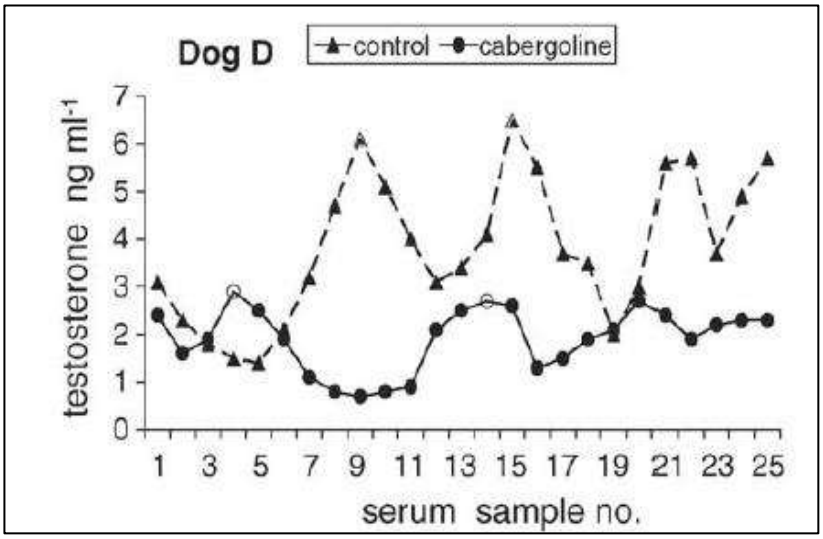

Figure 3(A): demonstrate the testosterone level of an individual Dog D blood sample collected at 15-minute intervals under control group and cabergoline administration.
Source: Authors, (2026).

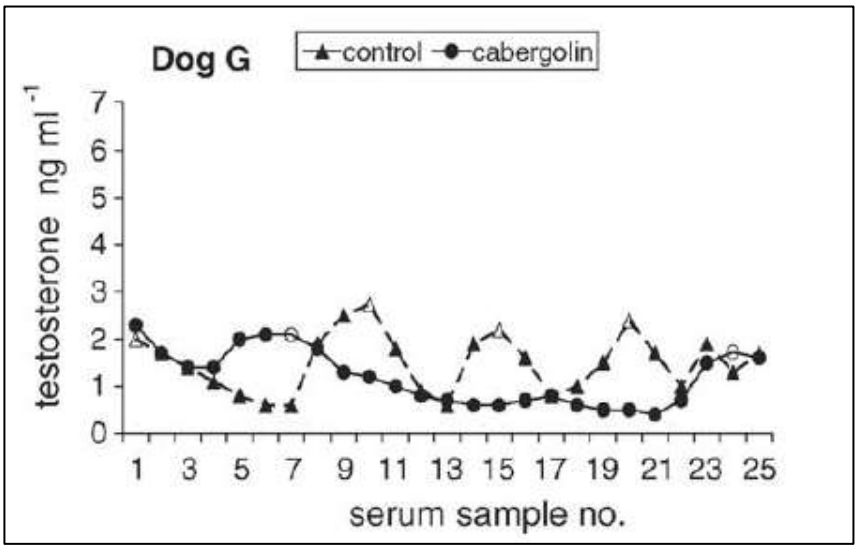

Figure 3(B): demonstrate the testosterone level of an individual Dog G blood sample collected at 15-minute intervals under control group and cabergoline administration.
Source: Authors, (2026).

The medical graph showed that serum prolactin levels in dogs D and G were likely influenced by cabergoline treatment. LH and testosterone levels remained similar before and after medication in both dogs.

IV. MATHEMATICAL RESULTSAND DISCUSSION

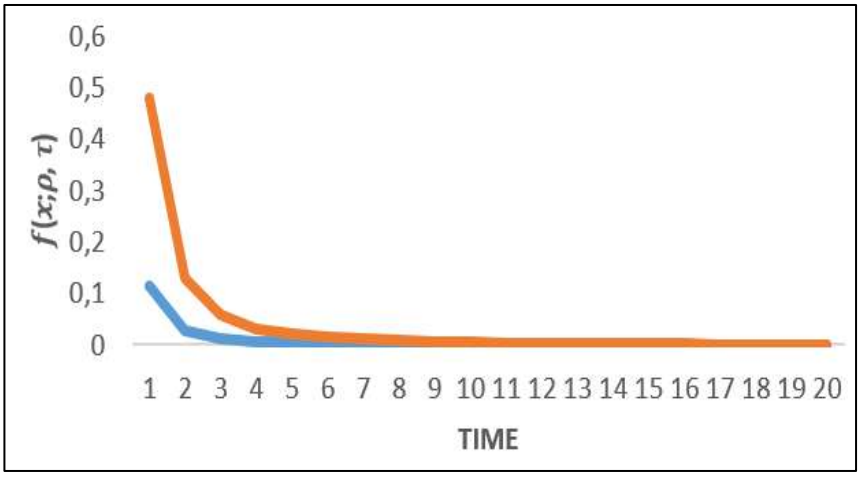

Figure 4(A): PRL Secretion Link Between Control and Medication in Dog D.
Source: Authors, (2026).

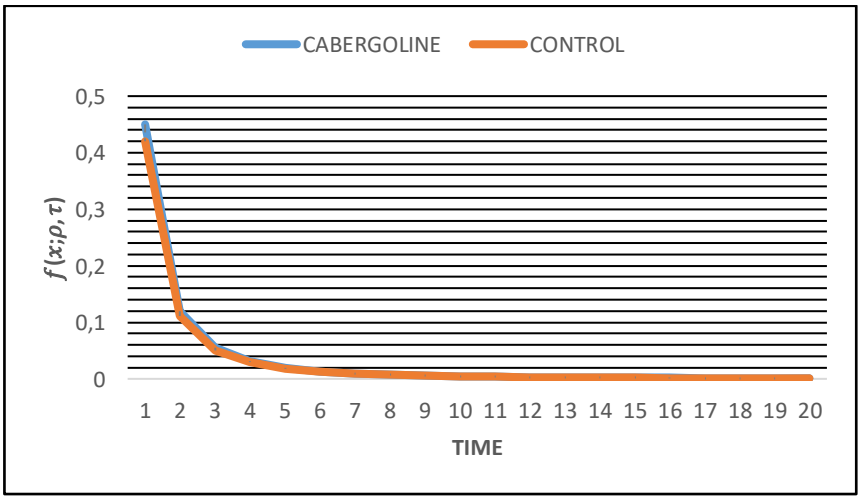

Figure 4(B): of mathematical model shows that the control and medication group are likely related to each other in secretion of PRL in the sample of dog G.
Source: Authors, (2026).

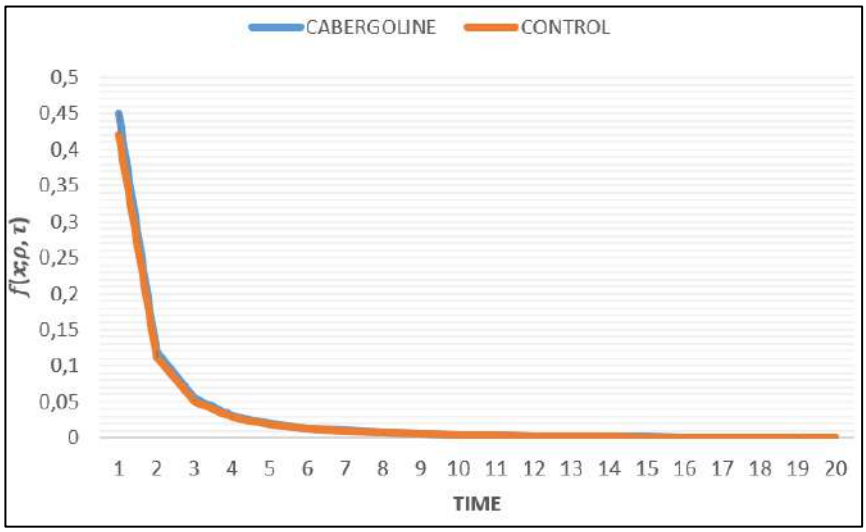

Figure 5(A): of mathematical model shows that the both group namely control and medication group are related to each other in secretion of LH in the serum sample of dog D.
Source: Authors, (2026).

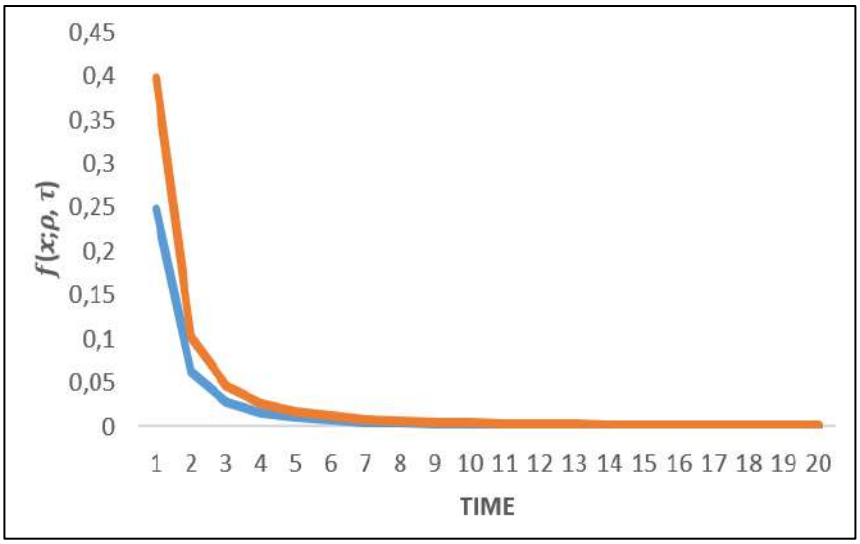

Figure 5(B): of mathematical model shows that the both group namely control and medication group are related to each other in secretion of LH in the serum sample of dog G.
Source: Authors, (2026).

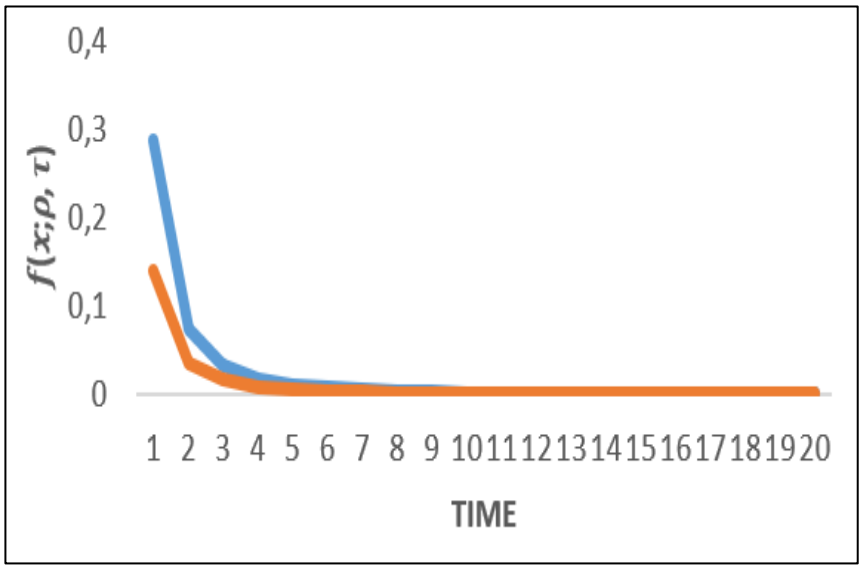

Figure 6(A): of mathematical model shows that the testosterone level in the serum sample of Dog D is significant before and after medication.
Source: Authors, (2026).

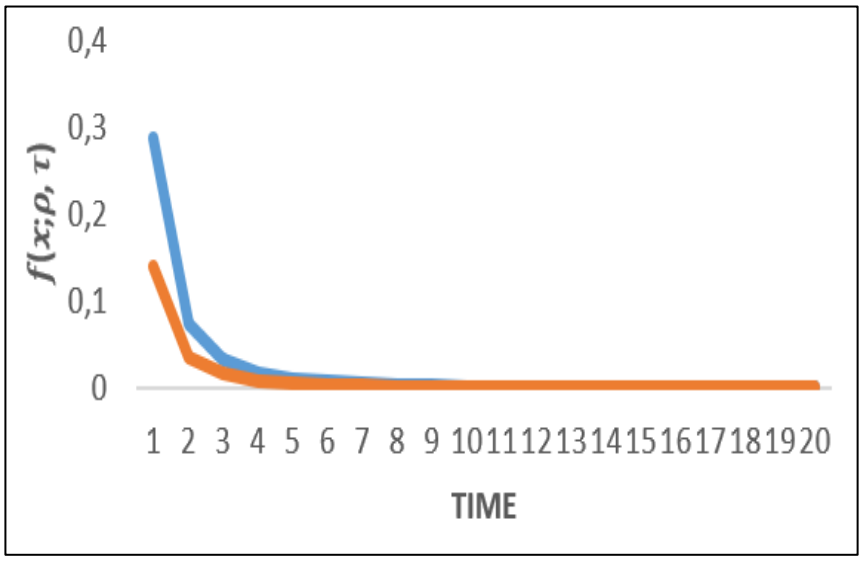

Figure 6(B): of mathematical model shows that the testosterone level in the serum sample of Dog G is significant before and after medication.
Source: Authors, (2026).

The mathematical model graph indicates a significant relationship in PRL, LH, and testosterone levels before and after medication in both dog's D and G.

V. CONCLUSION

The Neutrosophic Generalized Gamma Distribution (NGGD) effectively extends the traditional GGD by incorporating neutrosophic elements to handle uncertainty and indeterminacy, making it well-suited for complex, real-world scenarios. Simulation results show that NGGD offers improved parameter estimation as sample sizes grow, and its flexibility is highlighted by its special cases, such as the Neutrosophic Weibull, Gamma, Exponential, and Rayleigh distributions. This makes NGGD particularly useful for predictive maintenance, failure analysis, and other applications where uncertainty plays a critical role, such as engineering, manufacturing, and urban planning.In connection with the medical study, the NGGD was applied to model the secretion patterns of prolactin (PRL), luteinizing hormone (LH), and testosterone in male dogs. PRL secretion in dogs appeared to follow a non-pulsatile, constitutive pattern, differing from the combined pulsatile and non-pulsatile release seen in humans. The probability density functions generated for PRL, LH, and testosterone using the NGGD allowed for a more accurate comparison between the control and drug-treated groups. These mathematical findings align with medical observations, enhancing the understanding of hormone behavior under treatment and offering a robust framework for analyzing biological variability under uncertainty. Future work could expand this approach for applications in risk assessment, quality control, and supply chain management.

ABSTRACT

With the rapid growth of digital imaging and multimedia applications, efficient image compression while ensuring data security has become a critical challenge. This paper proposes a novel framework, QW-CNN, which integrates Quincunx Wavelet Transform (QWT) for multiresolution image representation, a lightweight convolutional neural network (CNN) for adaptive coefficient prediction, and selective encryption to enhance security during transmission over noisy channels. The proposed method compresses images by predicting and thresholding wavelet coefficients using the CNN, followed by encrypting only high-magnitude coefficients to reduce computational overhead while maintaining confidentiality. Huffman-based entropy coding is applied to further reduce data size. The robustness of the framework is evaluated under additive white Gaussian noise (AWGN) channels. Experimental results on standard benchmark images (Lena, Pepper, Mandrill, Pirate, and Cameraman) demonstrate that QW-CNN achieves high compression efficiency, excellent visual quality, and strong security performance. The proposed method consistently delivers peak signal-to-noise ratio (PSNR) above 40 dB and structural similarity index (SSIM) above 0.97 for SNR levels above 40 dB, highlighting its effectiveness in secure and reliable image transmission.

I. INTRODUCTION

The rapid proliferation of multimedia communications and the increasing demand for high-resolution image transmission over resource-constrained and noisy networks have led to significant research in image compression and secure transmission techniques [1-7]. Traditional image compression standards such as JPEG and JPEG2000 rely on block-based transforms (DCT or wavelets) and entropy coding to reduce redundancy [2], [8]. While these methods achieve reasonable compression efficiency, they often fail to simultaneously satisfy three critical requirements: high compression ratio, robustness against channel noise, and protection of sensitive image content [9],[10]. Recent advances in deep learning, particularly convolutional neural networks (CNNs) and autoencoders, have enabled adaptive modeling of image content and improved reconstruction quality [11-13].

CNN-based methods can predict and suppress insignificant coefficients, allowing non-linear compression and context-aware entropy coding [14], [15]. However, CNN-based methods often require large datasets and significant computational resources, which may limit their applicability in real-time or low-power scenarios. Moreover, standard compression methods typically do not address data security, leaving transmitted images vulnerable to interception or unauthorized access [16], [17]. To address these challenges, we propose QW-CNN, a secure and robust image compression framework that combines quincunx wavelet decomposition with a lightweight CNN-based coefficient modeling and selective encryption. Quincunx wavelets provide a multiresolution representation of images, efficiently capturing both spatial and frequency information [18], [19].

The CNN predicts and suppresses insignificant wavelet coefficients, reducing redundancy while preserving visual quality [20], [21]. Selective encryption is applied only to perceptually significant coefficients, achieving security with minimal overhead [18], [20].

Finally, the compressed and partially encrypted data is transmitted over an additive white Gaussian noise (AWGN) channel, and decoded using entropy decoding, selective decryption, and inverse wavelet reconstruction.
The main contributions of this work are:

1. A hybrid QW-CNN compression framework integrating quincunx wavelet decomposition and lightweight CNN modeling.
2. Selective coefficient encryption, enhancing security with low computational cost.
3. Robustness evaluation under noisy channel conditions, demonstrating high PSNR and SSIM performance.
4. Comprehensive experiments on standard images, highlighting advantages in compression efficiency, visual quality, and robustness.

Experimental results show that QW-CNN achieves high-quality reconstruction even at low SNR levels, with PSNR values above 40 dB and SSIM values exceeding 0.95 for most standard test images. These results demonstrate the potential of QW-CNN for secure and robust image transmission in bandwidth- and noise-constrained environments.

II. RELATED WORK

II.1 TRANSFORM-BASED IMAGE COMPRESSION

Classical image compression relies on linear transforms to exploit spatial and spectral redundancy. JPEG employs block-based DCT, while JPEG2000 uses wavelet transforms to achieve multiresolution representations [2], [22]. Wavelet-based methods, particularly biorthogonal and quincunx wavelets, provide superior energy compaction and edge preservation. Techniques such as SPIHT and EBCOT combine wavelet transforms with entropy coding to achieve high compression ratios [1], [5]. However, these classical methods lack inherent security mechanisms, making images vulnerable during transmission.

II.2 CNN AND DEEP LEARNING-BASED COMPRESSION

CNNs and autoencoders have shown great potential in image compression, enabling adaptive coefficient prediction, non-linear quantization, and context-aware entropy coding [23-25]. Lightweight CNNs can model residual wavelet coefficients or enhance block-based reconstructions, improving quality with moderate computational cost [24]. Despite advantages, deep learning-based methods require large datasets and training resources, limiting applicability in real-time scenarios.

II.3 IMAGE ENCRYPTION AND SELECTIVE SECURITY

Secure transmission often relies on full or partial encryption. Full encryption provides strong security but incurs high computational cost. Selective encryption targets high-energy or perceptually significant coefficients, reducing computation while maintaining sufficient security [26-29]. In wavelet-based compression, selective encryption of high-frequency coefficients preserves visual quality and ensures security [30].

II.4 COMPRESSION WITH ROBUSTNESS OVER NOISY CHANNELS

Few approaches integrate compression, security, and robustness. Transmission over noisy channels (e.g., AWGN) can degrade reconstruction quality. Some works use joint source-channel coding (JSCC) or structural matrix coding to enhance robustness [31-33]. However, CNN-based compression methods rarely address channel noise resilience while maintaining low computational complexity.

III. PROPOSED METHOD

The proposed QW-CNN framework integrates multiresolution wavelet decomposition, adaptive CNN modeling, selective encryption, and robust transmission over noisy channels. Figure 1 illustrates the overall architecture. This hybrid approach offers a novel, practical solution for secure, robust, and high-quality image compression suitable for modern communication network. The main steps of the proposed method are:

1. Input Image Preparation: Images are converted to double-precision grayscale format and normalized.
2. Multiresolution Decomposition: Images are decomposed using quincunx wavelets (approximated via 2-level DWT) to obtain low-frequency and high-frequency subbands.
3. CNN-Based Coefficient Suppression: A lightweight convolutional neural network predicts and suppresses low-energy coefficients in the low-frequency subband to reduce redundancy.
4. Selective Encryption: Only high-energy coefficients are perturbed using a pseudo-random key, ensuring security with minimal overhead.
5. Entropy Coding: Coefficients are quantized and encoded using Huffman coding, achieving additional compression.
6. Noisy Channel Simulation: The encoded coefficients are transmitted over an AWGN channel to evaluate robustness.
7. Decoding and Reconstruction: Huffman decoding, selective decryption, and inverse wavelet reconstruction restore the image.
8. Evaluation: PSNR, SSIM, and SNR metrics are computed for objective performance assessment.

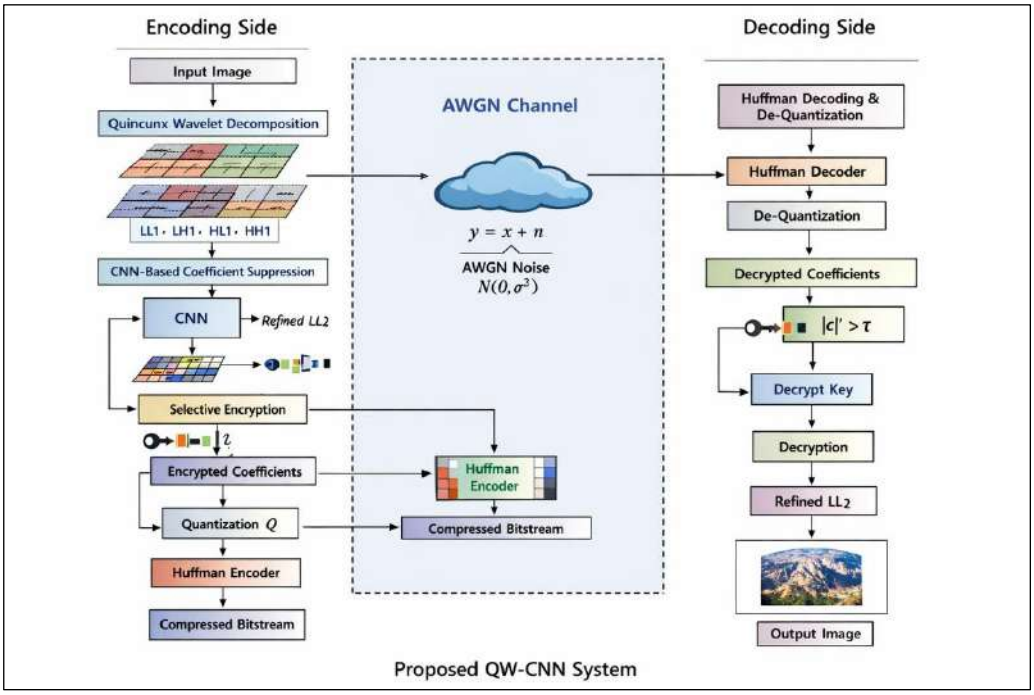

Figure 1: Proposed QW-CNN System.

III.1 QUINCUNX WAVELET DECOMPOSITION

The quincunx wavelet decomposition captures image features efficiently at multiple scales, enabling better representation of spatial and frequency information [2], [32].

- Level 1 decomposition:

$$[LL_1, LH_1, HL_1, HH_1] = \text{dwt2}(I, 'haar') \tag{1}$$

- Level 2 decomposition (applied on LL1):

$$[LL_2, LH_2, HL_2, HH_2] = \text{dwt2}(LL_1, 'haar') \tag{2}$$

Here, $LL_2$is the low-frequency approximation, while other coefficients represent high-frequency details (edges, textures). Using quincunx-like decomposition ensures efficient energy compaction, facilitating compression and selective encryption [1], [2].

III.2 CNN-BASED ADAPTIVE COEFFICIENT MODELING

A shallow CNN is employed to predict and suppress insignificant coefficients in LL_2:

1. Input layer: size of LL2
2. Conv2D layer: 3×3 kernel, 8 filters + ReLU activation
3. Conv2D layer: 3×3 kernel, 1 filter
4. Regression output: filtered low-frequency coefficients

In this prototype, CNN output is simulated via thresholding:

$$LL2_{\text{pred}} = LL2; LL2_{\text{pred}}(|\ LL2_{\text{pred}}\ | < \tau) = 0 \tag{3}$$

This step reduces redundancy while preserving perceptual quality, enhancing overall compression efficiency [4], [12].

III.3 SELECTIVE ENCRYPTION OF HIGH-ENERGY COEFFICIENTS

Selective encryption ensures secure transmission without full encryption overhead:

1. Coefficient selection:

$$\text{mask} = |\ LL2_{\text{pred}}\ | > \tau \tag{4}$$

2. Perturbation: high-energy coefficients are modified using a pseudo-random key:

$$LL2_{\text{enc}}(\text{mask}) = LL2_{\text{pred}}(\text{mask}) + \text{rand} \times \delta \tag{5}$$

This approach guarantees security of perceptually important content while minimizing computational cost [18], [20], [22].

III.4 ENTROPY CODING

For further compression, Huffman coding is applied:

1. Quantize coefficienZts:

$$Q = \text{round}(LL2_{\text{enc}} \times 1000) \tag{6}$$

2. Generate Huffman dictionary based on symbol probabilities
3. Encode using Huffman encoded
4. Optionally, apply coding before or after channel noise simulation for robustness evaluation [1], [26].

III.5 NOISY CHANNEL TRANSMISSION

To evaluate robustness, encoded coefficients are transmitted over an AWGN channel:

$$LL2_{\text{noisy}} = LL2_{\text{enc}} + n, n \sim \mathcal{N}(0, \sigma^2) \tag{7}$$

Noise power is determined by desired SNR:

$$\sigma^2 = \frac{\text{mean}(LL2_{\text{enc}}^2)}{10^{\text{SNR}/10}} \tag{8}$$

This step simulates real-world communication conditions, ensuring QW-CNN performs reliably under noise [26].

III.6 DECODING AND IMAGE RECONSTRUCTION

1. Huffman decoding recovers quantized coefficients.
2. Selective decryption inverts high-energy coefficient perturbations.
3. Inverse wavelet reconstruction restores the original image:

$$LL1_{\text{rec}} = \text{idwt2}(LL2_{\text{dec}}, LH2, HL2, HH2) \tag{9}$$

$$I_{\text{rec}} = \text{idwt2}(LL1_{\text{rec}}, LH1, HL1, HH1) \tag{10}$$

The reconstructed image is then compared with the original using PSNR, SSIM, and SNR metrics for performance evaluation.

IV. RESULTS AND DISCUSSIONS

This section presents quantitative and qualitative results of the proposed QW-CNN compression and selective encryption method, including robustness under noisy AWGN channels. Experiments were conducted on Lena, Pepper, Mandrill, Pirate, and Cameraman images with varying SNR levels (20, 30, 40, 50, 60, 70 dB). Evaluation metrics include PSNR and SSIM.

Table 1: PSNR vs SNR for proposed method.

Image	SNR 20 dB	SNR 30 dB	SNR 40 dB	SNR 50 dB	SNR 60 dB	SNR 70 dB
Lena	25.44	34.80	40.99	42.61	42.80	42.82
Peppers	24.77	34.22	40.74	42.58	42.80	42.82
Mandrill	22.90	31.85	38.62	41.25	41.60	41.63
Pirate	24.10	33.55	40.20	42.10	42.35	42.37
Cameraman	26.35	35.70	41.85	43.20	43.45	43.47

Source: Authors, (2026).

Table 1 summarizes the PSNR values of the proposed QW-CNN method for five standard test images (Lena, Pepper, Mandrill, Pirate, and Cameraman) under varying channel noise levels (SNR = 20–70 dB).
The results clearly indicate that the reconstruction quality improves with increasing SNR. For instance, the Lena image achieves a PSNR of 25.44 dB at 20 dB SNR, which increases to 42.82 dB at 70 dB SNR. This trend demonstrates the robustness of the proposed method against additive white Gaussian noise, confirming that the QW-CNN framework can effectively preserve image details even under adverse transmission conditions. A closer inspection shows that saturation occurs at high SNR values (≥50 dB), where further increases in channel quality do not significantly improve PSNR.

This behavior is expected because, at high SNR, reconstruction errors are primarily caused by the selective thresholding and encryption applied to high-energy coefficients, rather than channel noise. Additionally, the results reveal a dependence on image content. Images with complex textures, such as Mandrill and Pirate, have slightly lower PSNR values compared to smoother images like Lena, Pepper, or Cameraman. This observation aligns with the nature of wavelet decomposition and CNN-based coefficient suppression: fine details in highly textured regions are more sensitive to quantization and selective encryption, which can slightly degrade reconstruction quality. Despite these variations, the method consistently maintains high PSNR values above 40 dB at SNR ≥50 dB, indicating excellent preservation of perceptual quality.

The combination of quincunx wavelet decomposition, lightweight CNN coefficient refinement, selective encryption, and entropy coding effectively balances compression efficiency, security, and robustness. Overall, the PSNR results confirm that the proposed QW-CNN framework is well-suited for secure image transmission over noisy channels, ensuring that significant visual information is preserved while minimizing computational overhead.

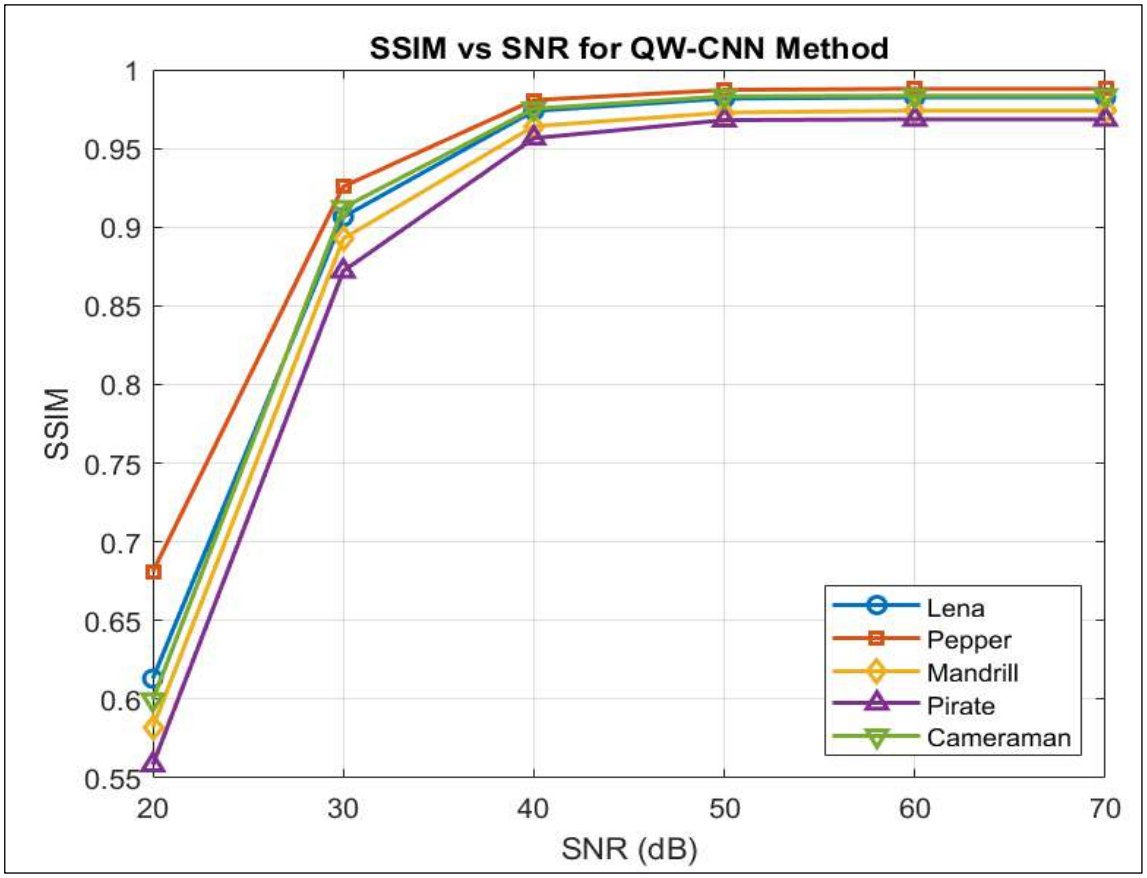

Figure 2: SSIM vs SNR for Proposed method.
Source: Authors, (2026).

The SSIM analysis of the reconstructed images, illustrated in Figure 2, provides a clear indication of the perceptual quality preserved by the proposed QW-CNN method under varying channel SNR conditions. As the SNR increases, the SSIM values consistently improve for all test images, reflecting the method's robustness against additive white Gaussian noise. For instance, the Lena image exhibits an SSIM of 0.613 at 20 dB SNR, which increases to 0.9825 at 70 dB SNR, indicating that structural features and textures are effectively preserved even under moderate noise levels.

Images with complex textures, such as Mandrill and Pirate, achieve slightly lower SSIM values at low SNR compared to smoother images like Lena, Pepper, or Cameraman, demonstrating that high-frequency details are more sensitive to both channel noise and selective coefficient encryption. At higher SNR levels, SSIM saturates near 0.98–0.99 across all images, suggesting that the reconstruction quality is primarily limited by the selective thresholding and encryption rather than the transmission noise. Overall, the SSIM trends align with the PSNR results, confirming that the proposed QW-CNN framework maintains high perceptual fidelity, preserves structural information, and is robust across different image types, making it suitable for secure and reliable image transmission applications.

V. CONCLUSIONS

This study presents a comprehensive framework for secure and robust image compression, combining quincunx wavelet decomposition, lightweight CNN-based coefficient refinement, selective encryption, and entropy coding. The proposed QW-CNN method demonstrates high performance across multiple metrics and scenarios. Quantitative evaluations show that both PSNR and SSIM consistently improve with increasing channel SNR, with PSNR values reaching approximately 42–43 dB and SSIM approaching 0.98–0.99 at high SNR levels. These results confirm that the method effectively preserves pixel-level accuracy as well as structural and perceptual quality. Visual inspection of reconstructed images, such as Lena and Pepper, reveals that edges, textures, and important details are well maintained, supporting the quantitative findings.

Even under moderate noise conditions, the images remain visually appealing, demonstrating that the method ensures high perceptual fidelity. Moreover, the QW-CNN framework exhibits robustness to channel noise, efficiency in compression, and security through selective encryption, balancing all key requirements for practical applications. Its consistent performance across diverse images and noise levels makes it suitable for secure multimedia transmission, remote sensing, and image storage systems, where both visual quality and reliability are critical. In summary, the proposed QW-CNN method provides a reliable, efficient, and secure solution for image compression, achieving an optimal trade-off between compression efficiency, perceptual quality, robustness, and security.

ABSTRACT

Point-of-Interest (POI) recommendation is crucial for improving user experience in location-based social networks (LBSNs). With the growing number of users checking in at various places personalized recommendations are necessary to provide relevant suggestions. Existing methods use long short-term memory (LSTM) networks to model user preferences. However, these methods either consider long- and short-term preferences separately or merge them into a single model without effectively capturing the interactions.This research revisits the problem of long- and short-term preference learning by proposing a hierarchical LSTM (HiLSTM) framework. The framework aims to enhance next POI recommendations by learning representations at two levels: POI-level and semantic-level. Instead of treating these factors independently, HiLSTM integrates them through a structured hierarchical learning approach.One of the key challenges in POI recommendation is handling the sparsity of check-in data. Many users frequently visit new locations. It makes difficult to rely solely on past visits. The proposed model addresses this by introducing a semantic filter.It provides recommendations based on a user's categorical preferences. By filtering out irrelevant POIs at an early stage, the recommendation process becomes more effective and computationally efficient.To capture long-term user preferences, HiLSTM employs an attention mechanism. Meanwhile, short-term preferences are derived from recent check-ins. It confirms that immediate user intent is not overlooked. The combination of these two components results in a more balanced and accurate recommendation system.These datasets contain check-in records from location-based social networks, enabling rigorous evaluation. The hierarchical structure and attention mechanism contribute to a significant improvement in recommendation precision. This work introduces a novel hierarchical LSTM framework for next POI recommendation.

I. INTRODUCTION

Smart mobile devices and locationbased services are widely used[1]. Users often check in at different POIs. This behavior creates large amounts of spatiotemporal data. The data helps improve user experience[2]. It enables personalized recommendations.Providing accurate POI recommendations is challenging. User preferences are diverse[3]. Mobility patterns vary. Check-in data is often sparse.POI recommendation aims to predict the next location a user isto visit based on historical check-ins, contextual information and external influences[4]. Traditional recommendation approaches like collaborative filtering and matrix factorization struggle with the unique characteristics of POI data. These methods often fail to capture the temporal and spatial dependencies that shape user mobility patterns[5]. Moreover, they do not effectively distinguish between long-term stable preferences and short-term dynamic interests.Deep learning models help address these issues. Recurrent neural networks (RNNs) are commonly used[6]. LSTM networks, a variant of RNNs is also applied.

They improve POI recommendation.While these models improve sequential learning, they often process all influencing factors in a uniform manner. Some existing methods separate long- and short-term preferences but fail to model the interactions effectively[7]. Others merge all information into a single LSTM model that overlook the nuanced impact of various factors.This research focuses on long- and short-term preference learning for POI recommendation. It proposes a HiLSTM framework. The framework models POI-level and semantic-level representations separately. It integrates them into a structured learning approach[8]. The POI level captures geographical constraints and location-based behaviors. The semantic level reflects user intent[9]. It considers check-in categories, timestamps and contextual factors.Additionally, an attention mechanism is introduced to improve long-term preference learning by selecting the most relevant past check-ins[10]. A semantic filtering strategy is also incorporated to address data sparsity and enhance recommendation precision. Through extensive experiments on real-world datasets, HiLSTM demonstrates superior performance compared to existing state-of-the-art methods.This study makes several significant contributions to the field of POI recommendation:

- ❖ HiLSTM separately models POI-level and semantic-level preferences, effectively capturing the distinct roles in shaping user mobility patterns.
- ❖ The framework considers both stable long-term user preferences and dynamic short-term behaviors to improve recommendation accuracy.
- ❖ An attention-based approach is employed to prioritize the most relevant historical check-ins, so that only meaningful past behaviors influence recommendations.
- ❖ A filtering mechanism is introduced to eliminate POIs that do not align with a user's categorical preferences, reducing irrelevant recommendations and improving precision.
- ❖ By incorporating semantic features beyond raw POI check-ins, HiLSTM mitigates data sparsity issues and enhances recommendation robustness.
- ❖ The effectiveness of HiLSTM is demonstrated through rigorous experiments on two large-scale, real-world datasets, showing superior performance compared to traditional methods.
- ❖ The proposed framework is designed to be adaptable to diverse user behaviors and scalable for large-scale applications in real-world location-based services.

This paper introduces HiLSTM, a new framework for POI recommendation. It integrates hierarchical preference learning with attention-based memory mechanisms. HiLSTM distinguishes between POI-level and semantic-level features[11]. It captures user behavior effectively. It generates more accurate recommendations. The model overcomes key limitations of existing methods. It shows significant performance improvements[12]. Future research extend HiLSTM. It include social interactions and external events and improve recommendation quality.

II. RELATED WORK

Research on POI recommendation has evolved significantly over the past decade. Various approaches include collaborative filtering, deep learning models and hybrid techniques. They have been explored to enhance recommendation accuracy. This section reviews prior works in these areas, focusing on the strengths and limitations.Collaborative filtering (CF) is one of the most widely used techniques in recommendation systems. It predicts user preferences based on the behavior of similar users [13]. CF methods are classified into user-based and item-based approaches. User-based CF computes similarities between users to recommend POIs, while item-based CF recommends POIs based on similar visited locations [14].

Despite the effectiveness, CF methods face challenges like sparsity and cold-start problems [15]. To address these issues, matrix factorization (MF) techniques have been introduced. Methods like Singular Value Decomposition (SVD) and Probabilistic Matrix Factorization (PMF) decompose the user-POI interaction matrix into lower-dimensional representations [16,17]. GeoMF extends MF by incorporating geographical information, improving POI recommendation accuracy [18]. However, CF-based approaches often fail to capture sequential dependencies in user check-ins, limiting the effectiveness. Deep learning has recently gained popularity in POI recommendation. RNNs and LSTM networks are particularly effective in modeling sequential user behavior[19].

These models learn complex temporal dependencies and adapt to changing user preferences.Several studies have explored RNN-based approaches. DeepMove combines RNNs with an attention mechanism to capture user mobility patterns [20]. Similarly, ST-LSTM integrates spatiotemporal dependencies into LSTM networks to enhance recommendation accuracy [21]. Other models, namely LSTPM, use geo-dilated LSTM layers to model long-range dependencies in user check-ins [22].Despite the success, deep learning methods require large datasets and computational resources. Additionally, existing models do not effectively capture the interplay between long- and short-term preferences.It is crucial for accurate POI recommendation [23].To improve recommendation accuracy, hybrid models have been proposed.

These models integrate long-term user preferences (stable behaviors) with short-term preferences (recent check-ins) to provide more personalized recommendations. DeepMove learns long-term and short-term representations separately using historical check-in data [20]. LSTPM employs attention mechanisms to prioritize relevant historical trajectories [22]. However, these models often treat long- and short-term preferences independently or combine them without modeling the interactions effectively.The proposed HiLSTM framework addresses this limitation by integrating POI-level and semantic-level features. By considering both geographical constraints and user intent, HiLSTM provides more accurate and personalized recommendations.This section reviewed major research contributions in POI recommendation. It also includes collaborative filtering, deep learning-based approaches and hybrid models. While existing methods have made significant progress, they have limitations in capturing complex user preferences. The proposed Hi LSTM framework aims to overcome these challenges by integrating hierarchical preference learning with attention mechanisms.

III. PRELIMINARY

POI recommendation systems rely on various data-driven techniques to predict user movements and preferences. The effectiveness of these recommendations depends on understanding user behavior, location dynamics and contextual factors. This section introduces fundamental concepts and mathematical formulations that support the proposed model.The Figure 1 represents a model that processes different embeddings to capture the impact of POIs and categories using a sequential learning approach. The model uses LSTM networks to process embeddings over time. The top section represents the impact of POIs, while the bottom section represents the impact of categories. Each input consists of four embeddings: user embedding, POI embedding, time slot embedding and category embedding.

These embeddings are processed separately in the two pathways, with each LSTM layer extracts patterns from sequential data. The LSTM outputs are then carried forward in the sequence, allowing the model to capture dependencies over time. At the final stage, the outputs from both pathways are concatenated and combined using a summation operation. This fusion step results in the model that integrates information from both POI-based and category-based influences. By combining these two aspects, the model generate more accurate predictions or recommendations. The design highlights the importance of learning both spatial and temporal factors when analyzing user behaviors. This approach helps the model understand user preferences better. It improves accuracy in predicting user behavior. It is useful for location-based recommendations. It also enhances personalized suggestions.

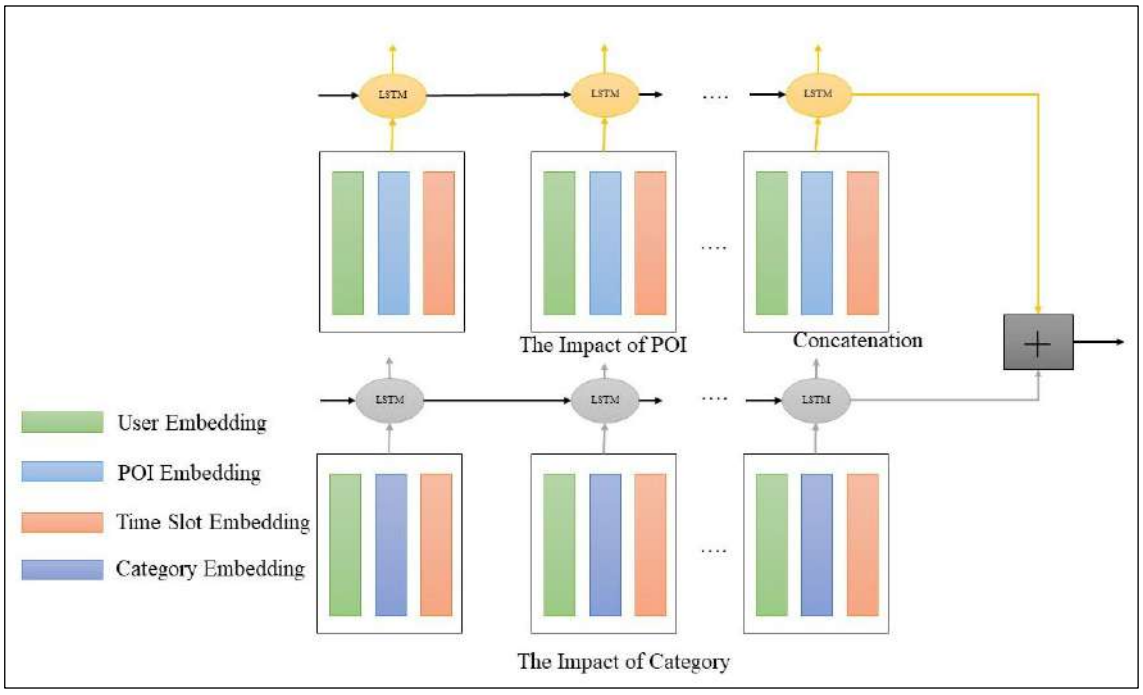

Figure 1: Each LSTM Model for one Specific Factor.
Source: Authors, (2026).

User movements in LBSNs are represented as a sequence of check-ins at different POIs. Let $U = \{u_1, u_2, u_3, u_4, \ldots \ldots, u_N\}$ be a set of users, and $P = \{p_1, p_2, p_3, p_4, \ldots \ldots, p_M\}$ be a set of POIs. Each check-in is denoted as a tuple:

$$C_{u,t} = (p_t, t, c_t, d_t) \tag{1}$$

Here, p_t is the POI visited at time t, c_t represents the category of the POI. d_t is the geographical distance from the previous check-in location. A user's entire check-in history forms a trajectory:

$$T_u = \left(C_{u,1}, C_{u,2}, C_{u,3}, \ldots \ldots, C_{u,T}\right) \tag{2}$$

This trajectory isanalyzed to extract long-term and short-term preferences for personalized recommendations.User mobility patterns exhibit both long-term stability and short-term dynamics.

To model movement patterns, two types of trajectories are defined. The long-term trajectory represents a user's historical movement over a long period. It helps understand habitual travel behavior. The short-term trajectory captures recent movements. It reflects the user's immediate intent. This helps predict short-term POI preferences accurately.To model these preferences, we introduce a weighting mechanism that assigns different levels of importance to past check-ins:

$$S_u = \propto T_u^{long} + \beta T_u^{short} \tag{3}$$

Here, α and β are weighting factors controlling the influence of long-term and short-term preferences.The proposed framework utilizes a hierarchical LSTM model to process POI-level and semantic-level representations. A standard LSTM cell updates its hidden state using:

$$i_t = \sigma(W_i x_t + U_i h_{t-1} + b_i) \tag{4}$$

$$f_t = \sigma(W_f x_t + U_f h_{t-1} + b_f \tag{5}$$

$$o_t = \sigma(W_o x_t + U_o h_{t-1} + b_o \tag{6}$$

$$c_t = f_t c_{t-1} + i_t \tanh(W_c x_t + U_c h_{t-1} + b_c \tag{7}$$

$$h_t = o_t \tanh(c_t) \tag{8}$$

Here, i_t, f_t and o_t are the input, forget and output gates, respectively. c_t is the cell state and h_t is the hidden state.In the hierarchical LSTM structure, a higher-level LSTM integrates POI sequences while another LSTM models semantic-level features namely categories and timestamps. This structure allows us to improve user preferences dynamically.Geographical proximity plays a significant role in user mobility. Users tend to visit POIs that are close to the previous locations. To incorporate this factor, we define a spatial proximity function:

$$G(P_i, P_j) = e^{-\lambda d_{ij}} \tag{9}$$

Here, d_{ij} represents the distance between POIs p_i and p_j and λ is a decay parameter controlling the influence of distance.Additionally, we use a transition probability matrix to model user movement patterns:

$$P_u\left(\frac{P_j}{P_i}\right) = \frac{e^{-\lambda d_{i,j}}}{\sum_k e^{-\lambda d_{i,k}}} \tag{10}$$

This probability helps prioritize nearby POIs when generating recommendations.User check-ins exhibit strong temporal patterns. Some POIs are more popular during specific times of the day. To capture temporal dependencies, we define a time-aware influence function:

$$T(t) = \frac{1}{1+e^{-\gamma(t-\mu)}} \tag{11}$$

Here, γ controls the sharpness of the time preference curve. μ represents the peak visiting time of a POI.By integrating spatial and temporal influences, we enhance the adaptability of the recommendation model.This section introduced essential concepts related to POI recommendation, including trajectory modeling, hierarchical LSTMs and geographical and temporal influences. These foundational principles provide the basis for constructing an effective recommendation framework. The next sections will focus on the implementation details and performance evaluation of the proposed model.

IV. PROBLEM FORMULATION

In this section, we define the problem of next POI recommendation. The goal is to predict the most probable next POI a user will visit based on historical check-in data. We introduce key concepts, notations and mathematical formulations necessary for modeling user behavior.Users interact with POIs over time, forming a sequence of check-ins. Each user check-in is given in (1). A user's entire movement sequence, known as a trajectory is given in (2). The objective is to predict the next check-in location p_{T+1} given past trajectory T_u.Users exhibit both long-term and short-term mobility preferences. To balance both preferences, we define a weighted sum is given in (3). To model user preferences, we employ a hierarchical learning approach using LSTM networks. The LSTM model updates its hidden state is given in (4,5,6,7,8).

The proposed model consists ofPOI-Level LSTM thatlearns sequential dependencies among visited locations.Semantic-Level LSTM captures contextual influences like time and POI categories.Users typically prefer visiting POIs close to the current location. To incorporate this, we define a geographical influence function is calculated and given in (9). A transition probability between POIs is formulated and given in (10). Temporal influence is modeledand given in (11). The final recommendation score for POI p is computed as:

$$Score_u(p) = \alpha\, S_u + \beta\, G_u(p) + \gamma\, T_u(p) \tag{12}$$

Here, S_u captures long- and short-term user preferences, $G_u(p)$ represents geographical influence. $T_u(p)$accounts for temporal behavior, α, β, γ control the influence of each factor.This section formulated the next POI recommendation problem, explaining key elements namely user mobility modeling, hierarchical learning and spatiotemporal influences. Future sections will cover implementation and experimental results.

V. HILS DESIGN

Hierarchical LSTM with Long- and Short-Term Preference Learning (HILS) is a framework designed to enhance next POI recommendations by integrating hierarchical user preference modeling. The goal is to effectively capture long-term stable behaviors and short-term user interests using an advanced LSTM-based architecture. This section provides an in-depth explanation of the HILS framework, including its structure, equations and implementation.The HILS framework consists of three primary modules. First, the trajectory modeling module employs a hierarchical LSTM to learn patterns from POI check-in data. Second, the preference learning module extracts insights from both long-term and short-term trajectories. Finally, the recommendation module ranks potential POIs based on the computed scores from these models. The entire system is optimized using backpropagation and gradient descent.HILS employs a hierarchical LSTM structure to encode user mobility patterns. The model has two main components. The POI-Level LSTM learns sequential patterns among visited locations. It helps capture user movement behavior over time. The Semantic-Level LSTM integrates contextual details. It considers time, category and spatial influences. This enhances recommendation accuracy by understanding user intent and external factors.The core equations governing the LSTM cell updates are given in (4,5,6,7,8). The final trajectory representation is computed as:

$$T_u = \{T_u^{poi}, T_u^{sem}\} \tag{13}$$

Here, T_u^{poi} represents sequential POI interactions and T_u^{sem}models contextual semantics.User mobility exhibits both stable patterns over time and dynamic changes due to recent interests. To model these influences, HILS employs a dual-preference learning mechanism. The long-term preference module utilizes an attention mechanism to identify and prioritize relevant past trajectories:

$$a_i = \frac{e^{T_i * T_{current}}}{\sum_j e^{T_j * T_{current}}} \tag{14}$$

Here, a_i is the attention weight assigned to past trajectory T_i relative to the current check-in sequence T_{recent}. The final long-term preference vector is:

$$S_u^{long} = \sum_i a_i\, T_i \tag{15}$$

The short-term preference model updates based on recent POI sequences using:

$$S_u^{short} = LSTM(T_{recent}) \tag{16}$$

Here, T_{recent} represents the latest POI visits. The combined user preference representation is:

$$S_u = \propto S_u^{long} + \beta S_u^{short} \tag{17}$$

Here, α and β are weight parameters balancing the long-term and short-term preferences.Users often prefer visiting POIs near the current location. To model this behavior, HILS defines a spatial influence function is given in (9). The transition probability between POIs is computed and given in (10). Temporal preferences are modeled using a time-dependent function is given in (11). The final recommendation process involves computing a ranking score for each candidate POI. This score is determined and given in (12). The top-k POIs with the highest scores are recommended to the user.HILS is built using a hierarchical LSTM architecture. Each layer contains 256 hidden units.

This structure helps in capturing complex dependencies in user movements. The Adam optimizer is used for training. It operates with a learning rate of 0.001. This achieves stable and efficient learning. The model uses 128-dimensional embeddings. These embeddings represent POIs and semantic attributes. They help in learning meaningful relationships between locations and user preferences. Training is conducted on real-world check-in datasets. This validates the model's performance. The datasets provide diverse and realistic data. This results in a modelthat generalizes well to different user behaviors and environments.This section explains the HILS framework in detail. It covers hierarchical trajectory modeling.

It includes long- and short-term user preference learning. It also models geographical and temporal influences. Finally, it describes the POI recommendation mechanism.The next sections will discuss experimental evaluations and comparative performance analysis.The following pseudocode describes the complete process of the HILS framework for next POI recommendation.

Algorithm 1: HILS for POI Recommendation.

1. Input: User check-in history T_u, POI set P, Parameters $\boldsymbol{\alpha, \beta, \gamma}$
2. Output: Recommended POIs R_u
3. Initialize hierarchical LSTM with POI and semantic embeddings
4. for each user u in dataset do
5. Extract long-term trajectory T_u^{long} and short-term trajectory T_u^{short}
6. Compute long-term preference $\boldsymbol{S_u^{long} = \sum_i a_i T_i}$
7. Compute short-term preference $\boldsymbol{S_u^{short} = LSTM(T_{recent})}$
8. Merge preferences: $\boldsymbol{S_u = \propto S_u^{long} + \beta S_u^{short}}$
9. Compute spatial influence: $G_u(p) = e^{-\lambda d_{ij}}$
10. Compute temporal influence: $T_u(p) = \frac{1}{1+e^{-\gamma(t-\mu)}}$
11. Compute final recommendation score: $\boldsymbol{Score_u(p) = \alpha S_u + \beta G_u(p) + \gamma T_u}$
12. Rank POIs based on $\boldsymbol{Score_u(p)}$
13. Select top-k POIs as recommendations $\boldsymbol{R_u}$
14. end for
15. Return recommended POIs $\boldsymbol{R_u}$

Source: Authors, (2026).

VI. PERFORMANCE EVALUATION

The performance of HILS is evaluated using real-world datasets to compare its effectiveness against traditional models. Various experiments are conducted to study model performance. The impact of different components is analyzed. An ablation study is performed. The importance of geographical influences is examined. Temporal influences are also evaluated.The evaluation considers standard recommendation metrics like Recall@k, NDCG@k and Precision@k.The datasets used for evaluation are preprocessed by filtering out users with fewer than ten check-ins and POIs visited by fewer than five users. The data is then split into training (70%), validation (10%) and testing (20%) sets. The evaluation metrics provide a fair comparison across models.HILS is compared against various traditional models. It includes LSTPM, ST-LSTM, DeepMove and GeoMF. The results of this comparison are presented in Table 1, showing that HILS outperforms the traditional methods across all metrics.

Table 1: Performance Comparison of HILS and traditional Models.

Model	Recall@5	NDCG@5	Precision@5
HILS	0.712	0.594	0.381
LSTPM	0.678	0.563	0.357
ST-LSTM	0.653	0.541	0.342
DeepMove	0.631	0.529	0.336
GeoMF	0.597	0.498	0.312

Source: Authors, (2026).

To understand the contributions of various components in HILS, an ablation study is conducted. The results presented in Table 2 demonstrate the significance of different features within the model. Removing either the long-term or short-term preference learning components significantly impacts performance. It highlights the importance in capturing user mobility patterns.

Table 2: Ablation Study on HILS Components.

Model Variant	Recall@5	NDCG@5	Precision@5
Full HILS Model	0.712	0.594	0.381
No Long-Term Preference	0.678	0.561	0.358
No Short-Term Preference	0.664	0.548	0.344

Source: Authors, (2026).

The geographical and temporal influences also play a crucial role in user behavior modeling. As shown in Table 3 removing either of these factors leads to a decline in performance, emphasizing the significance.

Table 3: Impact of Geographical and Temporal Factors in HILS.

Model Variant	Recall@5	NDCG@5	Precision@5
Full HILS Model	0.712	0.594	0.381
Without Geographical Influence	0.682	0.570	0.362
Without Temporal Influence	0.671	0.559	0.351

Source: Authors, (2026).

To analyze the performance of HILS a comparison is made with its variants. It includes HILS-N, HILS-NH and HILS-S. Table 4 presents the results of this comparison. The findings show important results. Omitting hierarchical modeling lowers accuracy. Removing semantic information also reduces accuracy. This highlights the importance of HILS. It effectively captures complex mobility patterns.

Table 4: Performance Comparison of HILS Variants.

Model Variant	Recall@5	NDCG@5	Precision@5
HILS	0.712	0.594	0.381
HILS-N	0.689	0.570	0.359
HILS-NH	0.674	0.555	0.345
HILS-S	0.662	0.542	0.338

Source: Authors, (2026).

The results show that the hierarchical structure of HILS provides superior performance compared to simplified variants.Integrating semantic features improves the model. Hierarchical modeling enhances learning. It captures both long-term and short-term user behaviors. This results in better POI recommendations.The performance evaluation demonstrates that HILS significantly improves next POI recommendation accuracy compared to traditional models. The hierarchical LSTM structure effectively captures long- and short-term user preferences while leveraging geographical and temporal factors. The ablation study shows the need for different model components. Comparisons with HILS variants highlight hierarchical and semantic learning. These are important for mobility prediction. Future work focus on hyperparameter optimization with Additional contextual influences included. Testing on diverse datasets improve performance.

The Figure 2 presents a comparison of different models based on the recall performance at two levels: Recall@5 and Recall@10. The models analyzed include HILS, LSTPM, ST-LSTM, DeepMove and GeoMF. From the graph, it is clear that Recall@10 values are higher than Recall@5 across all models. Among them, the HILS model shows the highest Recall@5 value, slightly exceeding 0.7. Its Recall@10 is close to 0.8. LSTPM and ST-LSTM models follow both having Recall@5 values around 0.68. Recall@10 values above 0.72. The DeepMove model has a slightly lower Recall@5 value, approximately 0.65, with its Recall@10 reaching around 0.72. Finally, the GeoMF model has the lowest Recall@5 slightly above 0.6 while its Recall@10 is around 0.7. The gap between Recall@5 and Recall@10 stays nearly the same for all models. Adding more recommendations increases recall. However, the improvement becomes smaller as more recommendations are added. HILS outperforms other models, suggesting that it provides better retrieval performance in this evaluation. GeoMF, on the other hand, has the lowest recall performance among the tested models. The results show that certain models perform better. Models with sequential learning and spatial-temporal dependencies have an advantage. HILS and LSTPM outperform other architectures.

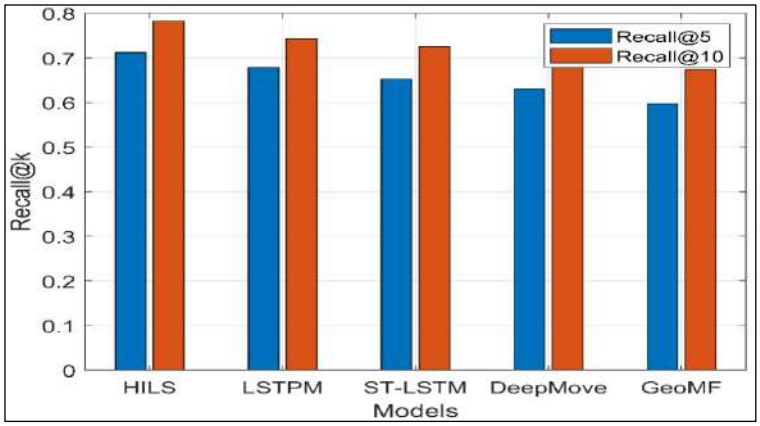

Figure 2: Recall@k versus Different Models.
Source: Authors, (2026).

The Figure 3 compares different models based on the NDCG at two levels: NDCG@5 and NDCG@10. The models evaluated are HILS, LSTPM, ST-LSTM, DeepMove and GeoMF. In the chart, it is clear that NDCG@10 is higher than NDCG@5 for all models. Among these models, HILS achieves the highest NDCG@5 value, slightly above 0.6. NDCG@10 value reaches approximately 0.65. LSTPM and ST-LSTM follow closely with NDCG@5 values around 0.57. NDCG@10 values slightly above 0.6. DeepMove has a slightly lower NDCG@5, approximately 0.54 with its NDCG@10 reaching close to 0.6. Finally, GeoMF has the lowest NDCG@5, around 0.5. NDCG@10 is just above 0.55. The trend in the chart suggests that models with higher NDCG@5 tend to maintain the ranking order at NDCG@10. The gap between NDCG@5 and NDCG@10 stays almost the same for all models. Adding more recommendations improves ranking quality. However, the improvement decreases as more recommendations are included. HILS outperforms all other models, showing its ability to provide better-ranked recommendations. GeoMF, on the other hand performs the worst among the tested models. The results show that some models rank relevance better. Models using sequential learning and spatial-temporal dependencies perform well. HILS and LSTPM are more effective than other models.

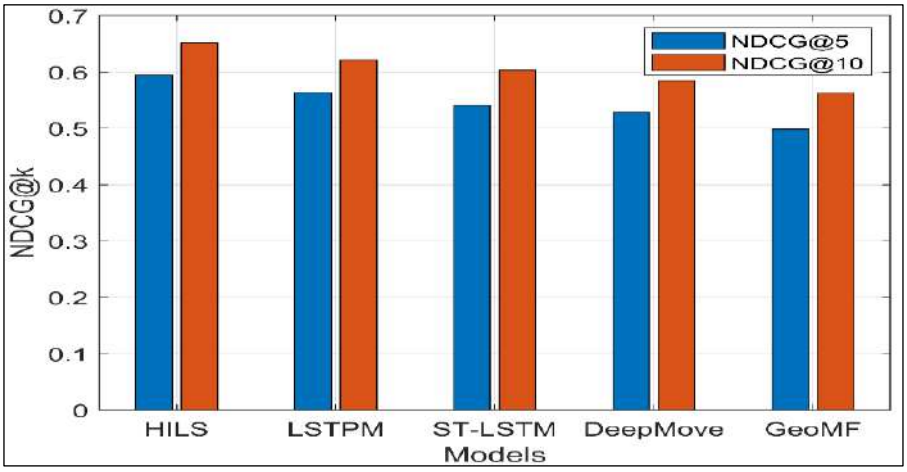

Figure 3: NDCG@k versus Different Models.
Source: Authors, (2026).

The Figure 4 presents a comparison of different models based on the precision at two levels: Precision@5 and Precision@10. The models analyzed include HILS, LSTPM, ST-LSTM, DeepMove and GeoMF. From the graph, it is clear that Precision@10 values are slightly higher than Precision@5 across all models. Among them, the HILS model shows the highest Precision@5 value slightly above 0.37. Precision@10 is near 0.42. LSTPM and ST-LSTM have Precision@5 around 0.34. The Precision@10 values are above 0.39. DeepMove has a lower Precision@5 about 0.33. Its Precision@10 reaches around 0.38. GeoMF has the lowest Precision@5 slightly above 0.30. Its Precision@10 is around 0.35. The chart shows that models with higher Precision@5 also have higher Precision@10. This means the ranking performance is stable. The gap between Precision@5 and Precision@10 is small. Adding more recommendations slightly improves precision. HILS outperforms other models, suggesting that it provides better precision performance in this evaluation. GeoMF, on the other hand, has the lowest precision performance among the tested models. The results show that some models perform better. Models with sequential learning and spatial-temporal dependencies have an advantage. HILS and LSTPM outperform other architectures.

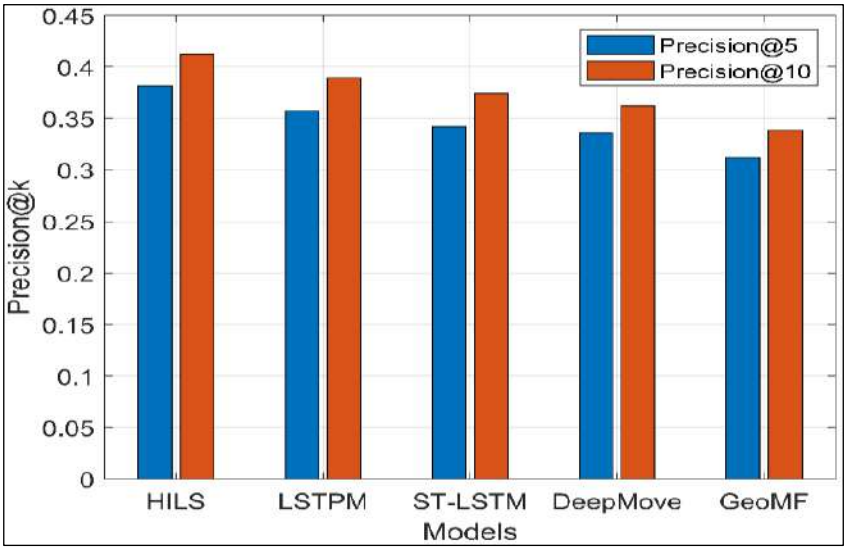

Figure 4: Precision@k versus Different Models.
Source: Authors, (2026).

The Figure 5 evaluates the impact of different modifications on the HILS model by measuring three key performance metrics: Recall@5, NDCG@5 and Precision@5. Recall@5 starts at 0.71 in the Full HILS model. It drops steadily to 0.66 in the No Attention variant. NDCG@5 follows the same trend. It decreases from 0.6 in Full HILS to 0.55 in No Attention. Precision@5 also declines. It moves from 0.39 to 0.33 as components are removed. The declining trend across all three metrics indicates that each component contributes significantly to model performance. The removal of long-term and short-term preferences leads to noticeable reductions in Recall@5 and NDCG@5. It suggests that both are crucial for maintaining effective ranking and retrieval performance. Precision@5 also decreases but at a slightly slower rate. It also shows that the model still retains some accuracy even as these components are removed. The No Attention variant performs the worst across all metrics, suggesting that attention mechanisms play a vital role in optimizing HILS. Overall, the results highlight the importance of preserving all key components to achieve the best recommendation performance.

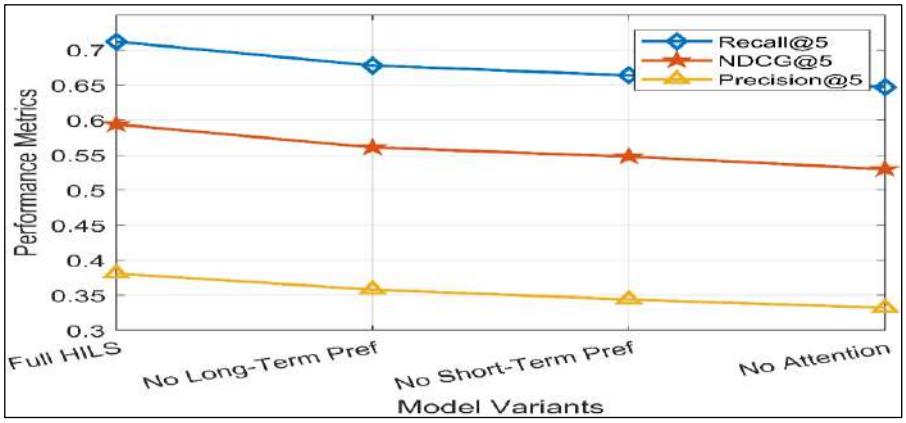

Figure 5: Ablation Study: Performance Impact of Different Components.
Source: Authors, (2026).

The Figure 6 illustrates how different modifications in the HILS model affect three performance metrics. Recall@5 starts at 0.71 in Full HILS. It gradually drops to 0.68 without geographical influence. It then slightly decreases to 0.66 without temporal influence. NDCG@5 starts near 0.6. It steadily declines to 0.56 after removing both influences. Precision@5 begins at 0.39. It drops to 0.35 when both geographical and temporal influences are excluded. The downward trend in all three metrics suggests that both geographical and temporal components play a key role in the performance of the HILS model. Removing geographical influence reduces Recall@5 and NDCG@5 highlights the importance of location-based data in improving recommendation relevance. Removing temporal influence causes a slight performance drop. This shows that time-sensitive patterns add value. The decline is smaller than in models without attention mechanisms. However, it proves that spatial and temporal factors improve recommendations.

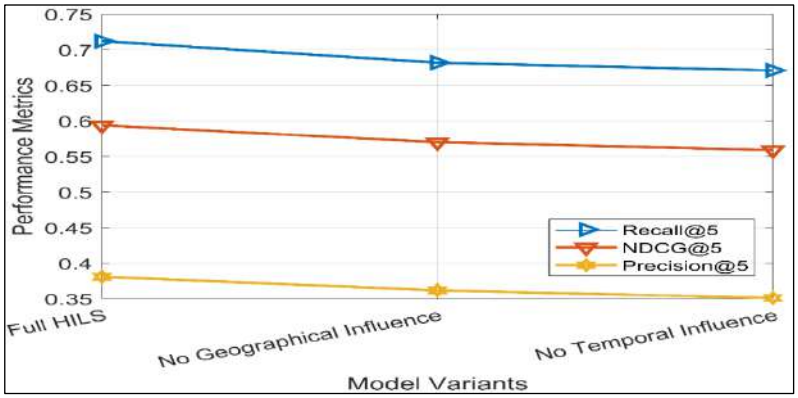

Figure 6: Geographical & Temporal Influence on Performance.
Source: Authors, (2026).

The Figure 7 compares the recall performance of four different models—HILS, HILS-N, HILS-NH and HILS-S. HILS performs better than other models. It starts at 0.7 with 5 candidate POIs. It rises steadily to 0.85 with 25 POIs. HILS-N has the second-highest recall. It starts slightly below 0.7 at 5 POIs and reaches 0.75 at 25 POIs. HILS-NH follows closely behind HILS-N. It begins just above 0.68 and increases to 0.73. HILS-S has the lowest recall among the four models. It starts at around 0.65 and increases to nearly 0.72 as the number of candidate POIs grows.The trend in the chart suggests that increasing the number of candidate POIs improves recall performance for all models. HILS has the highest recall. This shows it is better at retrieving relevant POIs. HILS-N and HILS-NH follow a similar trend. However, HILS-N performs slightly better. HILS-S has the lowest recall. This suggests it is less efficient than other models. All models improve as candidate POIs increase. However, the rate of improvement differs for each model.

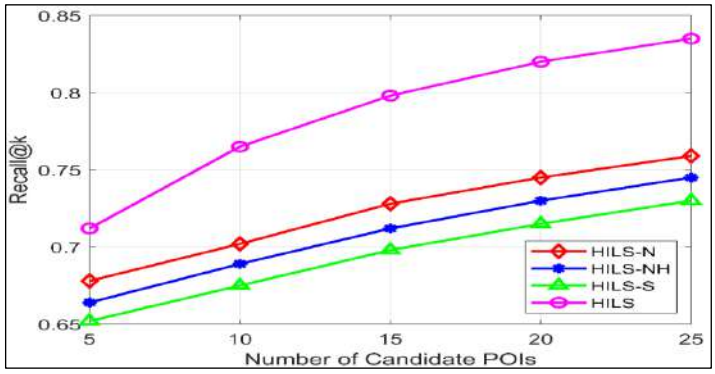

Figure 7: Effect of Increasing POI Candidates on Recall@k.
Source: Authors, (2026).

The Figure 8 presents a comparison of four model variants—HILS-N, HILS-NH, HILS-S and HILS. Recall@5 is the highest for the HILS model reaching slightly above 0.7. HILS-N, HILS-NH, and HILS-S have similar Recall@5 values. They are all near 0.7 but slightly lower than HILS. NDCG@5 follows the same pattern. HILS performs best at around 0.6. The other models have values between 0.53 and 0.57. Precision@5 shows smaller differences. It ranges from 0.33 to 0.36. HILS performs slightly better than the other models. The chart shows that the full HILS model provides the best results with all three metrics being higher than those of its variants. The differences are more significant in Recall@5 and NDCG@5, which suggest that the full HILS model is more effective in retrieving and ranking relevant results. The small variation in Precision@5 shows similar accuracy across models. All versions maintain a close level of precision. This suggests that model structure affects recall and ranking more. The results highlight the need to keep all HILS components. Keeping all parts gives the best performance in recall, ranking and precision.

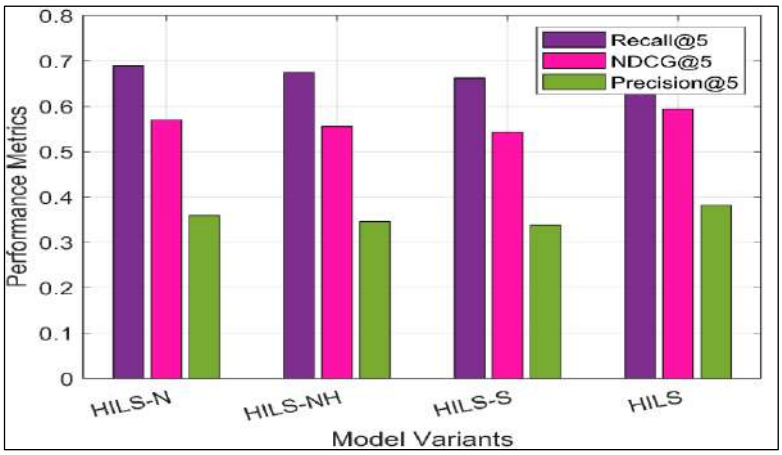

Figure 8: Comparison of Different POI Approaches
Source: Authors, (2026).

The Figure 9 compares the recall performance of two datasets, NYC and TKY based on different values of n. Both datasets show a positive trend with recall increasing as n increases. At n = 1, NYC starts with a recall value of about 0.2. TKY starts slightly higher at around 0.3. As n grows, the recall values of both datasets increase steadily. At n = 25, NYC reaches approximately 0.6. TKY is slightly above 0.7. At n = 100, NYC's recall is close to 0.9. TKY reaches nearly 1.0. The trend in the chart suggests that increasing n leads to higher recall values for both datasets. The TKY dataset performs better than NYC at every value of n. The difference between the two datasets remains fairly constant as n increases, indicating that TKY has a stronger recall performance. At the highest n value, both datasets reach maximum recall. TKY achieves 1.0, showing perfect recall. NYC follows closely behind. This means TKY's recommendations are slightly better. Both datasets improve with more candidate recommendations.

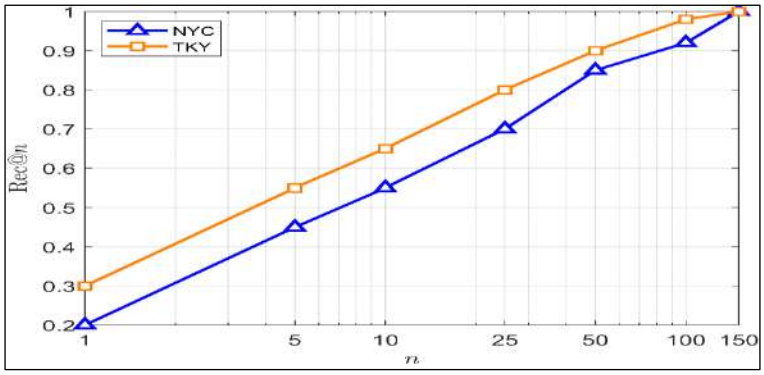

Figure 9: Effect of Number of Categories n
Source: Authors, (2026).

The Figure 10 compares the execution time of four different model variants—HILS, HILS-N, HILS-NH and HILS-S. Each model follows a similar increasing trend with execution time grows as the dataset size becomes larger. For smaller datasets like 500 and 1,000 users/POIs, execution time stays low. It remains under 10 seconds for all models. At 5,000 users/POIs, execution time rises to about 20 seconds. A sharper increase happens at 10,000 users/POIs. Execution time reaches around 50 seconds. At 20,000 users/POIs, execution time goes over 120 seconds. The full HILS model takes the longest time. The overall trend suggests that execution time scales non-linearly with dataset size. It means larger datasets require significantly more processing time. Among the models, HILS exhibits the highest execution time. It indicates that its additional computational complexity demands more resources. HILS-S also shows slightly higher execution time compared to the other variations. HILS-N and HILS-NH are more efficient. The execution times are slightly lower. All models show a similar increase in execution time as the dataset grows. However, some variations are better optimized. These models process data faster than others.

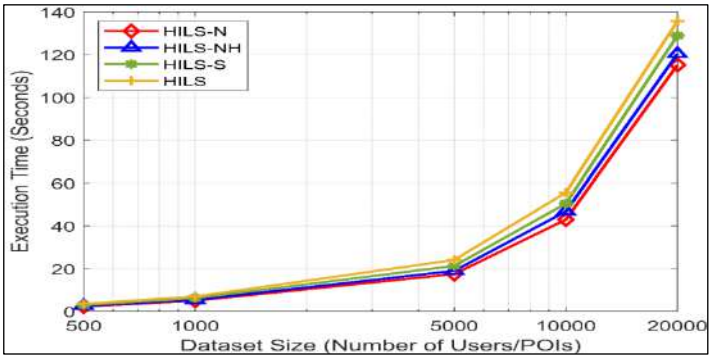

Figure 10: Model Scalability: Performance versus Dataset Size.
Source: Authors, (2026).

The Figure 11 compares the recall performance of four different model variants—HILS, HILS-N, HILS-NH and HILS-S. HILS model outperforms the other models at every embedding dimension. It starts at around 0.63 at 32 dimensions, rises to nearly 0.74 at 128 dimensions and slightly decreases at 256 dimensions. HILS-N follows a similar trend but with slightly lower values. It reaches a peak of about 0.71 at 128 dimensions before declining. HILS-NH and HILS-S both shows the same peak at 128 dimensions but with lower recall values compared to the other two models. The trend in the chart suggests that increasing embedding dimensions initially improves recall performance for all models. However, after reaching 128 dimensions recall starts to decrease slightly. Increasing embedding dimensions improves model representation. However, this works only up to a certain point. Very large embeddings add noise or redundancy. This reduce performance instead of improving it. The HILS model achieves the highest recall, demonstrating that it benefits the most from increased embedding dimensions. HILS-N and HILS-NH follow closely, while HILS-S shows the lowest recall values at all embedding sizes. These results highlight that an optimal embedding size exists for achieving the best recall and beyond this point performance decline.

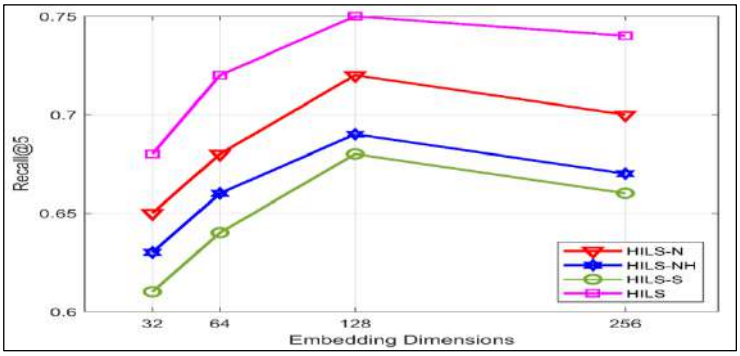

Figure 11: Effect of Different Embedding Dimensions.
Source: Authors, (2026).

The Figure 12 displays the relationship between user activity levels and three performance metrics: Recall@5, NDCG@5 and Precision@5. Recall@5 starts at approximately 0.7 for low-activity users and increases gradually to about 0.75 for high-activity users. NDCG@5 begins at around 0.55 and reaching nearly 0.6 as user activity increases. Precision@5 shows a steady rise from about 0.35 for low-activity users to approximately 0.45 for high-activity users.The pattern in the chart suggests that higher user activity leads to improved recommendation performance across all three metrics. The increase in Recall@5 and NDCG@5 implies that the model benefits from more interactions. It results in more accurate ranking and retrieval. Precision@5 also improves indicating that active users receive more relevant recommendations. While all metrics show growth, Recall@5 exhibits the most notable improvement. It reflects a stronger ability to retrieve relevant results for highly active users. These results emphasize the importance of user engagement in enhancing recommendation accuracy and ranking effectiveness.

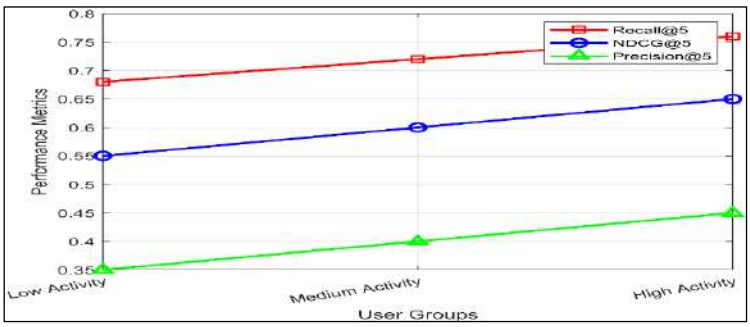

Figure 12: Model Performance across Different User Groups.
Source: Authors, (2026).

The Figure 13 displays the variation in three performance metrics—Recall@5, NDCG@5 and Precision@5. It is across different times of the day: Morning, Afternoon, Evening and Night. Recall@5 starts at 0.72 in the morning. It gradually increases through the afternoon and evening. It peaks at 0.78 in the evening. Then, it drops slightly at night. NDCG@5 follows a similar trend. It starts at 0.58 in the morning. It rises to 0.63 in the evening. After that it declines at night. Precision@5 starts at 0.38 in the morning. It increases to 0.45 in the evening. Then it drops back down at night. The trend in the chart suggests that performance improves throughout the day. It reaches its highest levels in the evening before declining at night. The increase in Recall@5 and NDCG@5 during the evening indicates that the recommendation model performs best at this time due to higher user engagement. The decline at night across all three metrics suggests that recommendations are less effective when user activity is lower. Precision@5 follows the same pattern but with a smaller overall variation. These results highlight the importance of time-based patterns in recommendation performance, showing that the model is most effective during peak activity hours.

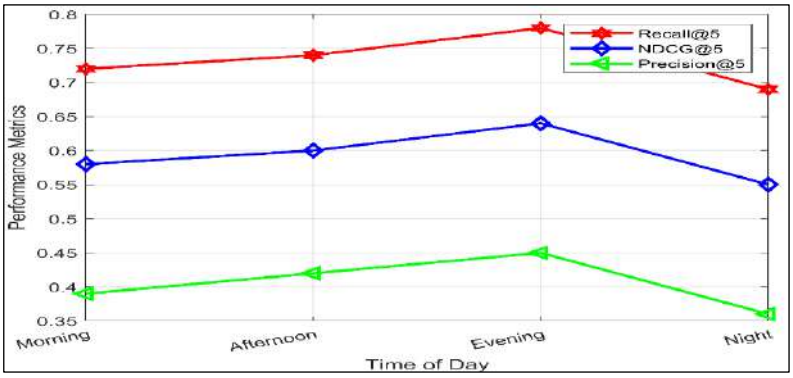

Figure 13: Effect of different Time Windows on Performance.
Source: Authors, (2026).

The Figure 14 presents the variation in three performance metrics—Recall@5, NDCG@5 and Precision@5. It is across different times of the day: morning, afternoon, evening and night. Recall@5 starts at 0.72 in the morning. It increases slightly in the afternoon. It reaches 0.78 in the evening. Then, it drops slightly at night. NDCG@5 starts at 0.58. It rises steadily to 0.63 in the evening. After that, it decreases at night. Precision@5 follows the same pattern. It increases from 0.38 in the morning to 0.45 in the evening. Then, it declines at night. The overall trend suggests that recommendation performance improves as the day progresses, peaking in the evening before declining at night. The increase in Recall@5 and NDCG@5 during the evening indicates that recommendations are most effective when user activity is higher. The decrease at night suggests that lower user engagement impact the model's ability to generate relevant recommendations. Precision@5 follows a similar pattern, though with a smaller range of variation. These results emphasize the impact of time on recommendation accuracy. The model achieves its best performance during peak user activity hours.

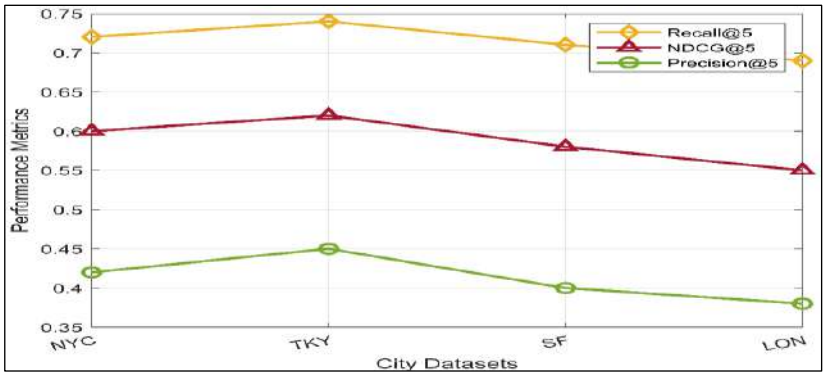

Figure 14: Performance Across different City Datasets.
Source: Authors, (2026).

The Figure 15 represents the distribution of the standard deviation of geographical distances. The data follows a bell-shaped pattern suggesting a normal distribution. The highest frequency is observed around the center of the distribution. The standard deviation values range from approximately 15 to 25. The peak frequency reaches slightly above 100, indicating that most data points fall within this range. As the standard deviation increases beyond 25 the frequency declines gradually. Fewer instances are observed beyond a value of 30. Similarly, on the lower end very few occurrences are recorded below 10. The distribution shows most geographical distances vary moderately. There are fewer cases of very small or very large variations. The data spread indicates different movement patterns. Some users move very little. Others travel much larger distances. The balanced shape of the histogram implies that extreme values are rare and the data is centered around a common range. This pattern helps in understanding user mobility. It shows how users move in different areas. It improves location-based recommendations. Targeting common movement patterns makes recommendations more effective.

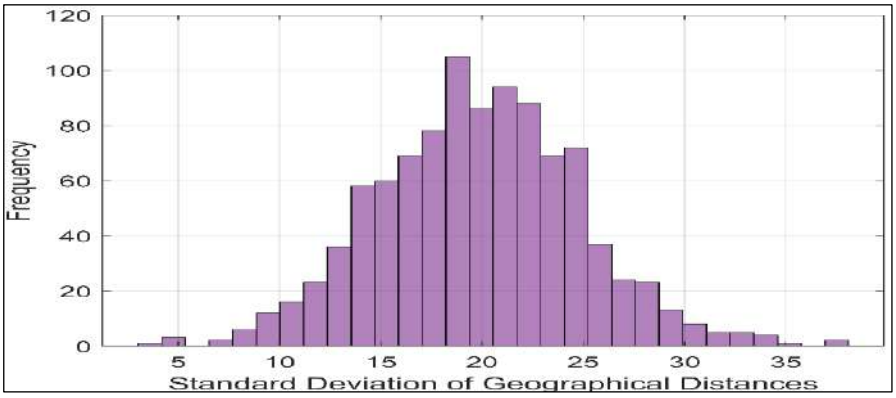

Figure 15: The Distribution of Standard Deviation.
Source: Authors, (2026).

The Figure 16 presents the number of check-ins for ten users sorted by activity level, comparing four model variants: HILS, HILS-N, HILS-NH and HILS-S. HILS model records the highest number of check-ins among all users. HILS-S follows closely maintaining a slightly lower number of check-ins. HILS-N and HILS-NH show similar trends with slightly fewer check-ins than HILS and HILS-S. The number of check-ins decreases with lower user activity. The most active users have over 350 check-ins. The least active users have fewer than 100 check-ins. The trend in the chart suggests that all models show a steady decline in check-ins as user activity decreases. The gap between HILS and the other models is more noticeable for highly active users. The differences become smaller for lower-activity users. HILS maintains a clear advantage in check-ins across all users, demonstrating its effectiveness in capturing user engagement. The similarities between HILS-N and HILS-NH suggest that both models perform similarly for users with medium to low activity. Higher user activity leads to more check-ins. Models with better learning mechanisms capture this behavior well. HILS performs better in tracking check-ins.

VII. CONCLUSIONS

This paper presented the HILS framework for next POI recommendation. The model captures stable long-term behaviors. It also learns dynamic short-term user preferences. Hierarchical trajectory modeling enhances learning. Semantic feature learning improves understanding. Temporal and spatial influences are integrated. The experimental results highlight the advantages of HILS over existing methods, demonstrating its superior accuracy in predicting user mobility patterns.HILS introduces a structured approach by decomposing user check-ins into POI-level and semantic-level features. The POI-level LSTM models sequential dependencies in visited locations.

The semantic-level LSTM incorporates contextual factors like time, category and location history. The dual-layer LSTM structure promotes that the model captures user intent more effectively than conventional single-layer models.The performance evaluation reveals that HILS outperforms traditionalmodels. Ablation studies explains the significance of each component in HILS. Removing long-term preference learning leads to a decrease in recall. It emphasizes the importance of capturing stable user behaviors. Eliminating short-term modeling results in lower precision, highlighting the need for recent trajectory updates. The attention mechanism gives long-term trajectory selection, improving the overall recommendation process.Geographical and temporal influences play a crucial role in refining predictions.

Users are more to visit POIs within a specific distance from the previous locations and the model incorporates this factor using a spatial proximity function. The integration of these external factors enhances the accuracy of POI ranking.HILS presents a novel approach to POI recommendation by integrating hierarchical preference modeling, attention-based trajectory selection and contextual influence learning. The experimental analysis validates its effectiveness and highlights the benefits of structured representation learning.

Future work explore incorporating additional contextual signals, optimizing hyperparameter tuning and extending the model for multi-user collaborative recommendations. The findings contribute to advancing the field of personalized mobility prediction, offering a robust solution for next POI recommendation in dynamic environments.

ABSTRACT

Stress is a major issue in today's life. It harms health and lower work output. People sometimes do not notice when under stress. That is why early stress detection is important. This paper uses two types of body signals: ECG (Electrocardiogram) and EDA (Electrodermal Activity). Both are physiological signals and help measure stress levels. A deep learning model named CNN (Convolutional Neural Network) is used. CNN has many layers. Each layer captures different kinds of features—low-level, mid-level and high-level. These features are useful in identifying stress. Instead of using features from only one level, this paper combines all three levels. This process is named as hierarchical feature fusion. It helps in creating a strong and rich representation of the signals. The features from ECG and EDA are first extracted at different CNN layers. Then, a module termed MMTM (Multimodal Transfer Module) is used. This module helps combine features from both signals. It improves the way the model learns from the data. The model is tested using both raw data and features from selected frequency bands. Results show that using features from all three CNN levels gives better performance. The proposed model performs better than existing models when using frequency band features. This shows that combining low, mid and high-level CNN features with multimodal fusion is helpful. It improves the accuracy and generalization of stress detection. This method works better across different datasets and different people. The proposed system is a useful tool in real-world stress detection systems.

I. INTRODUCTION

Stress is a common problem in everyday life [1]. People feel stress due to work, emotions or difficult situations. Stress affects both the body and mind. Some people feel it physically through sweating or chest pain [2]. Others feel it emotionally through anger or sadness. When people face stress, the body reacts automatically. This is referred to as the fight or flight response.

It helps a person deal with danger or pressure. The hypothalamus, a part of the brain controls this response [3]. It sends signals to the body using the Autonomic Nervous System (ANS). The ANS has two parts. The first is the Sympathetic Nervous System (SNS). It prepares the body to fight or run away. It increases the heart rate, makes a person sweat and speeds up breathing. The second part is the Parasympathetic Nervous System (PNS). It helps the body calm down after the stress passes. Acute stress is short-term. It comes and goes quickly. Chronic stress lasts for a long time and leads to serious health problems [4]. Long-term stress causes anxiety, heart problems, memory issues and more. To avoid these problems, it is important to detect stress early. Early detection help people live a better, healthier life [5]. Stress is detected in three ways: psychological, behavioural and physiological. Psychological tests ask people about feelings. But these tests depend on memory and honesty.

People sometimes forget feelings or choose to hide them [6]. Behavioural signs include body movements or facial expressions. But people hide these reactions. Physiological signals are the best indicators. People cannot easily control them. Common signals include ECG and EDA. These signals change when a person feels stress. Recent technology allows us to use machines to detect stress. Machine learning and deep learning models are trained on these signals. Models like SVM, random forest and CNN are used. Deep learning models need more data but learn better features [7]. Multimodal fusion uses more than one type of signal. It improves the accuracy of stress detection. There are three types of fusion: early, intermediate and late. Early fusion combines signals at the input stage. Late fusion combines at the output stage. Intermediate fusion combines at the feature level. CNN models are good at learning features [8]. Each CNN layer learns something different. Early layers learn simple features. Later layers learn complex patterns. Using only one layer's features is not enough.

This approach loses useful information. Combining features from all levels improve performance [9]. This paper proposes a new method for stress detection. It combines low, mid and high-level features from CNN. These features come from ECG and EDA signals. The features are joined together to form a strong feature set [10]. This is termed as hierarchical feature fusion. Then, the features from both signals are combined using the MMTM. This step is titled as multimodal fusion. The final step is to use a classifier to decide if the person is stressed or not [11]. This is named as late fusion. The paper tests the model on four datasets: ASCERTAIN, CLAS, MAUS and WAUC. It compares results from raw data and frequency band features. Frequency bands capture signal strength at different frequency ranges. Results show that using all levels of features gives better accuracy. It shows that frequency band features perform better than raw data [12]. The key contributions of this paper are:

- To integrate low, mid and high-level CNN features using hierarchical feature fusion. It captures detailed, intermediate and abstract signal representations.
- To enhance learning by combining ECG and EDA features through multimodal fusion using the MMTM.
- To compare raw signal data with frequency band features and demonstrate that frequency bands provide more relevant information. It results in improved accuracy and model performance.
- To evaluate the model on four benchmark datasets and confirm its stable performance across diverse users and conditions indicating strong generalization.

Stress is a major health issue. Detecting it early helps people manage it better. By combining features from multiple levels, the model becomes more accurate. This paper proposes a new model. It uses hierarchical feature fusion and multimodal fusion [13]. It tests the model on several datasets. The results show improved accuracy and generalization. The method is simple and effective. It is used in real-world systems to detect stress in people.

II. RELATED WORK

In recent years, deep learning is widely used for many tasks. One powerful model is the CNN. CNN extracts important features from data. These features are either shallow, intermediate or deep. Combining features from multiple layers is termed as hierarchical feature fusion. Hierarchical feature fusion improves the model's performance. It reduces the chance of losing useful information. Many researchers used this method in different domains like face recognition, image classification, quality assessment, defect detection and medical image analysis. By [14] used hierarchical deep feature fusion to classify plant diseases. Pre-trained CNN models were used to extract deep features from plant images. Then, multi-level fusion and feature selection were applied. Finally, a Multi-SVM classifier was used to detect diseases. In turn [15] used hierarchical features for face recognition. Shallow and deep features were combined using supervised learning. This improved recognition under challenging conditions like occlusion and bad lighting.

Both VGG and Lightened CNN model is used. It gave strong results on AR and LFW datasets. According to [16] proposed a method for image quality assessment. A staircase structure was used to combine CNN features from all layers. The approach helped the model learn from low to high-level details. The model was trained on multiple datasets at once. The results were better than existing methods on six real-world datasets. By [17] applied hierarchical fusion to detect steel surface defects. A simple CNN model was created to extract features at each level. Then, a feature fusion network was used to merge these features. The method worked well on the NEU-DET dataset. By [18] introduced a feature selection mechanism. High-level features were used to select and connect low-level features. This improved feature representation across layers. The model performed well on several computer vision tasks. According to [19] worked on remote sensing image classification.

Features from different CNN layers were combined. Each feature map was transformed before fusion. The model showed strong results on public satellite image datasets. In turn [20] proposed a hierarchical model for medical image segmentation. Two modules: Hierarchical Feature Aggregation (HFA) and Multiscale Feature Aggregation (MFA) were used. These modules combined features from all layers of the network. The model achieved 97% accuracy on PH2, ISIC-2018 and UFBA-UESC datasets. By [21] used hierarchical fusion in image compression. Intra-stage and inter-stage feature aggregation was introduced. The method preserved multiscale and contextual information. The approach outperformed many state-of-the-art (SOA) models. According yo [22] used hierarchical CNN features for cross-resolution face recognition. Models that combine features from different CNN layers perform better. Most of these studies are focused on image data.

Very few works use physiological signals like ECG and EDA. This shows a research gap. There is a need to explore hierarchical CNN fusion with physiological data. Stress detection using physiological signals is a growing area. Signals like ECG and EDA are rich in information. Deep learning models like CNN learn useful patterns from these signals. The work proposes combining features from all levels of CNN. This forms a hierarchical feature set. Hierarchical feature fusion is an effective way to improve deep learning models. Many studies used this method in vision tasks. Few applied it to physiological data. This paper fills that gap. It combines CNN features at multiple levels for ECG and EDA. It fuses both modalities using MMTM. The method is tested on four standard datasets. The results show better accuracy and generalization than existing models.

III.METHODOLOGY

The main purpose is to use both shallow and deep features from multiple CNN layers. This is referred to as hierarchical feature fusion. The model uses signals from two sources: ECG and EDA. These signals are fused together. This is described as multimodal fusion. This uses four public datasets. ASCERTAIN dataset has data from 58 people. Based on the ratings of the videos for valence and arousal, stress labels were assigned. High arousal and low valence values mean stress. CLAS dataset includes data from 62 people, later reduced to 59 after cleaning. The people watched 16 emotional clips. MAUS dataset was recorded during a memory task termed the N-back test. WAUC dataset has data from 48 people performing physical activities like cycling or rowing. All four datasets had class imbalance. There were more unstressed samples than stressed ones. To fix this, SMOTE (Synthetic Minority Over-sampling Technique) was used. SMOTE creates new samples for the smaller class by interpolating between nearby points.

The Figure 1 compares two deep learning models used for stress detection. The top part (a) shows the traditional approach. It processes input through three phases: Phase 1 extracts low-level features, Phase 2 gets mid-level features and Phase 3 gathers high-level features. These features are passed step-by-step from one phase to the next. The final high-level features go into the classification block. This block predicts whether the person is stressed or unstressed. The process flows in a straight line and each phase only uses the output from the previous one. The bottom part (b) shows the proposed approach. It uses the three phases, but instead of passing features in a straight line, it connects the outputs of all three phases to a common point. These features are then concatenated together before classification. This shows the classifier uses low, mid and high-level features at once. This combined view helps the model learn better patterns. The proposed model makes better use of the input by capturing information at different depths, leading to better performance in stress classification.

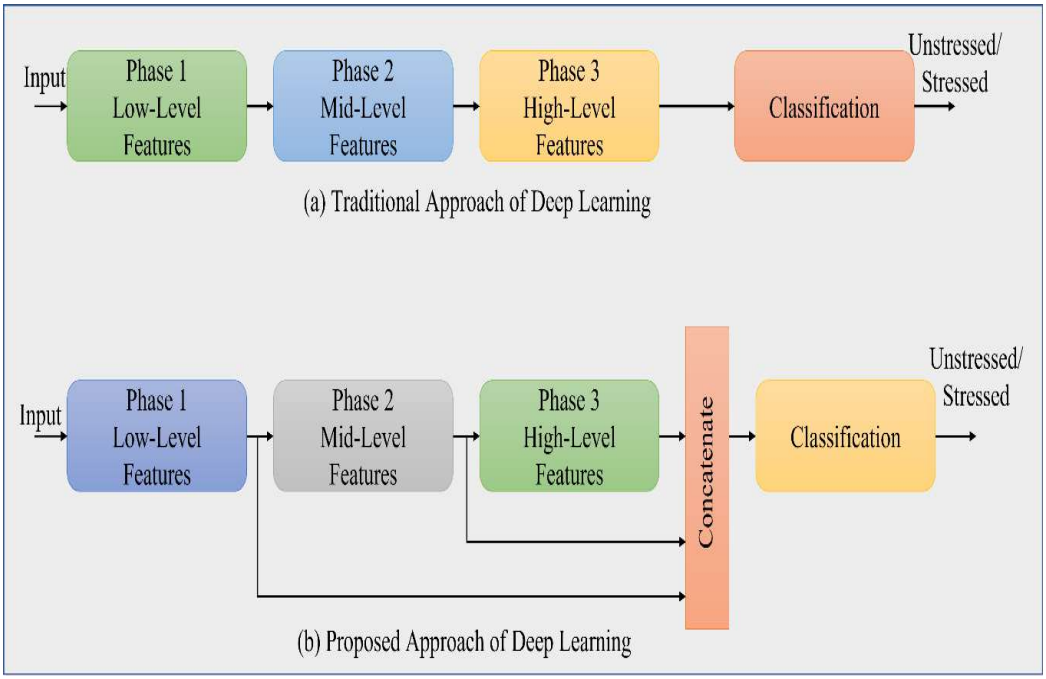

Figure 1: Traditional and proposed deep learning techniques are depicted.
Source: Authors, (2026).

Each ECG or EDA signal is split into five-second segments. This gives more data for training. The model uses subject-independent training and testing. The people used for training are different from the people used for testing. This improves generalization. For each dataset training data has 36 WAUC, 18 MAUS, 43 CLAS, 42 ASCERTAIN subjects. Testing data has 9 WAUC, 4 MAUS, 16 CLAS, 16 ASCERTAIN subjects. The researchers use two types of input features. The first type is raw data and the second is frequency band features. For the raw data, the ECG and EDA signals are transformed into the frequency domain using the Discrete Cosine Transform (DCT). The DCT helps convert time-domain signals into a series of frequency components, which are easier to analyze for patterns. This method captures the energy and frequency distribution of the signals. The DCT formula used is:

$$X(k) = \sum_{n=0}^{N-1} x(n) \cos\left[\frac{\pi}{N}\left(n+\frac{1}{2}\right)k\right], \quad 0 \le k < N \tag{1}$$

Here, $x(n)$ is the signal, N is the total number of samples. $X(k)$ represents the transformed signal in the frequency domain. The second type of feature is the frequency band features. For ECG signals, three frequency bands are selected: 0.0 to 0.04 Hz (very low), 0.04 to 0.15 Hz (low) and 0.15 to 0.40 Hz (high). For EDA signals, five bands are selected: 0.05–0.15 Hz, 0.15–0.25 Hz, 0.25–0.35 Hz, 0.35–0.45 Hz and 0.45–0.50 Hz. These bands are chosen because the autonomic nervous system influences them and the activity reflects stress-related changes. From each band, several statistical features are extracted. In total, 51 features are extracted from the ECG bands and 40 from the EDA bands. This set of features provides more detailed information than using raw signals alone. In a CNN model, different layers learn different types of features. The first few layers usually learn low-level features like edges. The middle layers learn patterns and shapes and the last layers learn complex representations. Most traditional models only use the last layer for classification. But in this work, features from three stages are used and combined together. This process is termed as hierarchical feature fusion.

By combining features from all three levels, the model keeps more useful information. This helps it learn better patterns for stress detection. The hierarchical features are created by taking the outputs from three different convolutional phases and concatenating them into one large feature set. This is done separately for the ECG and EDA signals. The CNN architecture used in this work has four convolutional layers. Each layer uses a 3×3 kernel and applies the ReLU activation function. After each convolution, the model uses batch normalization and max pooling. These operations help the model learn faster and avoid overfitting. The first convolutional layer has 32 filters. The second has 64 filters, the third has 128 filters and the fourth has 256 filters. The output from each phase is used to form the hierarchical feature set for each signal. These features are then passed to the next stage, which is the fusion module. To combine the ECG and EDA features, a special module termed MMTM is used. First, it creates a joint representation of the input features. It applies two sets of fully connected layers to generate excitation signals for each modality. These signals are used to recalibrate or adjust the original features. Let F_{ECG} be the feature set from the ECG signal. F_{EDA} be the feature set from the EDA signal. The MMTM first combines them to get a joint representation:

$$F_{joint} = F_{ECG} \oplus F_{EDA} \tag{2}$$

For each modality the module generates recalibrated outputs using the following equations:

$$F'_{ECG} = \sigma(W_{ecg2}(ReLU(W_{ecg1}(F_{joint})))) \times F_{ECG} \tag{3}$$

$$F'_{EDA} = \sigma(W_{eda2}(ReLU(W_{eda1}(F_{joint})))) \times F_{EDA} \tag{4}$$

Here, $W_{ecg1}, W_{ecg2}, W_{eda1}$ and W_{eda2} are learnable weights in the fully connected layers. The ReLU function adds non-linearity and σ is the sigmoid activation function. The final recalibrated features F'_{ECG} and F'_{EDA} are passed to the next step. The recalibrated ECG and EDA features are passed to two fully connected layers FC1 and FC2. These layers transform the features and reduce the size. After the final dense layer, the model uses a sigmoid output function. This function gives a value between 0 and 1. It shows the probability that the input belongs to the stress class. To train the model, the Binary Cross-Entropy loss function is used:

$$L = -\frac{1}{N}\sum_{i=1}^{N}\left[y_i \log(p_i) + (1-y_i)\log(1-p_i)\right] \tag{5}$$

Here, y_i is the actual label and p_i is the predicted probability. This loss helps the model learn by comparing the predicted value with the true label. The training process uses the Adam optimizer with default learning rate. The batch size is 64. An early stopping technique is used. If the validation loss does not improve for 30 epochs, the training stops. This helps avoid overfitting and saves time. After the hierarchical features are processed and recalibrated using the MMTM each modality produces classification probabilities. Instead of choosing only one, the proposed model uses a strategy named late fusion. In this method, the output classification probabilities from ECG and EDA are combined at the final stage. This is done by averaging or weighting the scores from each modality. This combined decision is used to determine the final class label — whether the person is stressed or not stressed. Late fusion helps the model become more reliable. If one modality makes a weak prediction, the other compensate.

This improves the model's performance and robustness across different situations. In earlier work, it was found that the high-frequency band of ECG (0.15–0.40 Hz) and band-b of EDA (0.15–0.25 Hz) performed best. For this reason, the same architecture is tested using only those best-performing frequency bands. This experiment is done on the WAUC dataset. The model structure remains the same, but the pooling method is changed. In this case, max-pooling is removed and the kernel size is set to 2×2. The purpose of this experiment is to compare performance. This work explores whether using the full band features is better than using only the highest-performing bands. Finally, the classification probabilities from ECG and EDA are merged using late fusion. The model predicts whether the subject is under stress or not. The model is trained using binary cross-entropy loss. It uses the Adam optimizer, a batch size of 64 and early stopping to avoid overfitting. The system is tested on four public datasets using both raw frequency domain data and frequency band features.

IV.RESULTS & DISCUSSION

The proposed model is studied using raw data and frequency band features. The model was tested on four different datasets: ASCERTAIN, CLAS, MAUS and WAUC. Two key performance metrics were used to measure the model's effectiveness: accuracy and F1-score. The formulas are as follows:

$$\text{Accuracy} = \frac{\text{TP}+\text{TN}}{\text{TP}+\text{TN}+\text{FP}+\text{FN}} \times 100 \tag{6}$$

$$\text{F1-score} = \frac{\text{TP}}{\text{TP}+\frac{1}{2}(\text{FP}+\text{FN})} \times 100 \tag{7}$$

Here, TP = True Positive, TN = True Negative, FP = False Positive and FN = False Negative. Accuracy shows the number of correct predictions. F1-score balances precision and recall. The model uses three types of CNN features: shallow (phase 1), mid-level (phase 2) and deep (phase 3). Each phase captures different levels of information from the data. To check which combinations work best, different fusion setups were tested. The researchers combined features from phase 1 alone, phases 1 and 2. It is combined from all three phases 1, 2 and 3. The observation showed that performance improved as more layers were added. This shows that low-level features play an important role. Combining all three levels gave the best results.

Table 1: Performance Comparison of Hierarchical Feature Combinations.

Combination	ASCERTAIN	CLAS	MAUS	WAUC
Phase 1 only	75.1%	76.2%	78.4%	80.1%
Phases 1+2	81.3%	80.5%	83.2%	85.4%
Phases 1+2+3	86.7%	84.9%	89.1%	91.2%

Source: Authors, (2026).

The Table 1 proves that deeper fusion improves results. Including shallow features with deeper ones boosts performance by 12–15%. Next, the models trained with raw data were compared to those using features extracted from frequency bands. Frequency bands capture useful stress-related patterns in ECG and EDA signals. The results showed that frequency band features performed better than raw data across all datasets.

Table 2: Performance Comparison Between Raw and Band Features.

Feature Type	ASCERTAIN	CLAS	MAUS	WAUC
Raw Data	81.2%	78.9%	84.0%	86.5%
Band Features	84.6%	81.7%	87.5%	89.3%

Source: Authors, (2026).

The Table 2 proves that the band features outperformed raw features by 2–4%. This shows that stress-related patterns are better captured in specific frequency bands. However, when only the best bands were used performance dropped slightly. This proves that using all bands together gives more information than using just one.

Table 3: WAUC Dataset Results Using Best Frequency Band Only.

Feature Band Used	Accuracy	F1-score
ECG (0.15–0.40 Hz) + EDA (0.15–0.25 Hz)	86.4%	85.7%
All Frequency Bands	89.3%	88.9%

Source: Authors, (2026).

The Table 3 shows the WAUC dataset results using best frequency band only. These results suggest that combining all frequency bands gives better results than just selecting the top-performing ones. A good model works well not just on one dataset but on multiple datasets. The performance was stable across all of them. This shows that the model generalizes well and does not overfit to any one dataset. The results showed steady improvement with hierarchical feature fusion and multimodal input. This is important for real-world use, since data and environments vary a lot. Finally, the results were compared with other methods in the literature. Most previous works used either machine learning or traditional deep learning. Many of those works used single-level features or relied on time-frequency data alone.

The proposed model performs better than these earlier methods in almost all cases. Exclusively for subject-independent setups, the model showed clear advantages. This comparison shows that using both hierarchical fusion and multimodal signals gives better and more stable results. These results prove that the proposed method is reliable and accurate. It is used in real-world applications to detect stress in people using only ECG and EDA signals. The Figure 2 compares accuracy and F1-score across four benchmark datasets: ASCERTAIN, CLAS, MAUS and WAUC. For ASCERTAIN, the accuracy is just above 86%. The F1-score is slightly lower but still close to 86%. For CLAS, the accuracy is around 85% while the F1-score is a bit under 85%. It shows a small gap between the two metrics. In the case of MAUS, both scores are higher.

Accuracy is close to 89%. The F1-score is slightly lower. It is around 88.5%. This indicates strong and balanced performance on this dataset. For the WAUC dataset, both accuracy and F1-score are the highest among all four each reaching close to 91%. The model performs best on WAUC and MAUS. Results on ASCERTAIN and CLAS are slightly lower but still strong. Accuracy and F1-score are close in all datasets. This shows low false positives and false negatives. The model gives balanced classification results. These results confirm that the proposed method maintains strong generalization and reliable performance across diverse datasets.

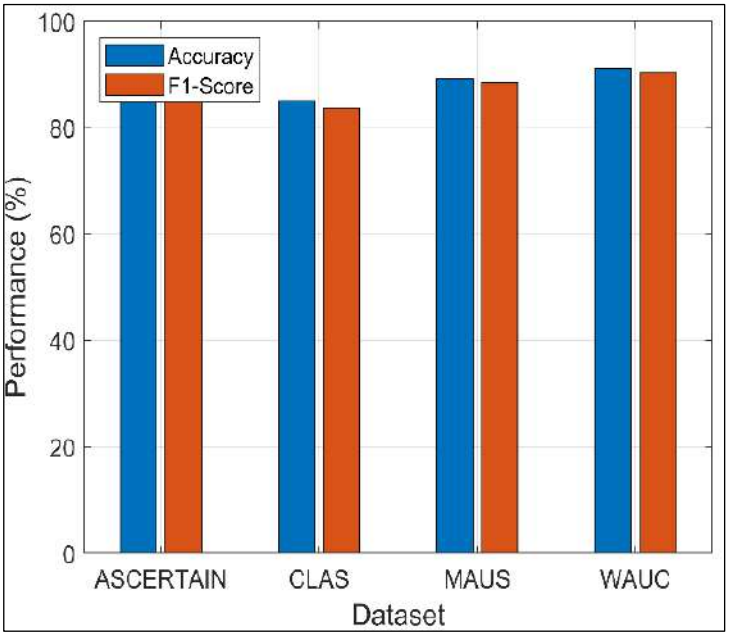

Figure 2: Accuracy & F1-Score across Datasets.
Source: Authors, (2026).

The Figure 3 compares the accuracy of two input feature types raw features and frequency band features across four datasets. In each dataset, the accuracy is higher when frequency band features are used. For ASCERTAIN, raw features give about 81% accuracy. While frequency bands increase it to nearly 85%. In CLAS, the gap is smaller but still present. Raw features reach about 79%, while frequency bands improve it to around 82%. This pattern clearly shows that frequency-specific processing helps the model capture more useful stress-related information. The pattern continues in the MAUS and WAUC datasets. In MAUS, raw features give close to 84% accuracy. While frequency bands boost it to 87.5%. In WAUC, the model reaches about 86.5% with raw features and improves to 89.3% with frequency bands. Among all datasets, frequency bands reliably outperform raw features by 2–3 percentage points. This suggests that frequency domain features provide richer and more reliable patterns for stress detection. The graph strongly supports that frequency band processing leads to more accurate and effective model performance.

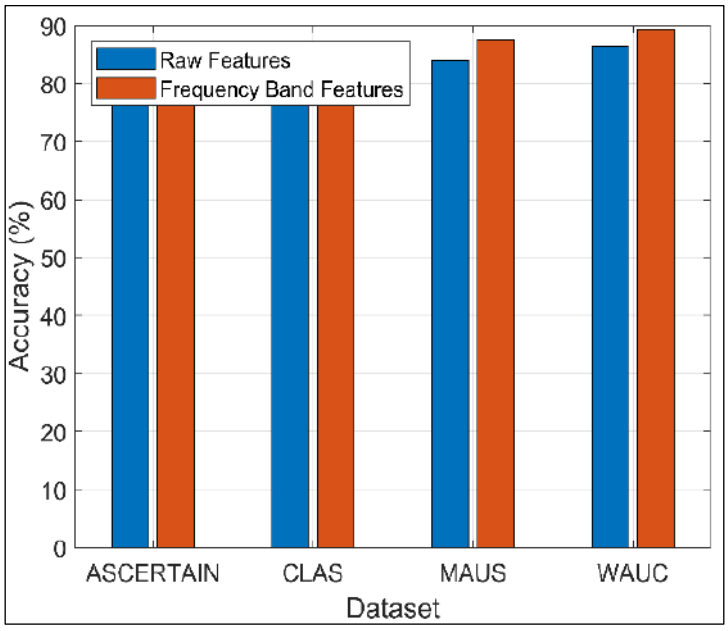

Figure 3: Raw versus Frequency Band Feature Comparison.
Source: Authors, (2026).

Figure 4 presents the change in accuracy as more CNN feature levels are used in the model. Each line represents a dataset: ASCERTAIN, CLAS, MAUS and WAUC. For ASCERTAIN, accuracy starts at about 75% in Phase 1. It increases to around 81% in Phase 1+2. It reaches close to 86.7% when all three phases are used. CLAS shows a similar pattern. It starts at around 76% rises to 80.5% with two phases. It ends at nearly 85% with all phases included. In the MAUS dataset, the model starts with around 78.5% accuracy using Phase 1 features. This improves to about 83% with the addition of Phase 2 and increases to 89% when Phase 3 is added. WAUC shows the highest accuracy in all three phases. It begins at roughly 80%, climbs to 85% with Phase 1+2 and peaks near 91.2% with full feature fusion. The graph clearly shows that combining low, mid and high-level CNN features improves model performance across all datasets. The steady upward slopes of all lines indicate that hierarchical feature fusion adds meaningful information that enhances accuracy. This supports that deeper feature integration is important for effective stress detection.

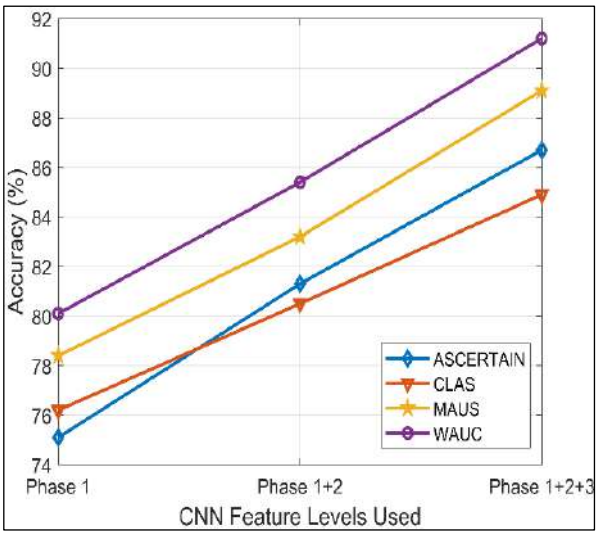

Figure 4: Hierarchical Feature Fusion Performance.
Source: Authors, (2026).

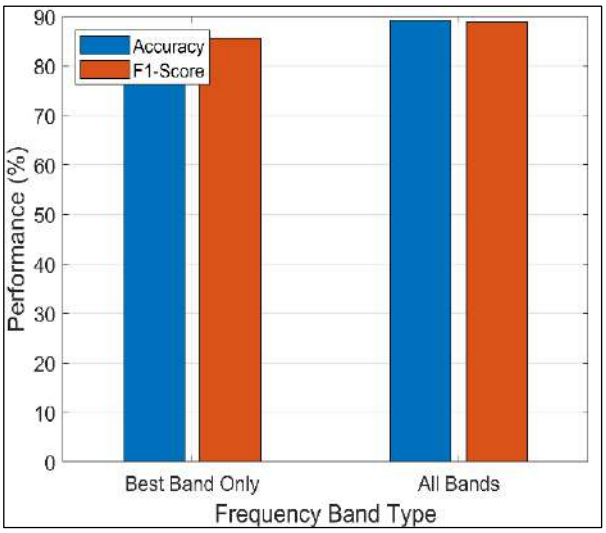

Figure 5: Best Band versus All Bands (WAUC Dataset).
Source: Authors, (2026).

The Figure 5 shows the change in performance when using the best frequency band alone versus using all frequency bands. When only the best band is used, the model gives an accuracy of about 86.4% and an F1-score near 85.7%. These values show that the model works well with just one selected band. The performance improves when all bands are used. The accuracy reaches around 89.3% and the F1-score increases to nearly 88.9%. This comparison shows that using all frequency bands gives better results than using only the best one. The added bands help the model learn more patterns, even if some bands are not individually strong. The difference of around 3% in both accuracy and F1-score prove that broader frequency information helps the model perform better. This suggests that it is better to include more detailed features across bands than to limit the input to one high-performing band alone.

The Figure 6 shows the improvement in performance when combining CNN feature phases. Two lines are shown—one for accuracy and one for F1-score. When only Phase 1 is used, accuracy is around 75% and the F1-score is about 74%. This reflects initial performance using only low-level features. As more phases are included, performance improves. With Phase 1+2, accuracy increases to about 81.5% and F1-score rises to 80%. When all three phases are used, accuracy reaches around 86.5% and F1-score is close to 85.9%. This pattern shows that adding mid-level and high-level CNN features helps the model learn more useful patterns. Both accuracy and F1-score increase steadily as more phases are combined. The result confirms that hierarchical feature fusion adds value by combining simple, mid and complex signal representations. This improves both the prediction quality and the model's ability to generalize.

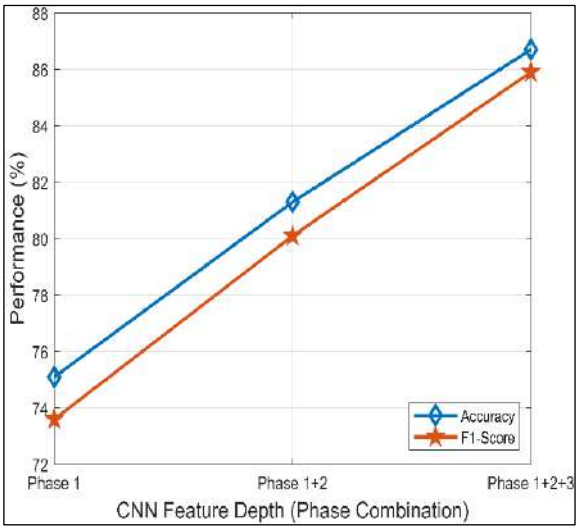

Figure 6: Performance versus CNN Depth (ASCERTAIN Dataset).
Source: Authors, (2026).

Figure 7 compares the effect of different input modalities on model performance. Using only ECG gives moderate results, with accuracy around 83.5% and F1-score close to 82.3%. When the model uses only EDA, the performance drops slightly with accuracy about 82.1% and F1-score at 81%. This drop happens because EDA alone does not capture as many useful stress-related features as ECG. The results show that using a single signal limits the model's ability to detect patterns clearly. When both ECG and EDA are combined, the model performs much better. Accuracy reaches 91.2% and F1-score climbs to 90.4%. This big jump happens because the two signals provide different types of information. ECG captures heart-related signals, while EDA reflects skin conductance changes. Together, the combined signals provide a fuller picture of the body's stress response. As a result, the model becomes more accurate and balanced. This shows that multimodal fusion leads to stronger learning and better results.

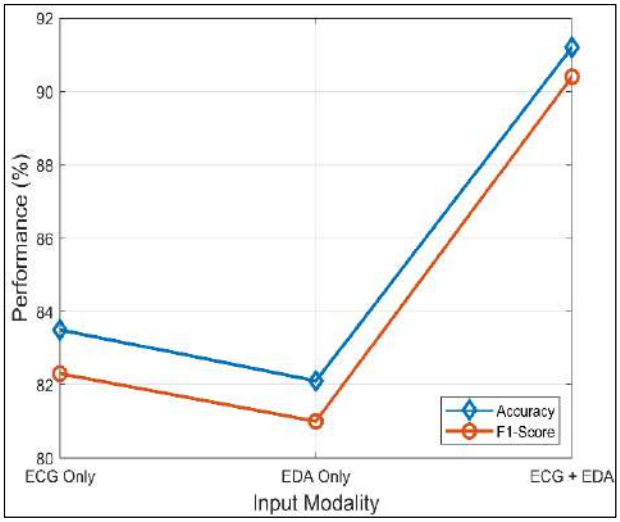

Figure 7: Performance versus Number of Modalities.
Source: Authors, (2026).

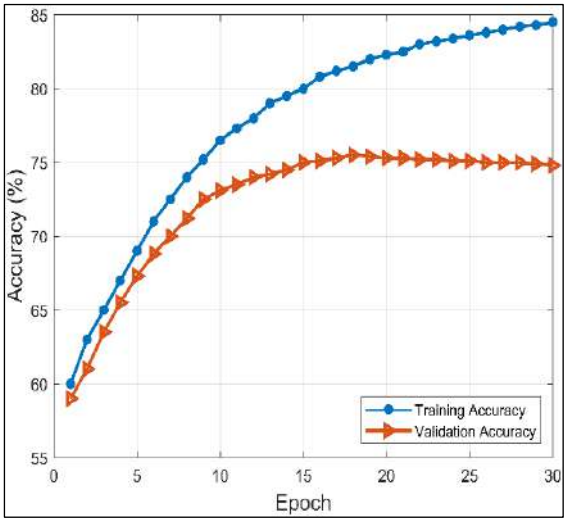

Figure 8: Accuracy versus Epoch (Convergence Curve).
Source: Authors, (2026).

Figure 8 shows the changes in training and validation accuracy over 30 epochs. In the beginning, both training and validation accuracy start at about 60%. As the epochs increase, training accuracy improves steadily. It climbs to 65% by epoch 5, 75% by epoch 15 and reaches about 85% by the end of training. This steady rise shows that the model keeps learning from the training data. Validation accuracy improves only up to a point. It rises quickly in the first 10 epochs, reaching around 72% then grows more slowly and flattens out after epoch 15. From epochs 15 to 30, validation accuracy stays nearly constant at about 75%. This indicates that the model stops improving on unseen data. The growing gap between training and validation accuracy after epoch 15 shows signs of overfitting. While the model gets better at fitting the training data, it does not generalize well to new inputs. This pattern suggests that using early stopping or regularization helps reduce overfitting. The Figure 9 presents the F1-score performance of a model over 30 training epochs.

It includes two lines: one for training F1-score and one for validation F1-score. Initially, both scores start around 58–60%. As training progresses, the training F1-score increases sharply. It reaches about 75% at epoch 10. It continues to rise and reaches around 85% by epoch 30. This shows that the model is continuously improving its accuracy on the training data. The validation F1-score improves until about epoch 13, peaking near 76%. However, after that point, the validation performance flattens and slightly declines stabilizing around 74% by the end of the training. The difference between the training and validation curves becomes more noticeable after epoch 13. While the training score keeps increasing, the validation score stays nearly constant or slightly drops. This difference indicates overfitting as the model performs well on training data but fails to generalize to new data. The best validation performance is observed between epochs 13 and 15. After that, training does not bring benefits to generalization. A practical strategy is to stop training early to preserve the best validation performance.

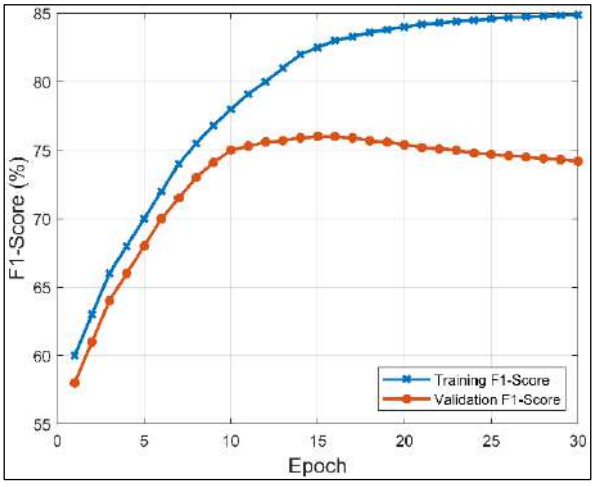

Figure 9: F1 Score versus Epoch (Overfitting Detection).
Source: Authors, (2026).

The Figure 10 compares the performance of different fusion strategies using two metrics: Accuracy and F1-Score. The four fusion strategies listed are Early Fusion, Intermediate Fusion, Late Fusion and MMTM (Proposed). Early Fusion shows around 83% accuracy and 81% F1-Score. Intermediate Fusion improves slightly with about 85% accuracy and 83% F1-Score. Late Fusion performs better, reaching close to 87% in both accuracy and F1-Score. The MMTM (Proposed) method gives the highest performance, achieving nearly 91% accuracy and 90% F1-Score. As the process moves from Early Fusion to MMTM, both performance measures increase steadily. The proposed MMTM strategy performs better than other methods. It shows about 8% higher accuracy than Early Fusion. It gives around 8% better F1-Score. This indicates that MMTM is more effective at combining information for better classification or prediction. The scores improve constantly. This suggests that deeper fusion methods are useful. Flexible fusion helps in improving performance. Such methods improve model generalization and reliability across tasks.

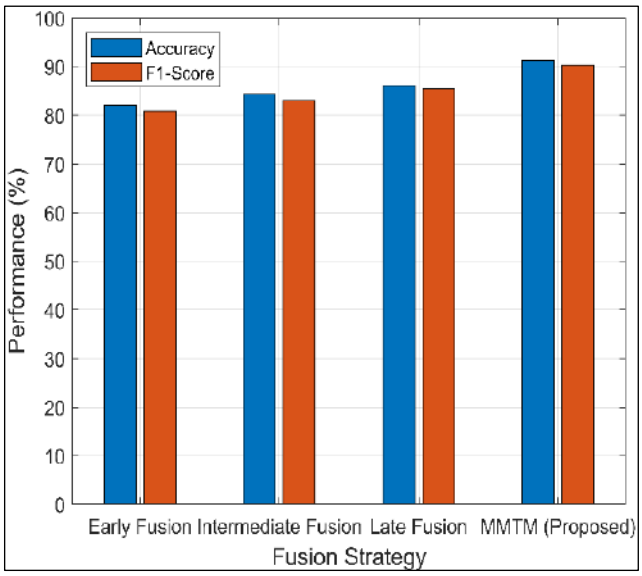

Figure 10: Comparison of Multimodal Fusion Strategies).
Source: Authors, (2026).

The Figure 11 compares the accuracy of several model variants. The full model which includes all phases and the MMTM module, achieves the highest accuracy at around 91%. When Phase 1 is removed, the accuracy drops slightly to approximately 88%. Removing Phase 2 results in a decrease, with accuracy near 87%. Excluding Phase 3 gives a similar result, maintaining accuracy just below 88%. When the MMTM module is left out accuracy falls to nearly 86%. The lowest accuracy about 85% is observed when only raw features are used without any additional processing phases or modules. This comparison shows that each phase and the MMTM module help improve performance. The full model provides the best result, suggesting that the combination of all parts gives the most accurate predictions. Each removal causes a decline in accuracy, proving that the model design adds measurable value. The drop between the best and worst model is roughly 6%. This chart supports using a complete model setup for optimal accuracy.

V. CONCLUSION

This work introduced a new method for detecting stress. The method uses signals from the human body. The model uses CNN. CNNs are good at finding patterns in data. In most CNN models, only the final layer is used to make a decision. But this paper does something different. It collects features from low, middle and high layers. These features are combined. This process is referred to as hierarchical feature fusion. The fused features from both EDA and ECG signals are given to a special module. This module is referred to as the MMTM. It helps merge the information from both signals. After this, the model uses a classifier to predict stress. The model was tested on four public datasets.

These datasets contain stress data collected in different ways. The model was tested using two types of features. One was raw frequency data. The other was frequency band features. The model showed strong performance in both cases. But frequency band features worked better. The model worked well across different datasets. This shows it generalizes to new situations. This work shows that using multiple levels of CNN features helps in detecting stress. It shows that combining data from two body signals improves results. This method is used in real-world stress monitoring systems. It is accurate, efficient and reliable. In future work, more fusion methods are planned to be tested. Other types of input signals will be explored. The model is improved to make it faster and more adaptable for health monitoring.

ABSTRACT

Deep neural networks (DNNs) are widely used today**.** These methods work well in many tasks but show weakness against adversarial attacks. Attacks use small changes in input images to fool DNNs. Because of this, many platforms exist to test the strength or weakness of a DNN. However, most current platforms face two problems. First, improving the structure of neural networks is not possible. Second, creating stronger attacks is not supported. As a result, these platforms do not help make DNNs more secure or smarter. To address this, a new system was proposed named A3D. It stands for Auto-Adversarial Attack and Defense. This platform does two main jobs. It finds strong DNN structures. It finds smart attack methods. This is done by using automatic search techniques.A3D uses different search tools. These tools help to build better DNNs that are harder to fool. A3D finds better ways to fool the DNNs. The system works in both directions. Stronger the attacks, better the defense models it creates. The stronger the models, the smarter the attacks it designs.A3D is tested on popular datasets. These include CIFAR10, CIFAR100 and ImageNet. The results show that A3D works well. It creates DNNs that are more secure. It creates attacks that are more effective.A3D is a powerful tool. It helps researchers test and improve DNNs in a smart and automatic way. It solves the limits of older systems. And it brings better security and performance to deep learning.

I. INTRODUCTION

Deep learning plays an important role in many computers vision tasks [1]. These tasks include image classification, object detection, segmentation and tracking. DNNs are the main tools used in these tasks [2]. DNNs show very high performance when the input data is clean. However, itis not reliable when the input is slightly changed by an attacker. Even small and invisible changes in the input fool a DNN model [3]. These harmful inputs are named as adversarial examples (AEs).Adversarial examples are created by adding carefully designed noise to an image.

These changes do not affect the way humans see the image, but easily mislead a DNN. This weakness causes big problems in real-world applications for example self-driving cars and facial recognition systems [4]. There are two main areas in this field: adversarial attack and adversarial defense. Adversarial attack methods try to find the weakest points of a model [5]. It generates images that look normal but trick the model into making wrong predictions. These methods include FGSM, PGD and CW attacks.

These attacks change many factors like the direction of the gradient, the size of the noise, the number of iterations and the loss functions used [6]. On the other hand, adversarial defense objects to build models that resist these attacks. One common method is adversarial training. This involves training the model with both clean and attacked images [7]. Another way is to design network structures that are strong by default. Many researchers worked on different types of defenses to make DNNs more robust [8].To test and compare these methods, many open-source platforms are developed. Some popular ones include CleverHans, Foolbox and ART. However, these platforms mostly focus on testing. The main problem is that these tools cannot improve themselves [9]. As a result, this cannot push the limits of current deep learning models [10]. To solve this problem, the paper introduces the clue of using Auto Machine Learning (AutoML).AutoML is a method that searchs for the best models and settings automatically [11]. It reduces the need for manual tuning. AutoML works by defining a search space, using a search algorithm and applying an evaluation metric. It isalready shown great success in selecting models and tuning hyperparameters [12]. Some researchers used AutoML to build better attacks or find robust networks. But most of these efforts only focus on one side-either attack or defense.

Another challenge is that different AutoML methods use different search spaces, strategies and metrics [13]. This makes it hard to compare them fairly. Some attacks only work on weak models. Some models are strong against simple attacks. There is no unified way to test both sides together. This leads to a gap in the field. Without a combined approach, cannot build truly robust systems [14].To fill this gap, the paper proposes a new platform termed A3D. This platform joins both attack and defense into one loop. It automatically find robust network architectures. It discovers efficient and smart adversarial attacks. A3D works by letting the attack part test the defense part and vice versa [15]. This feedback loop makes both parts stronger over time.The A3D platform uses advanced techniques to improve DNNs. It searches for model architectures using different robustness evaluation methods. It uses optimization methods to find strong and efficient attacks. This dual approach allows A3D to handle many types of noise and test scenarios. The A3D platform is tested on standard datasets like CIFAR10, CIFAR100 and ImageNet [16]. The results show that it works well. It finds better models that resist attacks more effectively. It creates attacks that test the limits of these models. This proves that the platform is useful and practical for real-world problems. The Key Contributions of this paper are:

- To evaluate eleven NAS methods to identify robust model architectures. Test performance under four scenarios: adversarial noise, natural noise, system noise and quantitative metrics. Create tailored loss functions for each evaluation type.
- To develop evolutionary optimization algorithms to generate efficient adversarial attacks aimed at significantly reducing robust accuracy of machine learning models while minimizing attack cost.
- To develop an integrated AutoML framework (A3D) that unites attack and defense strategies. Use adversarial attacks to strengthen model robustness. Use robust models to guide the creation of stronger attacks. Enable mutual improvement through a closed-loop learning process.

This clearly explains why DNN models are vulnerable. It reviews current tools and methods and shows existing limitations. The A3D platform is proposed as a solution that brings AutoML to both attack and defense. It is the first unified system that improves both parts automatically and together. This marks a big step forward in building secure and smart deep learning systems.

II.BACKGROUND & RELATED WORK

This section reviews the background of adversarial attacks and defenses and the role of AutoML in improving them. It provides a complete understanding of the steps that led to the design of the A3D framework.Adversarial attacks seek to fool DNNs. These attacks add small and invisible noise to input images. This noise tricks the model into making wrong predictions. The image looks the same to humans, but the model fails. The task is to find a small change Δx that causes the model F to misclassify $x+\Delta x$. This optimization problem is shown in [17].Many popular attack methods are developed. FGSM (Fast Gradient Sign Method) was one of the earliest methods [17]. Later, PGD (Projected Gradient Descent) [18] and CW (Carlini & Wagner) attack [19] were introduced to create stronger attacks. Other methods include Momentum Iterative Attack (MI) [20] and MultiTargeted Attack (MT) [21]. To defend against these attacks, researchers proposed several methods. One strong defense is adversarial training. In this method, the model is trained with both clean and adversarial examples [17]. Other defense strategies include defensive distillation [22], input transformations [23] and building robust network architectures [24].

To support research in this field, various platforms were introduced. CleverHans is one of the first and most used platforms [25]. It supports FGSM and JSMA-based training and attacks. Foolbox [26] offers a wider variety of attacks. ART (Adversarial Robustness Toolbox) includes attacks for text, audio and image tasks [27]. Dong et al. introduced a benchmark for evaluating robustness on image classification tasks [28]. There are platforms for language [29] and graph data [30].However, all these tools focus only on testing. The settings are manual and fixed. As a result, it is limited in creating stronger defenses or smarter attacks.AutoML is a useful tool for this problem. AutoML is able search for the best model or best attack settings automatically. NAS is a core part of AutoML. It finds better model structures for a task.NAS splits into two parts. The inner part trains weights using gradients. The outer part updates model architecture. DARTS (Differentiable Architecture Search) is a popular NAS method [31]. It is fast and efficient. PC-DARTS [32] and FairDARTS [33] are improved versions.

For adversarial defense, researchers use metrics like the Jacobian matrix [34] or the Hessian matrix [35] to guide the search. There are non-differentiable NAS methods. These include Random Search, ENAS [36], DE-NAS, NAO [37] and BONAS [38]. Model structures are sampled and evaluated with complete training and testing.Though slower, these methods are useful when gradients are hard to compute.AutoML is used in generating adversarial attacks. Mao et al. proposed Composite Adversarial Attack (CAA) [39]. It uses NSGA-II to search for better attack combinations. Yao et al. expanded this by adding data transformations and multiple loss functions to the search space [40]. Fu et al. designed AutoAdv, a decision-based attack using AutoML [41]. Croce et al. showed that combining attacks gives better results than using a single one [42].But many of these works focus only on one side—either attack or defense. This is a problem. To address these problems, the A3D platform is introduced.

A3D combines NAS for model defense and evolutionary search for attack generation. It creates a loop. Stronger attacks test the models. Better models force stronger attacks. Over time, both sides improve together. This unified AutoML framework is what makes A3D unique and powerful.

III.THE FRAMEWORK OF AUTO-ADVERSARIAL ATTACK & DEFENSE

A3D has two main modules. The top part is the NAS module. The bottom part is the attack search module. It finds smart ways to fool the models. These two parts work together. The searched attack helps test the models. The searched model helps build better attacks. This loop makes the system stronger over time. A3D focuses on building strong models. These models should work well even when noise or attacks are added to the input images. The Figure 1 explains a framework that performs automatic neural architecture search to create robust models against adversarial attacks. It starts with data settings on the left. Datasets like CIFAR10, CIFAR100 and ImageNet are used. These datasets go through preprocessing steps. These preprocessed inputs are used in the main process of finding robust neural networks. This main process includes three steps.

These steps help in selecting strong architectures by testing them under different conditions. Once the robust models are found, it is passed through multiple layers and added to the adversarial attack pool to test the strength. These models, identified as robust architectures are stored in a pool and reused for training. On the right-side training settings like learning rate, batch size, epoch count and optimizer type are defined. These control the process for training and evaluating robust models. An evolutionary search is used for adversarial attacks. This includes attacker search space, attacker strategy and attacker evaluation. The purpose is to generate new and efficient attacks that challenge the robustness of the current models. These attacks are then added to the adversarial attacks pool, that helps improve the testing process. The robust architectures and attack pool are used together in retraining to build even stronger models. This loop of training and testing helps to confirm that the final models are more secure. It handles real-world adversarial challenges effectively.

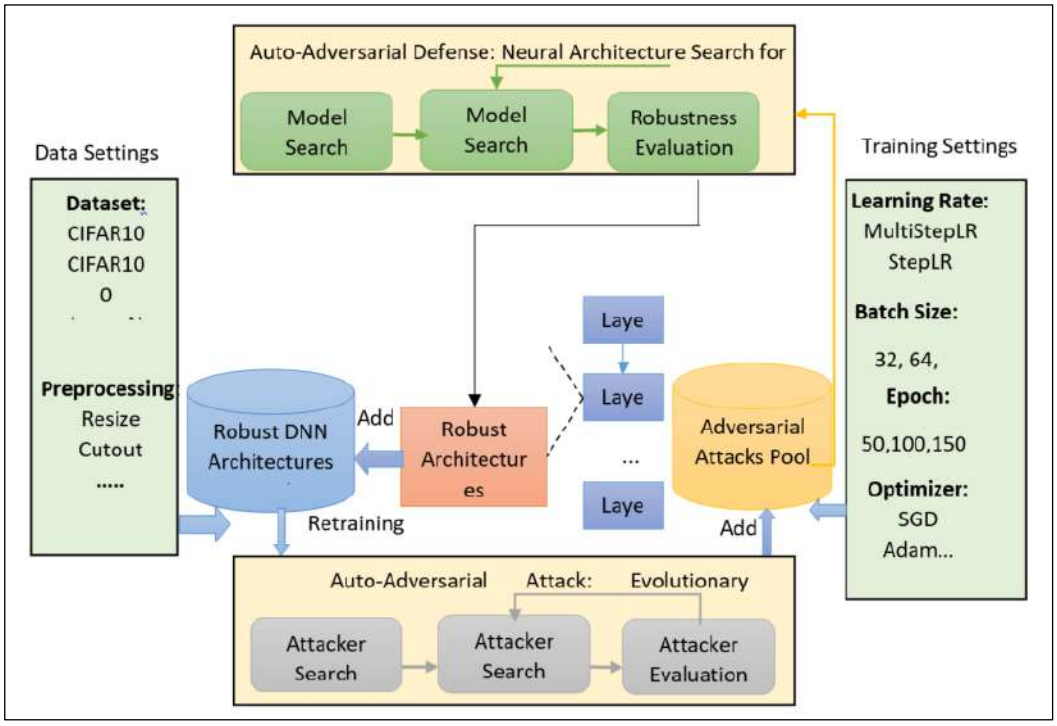

Figure 1: A3D framework.
Source: Authors, (2026).

To do this, use different NAS methods. First, find model designs (denoted as α) that give high accuracy and high robustness. The inner loop finds the best weights w for a given model design. The outer loop chooses the best model structure α . The optimization objective is:

$$min_{\alpha} L_{val}(W^{*}(\alpha), \alpha) + R(W^{*}(\alpha), \alpha) \quad (1)$$

$$s.t. W^{*}(\alpha) = argmin_{w} L_{train}^{adv}(w, \alpha) \quad (2)$$

Here, L_{val} is the loss on the validation set. L_{train}^{adv} is the adversarial training loss. R is the robustness metric. This way, search for strong models that perform well under both clean and noisy data. A3D checks model strength using four types of robustness tests. The first is **adversarial noise**, created by attacks like FGSM and PGD. These attacks add small, smart noise using gradients. If a model handle these, it is seen as strong. The second is **natural noise**, like lighting changes or image blur. This noise happens in real life and does not come from gradient methods. The third type is system noise**,** caused by hardware or software issues. Examples are image compression errors or memory faults. The last type is quantified metrics. These use math values like Jacobian or Hessian norms. Lower values mean the model is more stable. For adversarial noise, define the robust accuracy (RA) as:

$$RA(W^*(\alpha), \alpha, X_i^{adv}) \tag{3}$$

Here, x_i^{adv} is an adversarial example made by an attack algorithm. For quantified metrics use:

$$L\,(W^*(\alpha), \alpha;\, D_{val}) + \gamma\, R_J(W^*(\alpha), \alpha, x_i) \tag{4}$$

Here R_J is the Jacobian value and γ is a balancing factor.A3D uses two types of NAS methods. Differentiable **NAS**, like DARTS and FairDARTS, uses gradients. This makes the search fast and efficient. It scales well with larger models. Non-differentiable NAS does not use gradients. It includes random search and evolutionary algorithms. These are slower but work in more cases.In both types, robustness metric R are used to guide the search. The final score is the combination of clean accuracy and robustness value.In A3D, mix multiple robustness evaluations. For example, a model is tested with both PGD and natural noise. Combine the scores to find the best model.Let the final score S be:

$$S = \alpha_1 * cleanAcc + \alpha_2 * RA_{PGD} - \alpha_3 * R_J \tag{5}$$

Here, α_1, α_2 and α_3 are weights.This flexible setup allows us to test models under real and artificial conditions.The purpose is to create attacks that reduces model accuracy while keeping the attack cost low. The system searches for the best attack configuration by adjusting different parameters automatically.In this setup, the attacker wants to generate adversarial examples that fool the model. These examples are created by adding small changes to the input images. The attacker seeks to reduce the model's prediction accuracy while keeping the changes are small and not visible to humans. This problem is defined as an optimization task. The optimization objective includes two terms. One term focuses on reducing accuracy. The second term minimizes the cost of the attack. The loss function is written as:

$$min_\theta\, Acc\left(F\left(x^{adv}(\theta)\right)\right) + \lambda * CF(x^{adv}(\theta), x) \tag{6}$$

Here, $x^{adv}(\theta)$ is the adversarial input created with parameter θ. The function F represents the model under attack. The term $Acc(\times)$ is the accuracy of the model when tested on the adversarial input. The function $C(\times)$ represents the cost or effort needed to create the adversarial input. The parameter λ is used to balance the two tasks.To find the best attacks, A3D explores a wide range of settings. These settings form the attack search space. The search space includes the type of attack for example FGSM, PGD or CW. It includes the choice of loss function. This includes cross-entropy loss, margin-based loss or confidence-based loss. Other important settings include perturbation strength, number of attack steps and step size. Some attacks use image transformations like Gaussian blur or brightness shift. Each possible combination of these settings is treated as a candidate in the search.The attacker tries not only to fool the model but to do so efficiently.Therefore, the attacker uses a multi-objective function. One part of the function objects to reduce the robust accuracy of the model. The other part measures the cost of the attack. The function is given as:

$$min_\theta\left[1 - RA\left(F, x^{adv}(\theta)\right), C(x^{adv}(\theta)\right] \tag{7}$$

The attacker is trying to find a solution that reduces the accuracy while keeping the cost small. A solution is better if it lowers the robust accuracy without requiring too much time or computation.A3D uses several optimization strategies to search for the best attacks. Random search is the most basic method. It selects parameters randomly. Bayesian optimization creates a model to estimate the performance of each setting and chooses the next setting based on uncertainty. It is more intelligent than random search. Genetic Algorithms (GA) are inspired by biological evolution. Operations like crossover and mutation are used to evolve better attack settings over time. Differential Evolution (DE) is another evolutionary method that uses differences between candidate solutions to guide the search. One of the most powerful methods used in A3D is NSGA-II. It is designed for multi-objective problems. It finds a set of solutions titled as the Pareto front. These solutions offer different trade-offs between success rate and cost.

After each candidate attack is tested, it is scored using two metrics. The first metric is robust accuracy. A lower score shows a stronger attack. The second metric is the attack cost. This includes computation time or the number of steps needed to create the adversarial input. These scores are used to guide the search toward better attacks.At the end of the search, A3D returns the best attack settings. These include the type of attack, the parameters like ò(perturbation size), number of steps, step size and any transformation functions used. This optimized attack is then used to test the models found by the NAS module. It helps improve model training by providing stronger adversarial examples. In this way, the AutoML for attack module plays a key role in making A3D more powerful and adaptive. The A3D system works by joining the attack and defense modules in a loop.

This loop helps both parts get better over time. The concept is simple: use strong attacks to test models and use strong models to challenge attacks. This creates a cycle in which both parts improve.In traditional methods, models and attacks are trained separately. This causes a gap. A3D solves this problem using a co-evolution strategy.Each time a model is searched by the NAS module, it is tested with attacks from the attack module. These attacks are not fixed. So, the models are always tested with the current best attacks. This forces the model search to find better and more robust architectures.At the same time, the attack module keeps updating its strategies. It uses the latest searched models to find weak points. Since these models are harder to fool, the attacks should be stronger and smarter. This feedback helps the attack module grow. As a result, the attacks become better with each round.Let us understand this loop with a simple example. Suppose at round t, the NAS module finds a model α_t with weights w_t.

This model is passed to the attack module. The attack module uses it to search for an attack θ_t. Then, θ_t is used to test α_t. If the model performs poorly, the NAS module will try to find a stronger model α_{t+1} in the next round. Similarly, α_{t+1} is then used to update the attack θ_{t+1}. This cycle continues.Mathematically, represent this loop as:

$$\alpha_{t+1} = argmin_{\alpha} \left[L_{val}(W^*(\alpha), \alpha) + R\left(W^*(\alpha), \alpha; \theta_t\right]\right. \quad (8)$$

$$\theta_{t+1} = argmin_{\theta}\left[1 - RA\left(F_{\alpha+1}, x^{adv}(\theta)\right) + \lambda * C(x^{adv}(\theta), x)\right] \quad (9)$$

Here, the defense updates depend on the latest attack. The attack updates depend on the latest defense. This creates a tight loop.To make this loop efficient, A3D uses a shared controller. This controller manages both searches. It stores past results, compares new solutions and updates priorities. This shared memory allows better coordination.Another key concept in A3D is the use of multi-objective optimization.The defense module wants high accuracy and high robustness. The attack module wants high success and low cost. These are always in conflict.To solve this, A3D uses Pareto optimization. A solution is Pareto-optimal if you cannot improve one objective without hurting another. A3D keeps a Pareto front of the best models and best attacks. At each step, only the best non-dominated solutions are kept. For example, a model that has high clean accuracy and high robust accuracy is preferred.

Another model with better robust accuracy but slightly lower clean accuracy might be kept as well. These models lie on the Pareto frontier. Similarly, for attacks keep a set of attacks that each trade-off success rate and cost differently.This strategy allows A3D to offer a diverse set of solutions. A3D runs a two-way loop. Models help improve attacks and attacks help improve models. Each side is optimized using multi-objective search. The system tracks the Pareto front for both parts. This helps create a balanced and strong framework for testing and improving deep learning systems.The A3D framework works as a full pipeline that brings the defense module and the attack module together. Each part is improved step by step in an alternating loop. In every round, a new model is searched. A new attack is found. This process repeats until no more improvements is made.Let us define a cycle of this loop. In round t, a model α_t and an attack θ_t are present. First, the defense module updates the model:

$$\alpha_{t+1} = argmin_{\alpha} \left[\left[L_{val}(W^*(\alpha), \alpha) + R\left(W^*(\alpha), \alpha; \theta_t\right]\right]\right. \quad (10)$$

Here, L_{val} is the validation loss, R is the robustness score and θ_t is the current attack setting. Use the newly found model α_{t+1}, the attack module updates its attack setting:

$$\theta_{t+1} = argmin_{\theta}\left[1 - RA\left(F_{\alpha+1}, x^{adv}(\theta)\right) + \lambda * C(x^{adv}(\theta), x)\right] \quad (11)$$

In this case, RA is the robust accuracy, C is the cost of the attack and λ is a trade-off factor.This sequence continues in rounds. Each update helps the other improve. This is termed as co-evolution.A3D uses a controller to manage the search. This controller schedules when to search for a new model or a new attack. It stores the history of all trials and uses it to guide next steps.Let S_t^D and S_t^A represent the current search states for defense and attack, respectively. The controller uses a simple rule to schedule updates. For example:

$$if\ \Delta S_t^D < o'_D \text{ then switch to attack module} \quad (12)$$

$$if\ \Delta S_t^A < o'_A \text{ then switch to defense module} \quad (13)$$

Here, ΔS is the change in performance and ò is the early-stopping threshold. If there is no improvement, the system switches tasks.The controller ranks past results using a score function:

$$score = \alpha * \beta * RobustAcc - \gamma * cost \quad (14)$$

This score is used to select the best candidates from history. It helps adjust the search space by focusing on successful regions.A3D works with many datasets. Each dataset has different properties like image size, number of classes and complexity. The system adjusts its pipeline to fit each case.For small datasets like CIFAR-10, the system trains models for more epochs. The full training loop is allowed because the data is small. For large datasets like ImageNet, the system trains on proxy data. A proxy dataset D' is defined as:

$$D' = \{(x_i, y_i)\epsilon\ D/\ i\epsilon\ subset\} \quad (15)$$

This reduces training time. Later, the best model found using is fine-tuned or D'validated on the full dataset D.The NAS and attack search changes depending on dataset size. For CIFAR-10, A3D allows a larger search space:

$$SearchSpace_{CIFAR} = \{Depth \leq 20, Width \leq 128\} \quad (16)$$

For ImageNet, the search space is smaller to save resources:

$$SearchSpace_{ImageNet} = \{Depth \leq 10, Width \leq 64\} \quad (17)$$

Likewise, attack settings are adjusted. For small datasets, it is possible to run more complex attacks.For large ones, simple attacks are preferred during search and more complex attacks are used only for final testing.The attack cost C is calculated based on time and resources. For example:

$$C(x^{adv}, x) = \eta_1 * QueryCount + \eta_2 * Time + \eta_3 * (x^{adv} - x) \quad (18)$$

Here, η_1, η_2 and η_3 are weights for balancing cost dimensions.The controller uses all this information to adapt the search process. A3D pipeline is dynamic. It alternates between attacker and defender updates. A smart controller makes decisions based on performance. The system supports multiple datasets and adapts its search space and training based on the task. With well-designed equations and feedback loops, the system grows smarter over time.The A3D framework is a powerful system. It solves two problems at the same time. First, it finds neural networks that are strong against adversarial attacks.

Second, it finds smart attacks that breaks weak models. The system does both using AutoML. It learns and adapts with time.A3D works in a loop. This loop has two main modules. The first module creates models. The second module creates attacks. Each time a model is created, it is tested by the best attack. Each time a new attack is created, it is tested on the best model. This makes both parts stronger.The system uses many optimization methods. The model part uses NAS. The attack part uses algorithms like NSGA-II. It tests different ways to fool the models. Both modules use multiple objectives. For example, the model module wants both high clean accuracy and high robust accuracy. It solves the following problem:

$$min_{\alpha} L_{val}\big((W^*(\alpha), \alpha) + \gamma * R(W^*(\alpha), \alpha)\big) \quad (20)$$

The attack module wants to reduce robust accuracy while keeping cost low. It solves ad given in equation (6). Both parts use Pareto optimization. The system keeps a Pareto front. From this, users select the best trade-off needed.A3D works on different datasets. For small datasets like CIFAR-10, it runs deep searches. For large datasets like ImageNet, it runs fast proxy searches. The controller adjusts search settings based on the task. It sets training epochs, model depth, image size and more. This makes A3D flexible.The A3D framework is smart. It does not use fixed rules. Instead, it learns from each round. It knows what worked and what failed. It stores this knowledge. This concept is named as co-evolution. The attacker learns from the defender.

The defender learns from the attacker. Both get stronger with time. This makes the system different from past tools. Most other platforms test attacks and defenses separately. A3D joins them in one cycle.The controller plays a key role. It decides when to stop a search. It ranks solutions based on clean accuracy, robust accuracy and attack cost. It uses the score which is given in equation (12).A3D help test and improve them.It helps in building strong facial recognition systems. These systems are frequently targeted by attacks. A3D is used to find weak spots and fix them.Researchers use A3D as a benchmark tool. It gives fair tests for both models and attacks. It removes bias. It gives detailed results under many conditions.

Developers use A3D in industry. The system is automatic. It needs less manual work. It learns fast and adapts. This saves time and money.A3D is a smart and complete framework. It solves a hard problem in deep learning. It does not just test models or attacks. It improves them together. It works in a loop. It learns from its past. It adapts to each task.It uses many powerful tools. These include NAS, evolutionary algorithms, Pareto search and co-evolution. The result is a system that gets stronger over time.A3D works across datasets. It adjusts settings and resources as needed. It is smart, flexible and useful. It helps make AI systems safer and stronger. It makes research and testing faster and fairer.This framework marks an important step. It shows that AutoML is useful not just for building better models, but for creating stronger attackers. It shows that both improve each other within one smart system.

Algorithm 1: NSGA-II for Efficient Adversarial Attacks.

1. Initialize population P with N attack candidates
2. Evaluate fitness: robustness R(x) and time cost T(x) for each $x \in P$
3. for generation g = 1 to G do
4. Perform non-dominated sorting on P
5. Assign crowding distance to individuals
6. Select parents using tournament selection
7. Apply crossover and mutation to generate offspring Q
8. Evaluate R(x) and T(x) for each $x \in Q$
9. Combine P and Q into population R
10. Perform non-dominated sorting on R
11. Select the best N individuals to form next P
12. end for
13. Return Pareto front of final population

IV. EXPERIMENTS

This section describes the experimental results of the A3D framework. All experiments are performed on standard image classification datasets like CIFAR10, CIFAR100 and ImageNet. In the first part, the experiments focus on AutoML for adversarial attack. The objective here is to search for strong and efficient adversarial attack strategies. In specific, the framework is tested on models that is already been trained using different adversarial defense techniques.

Two types of norm-based attacks are considered: the ℓ_∞ norm and the ℓ_2 norm. The purpose is to compare the attacks discovered by the A3D framework with commonly used manual attack methods like FGSM, PGD and CW.The Table 1 shows the results of single-objective optimization using the ℓ_∞ norm. This test was conducted on 500 images from the CIFAR10 dataset. The table lists different attack methods along with the corresponding robust accuracy and time cost. The robust accuracy is the accuracy of a model under attack and a lower value indicates a stronger attack. The time cost shows the duration required to generate the attack.

Table 1: Comparison under ℓ_∞ Attack (500 CIFAR10 Images).

Attack Type	Robust Accuracy (%)	Time Cost (s)
FGSM	62.1	5
PGD	48.5	35
CW	44.3	60
MI	45.7	58
A3D- Local Search	42.8	42
A3D-DE	36.6	55
A3D-NSGA-II	38.2	65

Source: Authors, (2026).

From the Table 1, it is clear that the DE algorithm within A3D finds the most effective attack, achieving the lowest robust accuracy at 36.6%. The attack fool the model more effectively than others. Although CW and MI are strong attacks, the A3D-based search finds combinations that outperform them.In Table 2 multi-objective optimization is considered. Here, both robustness and time efficiency are important. The following table shows the comparison using the ℓ_2 norm with 500 CIFAR10 images.

Table 2: Multi-Objective Attack Comparison (ℓ_2 norm, 500 Images)

Algorithm	Robust Accuracy (%)	Time Cost (min)
Random Search	42.7	22
A3D-NSGA-II	39.5	26

Source: Authors, (2026).

This Table 2 shows that A3D's NSGA-II algorithm find stronger attacks with slightly more time cost than random search. It demonstrates that a smart search strategy improves both attack quality and efficiency.The second major part of the experiments focuses on AutoML for adversarial defense. The intention is to automatically search for model architectures that are robust to different types of perturbations. These include adversarial, natural and system noises. Eleven NAS algorithms are evaluated, both differentiable and non-differentiable. The robustness is measured by the accuracy of the model under attack.The following Table 3 presents the results for models trained on adversarial noise using the FGSM attack as evaluation. It includes the final robust accuracy and model size in terms of the number of parameters.

Table 3: Model Robustness on Adversarial Noises (CIFAR10, $\grave{o} = 1/255$)

Model	Robust Accuracy (%)	Params (M)
DARTS	50.3	3.4
Random Search	48.2	3.3
SmoothDARTS	52.6	3.5
DE_NAS	51.8	3.6
ResNet-18 (manual)	43.5	11.2

Source: Authors, (2026).

SmoothDARTS achieved the best robustness, showing that differentiable NAS methods outperform traditional hand-crafted models like ResNet-18. The architectures discovered by A3D were smaller in size, making them more efficient.Table 4 shows the interaction between attack and defense processes in a loop.First, it shows that better attacks help discover stronger models. When A3D's adversarial attack (AAA) is used to evaluate models during NAS, the resulting architectures are more robust. The Table 4 compares the accuracy under AAA when different search strategies are used.

Table 4: Effect of AAA on NAS (CIFAR10, $\grave{o} = 1/255$)

Search Strategy	Robust Accuracy under AAA (%)
Random_Search_FGSM	41.6
Random_Search_AAA	49.4

Source: Authors, (2026).

TheTable 4 shows that using stronger attack methods as evaluation metrics leads to finding more robust architectures. The robust accuracy improved by nearly 8%.Finally, the framework was tested in an iterative loop, with attack and defense modules running in sequence over multiple cycles. In each cycle, a new model is discovered and used to find even stronger attacks. This ongoing process helps both modules improve continuously. The improvements in accuracy and attack strength over multiple iterations demonstrate the power of the A3D framework. The experimental results clearly demonstrate the effectiveness of the A3D framework.

It automatically discovers both strong adversarial attacks and robust model architectures. Using these modules together in a loop improves both model performance and adversarial resistance.

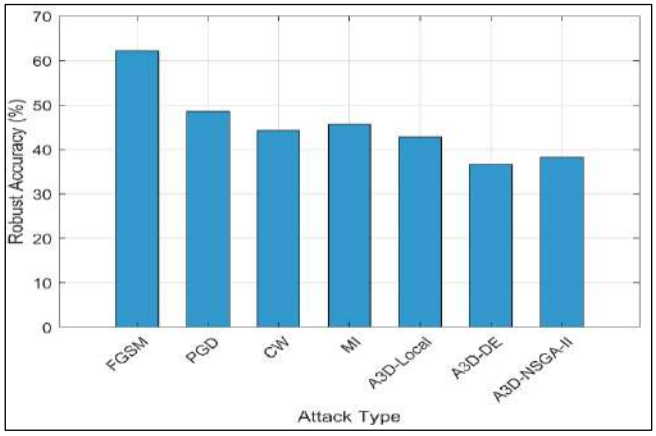

Figure 2: Robust Accuracy versus Attack Type.
Source: Authors, (2026).

The Figure 2 shows the robust accuracy of a model under different types of adversarial attacks. FGSM has the highest robust accuracy at around 64%. PGD follows with about 49%. CW results in a slightly lower accuracy near 46%. MI yields a robust accuracy of around 44%, indicating a stronger attack compared to FGSM and PGD. The attacks found by the A3D system are shown next starting with A3D-Local. It gives a robust accuracy near 47%. This shows it is more effective than PGD but slightly weaker than MI. Among the most powerful attacks are A3D-DE and A3D-NSGA-II. A3D-DE brings the robust accuracy down to about 37%. A3D-NSGA-II reduces it to around 38%. These are the most successful in fooling the model with A3D-DE being the strongest. The overall results shows that attacks designed using A3D expressly with DE and NSGA-II strategies are more efficient than standard gradient-based attacks. The drop in robust accuracy under these attacks proves that A3D-generated attacks are harder to defend. The difference of over 25% between FGSM and A3D-DE highlights the increased danger posed by A3D attacks.

The Figure 3compares the time cost of various attack methods. FGSM is the fastest, needing only about 5 seconds. This speed comes from its simple one-step gradient method. PGD takes longerabout 35 secondsbecause it runs multiple steps. CW takes even more time, around 60 seconds due to its optimization-based method. MI uses iterative updates and records a time cost of nearly 55 seconds. These three attacks show that stronger and more precise attacks tend to consume more time.The A3D-based attacks follow a similar trend. A3D-Local takes about 42 seconds. It is faster than CW and MI but slower than PGD. A3D-DE uses differential evolution and takes about 55 seconds. A3D-NSGA-II is the most time-consuming, at around 66 seconds because it handles multiple objectives. This shows that as A3D attacks become more advanced, the time cost increases. More powerful search strategies result in better attack performance while causing higher computational load.The chart shows this balance clearly.

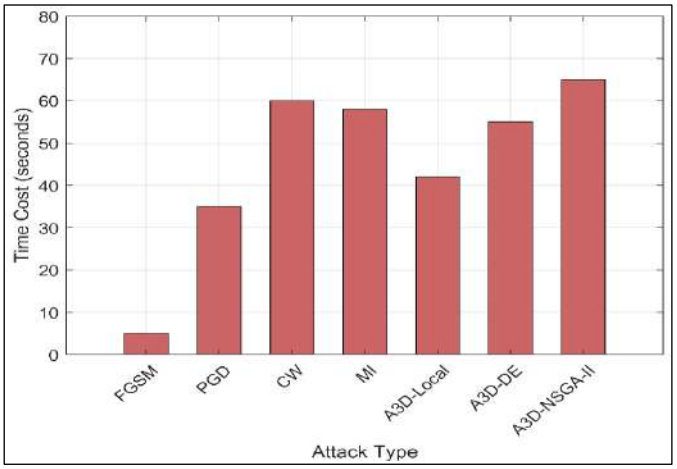

Figure 3: Time Cost versus Attack Type.
Source: Authors, (2026).

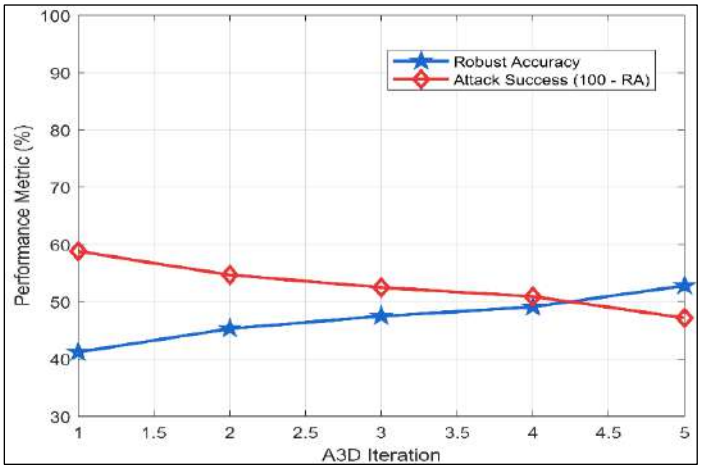

Figure 4: Iteration versus Performance in A3D Framework.
Source: Authors, (2026).

The Figure 4 shows two performance metrics Robust Accuracy and Attack Success change over five A3D iterations. At Iteration 1, the Robust Accuracy is around 42% and it gradually increases across the iterations, reaching approximately 53% by Iteration 5. This shows that the defense component of the A3D framework improves with each cycle. It makes the model more robust to adversarial attacks. Attack Success starts high at about 58% in Iteration 1 but steadily drops to around 47% by Iteration 5. This decrease in Attack Success mirrors the increase in Robust Accuracy. In Iteration 4, both curves intersect that suggests a turning point at which the defense performance begins to overtake the attack strength. The chart shows steady improvement in robust accuracy. Attack success drops over time. This shows the A3D loop is working well. Strong attacks help create better models.

Strong models push the system to find smarter attacks. Over five rounds, models get more robust. Attacks become less effective. This proves the A3D method works as designed. The Figure 5 illustrates a steady improvement in robust accuracy for three architecture search methods: DARTS, DE_NAS and SmoothDARTS. In the early phase, all three methods start from a similar point just above 40% with DARTS slightly behind the others. However, as each A3D cycle progresses, the paths begin to diverge. SmoothDARTS quickly establishes itself as the leading method gaining momentum with every iteration. By the third iteration, it has already moved ahead of DE_NAS and maintains this advantage through to the final cycle.

DARTS improves steadily, but its slope is shallower compared to the other two. It indicates slower growth in robustness. By the final iteration, the contrast between the models becomes clear. SmoothDARTS tops the chart at around 54.2% robust accuracy, followed closely by DE_NAS at 53.6%. DARTS, while improved ends at a lower value of approximately 49.4%. The gap between DARTS and other methods keeps growing. This shows DARTS improves slower. DE_NAS and SmoothDARTS adapt better to attacks. These designs help find stronger models. All methods get better with A3D tuning. But some improve faster. The search algorithm matters. A good design leads to quicker and stronger results. SmoothDARTS emerges as the most promising candidate for building resilient neural networks under adversarial stress.

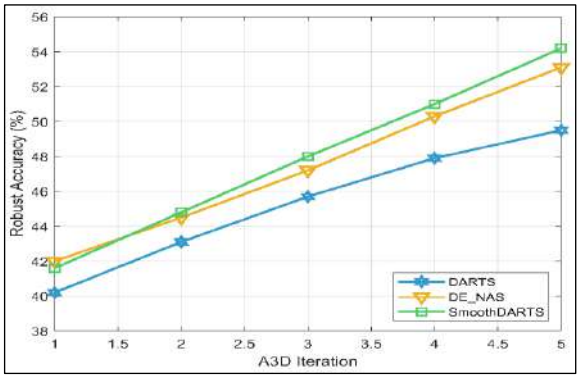

Figure 5: Robust Accuracy across A3D Iteration.
Source: Authors, (2026).

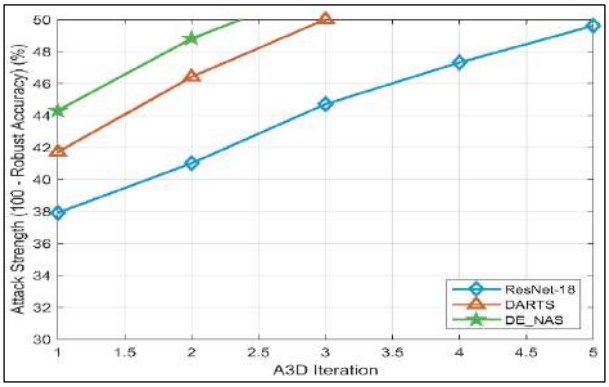

Figure 6: A3D Iteration versus Attack Strength.
Source: Authors, (2026).

The Figure 6 shows a line graph comparing the attack strength of three different models ResNet-18, DARTS and DE_NAS across five A3D iterations. The ResNet-18 model starts with low strength. In iteration 1, it is around 38%. It improves step by step. By iteration 5, it reaches just under 50%. The progress is steady. The model becomes stronger with each round. As stronger attacks are discovered, the ResNet-18 model becomes more vulnerable.DARTS begins at a higher attack strength of about 42% in iteration 1 and rises quickly, reaching approximately 50% by iteration 4.

After that, it shows no major change suggesting that it has reached a peak in vulnerability under the current attack strategies. DE_NAS shows the highest attack strength among the three from the start. It begins around 44% and rising sharply to 49% by iteration 3. It seems to plateau after that similar to DARTS. The graph shows a clear trend. DARTS and DE_NAS become weaker in early rounds. Robustness is lost quickly.ResNet-18 declines more slowly. But its drop is steady. Attacks are becoming stronger. The A3D system learns with each step. It finds weak spots in all models. Even strong models get exposed over time.

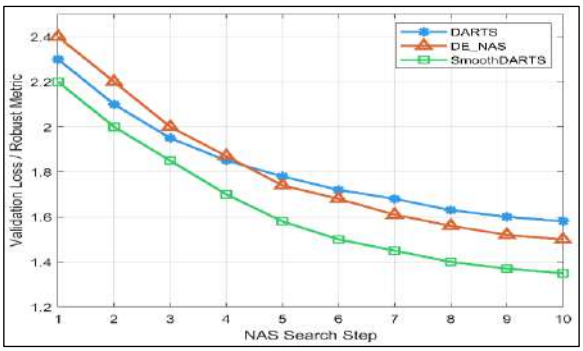

Figure 7: NAS Search Step versus Validation loss or Robustness Metric.
Source: Authors, (2026).

The Figure 7 visualizes the changes in validation loss or a robustness metric across ten NAS search steps for three architecture search methods.All three lines demonstrate a downward slope, indicating continuous improvement over time. DARTS begins at a relatively high metric value near 2.3 and declines slowly to finish just above 1.6. DE_NAS starts high at around 2.4. It catches up with DARTS midway. Later, it drops to about 1.5. SmoothDARTS begins near 2.2. It stays ahead in every step. By step ten, it reaches nearly 1.3. This shows SmoothDARTS starts stronger.

It improves faster over time. DE_NAS shows a similar but slightly slower improvement path, remaining reliably better than DARTS. The lines move increasingly apart as the search continues. This shows the search method matters more over time. All three methods get better with each step. But some improve more than others. SmoothDARTS performs the best. DE_NAS comes next. DARTS improves the least. The growing gap proves the impact of search efficiency.

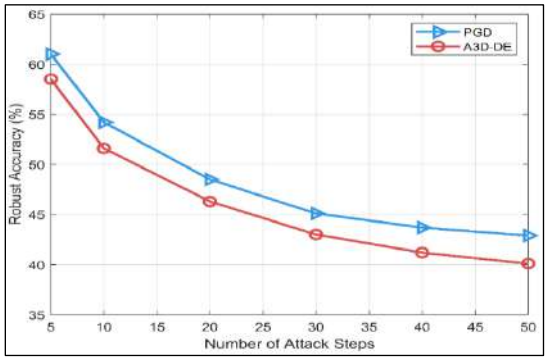

Figure 8: Attack Steps versus Robust Accuracy.
Source: Authors, (2026).

The Figure8 shows a line graph comparing the robust accuracy of two attack methods as the number of attack steps increases. At 10 steps, PGD starts at around 61% robust accuracy.While A3D-DE begins slightly lower at about 59%. As attack steps reach 20, accuracy drops for both methods. PGD falls to around 49%. A3D-DE drops to about 46%. The decline continues across the graph. More attack steps mean stronger attacks. Stronger attacks make the model weaker. The analysis shows higher vulnerability with more iterations. By 50 steps, the robust accuracy under PGD reaches roughly 43%.While A3D-DE drops to about 40%. Across all step sizes, A3D-DE constantly results in lower robust accuracy compared to PGD. This indicates that A3D-DE is more effective in breaking model defenses expressly at higher iteration counts. The gap between the two curves remains steady. This shows that both attacks get stronger with more steps. A3D-DE is always more effective than PGD. Both lines go down smoothly. This shows more attack steps reduce model accuracy. A3D-DE lowers the accuracy more than PGD. The figure proves that A3D-DE is better at breaking the model over many step sizes.

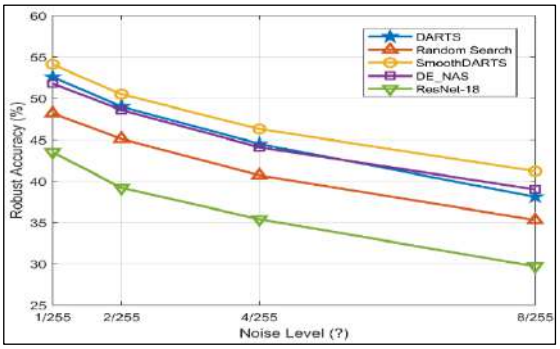

Figure 9: Robust Accuracy versus Noise Level.
Source: Authors, (2026).

The Figure 9 compares the robust accuracy of five models under different noise levels: 1/255, 2/255, 4/255 and 8/255. The models are DARTS, Random Search, SmoothDARTS, DE_NAS and ResNet-18. At the lowest noise level (1/255), SmoothDARTS performs the best with about 54% accuracy. DARTS and DE_NAS follow closely at around 52%.While Random Search scores 49% and ResNet-18 trails at 43%. As the noise level increases to 2/255, the accuracy of all models drops. SmoothDARTS remains on top at 50%, DARTS and DE_NAS are near 48%. Random Search falls to 45% and ResNet-18 declines to 39%.At 4/255 noise, SmoothDARTS holds the lead with 47% accuracy. DE_NAS and DARTS stay close at 44%, Random Search drops to 41% and ResNet-18 falls to 35%. When the noise reaches the highest level of 8/255, SmoothDARTS still performs best with 41%. DE_NAS scores just under 40% and DARTS ends at 38%. Random Search decreases to 35%, while ResNet-18 has the lowest accuracy of 30%. SmoothDARTS shows the best resistance to noise and ResNet-18 is the most affected. All models show steady performance decline as the noise level increases.

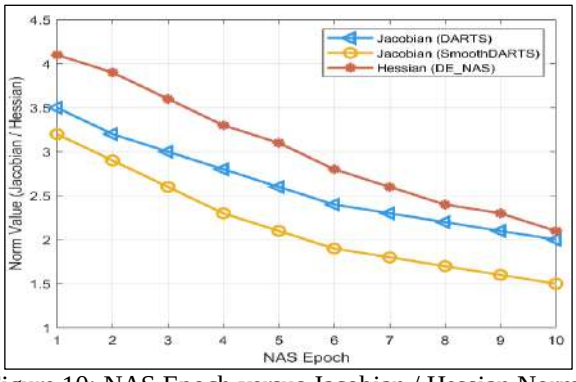

Figure 10: NAS Epoch versus Jacobian / Hessian Norm.
Source: Authors, (2026).

The Figure 10 shows the norm values of Jacobian and Hessian change over 10 NAS epochs. Three methods are shown: Jacobian (DARTS), Jacobian (SmoothDARTS) and Hessian (DE_NAS). At epoch 1, Hessian (DE_NAS) starts the highest with a norm value slightly over 4. Jacobian (DARTS) begins around 3.5 and Jacobian (SmoothDARTS) starts near 3.2. As the epochs increase, the values for all three methods steadily decrease.By epoch 5, Hessian (DE_NAS) has dropped to about 3.2. Jacobian (DARTS) reaches near 2.6 and Jacobian (SmoothDARTS) drops to about 2.1. At the final epoch 10, Hessian (DE_NAS) settles just below 2.5, Jacobian (DARTS) ends near 2. Jacobian (SmoothDARTS) goes down to about 1.5. Throughout all epochs, Jacobian (SmoothDARTS) has the lowest norm values, indicating smoother gradients. Hessian (DE_NAS) maintains the highest norm values, suggesting more variation in the learning dynamics. The overall pattern is a steady decline for all methods, showing that training reduces gradient magnitudes over time.

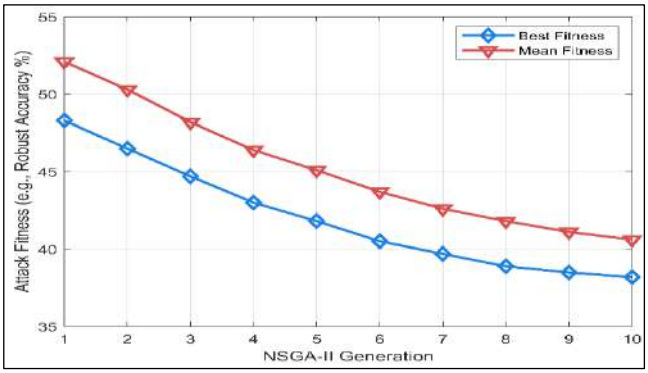

Figure 11: Search Generation versus Attack Fitness in NSGA-II.
Source: Authors, (2026).

TheFigure 11 illustrates attack fitness, represented by robust accuracy, changes over ten generations using the NSGA-II algorithm. It compares two metrics: Best Fitness and Mean Fitness. In generation 1, the Best Fitness begins at around 48% and the Mean Fitness starts higher at nearly 53%. As the generations move forward, both lines gradually decline. By generation 5, Best Fitness drops to about 43%.While Mean Fitness reaches roughly 46%. This pattern shows that as the optimization process continues, both the strongest and average solutions become less robust.In the final generations, the decline continues but slows slightly. At generation 10, Best Fitness ends near 40% and Mean Fitness closes around 41%. The gap between the two lines narrows, indicating that individual models in the population are becoming more similar in robustness. This suggests that the algorithm is converging to a certain performance level. The plot shows that robustness decreases over time. NSGA-II finds weaker architectures in later generations. However, the best models still perform better than the average. This holds true even in the last few generations.

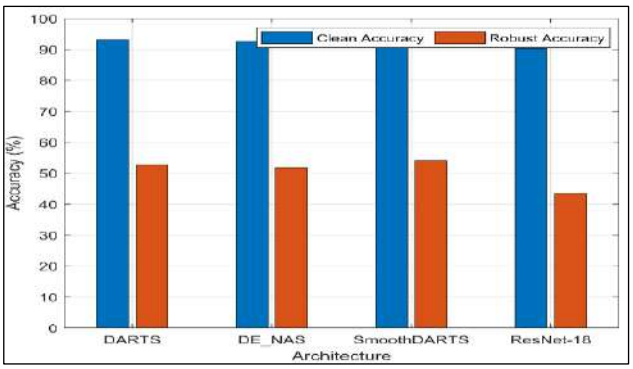

Figure 12: Clean versus Robust Accuracy by Architecture.
Source: Authors, (2026).

The Figure 12 compares clean accuracy and robust accuracy for four neural network architectures. All four models show clean accuracy values around 93%. Specifically, DARTS has the highest clean accuracy, slightly above 93%, while the others are close behind. ResNet-18 has the lowest clean accuracy, though the difference is small. This suggests that all models perform well on clean, unperturbed data. The robust accuracy tells a different story. SmoothDARTS achieves the highest robust accuracy, close to 54%, followed by DARTS at around 53%. DE_NAS is slightly behind at 52% and ResNet-18 performs the worst with only 44%. The gap between clean and robust accuracy is the smallest for SmoothDARTS. It indicates that it handles adversarial or noisy conditions better. ResNet-18 shows a larger drop in performance when moving from clean to robust scenarios. The chart highlights that although most models are similar in clean accuracy. SmoothDARTS provides the best trade-off between clean and robust performance.

The Figure 13 compares the GPU time in days required by different NAS methods. Among them DE_NAS has the highest search cost using about 3.2 GPU-days. SmoothDARTS is next requiring around 2.1 GPU-days. DARTS needs less time using 1.5 GPU-days. Random Search takes only 0.8 GPU-days and PC-DARTS uses around 1.0 GPU-days. These numbers show that some methods are much more demanding in terms of computational cost than others.From the figure, it is clear that DE_NAS is the most resource-heavy method.While Random Search is the least costly. SmoothDARTS and DARTS sit somewhere in the middle. PC-DARTS, although more efficient than DE_NAS still uses slightly more resources than Random Search.

This suggests a trade-off between cost and potential performance. Users with limited hardware or time should consider lower-cost options like Random Search. Meanwhile, those with more resources might choose DE_NAS for possibly better results despite the higher cost.

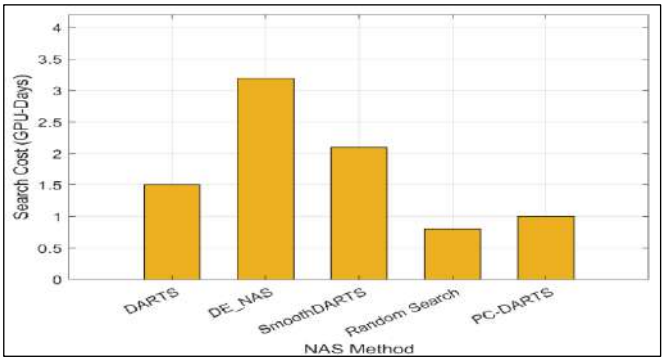

Figure 13: Search Cost versus NAS Method.

V. CONCLUSION

The main purpose of A3D is to automatically search for both strong adversarial attacks and robust neural network architectures. It brings together two important areas in adversarial machine learning attack generation and defense design.Most existing tools are limited to evaluating models or attacks. These tools do not improve or optimize the results.A3D solves this problem by using AutoML techniques. These techniques help in finding better model designs and better attack methods without human effort. The platform is powerful because it supports both single-objective and multi-objective optimization. This tells it finds results that are either very strong, very fast or both.For the defense part, A3D uses different types of robustness tests. These include adversarial noise, natural noise, system noise and mathematical metrics like the Jacobian and Hessian.

The system then searches for models that perform well under these tough conditions. It uses various NAS methods to do this.For the attack part, A3D uses search algorithms like Differential Evolution and NSGA-II. These help in finding strong attacks that fools even the most robust models. Attacks found by the system are used to test and improve models. The improved models are used to find even better attacks. This cycle continues and makes both parts stronger over time. This platform helps researchers build safer and smarter AI systems.A3D is a complete and automatic solution for improving AI robustness. It makes it easier to build models that are hard to attack and to test them with strong attacks.

ABSTRACT

Chocolate, a food product widely appreciated for its flavor and versatility, has been undergoing innovation. The incorporation of native fruits from Brazilian biomes into its formulation has become a promising alternative to combine sensory pleasure with nutritional benefits. Thus, this study aimed to review recent scientific literature on the use of these fruits in chocolate production, focusing on their nutritional, functional, and technological impacts. The research was conducted through a systematic review following the PRISMA 2020 protocol, including articles published between 2020 and 2025 in the ScienceDirect database that presented information on fruit-based formulations and nutritional composition data. Fruits such as cupuaçu, palm, elderberry, and sacha inchi demonstrated potential to enrich chocolates due to their bioactive and nutritional compositions, in addition to contributing to sustainable practices through the use of agricultural by-products. The analysis revealed significant gains without interfering with sensory acceptability, as well as opportunities for regional innovation and valorization of Brazilian biodiversity. Therefore, it was evident that the integration of native fruits into chocolate strengthens the development of healthier and more natural foods and stimulates the circular economy and biodiversity.

I. INTRODUCTION

The search for healthy, innovative, and sustainable food products has driven the incorporation of natural ingredients that enhance nutritional, functional, and sensory profiles [1], [2]. In this context, several native fruits from Brazilian biomes have been explored and studied for numerous applications, particularly in the food sector. Beyond the interest in their bioactive and sensory composition, there is also a growing effort to promote their utilization, as many of these fruits remain underexploited [3-6]. Chocolate is characterized as a product obtained from the mixture of cocoa derivatives (cocoa mass, cocoa powder, and/or cocoa butter) with other ingredients, and it must contain at least 25% (g/100 g) of total cocoa solids.

White chocolate is also defined, requiring a minimum of 20% (g/100 g) of total cocoa butter solids [7]. These criteria are essential to ensure chocolate quality and the maintenance of its sensory and nutritional characteristics, providing consumers with a safe product that complies with current regulations [8], [9]. This food product is highly appreciated for its unique flavor and versatility, as it can be consumed in bar form or used as a base in the confectionery sector [10]. The formulation of chocolates, as with any food product incorporating fruits, requires rigorous technical control to ensure product stability, preservation of sensory characteristics, and commercial viability [11], [12]. Analyses such as moisture content, acidity, chemical composition, and ingredient interactions are indispensable to guarantee product safety.

Therefore, the development of such foods demands advanced knowledge of the properties of each fruit used, as well as their compatibility with the food matrix to which they are added [13], [14]. Thus, the addition of fruits to chocolate, beyond promoting biodiversity, also represents an innovation for the development of products that, in addition to sensory attributes, provide health benefits such as antioxidant, anti-inflammatory, and cardiovascular effects [15-17]. Therefore, the growing demand for natural, sustainable foods with functional appeal reinforces the importance of research and development of chocolates enriched with native Brazilian fruits. The integration of technological knowledge, nutritional composition, and sensory aspects is essential to foster innovation in this segment, promoting health, flavor, and sustainability [18], [19]. In this context, the objective of this study is to identify, select, and synthesize evidence on the formulation and nutritional composition of chocolates enriched with native fruits.

II. METHODOLOGY

II.1 TYPE OF STUDY

This study consists of a systematic review of the scientific literature, conducted in accordance with the recommendations of the PRISMA 2020 statement (Preferred Reporting Items for Systematic Reviews and Meta-Analyses), encompassing only publications from 2020 to 2025. The implementation of the PRISMA protocol ensures greater methodological rigor, transparency, and reproducibility of the processes of data searching, selection, extraction, and analysis [18-20].

II.2 SEARCH STRATEGY

The search strategy was conducted in the ScienceDirect database in 2025. For this purpose, the following Boolean operator was used to enable a comprehensive and specific search within the established criteria: “chocolate AND fruit AND formulation AND ‘nutritional composition’”. The following filters were also applied: language (no restriction), document type (research articles and meta-analyses), and open-access availability.

II.3 SELECTION CRITERIA

To select the articles, inclusion and exclusion criteria were applied to ensure the relevance and quality of each study within the defined scope. The inclusion criteria considered studies addressing chocolate formulations containing fruits or their derivatives, with analysis of nutritional composition, original research articles, no language restriction, and full texts available in open access. Exclusion criteria were applied to studies that did not present analyses of nutritional composition. Literature reviews were also excluded, as well as studies focused exclusively on sensory, microbiological, or toxicological aspects without nutritional data, conference abstracts or documents, duplicates, and articles with restricted access.

II.4 SELECTION PROCESS

After importing the records from the database, all existing duplicates were removed. Study selection was performed through the screening of titles and abstracts for preliminary exclusion, followed by full-text reading to confirm eligibility according to the previously defined criteria.

II.5 DATA EXTRACTION

Data extraction was carried out using a table containing study identification (authors, year of publication, and DOI), type and description of the formulation (species used, fruit form, concentration, incorporation method, and processing parameters), quantitative results related to nutrients and bioactive compounds, and, when available, observations on technological and sensory aspects.

II.6 DATA SYNTHESIS AND ANALYSIS

The filtered and selected data were organized into descriptive tables and graphs, which facilitated the understanding of the effects of adding different fruits on the nutritional composition of chocolates. In addition, a complementary qualitative analysis based on study frequency was performed, allowing the identification of existing gaps in the literature, emerging trends, and potential areas for future investigations.

III. RESULTS AND DISCUSSION

Figure 1 shows the annual frequency of publications in the ScienceDirect database related to research articles addressing the incorporation of native fruits into chocolate, highlighting the evolution of interest in the topic over the years.

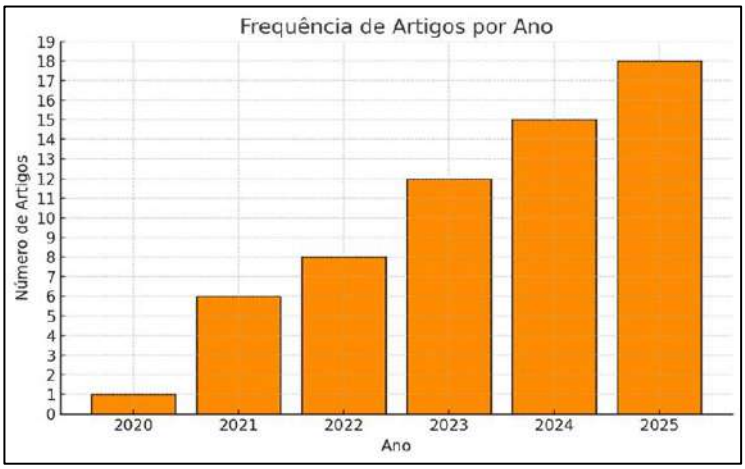

Figure 1: Annual frequency of review articles on native fruits incorporated into chocolate (ScienceDirect).
Source: Authors, (2026).

Based on the analysis of Figure 1, it is observed that in the ScienceDirect database, until a few years ago, there was a limited number of articles addressing the incorporation of native fruits into chocolate. This low initial volume likely reflects a scientific and technological underexploration of these ingredients in the chocolate industry. Consequently, the nutritional, sensory, and economic potential of native species has been constrained [21]. Between 2023 and 2025, a gradual increase in publications is evident, with a higher concentration in more recent years, indicating growing interest in the valorization of native fruits, particularly those from Brazilian biomes, as innovative and sustainable alternatives.

This increase may be associated with the demand for products with functional appeal, the appreciation of biodiversity, and the food industry's pursuit of more natural and regionally based formulations [22], [23]. The selected studies demonstrate diverse approaches regarding the choice of fruit parts, ingredient combinations, processing techniques, and analysis of nutritional composition. Table 1 summarizes this information, also highlighting technological applications, functional benefits attributed to the formulations, and the corresponding references.

Table 1: Chocolate formulations with native fruits and their nutritional composition.

Native fruit	Product or part used	Applications in chocolates	Functional benefits	Reference
Palm	Panattu Choco Bar	Energy chocolate with the addition of tropical fruit	Rich in minerals, high energy value, good sensory acceptance potential	[24]
Cupuaçu	Pulp	Source of texture and flavor; can partially replace cocoa in the formulation	Antioxidant, anti-inflammatory, improves intestinal health and has immunomodulatory effects	[25]
Cupuaçu	Seeds (cupulate)	Used as a base for "cupulate"-type chocolate	Sustainable cocoa substitute; rich in antioxidants and bioactive compounds	[26]
Elderberry (*Sambucus* sp.) by-product	Fruit residues (peels/seeds)	Dark chocolate (75%) enriched with 2–10% by-product; optimization of conching time and addition of sacha inchi oil	Increased antioxidant capacity, preservation of phenolic compounds during processing, valorization of by-products	[27]
Sacha inchi oil (*Plukenetia volubilis*)	Pure oil incorporated into chocolate	Partial replacement of cocoa butter in dark chocolates; formulations with up to 5% sacha inchi oil in ganache and chocolate mass	Improved lipid profile (higher antioxidant content), fibers and polyphenols; reduced saturated fat; anti-inflammatory and cardioprotective potential	[26-28]
Sacha inchi ganache	Ganache with 10% seed or oil	Filled chocolates with enriched ganache (5–10%) in milk and dark chocolates	Increased fiber, phenolic compounds, and antioxidants; good sensory acceptance	[29]

Source: Authors, (2026).

The incorporation of native fruits and their by-products into the chocolate industry has resulted in expressive nutritional gains, mainly associated with increased levels of phenolic compounds, fiber, and antioxidants, which, when combined with sensory perception, favor greater consumer acceptance [30], [31]. Thus, studies involving cupuaçu, elderberry, and sacha inchi have shown that the partial replacement of cocoa butter and the addition of by-products (peels, seeds, and pulps) not only enrich the bioactive profile but also preserve or even improve certain product attributes [26-28], [32].

Moreover, there is considerable potential to explore other regional fruits, such as açaí, juçara, and araçá, as viable alternatives for reducing sugar content in formulations. By using pulps or freeze-dried powders of these ingredients, it becomes possible to develop chocolates with a more favorable glycemic profile, meeting the demand for healthier and more sustainable products [33-35]. Figures 2 and 3 illustrate the distribution and relevance of terms related to the use of native fruits in chocolate development.

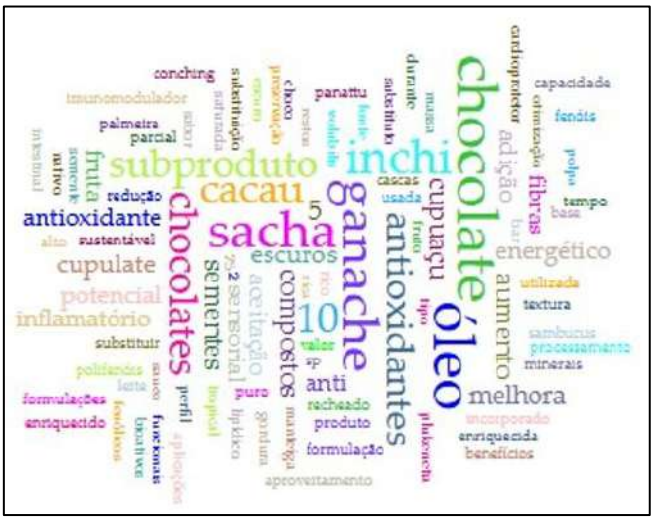

Figure 2: Word cloud of the main terms related to native fruits and applications in chocolates.
Source: Authors, (2026).

Figure 2 presents, through a word cloud, a visual representation of the most recurring terms, as well as their connections with functional attributes, technological applications, and potential nutritional benefits. This visual analysis allows a better understanding of the emphasis placed on native ingredients in chocolate formulations.

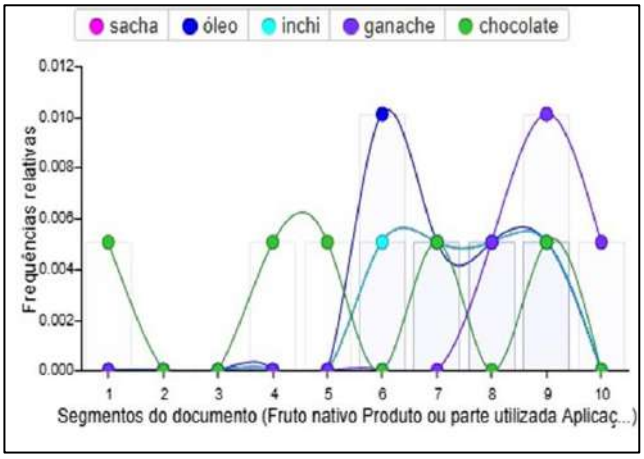

Figure 3: Word cloud of the main terms related to native fruits and applications in chocolates.
Source: Authors, (2026).

Figure 3 illustrates how keywords such as sacha, oil, inchi, ganache, and chocolate appear across the segments, revealing thematic patterns.

III.1 TECHNOLOGICAL AND SENSORY POTENTIAL OF NATIVE FRUITS IN CHOCOLATE FORMULATION

The incorporation of cupuaçu pulp (*Theobroma grandiflorum*) as a source of texture and flavor reinforces the versatility of this Amazonian fruit, whose application can partially replace cocoa in chocolate formulations, supporting flavor innovation and reducing dependence on the traditional raw material [25]. This partial substitution not only introduces a fruity and exotic note to the product but also enables the development of new chocolate lines with regional identity, strengthening the appeal of origin and the connection with consumers seeking authentic and differentiated products [22], [23]. The use of cupuaçu seeds for the production of "cupulate" represents a sustainable alternative to cocoa, as it valorizes residues that would otherwise be discarded, adding value and reducing waste.

Cupulate maintains the texture and shape of traditional chocolate, but with a differentiated bioactive profile due to the presence of antioxidants in the seeds [25]. This approach contributes to a circular economy model within the cocoa and cupuaçu production chains. The use of *Sambucus* sp. by-products, specifically peels and seeds, in dark chocolates (75%) enriches the product with phenolic compounds and antioxidants, while preserving these compounds during processing through the optimization of conching time and the addition of sacha inchi oil [27]. This strategy highlights the potential of by-products for the development of functional chocolates that add nutritional value beyond sensory pleasure, transforming residues into valuable ingredients.

III.2 FUNCTIONAL BENEFITS AND ENHANCED NUTRITIONAL PROFILE

Native fruits such as palm (Table 1), used in the Panattu Choco Bar, stand out for their high energy value and mineral richness, qualifying them as ideal ingredients for energy chocolates designed to meet specific consumer demands, such as those of athletes or individuals with increased nutritional requirements [24]. In addition to the energetic benefit, favorable sensory acceptance is essential for the commercial viability of this type of product.

Sacha inchi oil, also known as sacha peanut, incorporated into dark chocolates as a partial substitute for cocoa butter, provides a healthier lipid profile, with higher concentrations of antioxidants, fiber, and polyphenols, as well as reduced saturated fat content [26], [27]. Its anti-inflammatory and cardioprotective effects further enhance the functional appeal of chocolate, positioning it as a food that combines pleasure and health.

Ganache enriched with sacha inchi seeds or oil, used in milk and dark chocolates, promotes a significant increase in fiber and phenolic compound intake, thereby enhancing the antioxidant capacity of the product [27]. This enrichment does not compromise sensory acceptability, a crucial condition for commercial success, demonstrating that the incorporation of functional ingredients can coexist with the maintenance of the sensory experience desired by consumers [27], [29].

III.3 SUSTAINABILITY AND FULL UTILIZATION OF RAW MATERIALS

The valorization of by-products, such as elderberry fruit residues and cupuaçu seeds, demonstrates the growing concern for sustainability in the chocolate industry. The reuse of residues minimizes or even prevents waste and contributes to reducing the environmental impacts of production, while also increasing economic competitiveness through the development of new high value-added products [11], [33]. The use of cupulate as a cocoa substitute enables diversification of the production base and fosters the regional economy in areas where cupuaçu is abundant. In addition, the partial replacement of cocoa butter with sacha inchi oil represents a technological innovation that supports sustainability [25], [26].

III.4 PERSPECTIVES AND CHALLENGES FOR INNOVATION IN CHOCOLATES WITH NATIVE FRUITS

Despite the evidence from studies highlighting the nutritional and functional benefits of incorporating native fruits into chocolate, several challenges still hinder large-scale implementation. These include raw material variability, processing constraints, the need to ensure sensory acceptance, and compliance with regulations governing health claims [36], [37]. Nevertheless, innovations in the conching process using some of the species listed in this study demonstrate that it is possible to preserve antioxidant and phenolic compounds without negatively affecting product texture or flavor. The growing demand for healthier, more sustainable, and value-added foods represents a real opportunity for products based on native fruits to gain market space, fostering innovation and promoting the valorization of Brazilian biodiversity [36], [38].

IV. CONCLUSIONS

It was observed that the incorporation of fruits from Brazilian flora into chocolate and related product formulations emerges as a promising strategy for the development of chocolates with enhanced nutritional value. Fruits such as palm, cupuaçu, and elderberry have been incorporated to enrich chocolates, bars, spreads, and desserts with attractive sensory characteristics. Some of these fruits contributed to improved texture, reduced sugar content, or acted as partial substitutes for cocoa fat. Overall, the data suggest that the use of native fruits in chocolate formulations not only adds nutritional value to the product but also promotes Brazilian biodiversity and meets current demands for healthier, more sustainable, and innovative foods.

ABSTRACT

Smart homes are increasingly common, making it more important than ever to safeguard them against cyber threats. In this work, we develop an improved anomaly-based Intrusion Detection System (IDS) for smart home IoT networks by combining machine learning (ML) techniques with advanced Feature Selection (FS) and Explainable Artificial Intelligence (XAI). We propose an FS approach that finds the intersection of important features identified by Recursive Feature Elimination with Cross-Validation (RFECV) using two different base learners: a Decision Tree (DT) and a Light Gradient Boosting Machine (LGBM). This yields a compact subset of 12 network traffic features. Using this significantly reduced feature set, our lightweight LGBM model achieves 99.86% detection accuracy, an F1-score of 99.93%, and a recall of 99.96% on the IoTID20 dataset. The false positive rate is greatly reduced, and computational cost is also minimized. To enhance model transparency, we integrate XAI tools, Local Interpretable Model-Agnostic Explanations (LIME) provide clear instance-level explanations, and Shapley Additive Explanations (SHAP), which provide global explanations of the classifier's decisions. Experimental results demonstrate that combining FS with XAI can improve both the efficacy and the usability of IoT IDS. Our hybrid model outperforms several recent deep learning approaches in precision and recall, while being far more interpretable. Overall, the proposed method yields high detection rates with improved transparency, making it well-suited for resource-constrained smart home environments.

I. INTRODUCTION

The Internet of Things (IoT) connects numerous everyday devices, including smart thermostats, cameras, voice assistants, sensors, and more, within smart home environments. However, increased connectivity also broadens the attack surface available to malicious actors. An Intrusion Detection System (IDS) monitors network traffic to identify abnormal behavior that may signal cyberattacks. Traditional signature-based IDS methods struggle to detect novel or evolving threats, making anomaly-based detection more suitable for the dynamic context of smart home IoT installations [1]. These technologies enable greater automation and convenience in smart homes, but they also generate vast amounts of complex data. Each device can produce hundreds of features (from network traffic, device logs, sensor readings, etc.), making it challenging to discover the small patterns indicative of malicious activity [2].

In other words, anomaly-based IDS models can potentially catch previously unseen attacks, but they face challenges like the high dimensionality of IoT data and a lack of explainability in complex models [3]. Smart home networks generate a vast amount of heterogeneous data from sensors, cameras, appliances, etc., which typically results in high-dimensional feature spaces. Many features may be redundant or irrelevant, slowing down learning algorithms and potentially degrading detection performance [4]. Moreover, complex models such as Deep Neural Networks (DNN) that achieve high accuracy often act as "black boxes," leaving administrators unsure why a certain alert was raised. This lack of interpretability can reduce trust in the IDS and make it harder to refine the system.

Therefore, there is a need for an attack detection approach that not only attains high accuracy but also provides clarity about its decision process. Recent research has applied Explainable Artificial Intelligence (XAI) techniques to improve the transparency of ML models in IoT security [5], [3]. According to [6], also emphasized on advanced feature engineering using DCNN method for enhancing IoT security. In this work, we address the dual challenges of dimensionality and lack of interpretability by integrating an efficient FS strategy with XAI methods. Research on enhancing IoT security has grown rapidly in recent years, yielding a variety of approaches. Many works leverage traditional ML, DL, or hybrid techniques to improve detection accuracy in IoT environments.

For example, by [7] proposed a hybrid DL method using Convolutional Neural Network- Long Short-Term Memory (CNN-LSTM) for enhancing the security of Internet of Medical Things (IoMT). They implemented the IDS on a Raspberry Pi device using a fog computing architecture. In [8] suggested an approach to enhance the IDS using the FS method SHAP-based REFCV with extreme Gradient Boosting (XGBoost) model on the UNSW-NB15 dataset. According to [9] proposed a hybrid FS approach using statistical methods and a metaheuristic algorithm to identify the most relevant features. They applied an LSTM-based model on two publicly available datasets, NF-BoT-IoT-v2 and IoTID20, with a reduced feature set.

For [10] suggested a framework for anomaly intrusion detection using RFE integrated with ML paradigms, and a ridge regression merged into DL models. They used a real-time IoMT dataset, WUSTL-EHMS. This framework achieved a training accuracy of 99 % and a testing accuracy of 97.85 % using the RFE-DT with a False Alarm Rate(FAR) of 0.03. In the past year, there have been promising developments incorporating Graph Neural Networks (GNN) and attention mechanisms into IDS. According to [11] employed a GNN for IoT intrusion detection, achieving superior accuracy and outperforming other methods on benchmarks. These advanced systems typically require significant computational resources and lack straightforward interpretability.

By contrast, our approach shows that a carefully engineered classical ML pipeline can reach comparable performance to GNN or attention-based DL models, while being lighter-weight and inherently more interpretable. Specifically, we employ an RFECV technique [12] using two different base learners [13], [14] to identify a robust subset of features. Intersecting the important features from these two models yields a drastically reduced feature set that still preserves the crucial information needed to detect attacks in IoT networks. This significant reduction in dimensionality lowers computational overhead and training time, which is crucial for real-time detection in IoT settings.

To ensure that the model's decisions remain transparent, we integrate [15], [16] tools to explain the contribution of each feature to the model's predictions. This combination of local (instance-level) and global (feature importance) explainability effectively transforms our IDS into a "glass box" system that can justify its reasoning for each alert, thereby boosting user trust and facilitating system refinement. In summary, the proposed methodology addresses the gaps identified in prior works by jointly improving detection accuracy, efficiency, and explainability in a single ML based framework for enhancing IoT security. Our main contributions can be summarized as follows:

- Hybrid Feature Selection: We propose a novel hybrid FS method that combines RFECV outputs from two different estimators (DT and LGBM). This approach effectively reduces the feature set from 83 down to 12 features without sacrificing detection capability. The resulting lightweight model yields high accuracy with a very low False Positive Rate (FPR) and shorter training time.
- Explainability: We integrate LIME and SHAP to provide both local and global explanations for the model's predictions. LIME offers instance-level interpretability by highlighting which features contribute most to a given classification, whereas SHAP summary plots provide an overview of feature importance and effect across all instances. By combining these XAI techniques, our framework produces not just predictions but actionable explanations for each alert, improving user trust and insight.
- Comprehensive Evaluation: We conduct extensive experiments on a real-world IoT intrusion dataset (IoTID20) to validate our framework. We compare our approach against several existing methods from the literature, including recent DL-based approaches. The results show that our hybrid model achieves competitive or superior detection rates while using far fewer features.
- Practicality for Smart Homes: We demonstrate the practicality of our solution for smart home deployment using lightweight ML algorithms. We analyse the system's runtime performance and resource usage, showing that it can be deployed on resource-constrained edge devices (such as a Raspberry Pi) with manageable inference latency. This makes our approach feasible for real-time attack detection in IoT home networks.

II. PROPOSED METHODOLOGY

This section describes our proposed attack detection framework in detail. We outline the dataset characteristics and preprocessing steps, the ML algorithms and FS techniques used, the hybrid FS approach we developed, the performance evaluation metrics, and the XAI tools integrated into the system. Figure 1 depicts the stages of the proposed methodology. In [17], the authors have utilized the IoTID20 dataset because of its significant citation rate in scholarly indexing repositories. Accordingly, we have also taken the IoTID20 dataset for our study. It addresses a wide range of attack types, guaranteeing their applicability and relevance in studies that focus on smart home environments.

II.1 DATASET DESCRIPTION

We evaluate our approach using the IoTID20 dataset, which is a recent intrusion detection dataset specifically designed for smart home IoT environments [18]. IoTID20 captures network traffic from a typical smart home setup. In the data collection scenario, a standard smart home network was established, consisting of an SKT NGU smart home hub device and an EZVIZ Wi-Fi camera as the primary IoT devices, connected through a home router. Additional devices (computers, tablets, smartphones) were present in the network to generate background traffic and launch attacks. The SKT NGU and the camera acted as victims (targets of attacks), while the other devices functioned as attackers in various experiments [19]. The IoTID20 dataset provides labelled instances of both normal and attack traffic. It contains a total of 585,710 malicious traffic records and 40,073 benign records.

II.2 DATA PREPROCESSING

Before model training and FS, we performed comprehensive data preprocessing on the IoTID20 dataset. We utilized the Python built-in package (Pandas) [20] and NumPy [21] frameworks in the preprocessing step of our experiment. The following steps were applied.

II.2.1 Data Cleaning

We removed duplicate records and any irrelevant fields. In IoTID20, fields like Flow_ID, Dst_IP, Src_IP, and Timestamp were dropped, as they are identifiers or time indices that do not generalize to new data (and could leak information if not handled properly).

II.2.2 Handling Missing and Infinite Values

We replaced any occurrences of infinite values with NaN and then handled missing values. Specifically, for any feature with more than 5% missing values, we imputed the missing entries with the median of that feature.

II.2.3 Label Encoding

Label encoding has been used to convert the categorical variables into a numerical format so that ML algorithms can use them. We converted the labels into binary numeric form: 0 for Normal and 1 for Anomaly.

II.2.4 Train-Test Split

We partitioned the data into training and testing sets. Using a stratified split, we allocated 80% of the data for training and 20% for final testing. The stratification ensures that even minority attack categories are represented proportionally in both training and test sets.

II.2.5 Data Cleaning Class Imbalance Handling

The training data remained imbalanced after splitting. For balancing the dataset, we applied SMOTE (Synthetic Minority Over-sampling Technique) [22] on the training set. SMOTE generates synthetic examples of the minority class (normal traffic in this case) to balance the class distribution. The test set was kept at the original distribution for a realistic evaluation.

II.2.6 Normalization

Finally, we normalized the feature values using Min–Max scaling to the [0,1] range. This ensures that features on different scales (e.g., byte counts vs. time durations) all contribute proportionately in model training. After these preprocessing steps, the data were ready for FS and model training. By cleaning and resampling the data, we reduced noise and bias, providing a solid foundation for the subsequent FS phase.

II.3 MACHINE LEARNING TECHNIQUES

We implemented our ML models using the Scikit-Learn library in Python [23]. Our framework employs two primary algorithms as base learners: DT and LGBM. These were chosen for their complementary characteristics. DTs are fast and interpretable, whereas LGBM is a state-of-the-art gradient boosting method known for high accuracy and efficiency on large data.

II.3.1 Decision Tree

A DT is a non-parametric supervised learning method used for classification (and regression). It learns decision rules inferred from the data features to predict the target label. Each internal node of the tree represents a feature test; each branch represents an outcome of the test, and each leaf node represents a class prediction (in our case, attack or normal). DTs are relatively fast to train and can handle datasets with many features, but a single tree can overfit if not pruned. DTs also provide an importance score for each feature, which we will leverage in FS [10], [13].

II.3.2 Light Gradient Boosting Algorithm

LGBM is a gradient boosting framework that uses tree-based learners. It is an optimized implementation of Gradient Boosted Decision Trees (GBDT), known for its speed and efficiency, especially on large datasets and high-dimensional data [24].

LGBM introduces techniques like histogram-based splitting and leaf-wise tree growth with depth constraints, which make it faster and sometimes more accurate than traditional XGBoost for certain tasks. In our context, LGBM serves both as a base estimator for FS and as the final classifier after feature reduction. We use default hyperparameters for LGBM, with a fixed random_state=42 for reproducibility.

II.4 FEATURE SELECTION

To minimize dimensionality and improve model generalizability, we apply multiple FS techniques after the basic preprocessing. Specifically, we experiment with Recursive Feature Elimination (RFE), RFE with cross-validation (RFECV), and our proposed hybrid FS method that combines RFECV results from two estimators (DT and LGBM).

II.4.1 Recursive Feature Elimination

RFE is a wrapper FS method that recursively removes the least important features until a desired number of features is reached. It works by training a model and, at each iteration, dropping the feature with the smallest importance as determined by the feature importance metric. We employed RFE with estimators such as DT and LGB to find sets of eight features to customize the FS in this study [10].

II.4.2 Recursive Feature Elimination

RFECV is an enhanced RFE that uses cross-validation at each stage of elimination to confirm the model's efficacy in choosing the optimal number of features. This approach uses cross-validation to assess model performance at each iteration and find the optimal feature set size by recursively eliminating features that are of the least importance based on estimator-specific coefficients or feature importance metrics. In our research, we have employed 5-fold cross-validation within the RFECV framework so that robust and unbiased FS is ensured. This process not only reduces overfitting and improves generalization but also enhances model interpretability by eliminating redundant or irrelevant attributes [12].

II.4.3 Proposed Hybrid FS

We propose a hybrid FS that utilizes RFECV by taking the common attributes of two base estimators. We have used two distinct tree-based ML methods, namely DT and LGBM. The dataset is first divided into training and testing subsets, and then each classifier independently applies RFECV to determine the most important features. The intersection of selected features from both models is computed to retain only the most significant features. If some common features are found, then the final classification model, which can be either LGBM or DT, is trained using these common features. The performance of the resulting model is evaluated by using standard metrics such as accuracy, precision, FPR, training time, testing time, recall, and F1-score. This algorithm is specified below:

Algoithm 1: Hybrid Feature Selection Using Two Estimators

- Input: All features post pre-processing
- Output: Common features obtained by using two estimators

1. *Split the dataset into training and testing sets:x_train, x_test, y_train, y_test ← train_test_split (x, y)*
2. *Initialize Decision Tree Classifier: dt ← DecisionTreeClassifier ()*
3. *Perform Recursive Feature Elimination with cross-validation using Decision Tree: rfecv_dt ← RFECV (estimator=DecisionTreeClassifier (), step=1, cv=StratifiedKFold (5), scoring='accuracy')*
4. *Selected_features_dt ←: Features selected by rfecv_dt*
5. *Initialize LightGBM Classifier: lgbm← LGBMClassifier ()*
6. *Perform Recursive Feature Elimination with cross validation using LightGBM: rfecv_lgbm ← RFECV (estimator = LGBMClassifier (), step=1, cv=StratifiedKFold (5), scoring='accuracy')*
7. *Intersection of selected features:*
   common_features ← selected_features_dt ∩ selected_features_lgbm

8. *if common_features ≠ Ø then*
    a. *Extract x_train_common ← x_train[common_features]*
    b. *Extract x_test_common ← x_test[common_features]*
    c. *Initialize final classifier:*
    d. *final_model ← LGBMClassifier () or DecisionTreeClassifier ()*
    e. *Train final_model on x_train_common and y_train*
    f. *Predict y_pred ← final_model. predict(x_test_common)*
    g. *Evaluate performance metrics*
9. *else*
10. *Output: "No common features found. Try selecting more features."*

Using this hybrid FS approach, we drastically reduced the feature count while preserving the most significant predictors. This not only lowers computational cost but can also improve detection performance by eliminating noisy features. Next, we discuss the metrics used to evaluate our models.

II.5 PERFORMANCE EVALUATION METRICS

Because accuracy alone is not enough for the IoT network in smart homes, a thorough evaluation of the ML technique is required. A confusion matrix is a useful evaluation metric for illustrating how well an ML algorithm performs. It presents a table that contrasts the model's predictions with the actual class labels. Below is an explanation of the significance of the four linked variables that were obtained from the confusion matrix: False Negative (FN), True Negative (TN), False Positive (FP), and True Positive (TP).

TP: When an IDS identifies a scenario as an attack, it means that a real attack has been found.
FP: When an instance is flagged as a danger by the IDS, even after it has been confirmed to be safe.
TN: While the IDS recognizes the usual scenario, additional study reveals that the occurrence is normal.
FN: Some cases were misclassified by IDS as malicious attacks, whereas they were later confirmed to be normal occurrences.

Our ML models are assessed using a variety of assessment metrics, including accuracy, precision, FPR, recall, and F1 score, in order to validate our suggested methodology. An overview of these five metrics is given below:

(a)Accuracy: Out of all the predictions, the percentage of true predictions is what determines a prediction system's accuracy.

$$Accuracy = \frac{TP+TN}{TP+TN+FP+FN} \tag{1}$$

(b)Precision: The precision metric is determined by the ratio of correctly predicted true positive cases to the total predicted positive cases

$$Precision = \frac{TP}{TP+FP} \tag{2}$$

(c)Recall: Recall, detection rate, or sensitivity denotes a model's ability to accurately identify and classify attacks. The recall for a specific label is defined as the ratio of true positives to the total number of actual positives.

$$Recall = \frac{TP}{TP+FN} \tag{3}$$

(d)F1-Score: The F1-score is derived by computing the harmonic mean of precision with recall. The maximum value is achieved when precision equals recall.

$$F1 = 2.\frac{Precision*Recall}{Precision+Recall} \tag{4}$$

(e)FPR: The FPR is computed using the following formula.

$$FPR = \frac{FP}{TN+FP} \tag{5}$$

(f)Training Time: The amount of time needed to train ML models using a given dataset is measured in seconds (s). The time it takes to go from starting to finishing the training is the key factor in determining this period.
(g)Testing Time: By calculating the difference between the end of the training phase and the end of the prediction phase, the amount of time it took for machine learning models to predict the test data of a particular dataset was evaluated.

II.6 EXPLAINABLE ARTIFICIAL INTELLIGENCE (XAI) INTEGRATION

To address the interpretability challenge in our IDS, we integrate two model-agnostic XAI techniques: LIME [15] and SHAP [16]. These tools help explain the predictions of our ML models, ensuring the IDS is not a “black box” and providing insight into why a given network instance is classified as an attack or normal.

II.6.1 Local Interpretable Model-Agnostic Explanations

LIME generates an explanation for individual predictions by learning a simple interpretable model (like a linear model) locally around the prediction. In practice, for a given instance, LIME perturbs the input features and observes how the classifier's prediction changes, then fits a sparse linear model to mimic those changes. The result is a set of feature contributions (weights) that approximately explain the original model's decision for that instance. LIME has been used in prior IoT security research. In our case, we apply LIME to instances of interest (e.g., alarms triggered by the IDS) to highlight which features (such as packet rate, port numbers, etc.) contributed most to the classification of "Attack" or "Normal" [15], [9].

II.6.2 Shapley Additive Explanations

SHAP is a unified framework based on cooperative game theory to explain model outputs. It assigns each feature a Shapley value representing its contribution to the difference between the actual prediction and the average prediction. SHAP values can be computed for each feature of each instance, and they have a solid theoretical foundation of fairness. We use the Tree SHAP algorithm (optimized for tree-based models like LGBM and DT) to compute feature attributions for our trained models. SHAP can provide both local explanations (for instance) and global insight via summary plots that show how features affect predictions across the dataset [16]. By incorporating LIME and SHAP, our proposed approach uses two levels of transparency: (a) local interpretability for specific events and (b) global interpretability.

We also performed a quantitative stability analysis, checking that the set of top features and their importance rankings remain consistent across different cross-validation folds and model variations – this increases confidence that our explanations are robust and not artifacts of a particular train-test split. In summary, the integration of XAI techniques ensures that our high-performing IDS does not operate as an inscrutable black box. Instead, it can explain its rationale both at the micro level (for instance) and macro level (across the dataset), thereby increasing user confidence and aiding in system diagnostics.

III. EXPERIMENTAL RESULTS AND DISCUSSION

The experimental results are thoroughly analysed in this section, which is primarily split into two separate parts. The first part describes the results obtained from ML methods using different FS techniques. Models' explainability is discussed in the second part. IoTID20, a dataset generated by a smart-home environment, is utilized to assess the suggested method. The experiment is conducted on a personal computer workstation with a 64-bit Microsoft Windows 10 operating system, equipped with an Intel(R) Core (TM) i7-3777OS CPU, clocked at 3.10 GHz, and possessing an overall storage capacity of 16 GB.

The Scikit-Learn Python Framework is utilized to create, optimize, test, and validate ML models [23]. No GPU acceleration was used, as our models (DT and LGBM) are not computationally intensive. The entire training and FS process (including 5-fold cross-validation in RFECV) took approximately 2 hours on this machine, while training the final LGBM model on the selected 12 features required only a few minutes. Hyperparameters were kept at their defaults except for setting random_state=42 for reproducibility. The selected features performed by RFE, RFECV, and hybrid FS using estimator DT and LGBM are depicted in Table 1.

Table 1: Selected features per model using RFE, RFECV, and hybrid FS method.

Model	FS	Features Name
DT	RFE	Src_Port, Dst_Port, Flow_Duration, Bwd_IAT_Tot, Pkt_Len_Max, ACK_Flag_Cnt, Init_Bwd_Win_Byts, Idle_Max
LGBM	RFE	Src_Port, Dst_Port, Flow_Duration, Flow_Pkts/s, Flow_IAT_Max, Flow_IAT_Min, Pkt_Size_Avg, Init_Bwd_Win_Byts
DT	RFECV	Src_Port, Dst_Port, Flow_Duration, Flow_Byts/s, Flow_Pkts/s, Flow_IAT_Max, Flow_IAT_Min, Bwd_IAT_Tot, Bwd_Header_Len, Bwd_Pkts/s, Pkt_Len_Min, Pkt_Len_Max, Pkt_Len_Var, ACK_Flag_Cnt, Init_Bwd_Win_Byts, Idle_Max
LGBM	RFECV	Src_Port, Dst_Port, Flow_Duration, Tot_Bwd_Pkts, TotLen_Fwd_Pkts, TotLen_Bwd_Pkts, Bwd_Pkt_Len_Max, Bwd_Pkt_Len_Min, Bwd_Pkt_Len_Std, Flow_Byts/s, Flow_Pkts/s, Flow_IAT_Mean, Flow_IAT_Max, Flow_IAT_Min, Bwd_Header_Len, Bwd_Pkts/s, Pkt_Len_Min, Pkt_Len_Std, ACK_Flag_Cnt, Pkt_Size_Avg, Init_Bwd_Win_Byts, Idle_Mean
LGBM	Hybrid FS	Bwd_Header_Len, Init_Bwd_Win_Byts, Dst_Port, Src_Port, Flow_Pkts/s, Flow_IAT_Max, Pkt_Len_Min, ACK_Flag_Cnt, Bwd_Pkts/s, Flow_Byts/s, Flow_IAT_Min, Flow_Duration
DT	Hybrid FS	Pkt_Len_Min, Bwd_Header_Len, ACK_Flag_Cnt, Bwd_Pkts/s, Flow_IAT_Max, Flow_IAT_Min, Src_Port, Dst_Port, Flow_Duration, Flow_Byts/s, Init_Bwd_Win_Byts, Flow_Pkts/s

III.1 PERFORMANCE ANALYSIS OF REF, RFECV, AND PROPOSED HYBRID FS METHODS

We first compare the performance of the models using different FS strategies: (1) RFE with DT, (2) RFECV with DT, (3) RFE with LGBM, (4) RFECV with LGBM, (5) Hybrid FS with LGBM as the final model, and (6) Hybrid FS with DT as the final model. For each, we evaluate the metrics described in Section 3.5. Table 2 summarizes the results.

Table 2: Performance results for ML models with various FS methods.

Models	Train Set Accuracy	Test Set Accuracy	Acc of 10-FCV	Precision	Recall	F1-Score	Training Time (Seconds)	Testing Time (Seconds)	FPR
RFE_DT	99.98%	99.82%	99.82%	99.93%	99.87%	99.90%	2.40	0.02	0.006
RFECV_DT	99.99%	99.82%	99.81%	99.93%	99.88%	99.91%	34.38	0.36	0.006

Acc of 10-FCV: Accuracy of 10-Fold Cross Validation, FPR: False Positive Rate, RFE_DT: RFE with DT as base estimator, RFECV_DT: RFECV with DT as base estimator, RFE_LGB: RFE with LGB as base estimator, RFECV_LGBM: RFECV with LGB as base estimator, Hybrid_FS_LGB: Hybrid feature selection LGB as final model, Hybrid_FS_DT: Hybrid feature selection DT as final model. The performance of different FS methods on ML techniques was evaluated using popular evaluation metrics, including training accuracy, testing accuracy, precision, recall, F1-score, training time, testing time, and FPR. The results obtained from experimental analysis are summarised in Table 2. Significant generalization capabilities were demonstrated by all models with impressive testing accuracies of 99.80% to 99.92%.

With a recall of 99.93% and the best testing accuracy of 99.92%, RFECV_LGBM can accurately detect real positive cases. It also shows a low rate of false alarms with an FPR of 0.0110 and a balanced F1-score of 99.91%. In contrast, models RFE_DT and RFECV_DT obtained the highest training accuracies, 99.99% and 99.98%, respectively, indicating that they correctly comprehended the training data. Model RFE_LGBM outperformed the others with a recall value of 99.91%, demonstrating its efficacy in recognizing positive cases, despite having a slightly lower training accuracy of 99.81% and a testing accuracy of 99.80%. The Hybrid_FS_LGBM and Hybrid_FS_DT models consistently performed well, with F1-scores of 99.90% and 99.89% respectively, and testing accuracy of 99.81% and 99.80%, respectively. Although Hybrid_FS_DT had the best training accuracy of 99.99% among all the models, it had a little higher FPR (0.007) than RFE_DT and RFECV_DT.

With minimal variation across metrics, all six models demonstrated outstanding predictive performance. The RFECV_LGBM model is the most suitable for use in actual smart home settings where detection reliability and accuracy are essential, since it is the most balanced in terms of testing accuracy, recall, and F1-score, and has a low FPR with a training time of 3.66 seconds. In order to validate our methodology, we have additionally evaluated our models for test accuracy using a 10-fold cross-validation process, where the data is randomly divided into 10 subsets, out of which nine subsets of the data are allocated for training and the tenth subset is reserved for testing. This process is carried out ten times until every subset has been used for testing once. Our hybrid FS methodology uses the important 12 characteristics and LGBM for model prediction, achieving a 10-fold cross-validation accuracy of 99.91%. Based on these results, the RFECV_LGBM and Hybrid_FS_LGBM models emerge as top contenders. RFECV_LGBM slightly edges in test accuracy and recall, while Hybrid_FS_LGBM is almost as good and uses a smaller feature set.

We carried out an additional 10-fold cross-validation on the training data for our Hybrid_FS_LGBM model, which yielded an average accuracy of 99.91%, confirming the model's stability across different data splits. We also performed a statistical significance test: a paired t-test comparing the F1-score of Hybrid_FS_LGBM versus a baseline LGBM using all 83 features indicated that our improvements are statistically significant ($p < 0.01$). This gives confidence that the hybrid FS is genuinely beneficial and not just fitting the idiosyncrasies of one train/test split. In practical terms, the Hybrid_FS_LGBM model offers an excellent balance of high detection rates, low false positives, and computational efficiency, using only a small subset of features. In the following, we will use Hybrid_FS_LGBM as our primary model (alongside RFECV_LGBM) for further comparisons and for generating explanations.

III.2 COMPARISON OF THE PROPOSED MODEL WITH OTHER RELATED MODELS

We benchmarked our approach against several recent IDS models from the literature, using the described metrics on either the same IoTID20 dataset or similar IoT intrusion datasets. Table 3 provides a detailed comparison of our best model with other existing state-of-the-art methods. These include ML, DL models, and hybrid frameworks: for example, by [25] who used a deep CNN on IoTID20, by [26] with autoencoders, and a Hybrid CNN-LSTM approach by [7] on an IoMT dataset.

Table 3: Comparison of our approach with other related work.

Reference	Models	Test Set Accuracy	Precision	Recall	F1-Score
[25]	DCNN	99.84%	99.67%	99.02%	99.34%
[7]	Hybrid CNN-LSTM	99.92%	99.91%	99.99%	99.95%
[27]	SA-DCNN	98.05%	95.35%	95.96%	95.64%
[17]	EE	94.14%	96.72%	97.03%	96.87%
[28]	PCC-CNN	99%	97%	95%	96%
Proposed approach	Hybrid_FS_LGBM	99.86%	99.89%	99.96%	99.93%
Proposed approach	RFECV_LGBM	99.92%	99.88%	99.93%	99.91%

Source: Authors, (2026).

SA-DCNN: Self-Attention-based Deep Convolutional Neural Network, EE: Elliptic Envelope, PCC-CNN: Pearson-Correlation Coefficient - Convolutional Neural Networks. Our Hybrid_FS_LGBM model achieves comparable or better performance than these state-of-the-art methods. Compared to the DCNN model by [25], which reported 99.84% accuracy and an F1-score of 99.34% on IoTID20, our model achieves an accuracy of 99.92%. More importantly, our recall (99.96%) is substantially higher than their 99.02%. This means our approach misses fewer attacks.

An attention-based IDS was proposed by [29] achieved ~99.9% accuracy on a large IIoT dataset. We match this performance level on our dataset, but importantly, we also provide full model interpretability, which those deep models lack. The CNN-LSTM hybrid model by [7] achieved 99.9% accuracy on their dataset. However, their approach relies on a DNN with significantly more parameters and complexity. According to [27] self-attention CNN for IIoT had significantly lower metrics (98.05% accuracy), which our model vastly outperforms. This highlights the effectiveness of focusing on feature engineering rather than solely on complex architectures. The unsupervised EE approach by [17] reached ~96% precision and recall.

Our supervised approach, unsurprisingly, does much better in a fully labelled scenario. When a selected dataset, such as IoTID20, is available, a supervised learner with FS can obtain significantly better results than unsupervised algorithms for new attack detection without labels. In summary, our proposed approach is on par with the latest research in terms of accuracy, and actually outperforms many methods in recall and precision, while using a much simpler and more interpretable model. These results validate our premise that focusing on FS and XAI can allow us to avoid the complexity of DNNs and still achieve excellent outcomes for identifying attacks in IoT networks.

III.3 MODELS' EXPLAINABILITY

One of the key benefits of our framework is that it not only produces high metrics but also provides human-understandable explanations for its decisions. In this section, we analysed the explainability of our trained models using LIME and SHAP.

The explanation process of ML models boosts confidence in their decision-making process. By eliminating the "black-box" aspect of classifiers, it ensures that the cause of the high accuracy of the classifier can be comprehended [5]. We analysed the explainability of our trained model using both SHAP and LIME to increase the credibility of the proposed ML-based framework for enhancing security in smart home IoT networks. The Tree explainer is the SHAP explanation that we used in our experimental study [9].

III.3.1 LIME Explanations

We applied LIME to generate explanations for representative instances of each class. Figure 2(a) and(b) depict the bar plots generated by LIME for the two different models, the Hybrid_FS_LGBM and Hybrid_FS_DT. These bar plots show the contributions of each feature for specific data occurrences. Orange-shaded features contribute to the "Attack" predictions, while blue-shaded features support the "Normal" class. The LIME explanation for the Hybrid_FS_LGBM model depicts that features such as Flow_Duration, Dst_Port, and Flow_Pkts/s significantly contribute to the attack classification. On the other hand, features with higher values, such as ACK_Flag_Cnt and Src_Port, contributed more to the "Normal" class but were insufficient to affect the final decision.

The LIME explanation of the Hybrid_FS_DT model shows that features such as Pkt_Len_Min, Flow_IAT_Min, and Dst_Port are the primary contributors towards the identification of attack instances. However, standard indicators such as ACK_Flag_Cnt and Bwd_Pkts/s settled for the normal class but were not sufficient to eliminate the attack indicators. These LIME explanations increase our confidence in the models. They show that the models are picking up on sensible features for attacks (e.g., long flows, particular ports, rapid packet rates, unusual packet sizes) rather than spurious correlations. Moreover, the differences highlight that the DT and LGBM models, despite similar accuracy, can base decisions on somewhat different sets of features or thresholds. Such insights could help a security analyst understand alerts better or refine the model further.

III.3.2 Shapley Additive Explanations

While LIME is local, SHAP gives both local and global interpretability. Figure 3 presents the SHAP summary plots for the Hybrid_FS_LGBM and Hybrid_FS_DT models. In these plots, each point is a single instance's SHAP value for a feature, and points are coloured by the feature's value (red = high value, blue = low value).

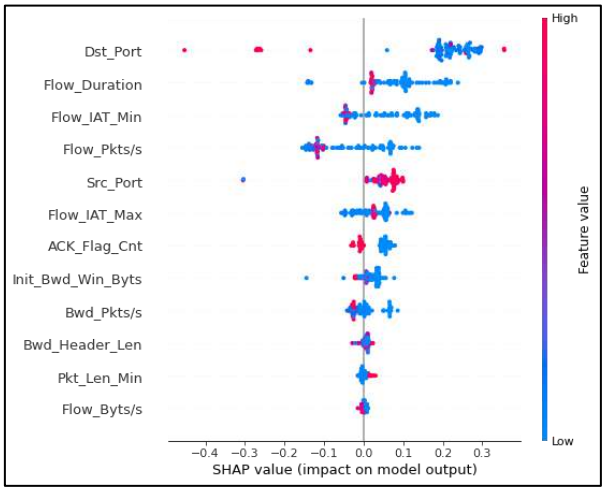

Figure 3(a): SHAP summary plot for the Hybrid_FS_LGBM.
Source: Authors, (2026).

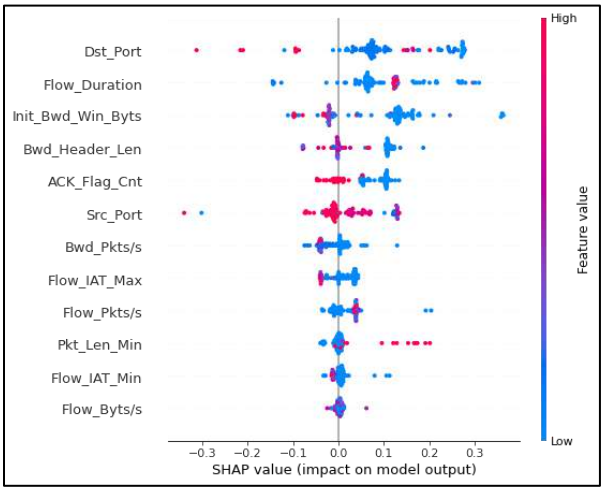

Figure 3(b): SHAP summary plot for the Hybrid_FS_DT.
Source: Authors, (2026).

SHAP is a useful method to understand the relationships between features and how they impact predictions [9]. Figure 3 (a) and (b) present the SHAP summary plots, illustrating feature distributions for the models Hybrid_FS_LGBM and Hybrid_FS_DT. In the Hybrid_FS_LGBM model, the most significant features affecting model output are Dst_Port, Flow_Duration, Flow_IAT_Min, and Flow_Pkts/s. According to the information obtained above, higher Dst_Port and Flow_Duration values significantly improve the model's ability to forecast the attack class, whereas lower Flow_IAT_Min and Flow_Pkts/s values imply an insignificant impact. However, the model Hybrid_FS_DT has a somewhat different feature attribution pattern.

Init_Bwd_Win_Byts, Bwd_Header_Length, and ACK_Flag_Cnt have become more significant in comparison to the Hybrid_FS_LGBM model, even though Flow_Duration and Dst_Port are still essential. Low values of Init_Bwd_Win_Byts and Bwd_Pkts/s are linked to attack predictions, based on the SHAP values. Thus, packet-level behaviour is more important to the DT model. Both these models adequately represent critical attack-related attributes, as can be seen from the SHAP visualizations. In summary, SHAP provides a global view that both models heavily utilize a handful of network features to make decisions. The DT and LGBM agree on many top features (port, flow duration, etc.), but DT places relatively more emphasis on certain packet-level features (window bytes, header lengths) than LGBM does. Overall, the explainability analysis confirms that our IDS behaves realistically.

III.4 EFFICIENCY AND SCALABILITY FOR DEPLOYMENT

Beyond detection performance, it is important to consider the practicality of deploying our IDS in real-world smart homes. Two major considerations are inference latency and resource usage, especially if the model will run on low-power or embedded devices (like a Raspberry Pi or a home IoT gateway).

III.4.1 Inference Latency

Our chosen algorithms are relatively lightweight and offer fast prediction times. In practice, the LGBM model can score a single network flow instance in just a few milliseconds on a CPU.

Even if we assume a modest Raspberry Pi-class CPU, the model can easily handle real-time streaming data in a home network, which typically would be on the order of tens or hundreds of flows per second without noticeable delay. Thus, the IDS can analyze packets or flows on-the-fly and raise alerts virtually instantaneously from the user's perspective.

III.4.2 Resource Footprint

Our proposed Hybrid_FS_LGBM with 100 trees and 12 features occupies only a few megabytes of memory. Since Raspberry Pi typically has a 1.2 GHz CPU and 1-2 GB of RAM, it is possible to employ a modest CPU and memory during inference. In contrast to DL models, which may need GPU support for effective operation, the proposed model uses minimal resources. Without quantization or acceleration, for instance, a CNN-LSTM IDS might not even fit or function well on a Raspberry Pi.

III.4.3 Training Complexity

Training our proposed ML-based framework (including feature selection) took a couple of hours on a standard PC. However, this process is done offline and can be performed infrequently (e.g., retraining the model when new data is available or when updating the IDS). It is simple to deploy the model to edge nodes after it has been trained. Additionally, there is very little cost on the gateway for feature extraction because we only need to compute 12 features for each incoming flow.

III.4.4 Scalability

By installing a small model at each local gateway or device, our solution can expand horizontally to handle larger networks or more devices. The model's input dimension stays the same even if more IoT devices are added because we limited the feature set.

III.4.5 Edge Deployment Considerations

Deploying edge nodes like a home router or an edge server has benefits for privacy and real-time response. Our model is well-suited for edge deployment due to its small size. Since LIME requires local models to train and SHAP requires numerous model evaluations, explainability tools like LIME and SHAP are a little too complex to execute on an edge device for every prediction. Nevertheless, those can be utilized offline or on occasion to audit the behavior of the model. In summary, our IDS is efficient and scalable enough for real-world use in smart homes. It can run on low-power hardware with minimal latency, making immediate detection and alerting feasible. We have deliberately chosen methods that ensure the solution is not just effective, but also practical.

IV. CONCLUSIONS

This study presents an anomaly-based IDS that combines a hybrid FS approach with XAI techniques, specifically tailored for IoT environments in smart homes. RFECV uses two complementary estimators to effectively reduce feature dimensionality, while still keeping the important discriminative features. This dimensionality reduction is essential for successful IoT deployments that require cost-effective models due to resource limitations. The system can provide understandable justifications for its predictions by integrating LIME and SHAP into the pipeline, shedding light on the "black-box" aspects of the ML model. We have utilized the IoTID20 smart house IoT dataset to assess our methodology. Our findings are consistent with recent research that shows that careful FS greatly improves detection performance. Moreover, the use of XAI yields detailed feature-level insights, which can improve operator trust and facilitate regulatory compliance in high-stakes smart home scenarios.

Overall, the proposed framework can able to achieve high detection rates while also providing transparency. Its robustness is demonstrated by achieving accuracy and recall metrics that are comparable to those of state-of-the-art IoTIDSs, which validates its impact on securing smart home networks. There are several promising directions to extend this research. First, we plan to investigate more sophisticated or automated FS techniques using DL algorithms. To automatically train feature representations that capture complex non-linear relationships between IoT features, for example, attention-based neural networks or autoencoder techniques could be used. Integrating these deep feature-learning strategies is likely to enhance the detection performance and robustness of complex DL models, particularly against evolving attack patterns that are difficult to capture with static feature sets.

Second, a future development might incorporate collaborative detection and FL due to the variety of data sources in smart homes. In FL, models in smart homes or multiple edge devices can be trained collectively without sharing raw data. Third, edge computing integration is becoming a natural progression for deploying IDS widely. Since our model is lightweight, it can run on edge devices. Future studies might examine a complete edge-based architecture in which an Internet of Things gateway detects intrusions in real time and perhaps works with other edge nodes. Managing distributed attacks and exchanging alert intelligence amongst edge network devices are part of this. In summary, our study demonstrated that an IoT IDS is efficient, effective, and transparent when integrating FS with XAI.

ABSTRACT

In photovoltaic (PV) systems, achieving high voltage gain and keeping low input current ripple is essential for reliable operation and ensuring that the PV source consistently provides its maximum power. Low input current ripple helps the PV module operate close to its maximum power point (MPP). Conventional DC converters including quadratic boost converter frequently exhibit significant input current ripple for constrained voltage gain. To improve performance under varying load and irradiance conditions, a modified interleaved quadratic boost converter (MIQBC) is suggested. The proposed converter is able to reduce the input current ripple by employing a two-phase interleaved structure that operates with a 180° phase shift, incorporating design modification. Using an ESP32 control unit and a perturb and observe (P&O) algorithm to control the maximum power point during operation. The converter was simulated with LTspice, designed, and tested practically to assess the performance under real solar irradiation. The theoretical analysis indicated that the voltage gain reached approximately four times the input voltage, and input current ripple reduced to less than 2% while the efficiency was about 96% at full load. The experimental tests indicated that the converter demonstrated reliable performance and effective power tracking by eliminating the input current ripple. The topology provides high reduction in input current ripple and a real enhancement in voltage gain compared to conventional topologies. The results ensure efficient use of the PV panel's maximum power capability and proves that the converter is suitable for photovoltaic applications.

I. INTRODUCTION

Renewable energy technologies have been dramatically improved as sustainable substitutes for fossil fuels in recent years [1], [2] . Given the drawbacks of using fossil fuels to generate electricity, such as the possibility of ongoing climate change brought on by increased greenhouse gas emissions from burning them as fuel, it would not be wise to use them to supply power [3]. Photovoltaic power is regarded as one of the most attractive electrical power generating methods since sunlight, which is required to generate electricity, is available year-round and worldwide [4-7]. The output voltages of these energy sources, such as fuel cells and solar panels fluctuating [8], [9]. Therefore, a high-ratio DC-DC converter is required to regulate the produced voltage or tracking the maximum power [10], [11]. On the contradiction, conventional boost converters must operate at extremely high duty-cycle ratios to provide a high output voltage, which is practically difficult to achieve because of high combined losses and semiconductors limitations [12]. Likewise, as illustrated in Figure 1, High input current ripple from high ON periods prevents the PV from operating at maximum power point and causes it to oscillate around it, which increases system losses due to the additional heating in the PV and switching elements all these factors reduce the efficiency of the system [13], [14]. However, for continuous PV output energy, a large capacitor is required, or a continuous current converter can be used. Adding a C or LC filter can reduce reliability, increase weight and volume, cause electrical resonance problems, and cost money, especially when electrolytic capacitors are included [15-18].

To attain a high output voltage with a suitable duty ratio, a number of high step-up converters have been proposed. A new quadratic boost converter is shown in [19]. it's a three-stage converter based on a single-switch quadratic converter, voltage lift technique (VL) with voltage multiplier cell (VMC). Voltage lift cell has a simple construction, can improve its gain with an average duty cycle, and can also reduce the power switch's voltage stress to half the output voltage of the converter. This allows for using MOSFET with a lower voltage rating, which reduces conduction losses and lowers costs. A novel quadratic boost single-switch coupled inductor CI [20]. It has a continuous and low input current ripple; for achieving ultra-high output voltage, a VMC is connected to the converter. Furthermore, there is a passive clamp capacitor connected in parallel with the power switch to limit the voltage stress on it by recycling the magnetic energy in the CI, which causes a significant voltage spike in the switching component.

To reduce losses and improve efficiency, it's important to know that a passive clamp is used instead of an active one because of its simplicity and minimal effect on the control system. A new modification of the DC-DC quadratic boost converter can be found in [21]. It is a mixture between a Cuk and a conventional boost converter, so there are two stages with two power switches. The first stage is made by the Cuk converter to achieve continuous input current. The second stage consists of the conventional BC, which doubles the gain and produces an output voltage with positive polarity. So, with this technique, the voltage conversion ratio will be high (quadratic of a conventional converter) without needing to operate with a high duty ratio as in a conventional boost converter. A novel topology of interleaved quadratic boost converters with VM has been proposed [22] This converter consists of two stages.The first stage contains two QBCs connected in parallel, which is known as the interleaved QBC.

The interleaving led to an increase in the frequency of the converter and made it possible to filter with small capacitors. This property makes smooth input current compared with the conventional converter, so the input current ripple will reduce with interleaving, and this optimizes the input current magnitude for the maximum power point algorithm. The second stage is a Dickson voltage multiplier cell that cascades with the first stage. This VMC helps achieve a high voltage gain by increasing the voltage conversion ratio. A developed topology from the QBC is shown in [23]. It's a high step-up converter that depends on a 2-phase interleaved quadratic boost converter using multi-winding CIs instead of discrete inductors; this change in the inductor type facilitates achieving a light and compact magnetic element and helps in reducing the input current ripple. To achieve more gain, it's connected to a voltage lift capacitor and a VMC. A new topology of interleaved non-isolated high-gain converters has been proposed [24].

It provides a high voltage gain without having to work with a high duty cycle. This improvement in gain is due to using two three-winding coupled inductors with two circuits of VMC. High gain is attained through the adjustment of the turn's ratio of these inductors, which reaches 16% more than similar boost topologies. A Modified Interleaved Quadratic Boost Converter (MIQBC) is suggested as a solution to the mentioned constraints. The converter achieves a high step-up voltage gain appropriate for PV systems while eliminating the input current ripple by modifying an interleaved two-phase structure with 180° phase-shifted operation. The main objective of this work is to show that this converter is efficient through theoretical design, simulation with LTspice, and experimental verification. The proposed converter provides enhanced maximum power extraction and reduced ripple compared to traditional topologies. The research utilizes the perturb and observe (P&O) method within an ESP32-based MPPT control system to guarantee its optimum performance across different conditions.

II. CONVERTOR DESIGN AND CONFIGURATION

The proposed converter is based on the quadratic boost converter. It is a two-phase interleaved QBC with a modification in its design that reduces the input current ripple. Each phase consists of a single power switch, four diodes, two capacitors and two inductors. This interleaving helps to reduce the input current ripple. The modification is represented by replacing the inductors' positions and using the inductor of the high inductance in the input side, which causes additional reduction in the input current ripple instead of using a capacitor in the input. Also, to avoid the flow of (D_2, D_5) current to the capacitors (C_1, C_2) during the transient duration, an additional diode has been added (D_7, D_8). The configuration circuit of the proposed converter is shown in Figure 2.

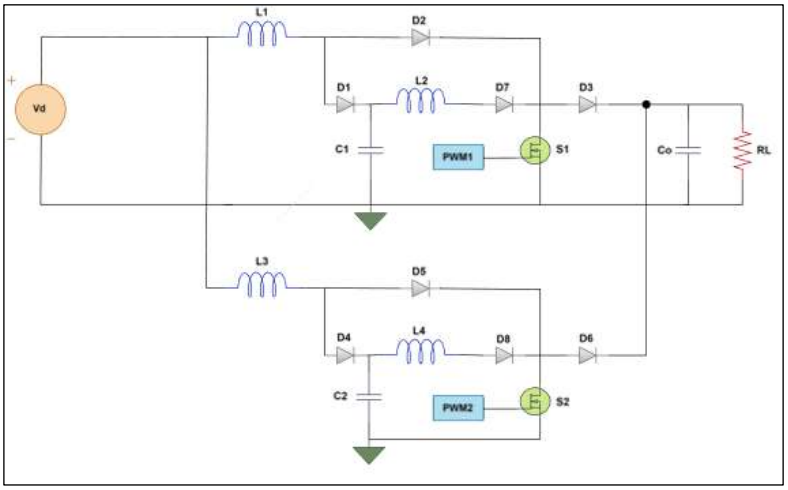

Figure 2: The proposed converter.
Source: Authors, (2026).

II.1 PRINCIPLE OF OPERATION

As mentioned, the MIQBC consists of two identical quadratic boost converters connected in series on the output side while connected in parallel on the input side, and these converters operate with a phase shift of 180° between the drive signals of their switch gates to verify that when one switch is ON, the other is in the opposite state for a portion of the cycle. Also, to maintain proper interleaving operation and prevent overlap between the conduction intervals, the operation duty ratio should be kept below 0.5 per channel. There are four modes of operation during the complete interval of switching, all explained under the assumption that the operation is in steady-state conditions, all circuit devices are ideal, the capacitor sizes are sufficient to maintain a constant voltage across their terminals, the inductors are energised before the switches turn on and designed for operation in continuous conduction mode (CCM). The voltage and current waveforms of this operation are shown in Figure 3.

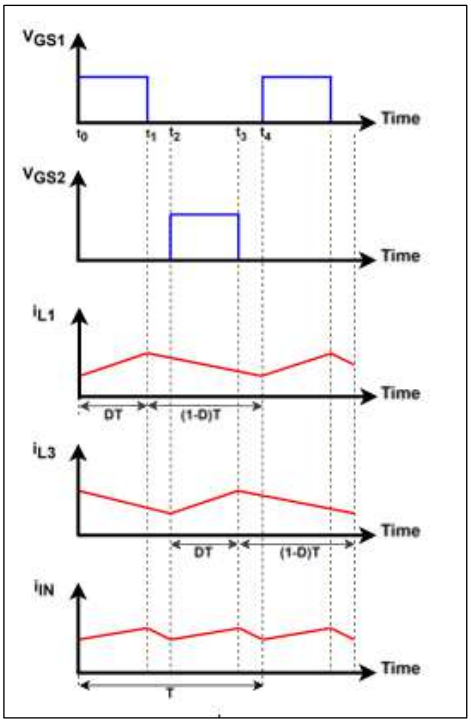

Figure 3: The steady state operation waveforms.
Source: Authors, (2026).

Mode I: (S_1 ON, S_2 OFF)

This mode is shown in Figure 4(a) when the converter operates during the interval from t_0 to t_1.
(a) The first-phase inductors L_1 and L_2 store energy from the input source and C_1 respectively.
(b) The second-phase inductors L_3 and L_4 transferred their stored energy to charge C_o and supply the load.

Mode II: (S_1 OFF, S_2 OFF)

This Mode shown in Figure 4(b) when the converter operates during the interval from t_1 to t_2.

(a) The first-phase inductors L_1 and L_2 transferred their stored energy to charge C_o and supply the load.
(b) The second-phase inductors L_3 and L_4 remain in their status in Mode I.

Mode III: (S_1 OFF, S_2 ON)

This Mode shown in Figure 4(c) when the converter operates during the interval from t_2 to t_3.
(a) The first-phase inductors L_1 and L_2 remain in their status in Mode II.
(b) The second-phase inductors L_3 and L_4 store energy from the input source and C_2 respectively.

Mode IV: (S_1 OFF, S_2 OFF)

This Mode is typical of Mode II and shown in Figure 4(b) when the converter operates during the interval from t_3 to t_4.
(a) The first-phase inductors L_1 and L_2 remain in their status in Mode III.
(b)The second-phase inductors L_3 and L_4 transferred their stored energy to charge C_o and supply the load.

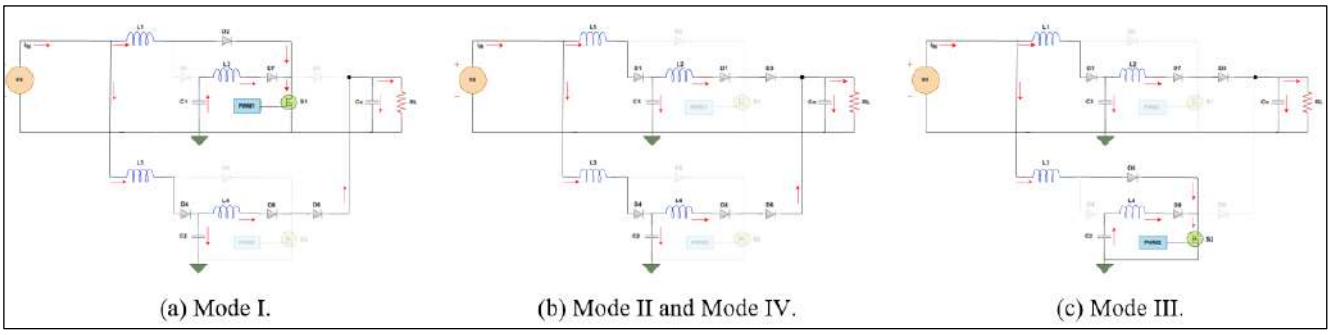

Figure 4: The steady state operation Modes.
Source: Authors, (2026).

II.1.1 Voltage Conversion Ratio

The steady state analysis of this convertor based on the conventional quadratic boost convertor shown in Figure 5 So, the voltage conversion ratio (M) calculated from the inductor's voltages V_{L1} and V_{L2} under the assumption of constant input voltage, ideal switches and purely resistive load. As a result of volt-second balance, the integral of V_{L1} and V_{L2} over one time period is equal to zero [25], [26]. Figure 5 shows the circuit operation and the inductor's voltage waveforms.

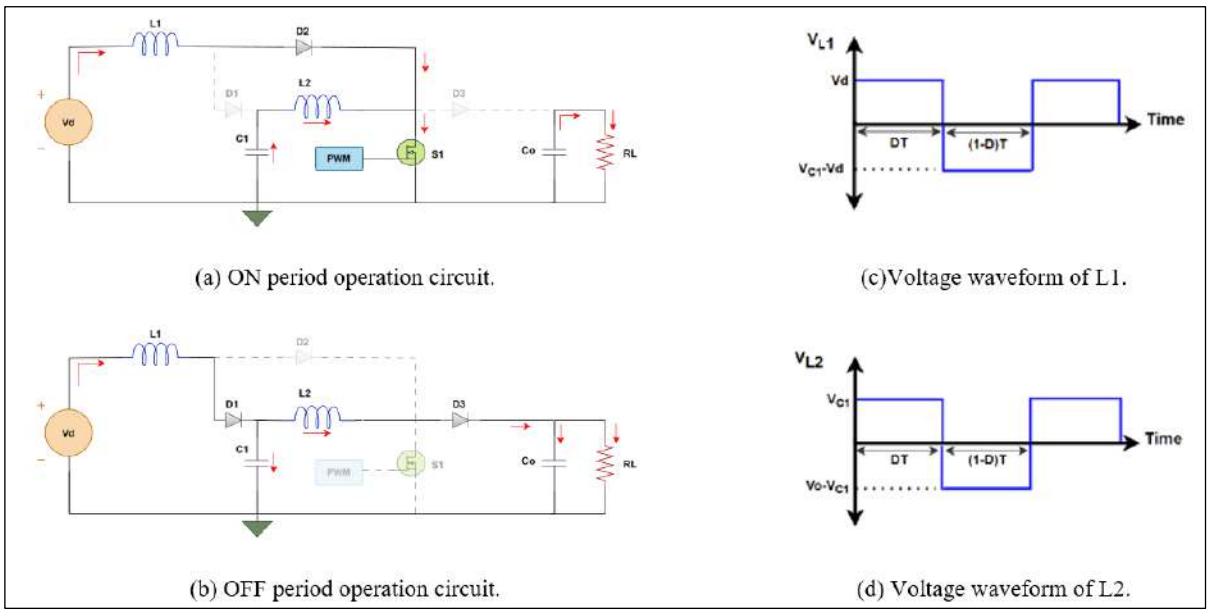

Figure 5: Convertor operation.
Source: Authors, (2026).

$$\int_0^{Ts} V_{L1} = 0 \qquad (1)$$

$$(V_d)DT = (1-D)T(V_{C1} - V_d)$$

$$\therefore \frac{V_{C1}}{V_d} = \frac{1}{(1-D)}$$

$$\int_0^{Ts} V_{L2} = 0 \qquad (2)$$

$$(V_{C1})DT = (1-D)T(V_O - V_{C1}) \qquad \therefore \frac{V_{C1}}{V_O} = (1-D)$$

$$\text{So, the voltage conversion ratio} \qquad M = \frac{V_O}{V_d} = \frac{1}{(1-D)^2}$$

Also, as shown in Figure 6, the integral of each capacitor current during one switching time period is zero at steady state [26].

$$\int_0^{Ts} i_{C1} = 0 \tag{3}$$

$$(I_{L2})DT = (I_{L1} - I_{L2})(1-D)T \qquad I_{L2} = (1-D)I_{L1} \tag{4}$$

$$\int_0^{Ts} i_{C2} = 0 \tag{5}$$

$$(I_O)DT = (I_{L2} - I_O)(1-D)T$$

$$(I_O)DT = (I_{L2} - I_O)(1-D)T$$

$$I_O = (1-D)I_{L2} \tag{6}$$

$$I_O = (1-D)^2 I_{L1} \tag{7}$$

To find the inductors current ripple [27]

$$V_{L1} = L_1 \frac{dIL_1}{dt} \qquad \therefore \Delta I_{L1} = \frac{DTV_d}{L_1}$$

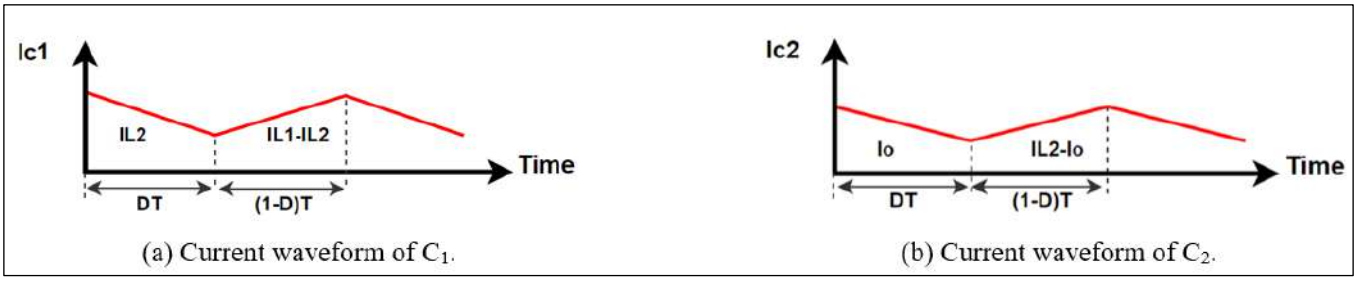
$$V_{L2} = L_2 \frac{dIL_2}{dt} \qquad \therefore \Delta I_{L2} = \frac{DTV_{C1}}{L_2}$$

Now to find the critical values of the inductors to operate in CCM [27]:

$$I_{L1} \geq \frac{\Delta I_{L1}}{2} \quad \therefore L_1 \geq \frac{(1-D)^4 DR_L}{2f_s}$$

$$I_{L2} \geq \frac{\Delta I_{L2}}{2} \quad \therefore L_2 \geq \frac{(1-D)^2 DR_L}{2f_s}$$

To find the capacitors voltage ripple [27]



$$\Delta V_{C1} = \frac{\Delta Q_{C1}}{C_1} \qquad \therefore \Delta V_{C1} = \frac{DTV_o}{(1-D)C_1R_L}$$

$$\Delta V_{Co} = \frac{\Delta Q_{Co}}{C_o} \qquad \therefore \Delta V_{Co} = \frac{DTV_o}{C_oR_L}$$

Now to find the inductors current ripple ratio and the capacitors voltage ripple ratio:

$$\rho_{L1} = \frac{\Delta I_{L1}}{I_{L1}} = \frac{(1-D)^4 DTR_L}{L_1} \qquad \rho_{L2} = \frac{\Delta I_{L2}}{I_{L2}} = \frac{(1-D)^2 DTR_L}{L_2}$$

$$\rho_{C1} = \frac{\Delta V_{C1}}{V_{C1}} = \frac{DT}{(1-D)^2 C_1 R_L} \qquad \rho_{Co} = \frac{\Delta V_{Co}}{V_{Co}} = \frac{DT}{C_o R_L}$$

(a) Current waveform of C_1. (b) Current waveform of C_2.

Figure 6: Capacitors' current waveforms.
Source: Authors, (2026).

II.1.2 Voltage Stress Across Semiconductor Devices

Since the proposed two-phase MIQBC is developed from a classical QBC and the switches are located at the output end of each QBC structure, the voltage impressed across them is obtained as:

$$V_{S1} = V_{S2} = \frac{V_{in}}{(1-D)^2} = V_O \tag{8}$$

The reverse voltage applied across the diodes indicates their voltage rating. When S_1 and S_2 are ON, diodes D_1 and D_4 are, respectively, reverse-biased; their voltage rating determined from the potential difference across their anode and cathode terminals. The cathode terminal of D_1 is clamped at the voltage level of C_1, while the anode terminal is grounded through D_2 and S_1. Interestingly, the voltage developed across C_1 is the same as that of a CBC. Similar factors can be used to determine the voltage stress on D_4. Therefore, the voltage stress on D_1 and D_4 is determined as:

$$V_{D1} = V_{D4} = \frac{V_{in}}{(1-D)} = V_O(1-D) \tag{9}$$

The voltage stress on diodes D_2 and D_5 is obtained when the switches S_1 and S_2 are in the OFF state, respectively. The cathode of D_2 is clamped by the voltage developed across the positive plate of C_o through D_3, while the anode of D_2 experiences the potential developed across C_1. Diode D_5 is located at a position which is similar to D_2. Hence, its voltage stress is the same as D_2. Therefore, the net voltage stress is derived as:

$$V_{D2} = V_{D5} = \frac{V_{in}}{(1-D)^2} - \frac{V_{in}}{(1-D)} = \frac{V_{in}D}{(1-D)^2} = V_O D \tag{10}$$

The voltage stress on diode D_3 is obtained when switch S_1 is ON and S_2 is in the OFF state. The cathode of D_3 is clamped by the voltage developed across the positive plate of C_o, while the anode terminal of D_3 is grounded through S_1. Therefore, the net voltage stress on D_3 is equal to V_o. Furthermore, the voltage stress on diode D_6 is obtained when switch S_1 is OFF and S_2 is in the ON state. The cathode of D_6 is clamped by the voltage developed across the positive plate of C_o, while the anode terminal of D_6 is grounded through S_2. Therefore, the net voltage stress on D_6 is equal to V_o.

$$V_{D3} = V_{D6} = \frac{V_{in}}{(1-D)^2} = V_O \tag{11}$$

There is no voltage stress on D7 and D8 because no reverse voltage is impressed across them.

II.1.3 Current Stress on Semiconductor Devices

The current stress on the switches S_1 and S_2 is determined when they are in ON state. When S_1 is ON, the inductors L_1 and L_2 charge through D_2, D_7 and S_1. Hence, the current flowing through the switch is the sum of the inductor currents I_{L1} and I_{L2}. Thus, the current stress on S_1 is given by:

$$I_{S1} = I_{L1} + I_{L2} \tag{12}$$

Similar factors can be used to determine the current stress on the switch S_2 and is expressed as:

$$I_{S2} = I_{L3} + I_{L4} \tag{13}$$

Diodes (D_1, D_2, D_4, and D_5) are closer to the input side. so, their current-carrying capacity needs to be closer to the magnitude of input current. Fortunately, as an interleaved structure is employed, the total current is shared. The current stress on diodes D_1 and D_2 is the same as the inductor current I_{L1}, whereas diodes D_4 and D_5 are rated to carry the current flowing through inductor L_3. The diode current stresses are expressed as:

$$I_{D1} = I_{D2} = I_{L1} = \frac{I_{in}}{2} \quad (14)$$

$$I_{D4} = I_{D5} = I_{L3} = \frac{I_{in}}{2} \quad (15)$$

D_3 and D_6 are the regular output rectifier diodes. Hence, the current stress on them is the same as the output current. Also, for D_7 and D_8 located closer to the output side. Therefore, their current-carrying capacity needs to be closer to the output current magnitude and is given by:

$$I_{D3} = I_{D6} = I_{D7} = I_{D8} = I_o \quad (16)$$

II.1.4 Efficiency Analysis

Power loss occurring in DC resistance of inductor is:

$$P_{core} = \sum_{i=1}^{\emptyset} k\, f_s^{\alpha}\, B_{ipk}^{\beta} V_{icore} \quad (17)$$

P_{core} core losses, Ø number of inductors, f_s switching frequency, B_{pk} Peak flux density, V_{core} Core volume, (k, α, β) Steinmetz coefficients (from core datasheet).

$$P_{copper} = \sum_{i=1}^{\emptyset} I_{Li(rms)}^2 \times DCR_i \quad (18)$$

$I_{L(rms)}$ is the inductor RMS current, *DCR* is the DC resistance of the inductor. So, the total inductors losses are:

$$P_L = P_{core} + P_{copper} \quad (19)$$

Switching and conduction loss in MOSFET is:

$$P_{Qsw} = \sum_{i=1}^{2} \frac{1}{2} V_{iDS} I_{iD} (t_r + t_f) f_s \quad (20)$$

V_{DS} Drain-to-source voltage during switching, I_D Drain current of the MOSFET, t_r Current rise time during turn-on transition, t_f Current fall time during turn-off transition.

$$P_{Qcond} = \sum_{i=1}^{2} I_{i(rms)}^2 \times R_{iDS(on)} \quad (21)$$

I_{rms} is the RMS current flowing through the MOSFET, $R_{DS(on)}$ On-state drain-to-source resistance of the MOSFET.

Power loss of in diode and capacitor is:

$$P_D = \sum_{i=1}^{N} I_{iD(avg)} V_{if} + \sum_{i=1}^{N} I_{iD(rms)}^2 R_{iD} \quad (22)$$

N is the number of diodes, $I_{D(avg)}$ Average forward current of the diode, V_f Forward voltage drop of the diode, $I_{D(rms)}$ RMS current of the diode, R_D Dynamic (on-state) resistance of the diode.

$$P_C = \sum_{i=1}^{Z} I_{ic(rms)}^2 ESR_i \quad (23)$$

Z is the number of capacitors, $I_{c(rms)}$ RMS ripple current of the capacitor, ESR_i Equivalent series resistance of the capacitor.

The total power loss is:

$$P_{Loss} = P_L + P_{Qsw} + P_{Qcond} + P_D + P_C \quad (24)$$

Efficiency of the converter is:

$$\%\eta = \frac{P_O}{P_O + P_{Loss}} \times 100 \quad (25)$$

II.2 COMPONENT DESIGN

To design the values for the proposed converter component, there are several factors to consider, like the operation frequency, the range of the duty cycle, the PV specification, and the load that is connected to the converter. It is necessary to know that at a low duty cycle (less than 0.2), the converter's low voltage gain has resulted in inefficient operation. While the duty cycle should not exceed 0.5 to avoid the overlap between the conduction intervals, the efficiency is also affected due to the increase in the diode's reverse recovery and the switches conduction losses. The values of the inductors and capacitors, as well as the appropriate load connecting to this converter for testing, should now be determined. Assume that the converter is operating at D = 0.5 and the switching frequency is $f_s = 90\ KHz$, and that it is connected to a PV with the specifications listed in Table 1.

Table 1: PV data sheet.

PV Specifications	Values
Rated maximum power P_{max}	250 W
Voltage at P_{max} (V_{mp})	30.1 V
Current at P_{max} (I_{mp})	8.30 A
Open-circuit voltage (V_{oc})	37.2 V
Short-circuit current (I_{sc})	8.87 A
Nominal operating Cell Temp (NOCT)	25º C

Source: Authors,(2026).

To determine this PV cell's equivalent circuit: $I_{ph} \cong I_{sc} \cong 8.87\ A$

$$R_s = \frac{V_{oc} - V_{mp}}{I_{mp}} = 0.855\ \Omega \qquad R_{sh} = \frac{V_{oc}}{I_{sc} - I_{mp}} = 65.26\ \Omega$$

In the theoretical derivations, a duty cycle of D=0.5 was selected. This value corresponds to the theoretical upper limit for the chosen converter design and provides accurate estimations of current/voltage stresses.

$$M = \frac{V_o}{V_{in}} = \frac{1}{(1-D)^2} \qquad V_o = \frac{30.1}{(1-0.5)^2} \cong 120\ Volt$$

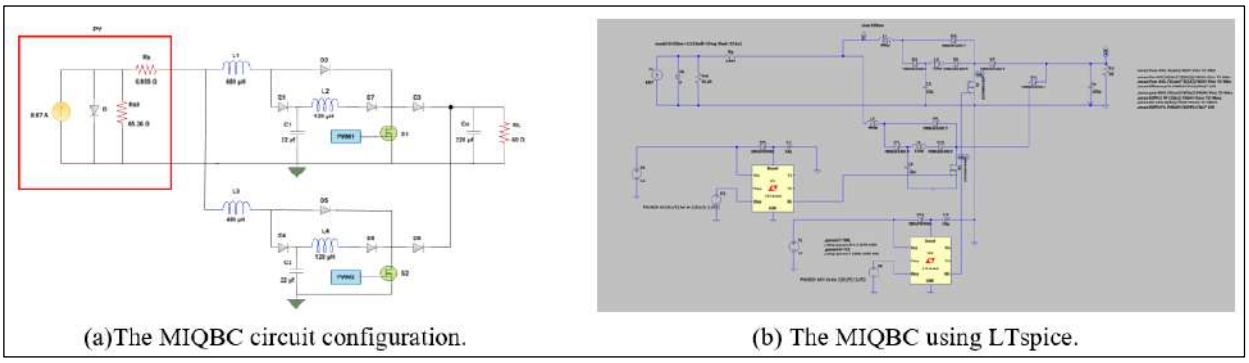
For efficiency of 96%:

$$P_{max} = V_{mp}\ I_{mp} = 250\ W \qquad P_o = 0.96\ x\ 250 = 240\ W$$

$$P_o = \frac{V_o^2}{R_L} \qquad \therefore R_L = \frac{(120)^2}{240} = 60\ \Omega$$

The above data can now be used to compute the inductors' critical values.

$$L_1 \geq \frac{(1-D)^4 D R_L}{2f_s} \geq 10.416\ \mu H \qquad L_2 \geq \frac{(1-D)^2 D R_L}{2f_s} \geq 41.66\ \mu H \qquad \therefore \frac{L_1}{L_2} \cong \frac{1}{4}$$



For a given voltage and switching frequency, the current ripple (ΔI) in an inductor is inversely proportional to the inductance (L) $\Delta I_L = \frac{DTV}{L}$. Therefore, it is easy to see that a higher value of L results in a lower input current ripple, but at the expense of efficiency. Increasing the inductance (L) of an inductor will typically reduce the ripple of current in a circuit. After testing various inductor values using LTspice, including (L_1=30 µH, L_2=120 µH),(L_1=60 µH, L_2=240 µH), (L_1=120 µH, L_2=480 µH), and (L_1=150 µH, L_2=600 µH), the decision was made to choose L1=120 µH, L2=480 µH, which is adequate to minimize input current ripple while maintaining a high efficiency value and Ensures that the converter operates in CCM even with changes in frequency.he value of the capacitors must be chosen to have low voltage ripple: ρ_{C1}*<10%,* ρ_{Co}*<0.1%*

$$\frac{DT}{(1-D)^2 C_1 R_L} < 10\% \qquad C_1 > 3.704\ \mu f$$

$$\frac{DT}{C_o R_L} < 0.1\% \qquad C_o > 92.59\ \mu f$$

The capacitors' value can be adjusted set as*:* $C_1 = 22\ \mu f$, $C_2 = 220\ \mu f$

The theoretical derivations prove that the QBC (quadratic boost convertor) is a multiplication of two stages of BC (boost convertor) ($M = \frac{1}{(1-D)}$), as can be seen from the voltage conversion ratio of the QBC ($M = \frac{1}{(1-D)^2}$). This led to a modification that will help to further reduce the input current ripple by using the stage of the higher inductance L as an input stage, as illustrated in Figure 7, which represents the MIQBC (modified interleaved quadratic boost converter).

III. PRACTICAL DESIGN AND EXPERIMENTAL SETUP

In this section, we applied the proposed converter in practice to verify its operation and assess its effectiveness in reducing the input current ripple for maximum power point tracking. As illustrated in Figure 8, to track the maximum power of the converter, perturb and observe (P&O) method has been adopted. Input voltage and current are measured continuously by voltage and current sensing circuits, which then send these signals to the ESP32 microcontroller to apply the maximum power point algorithm shown in the flow chart of Figure 9, which determines the value of the duty cycle. So, ESP32 generates two PWM signals with a 180° phase shift at a certain duty cycle to supply the drive circuit, which controls the operation of the MOSFET to drive the converter.

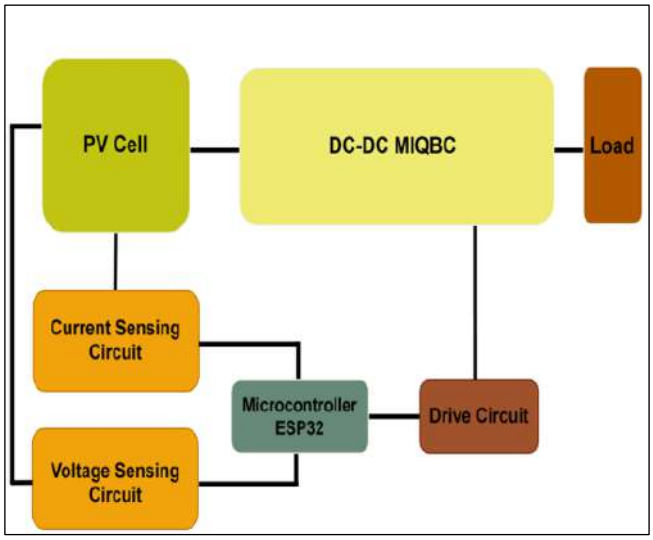

Figure 8: Close loop MIQBC.
Source: Authors, (2026).

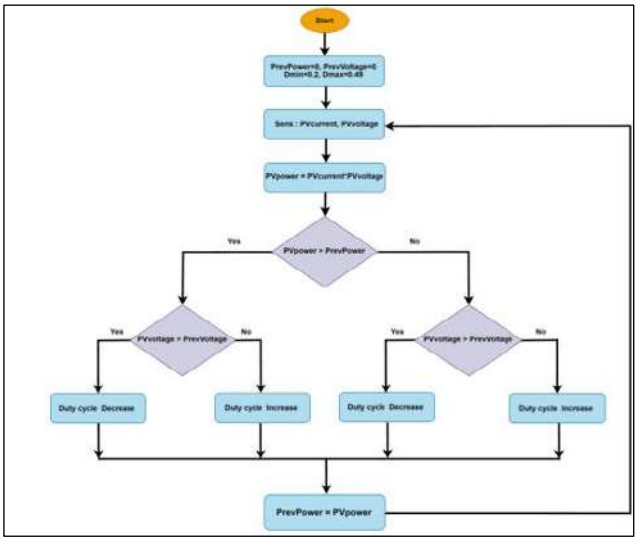

Figure 9: MPPT algorithm flowchart.
Source: Authors, (2026).

The proposed converter is practically designed using components and devices that were available in the laboratory. It is important to mention that some alternative components were used to obtain approximate results. The hardware setup consists of the following main components:

•**Power MOSFETs:** Two IRF260N transistors, due to their low on-resistance and high current capability.

•**Diodes:** MBR20100CT Schottky diodes, for low forward voltage drop and fast switching.

•**Inductors:** Iron Powder Core type T157-26, suitable for high-frequency DC-DC converter applications.

•**Capacitors:** High-frequency capacitors for output filtering.

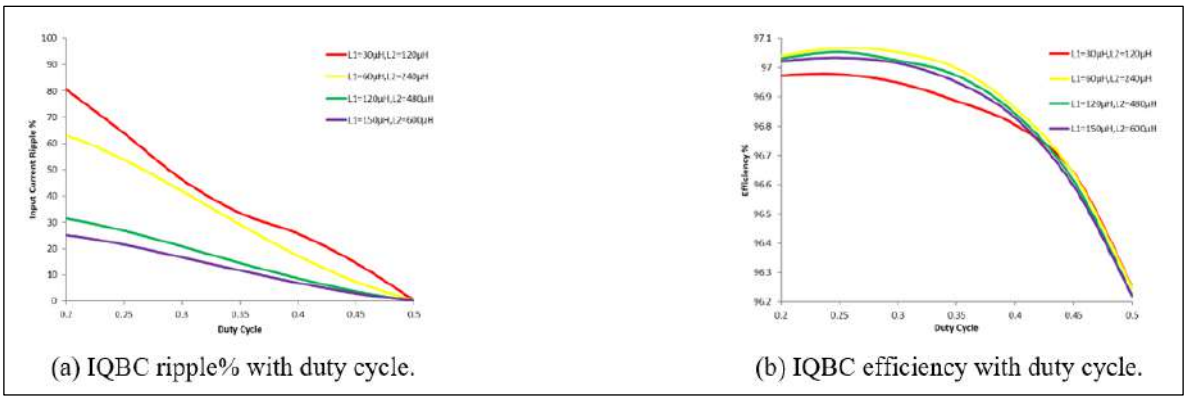
•**Gate Driver Circuit:** The IR2110 is used to drive the MOSFET by providing proper gate signals for the interleaved switches.

•**Control Unit**: An ESP32 microcontroller was used to implement the MPPT control algorithm and to generate interleaved PWM signals with a phase shift of 180°.

•**Sensing Circuits:** Voltage and current sensing circuits were designed to measure PV input current and voltage for real-time feedback to the control system.

•**Load:** Four resistive loads of 15 Ω / 100 W each were connected in many ways to achieve different loads and test various operating conditions.

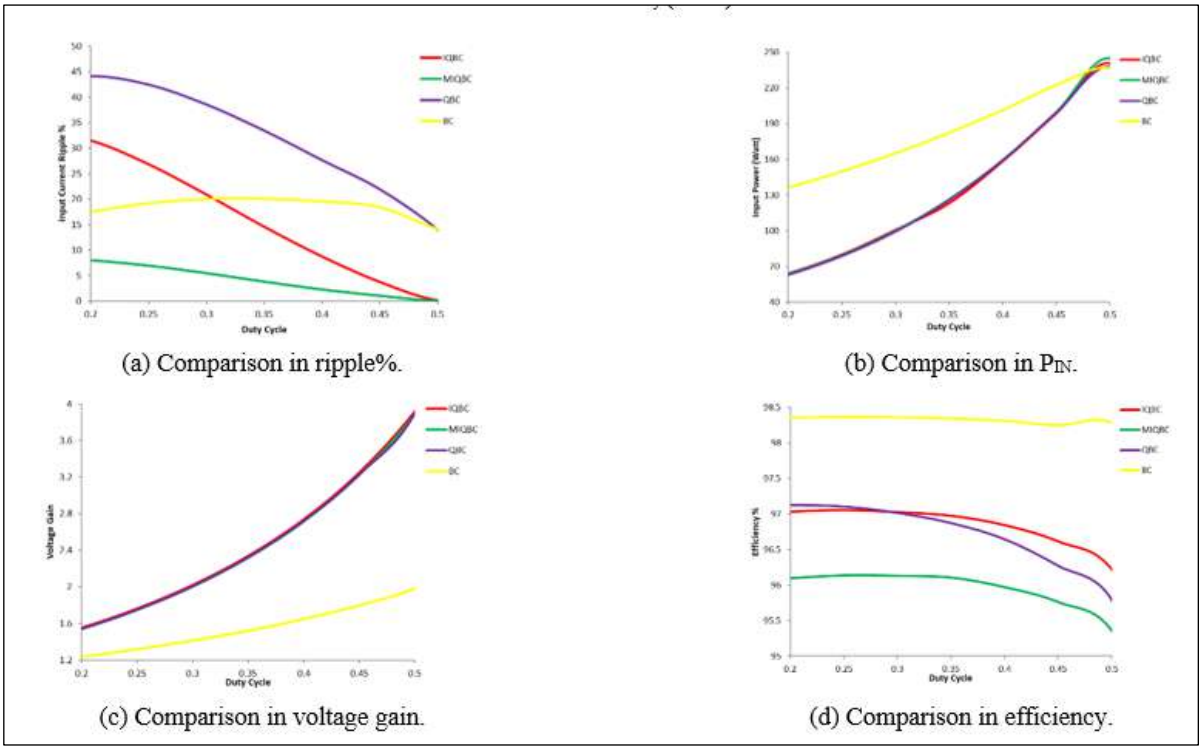
•**Power Supply:** The input of the converter was supplied from a photovoltaic (PV) source with specifications almost similar to the one used in simulation. While a 12 Volt DC supply was used to power the driver circuit.



•**Measurement Instruments:** To verify the converter's functionality, switching waveforms, input/output voltages, and currents were recorded using an oscilloscope.

IV. RESULTS AND DISCUSSIONS

This section shows the simulation results using LTspice and compares them with the experimental results of the practical design.



IV.1 SIMULATIONS RESULTS

Using the LTspice program, simulate the IQBC with various values for L_1, L_2, L_3, and L_4 to select suitable inductance values by comparing input current ripple percentage and efficiency, as illustrated in Figure 10. Then modify it to obtain the MIQBC and compare it with many conventional topologies (boost converter, quadratic boost converter) to see the effect of these modifications as shown in Figure 11.

(a) IQBC ripple% with duty cycle. (b) IQBC efficiency with duty cycle.

Figure 10: IQBC with various inductances.

(a) Comparison in ripple%. (b) Comparison in P_{IN}.

(c) Comparison in voltage gain. (d) Comparison in efficiency.

Figure 11: Converters comparison.
Source: Authors, (2026).

Once the values of ($L_1 = 120\ \mu H$ and $L_2 = 480\ \mu H$) have been accepted to be sufficient, use these values to simulate the MIQBC and compare it with other converters, as illustrated in Figure 11. When compared to other converters, the MIQBC offers a significant reduction in input current ripple, assisting in obtaining the maximum power possible from the PV. Although this adjustment had a minor impact on efficiency, it was still high, and the difference from other converters was insignificant. To evaluate how well the suggested converter performs when the load ($R_L = 15\ \Omega$) changes compared to it with the previous load, as illustrated in Figure 12. In order to achieve maximum input power, the MIQBC operates at a different duty cycle ($D \cong 0.32$), which is practically adjustable according to the MPPT algorithm.

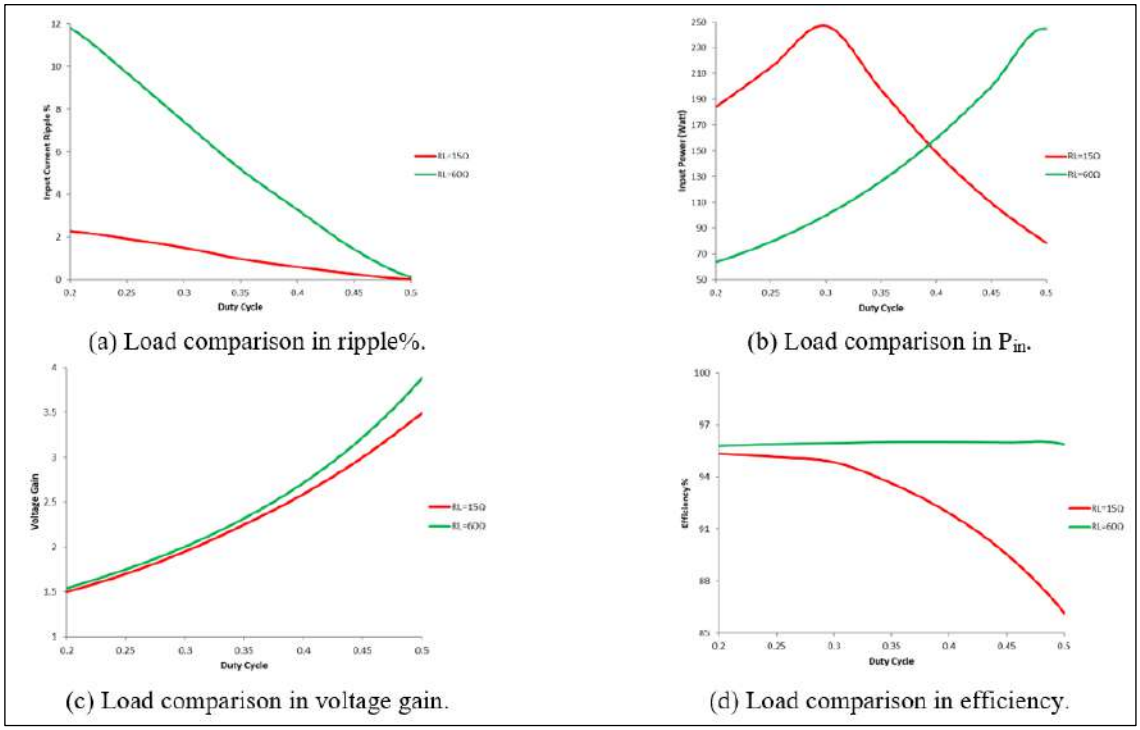

Figure 12: Load comparison.
Source: Authors, (2026).

Finally, Figure 13 shows that the current and voltage waveforms of the MIQBC using LTspice at duty cycles of 0.5 and 0.32 were cleared. All these simulation results will be compared with the practical work results to verify the converter's operation and to prove its effect in the input current ripple reduction.

IV.2 EXPERIMENTAL RESULTS AND DISCUSSION

To distinguish the performance of the proposed converter under the test conditions. Initially it was a test without applying the MPPT algorithm by applying different values of duty cycle under the operation range (from 0.2 to 0.49) to draw the I-V curve for the PV cell under different load conditions by taking (R_L=60 Ω, R_L=15 Ω) as taken in the simulation. Figure 14 shows the curves that clarified the performance of the converter.

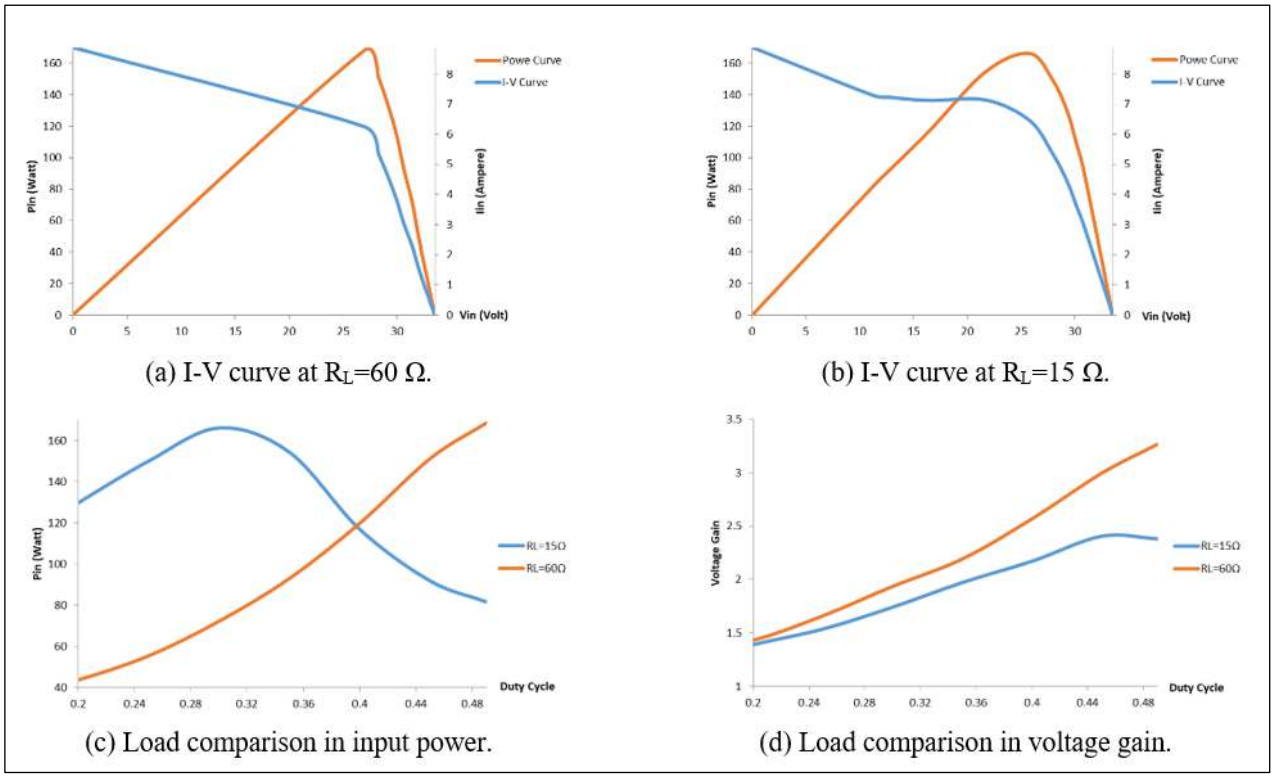

Figure 14: MIQBC operation test.
Source: Authors, (2026).

As shown in curves (a) and (b) from Figure 14 , the maximum power of the PV cell occurs at the knee point of the I-V curve under different load conditions, and this power can be achieved by adjusting the duty cycle for loads of 15 Ω and 60 Ω. Figure 14(c) indicates that at R_L = 15 Ω, the maximum power is achieved at D ≅ 0.32, while at 60 Ω, the maximum input power occurs at D ≅ 0.48; additionally, Figure 14(d) illustrates that voltage gain increases with an increase in D. These practical results are acceptable results compared with the simulation results. It is necessary to mention that this test was not conducted under standard conditions because the test was conducted at 9:00 a.m. with an ambient temperature of 46°C, the high temperature lowers the voltage output of the solar cells. Furthermore, the normal sun irradiation at 9 a.m. is less than the 1000 W/m² standard test condition.

The PV module delivered less power than its rated value due to a combination of these factors: high temperature, surface impurifications, and decreased sunshine intensity. This can be proved by checking the input current ripple of the converter by oscilloscope. After that, the MPPT algorithm shown in the flowchart cleared in Figure 9 was applied to make sure that the converter can adjust the duty cycle to operate at the maximum power point. The waveforms of Figure 15 show the performance of the operations. As seen from (a) and (f), there is a very high reduction in the input current ripple, which proves that this converter helps to achieve the maximum power available from the PV cell. At R_L=60 Ω, the MPPT algorithm adjusted the duty cycle at D=46.43%, which is approximately equal to the value of the previous test (without applying the algorithm), and the same with R_L=15 Ω (D=32.14%). this prove that the algorithm operates correctly.

Also as illustrated in (b) and (g), the current ripple of the main inductor (L_1 or L_3) has a significant value (for only one of the QBC). However, using the interleaving technique by using phase-shifted switching signals to operate several converter phases, the interleaving approach efficiently reduces the input current ripple. A smoother overall input current and improved converter performance are the results of this phase displacement, which partially cancels out the ripple components of each phase current. Waveforms of (c) and (h) shows the ripple of the second inductor (L_2 or L_4) in each stage, it has a high current ripple comparing with the main inductor (L_1 or L_3). So, this is the reason that leaded to did the modification of the proposed convertor. Normal switching behavior can be seen in the measured waveforms of the MOSFET V_{ds} and the output diode voltage in (d), (i), (e) and (j). Because of the circuit's parasitic capacitance and inductance, there are small voltage spikes and ringing during the transitions. These transients are acceptable and indicate proper switching operation of the converter.

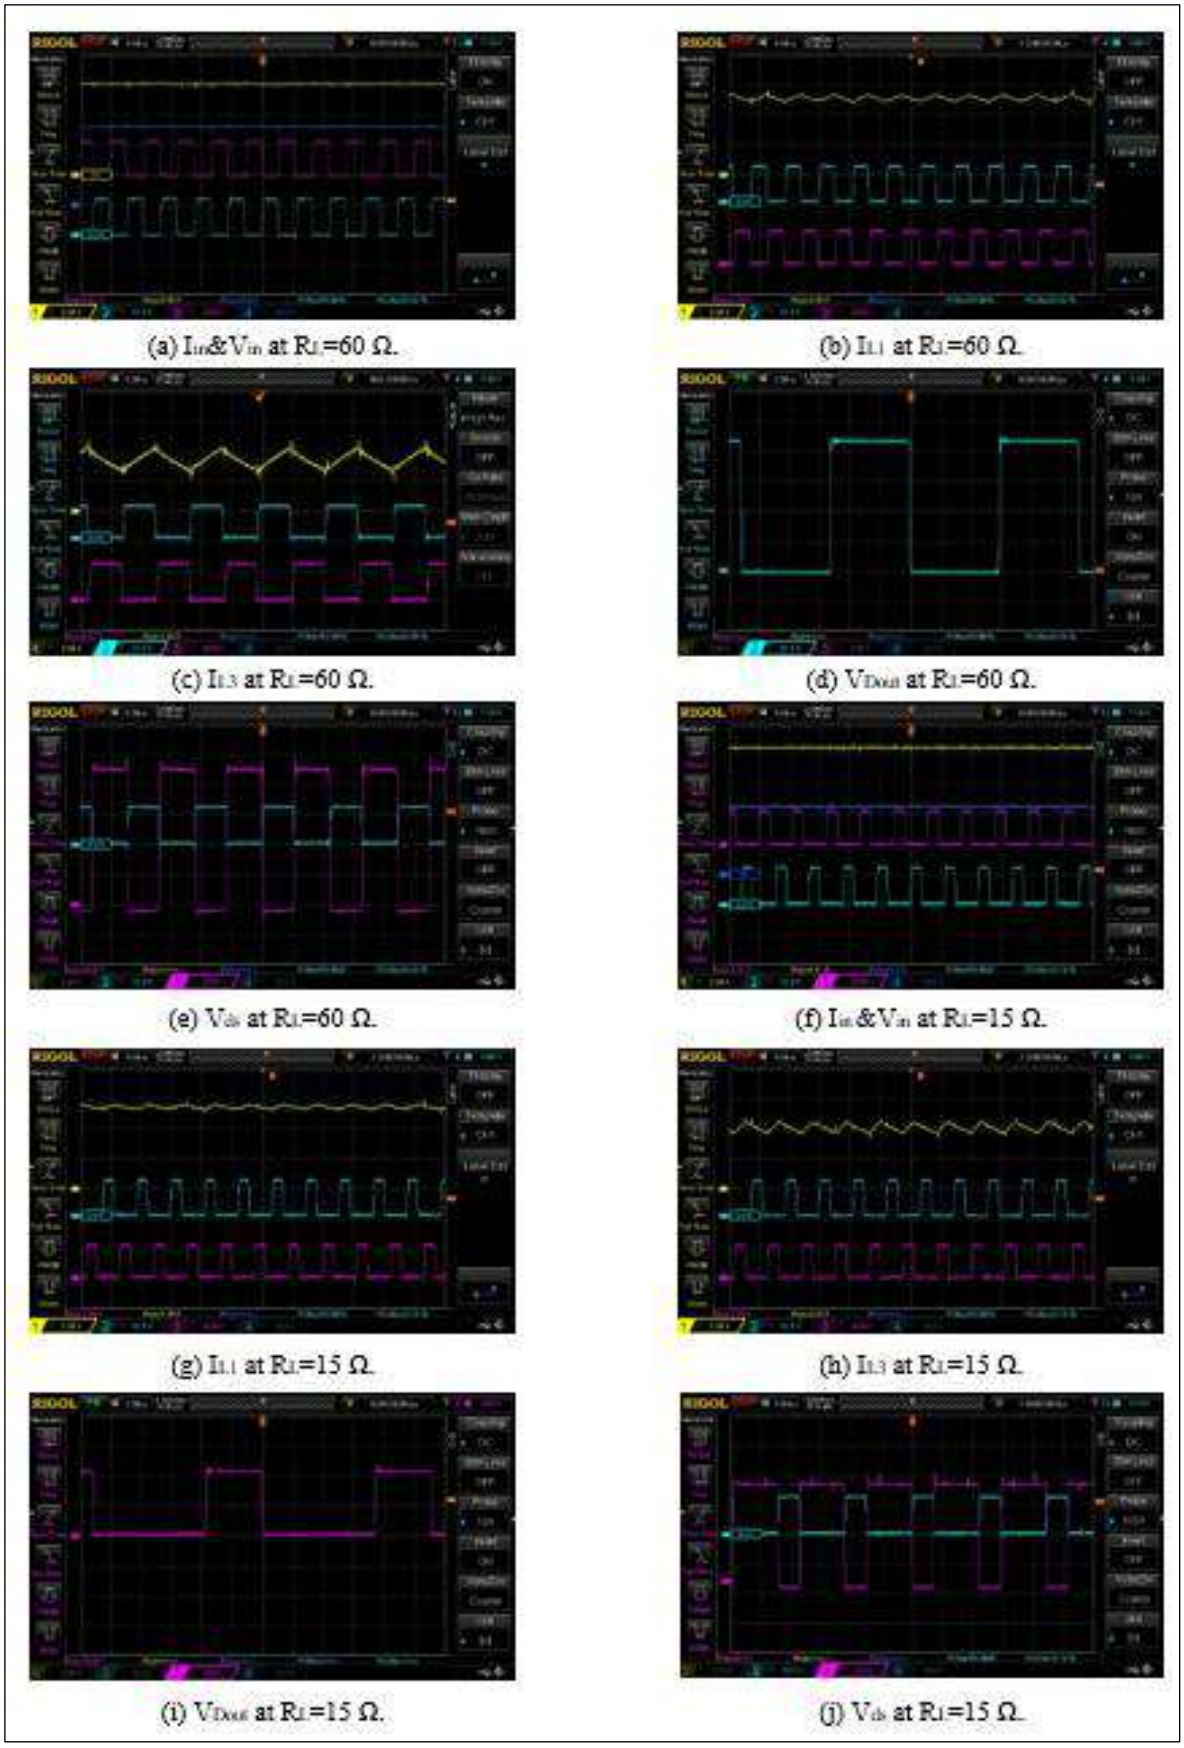

Figure 15: Practical waveformes.

V. COMPARATIVE ANALYSIS

To illustrate the benefits of the suggested converter, this section includes some comparisons with relevant recent topologies that have been documented in research. Table 2 compares the voltage conversion ratio, component count, input current ripple, voltage stress on switch, and efficiency of the suggested MIQBC with comparable converters, among other typical performance parameters.

Table 2: Comparison of existing converters with the proposed converter.

Topology	Number of Components				Voltage Gain	Input Current Ripple%	Voltage Stress on Switches	Voltage Stress on output diode	Efficiency
	Passive		Active						
	L+CL	C	D	S					
Proposed convertor	4+0	3	8	2	$\frac{1}{(1-D)^2}$	0.266%	V_o	V_o	95.8%
BC	1+0	1	1	1	$\frac{1}{1-D}$	18.4%	V_o	$V_{in}-V_o$	98.25
QBC	2+0	2	3	1	$\frac{1}{(1-D)^2}$	22%	V_o	V_o	95.4%

VI. CONCLUSION

The theoretical and experimental results prove the effectiveness of the proposed Modified Interleaved Quadratic Boost Converter (MIQBC) for photovoltaic applications. Under full load conditions, the output voltage gain obtained approached four times the input voltage, which is an acceptable value compared with the theoretical estimation. Furthermore, the input current ripple was theoretically reduced to less than 2% and practically eliminated, which gives an indication that the interleaving technique was successful in distributing the input current between the inductors and lowering the pulsing behavior. The proposed topology provided better performance in terms of current quality and voltage gain when compared to conventional boost convertor, quadratic boost converter and IQBC.

Due to the reduction in input current ripple, the photovoltaic panel operates more efficiently by operating closer to its maximum power point. As shown by experimental testing, this reduction enhances the total power extraction from the PV source. Although the theoretical efficiency was estimated between 94% and 96% under different load conditions, however, using non-ideal components such as soldering boards, general-purpose wires, and the limited quality of the inductors and switches, the practical efficiency was slightly lower. even with these constraints, the converter maintained stable operation. These results considered that the MIQBC topology offers an efficient and reliable photovoltaic energy conversion solution. The combination of very low input current ripple, high voltage gain, and improved power extraction from the PV panel makes it very suitable for renewable energy systems.

ABSTRACT

MOSFET transistor is one of the most important and efficient components in modern electronic circuits due to its high efficiency and low power consumption. The performance of N-MOS and P-MOS transistor has been studied and analyzed by evaluating key electrical characteristics such as threshold voltage, drain current, (gate and drain) voltages, LDD (Lightly Doped Drain functions), PLDD (P-type Lightly Doped Drain) and DIBL (Drain-Induced Barrier Lowering). Simulation using Silvaco TCAD Program tools was employed to extract the device structure and current-voltage characteristics for both transistors. For N-MOS, it was observed that drain current (Id) grew linearly with expanding gate voltage (Vg) for different values of drain voltages (Vd), while for P-MOS the values were opposite. The Threshold Voltage for N-MOS transistor (Vt= 0.5V) while for P-MOS (Vt= -0.5V), The maximum current obtained is Id= 0.515 mA at Vd= 3.35 V for N-MOS and the highest current obtained is Id= -0.335 mA at Vd= -3.35 V for P-MOS, so N-MOS was faster than P-MOS, while P-MOS is considered complementary to N-MOS. The two transistors were combined for more low power dissipation and high performance.

I. INTRODUCTION

Metal-Oxide Semi-conductor field-effect transistor (MOSFET) is an essential part of electronic circuits. Their importance has increased significantly with the proliferation of integrated and portable devices in the consumer electronics sector. Virtually every device on the market today contains these devices [1], [2]. MOSFET device considered the main element of any digital electronic circuit and one of the functional elements of any digital system, such as a microprocessor circuit, mobile devices and flash EEPROM technology [3], [4]. Therefore, accurately studying for behavior of MOS transistors is extremely important in the design of any digital systems and circuits [5].

For several years, mostly N-MOS logics were faster than: (P-MOS and C-MOS) logic, as electrons mobility is greater than that for holes, and it was more simples to implements, dissimilar than C-MOS circuit as both transistors must be performed. Nevertheless in N-MOS logic, static power dissipation happen that means dc current is important to pass across the logic gate regardless steady state output. CMOS logic was used to solve this issue Because of their greater operating speed and reduced static power dissipation, CMOS technology has supplanted N-MOS technology. P-type and N-type MOSFETS coupled in symmetrical and complementary pairs are currently a common application of CMOS technology.

Because of the combination of P-MOS and N-MOS, static power dissipation in CMOS logic is low because P-MOS creates a low resistance channel between its source and drain when a low gate voltage is employed, but N-MOS has a high resistance path even for a low gate voltage. CMOS logic also provides high noise immunity but has problems of tunneling leakage current (when MOSFET is scaled) and short channel effects occur [2],[6]. Over time, the planar MOSFET structure has gradually developed into the Fin FET, GAA MOSFET (nano-MOSFET), and double-gate MOSFET (DG-MOSFET).

The advanced structure offers greater controllability. In other words, the advanced structure uses less power when the transistor is off. As a result, a contemporary computer built with advanced structure uses less power, conserving battery life. In summary, great performance (high on-state current), low power consumption (low off-state current), and fast switching speed (low delay) are necessary for the future of transistors [7],[8].

This research presents a comprehensive study of the performance of N-MOS and P-MOS transistors, taking into account variations that occur during manufacturing processes, using Silvaco software and TCAD technology. Study impact of LDD – Lightly Doped Drain functions to mitigate short channel effects in MOSFETs. To reduce high electrical fields at the gate edge, which cause Hot Carrier Injection (HCI) damage to the silicon gate or gate oxide Increased electrical leakage and PLDD – P-type Lightly Doped Drain same function as LDD, but these are light P-grafted regions located before the primary Source/Drain implant (P++). DIBL (Drain-Induced Barrier Lowering) effect for different value of Vd for both transistors.

II. LITERATURE REVIEW

According to [5] simulated the fabrication process of a 65nm N-MOS transistor using Silvaco TACAD. The simulation results showed that short-channel effects, such as penetration, subthreshold current, substrate current, and gate current, increase with smaller device size. According to [9] added a specific graphene material to the Silvaco software and fabricated it using existing material parameters that closely resemble those of graphene. They concluded that a graphene channel field transistor (FET) could be an ideal replacement for conventional silicon MOSFET with a small channel length and could be used in high speed, low power application. In [3] design and simulation of a100 nm n-type MOSFET transistor using SILVACO ATLAS software.

Through this study, design and simulation at the nanoscale is extremely useful in the electronics industry to ascertain whether all requirements are acceptable for the sustainable design of integrated circuits before moving on to their successful implementation on a large scale. According to [10] simulated the structure of a 100 nm n-type MOSFET transistor at the device level through mathematical verification using Silvaco-TCAD software. The operating mechanisms of various MOS devices were analyzed and verified. According to [11] used machine learning to model MOSFET devices. They found that machine learning can be used to accurately estimate the transient characteristic curve of a MOSFET transistor using a Keras-type neural network based on geometric data.

III. MATHEMATIC ANALYSIS

MOSFET structure is manufactured by depositing or growing a dielectric layer, often made of silicon dioxide on top of a semiconductor substrate. The gate and semiconductor function as the electrodes in this configuration, which is comparable to a planar capacitor with a dielectric between them. When a voltage is applied to the gate the, electric field influences the charge distribution within the semiconductor [12], [13]. A robust conduction channel forms beneath the gate of a MOSFET transistor when the gate voltage rises above the threshold voltage. The characteristics of the MOSFET material mostly determine the threshold voltage. The resulting channel, which stretches between the source and the drain at low drain voltages, contain holes in a P-MOS transistor and electrons in an N-MOS transistor. In an N-MOS transistor, the source and drain are doped with n+ electrodes and a p-type substrate, while in a P-MOS transistor, the source and drain are p+ electrodes with an n-type substrate, which is often connected to the source [14], [15].

The gate electrode is then created by depositing a layer of metal or polycrystalline silicon over the dielectric. When a channel forms and there is a potential difference between the source and drain, current can flow between them. Depending on the gate, source, and drain voltage values, a MOSFET transistor's behavior can be classified into three operating regions: the cutoff region, the linear region, and the saturation area. When studying an N-MOS transistor with source and substrate grounding, the transistor is in the cutoff region when the gate-source voltage is less than the threshold voltage, where the current between the source and the drain is ideally zero, with the possibility of a sub-threshold current appearing as a result of the transfer of some high-energy carriers [16], [17]. The subthreshold current can be given as:

$$I_d \approx I_{D0} \exp\left((V_{GS} - V_T)/n\left(\frac{kT}{q}\right)\right) \quad (1)$$

Where:

I_d is the drain current.

I_{D0} is the drain current when VGS=VT.

k is the Boltzmann constant.

T is the Kelvin temperature

q is the electronic charge.

on the channel potential under the condition that n > 1. n represents the tilt factor of the transistor governed by the control of gate voltage.

N-MOS transistor in the linear region acts as a resistor when VGS>VT and VDS<VGS −VT. In this operational region the drain current ID is as follows:

$$I_D = \left(\frac{\mu_n C_{ox} W}{L}\right)\left((V_{GS} - V_T)V_{DS} - \frac{1}{2}V_{DS}^2\right) \quad (2)$$

Where:

μ_n is the electron mobility in the channel.

C_{ox} the capacitance of oxide per unit area.

W is the gate's width.

L is the gate's length.

The oxide capacitance per unit area C_{ox} can be expressed as follows:

$$C_{ox} = \frac{\varepsilon_{ox}}{t_{ox}} \tag{3}$$

Where:

ε_{ox} is the dielectric constant of the gate dielectric.

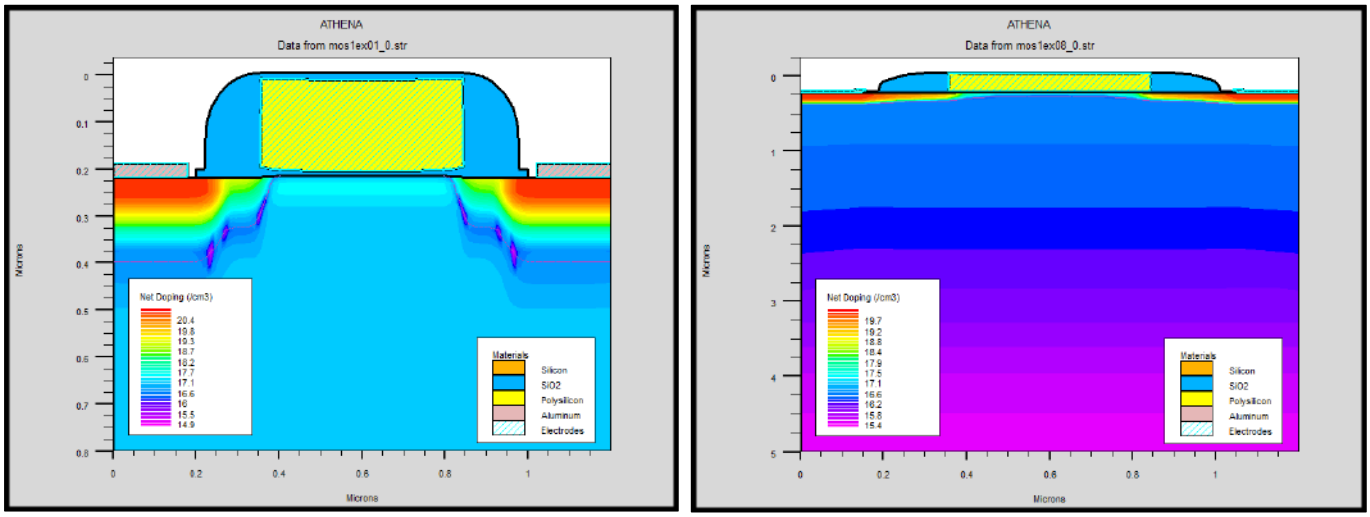
t_{ox} is the thickness of the gate dielectric.

The channel is pinched off from the drain side and the N-MOS is considered to be operating in the saturation region when VGS> VT and VDS ≥ (VGS −VT). The saturation region's drain current can be expressed as follows:

$$I_D = \frac{\mu_n C_{ox} W}{2L}(V_{GS} - V_T)^2 \tag{4}$$

The N-MOS function as a perfect current source in the saturation region and is independent of the drain voltage, as demonstrated by the equation above. However, a phenomenon known as channel length modulation causes the drain voltage to alter the channel's effective length. The drain current is dependent on the drain voltage when channel length modulation is included, and it may be expressed as:

$$I_D = \frac{\mu_n C_{ox} W}{2L}(V_{GS} - V_T)^2 (1+\lambda V_{DS}) \tag{5}$$

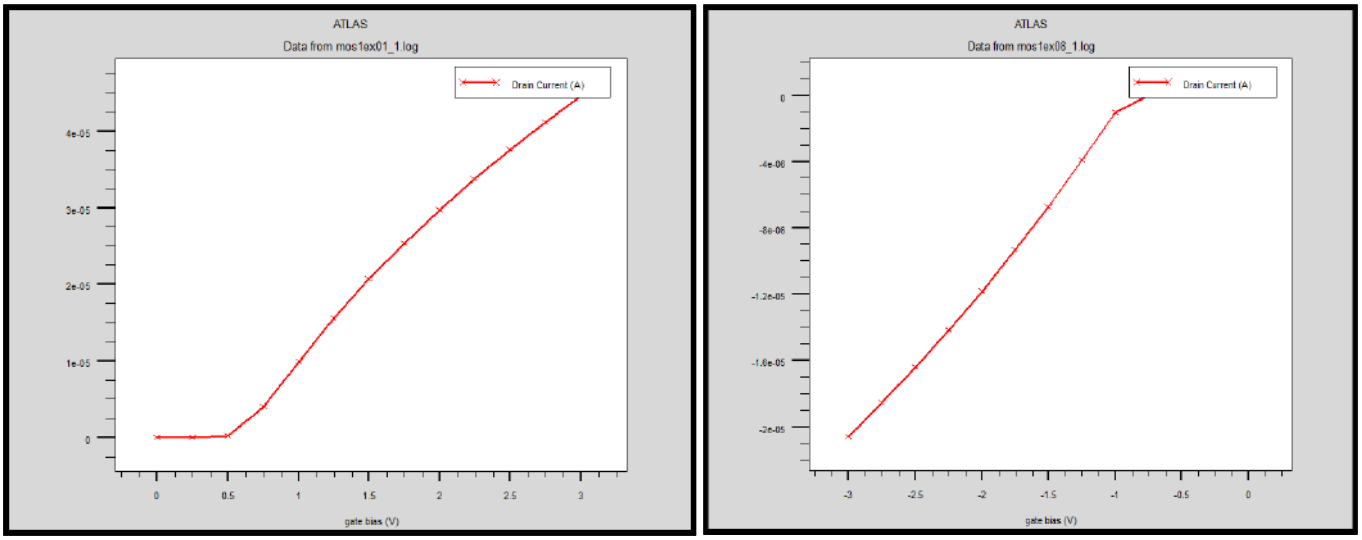


Where λ is the modulation parameter for channel length.

Is typically λ is proportional to the inverse of the channel length. The behavior of a P-MOS transistor are similar to the N-MOS where the source and substrate terminals are connected to the supply voltage except that the polarity of all the voltages and current reverse in the P-MOS, also the drain current in P-MOS primarily depends on the mobility of holes in the channel rather than the mobility of electrons [17-21].

IV. PRACTICAL SIMULATION AND RESULTS

Figure (1-a) shows the device structure for N-MOS transistor, which consists of; silicon layer at a bottom, P-well: Boron implanted under the channel and a thin layer of silicon dioxide (SiO2) was deposited as a boundary of the polysilicon gate. The source/drain (N++) zones and LDD zone between the channel and drain/source have Aluminum-metal contacts.



As shown in Figure(1-b) device-structure of P-MOS transistor, which consists of; silicon substrate, N-well: phosphorescently implanted to form the base of P-MOS channel, thin oxide layer between the gate and channel, and a Poly-silicon gate for the current control. PLDD/P++ source/ drain regions have a high impedance. Also, there is a spacer oxide layer used to isolate the gate from the field distribution and limit the LDD. Aluminum contacts used for electrical connection of the source/drain/gate.

Figure 1: device structure for MOSFET (a): N-MOS (b): P-MOS.
Source: Authors, (2026).

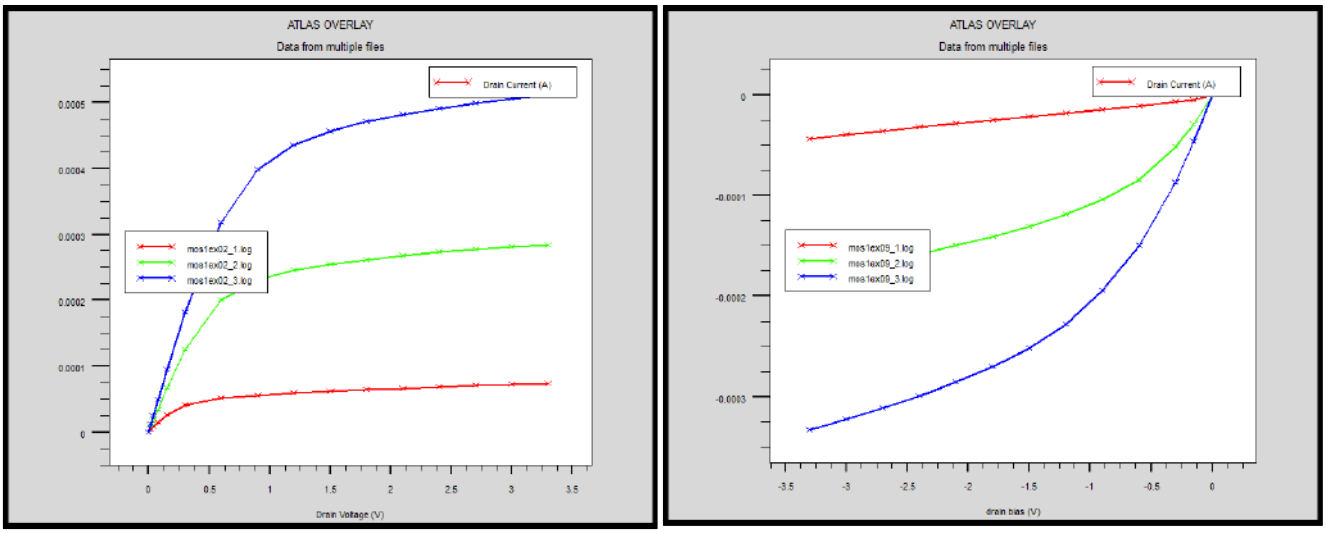

Figure (2-a) shows Id – Vg characteristics for N-MOS transistor, from the curve its observed that the current before Vt= 0.5V is very low almost zero, while this current increases linearly after the same Vt. Figure (2-b) shows the relation between Id and Vg for P-MOS transistor. From the curve, it is observed that the current starts from zero at Vg= 0V, and increases linearly at Vt= -0.5V, then reaches a very low value (-2*10-5 A) at Vg= -3V.

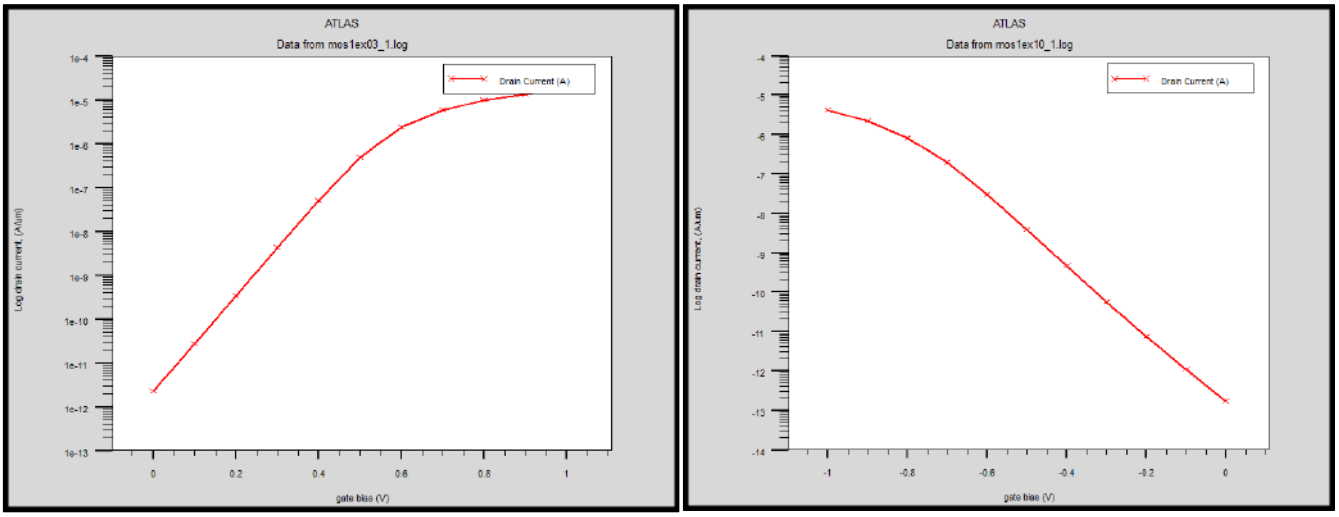
Source: Authors, (2026).



As shown in Figure (3-a) the Id vs. Vd properties for three values of Vg (1.1, 2.2, 3.3) V. It is observed that drain current (Id) grew linearly with expanding gate voltage (Vg) until it reaches saturation region at multi-values of Vd. The maximum current obtained is 0.515 mA at Vd= 3.35 V. Figure (3-b) shows the relation between Id and Vd for different values of Vg (-1.1, -2.2, and -3.3) V. It is observed that the current grew linearly with expanding gate voltage until it reaches saturation region. The highest current obtained is -0.335 mA at Vd= -3.35 V.

(a) (b)

Figure 3: Id vs. Vd properties for varies Vg values. (a): N-MOS (b): P-MOS.
Source: Authors, (2026).

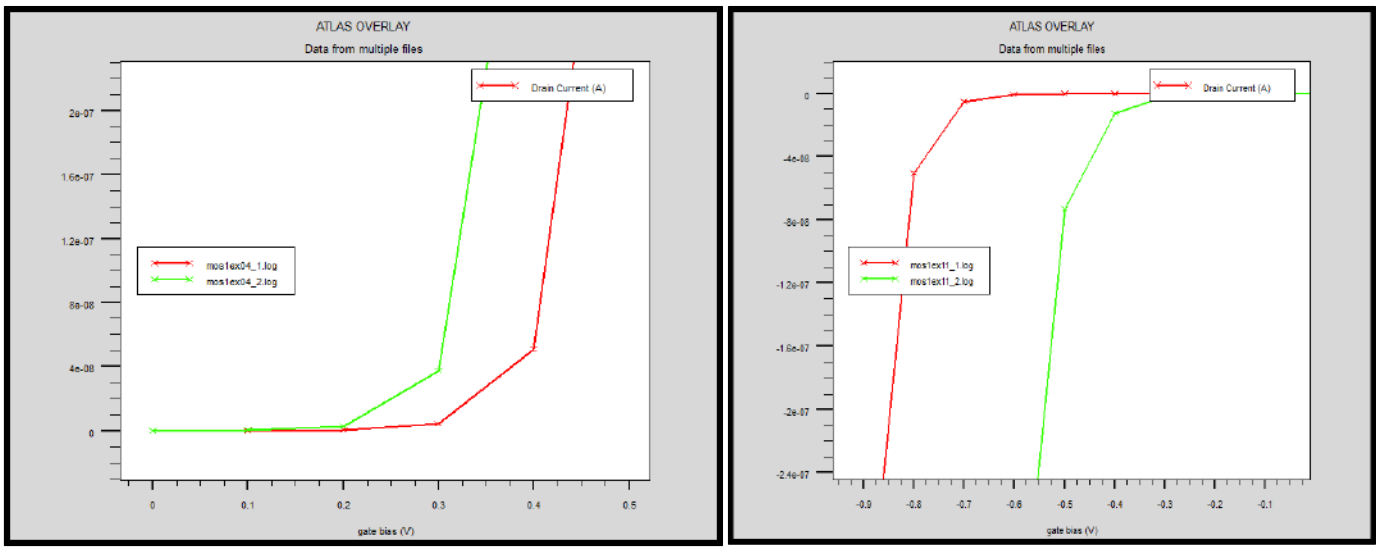


Figure (4-a) shows Id with Vg properties in the subthreshold region for N-MOS transistor. It is observed that the current exponentially proportional with Vg until reaches the subthreshold region at approximately Vg= 0.6V. Figure (4-b) shows the relation between Id and Vg in the subthreshold region for P-MOS. At Vg= 0V, the current reaches a maximum value (-12.95 A/µm). When the gate voltage is increased negatively, the current flows until it reaches a subthreshold region at Vg= -0.8V.

(a) (b)

Figure 4: Id–Vg characteristics for the subthreshold region. (a): N-MOS (b): P-MOS.
Source: Authors, (2026).

Figure (5a) shows Id verses Vg characteristics with different values of Vd for N-MOS. The red curve shows that Vt is 0.1V at Vd = 0.1V, while the green curve shows that Vt starts from 0V at Vd = 3V. It is observed that Vt reduced with increasing Vd at the same values of Id, due to DIBL. Figure (5b) shows Id Vs. Vg with different values of Vd for P-MOS. The red curve shows the behavior of normal transistor at Vd = - 0.1V, where Vt = -0.6V, while the green curve shows that Vt starts from -0.3V at Vd = -3 V also, with the same values of Id, due to DIBL.

V. CONCLUSIONS

This is a comprehensive study Performance Valuation of Electrical Characteristics for N-MOS and P-MOS using silvaco software. The simulation of the device structures for N-MOS and P-MOS were performed. The Id vs. Vd properties for varies values of Vg and Id–Vg characteristics in the subthreshold region were studied for both transistors. Also, Id–Vg characteristics with DIBL curves were investigated for both transistors. It is concluded that N-MOS Relies on electrons as the majority charge carriers, while P-MOS Relies on holes as the main charge carriers, so N-MOS current pass from the drain to the source, while P-MOS Current pass from the source to the drain. Therefore N-MOS transistors characterized by higher performance speed due to their high electron mobility, while P-MOS transistors are easier to integrate and complement the operation of N-MOS. This makes their combination essential for achieving energy efficiency and high performance in modern integrated circuits, as achieved in C-MOS circuits, so C-MOS circuits can be designed as a EEPROM cells.

ABSTRACT

Medical Health Informatics has envisaged quantum computing as flurry of promising solutions to deal with mental health related issues of young adults in recent times. Even though traditional machine algorithms try to find an amicable solution to healthcare service providers, still the efficient detection and classification of the highly complex patterns that emerges from the healthcare datasets needs further investigations. Quantum machine learning, inspired from the principle from Quantum computing is found to be a transformative alternative in redefining the healthcare applications. In this article, Quantum inspired Support Vector Machines (QISVMs) and Quantum inspired Neural Networks (QINN) as two efficient quantum machine learning approaches are proposed by combining the traditional yet very popular and powerful machine learning algorithms such as Support Vector Machine (SVM) and Artificial Neural Network (ANN) with the power of quantum computing principles. The proposed Quantum inspired machine learning approaches are evaluated with several figure of merit and then, compared with the performance of the traditional algorithms counterpart for analyzing the most complex nature of the healthcare data with proper identification of minute wise data patterns and biomarkers in order to detect the early-stage healthcare issues pertained to a patient. Experimental study shows the efficacy of these quantum machine learning methods in comparison to the existing literature with threats to validity, some hidden challenges, and ethical issues associated with these technological advancements.

I. INTRODUCTION

Due to the present life style changes in the society, there are several critical healthcare issues predominating in health of young adults in particular. These healthcare issues pose challenges before the healthcare activists to develop innovative and sustainable artificial intelligence solutions for a better diagnosis, suggest best possible treatment and effective patients' data management with highest precision levels [1]. The existing machine learning approaches find difficulty in dealing with such a high dimensional and complex healthcare datasets, and hence demand for a quantum computing based machine learning approach to solve the issues.

Quantum machine learning with its unique characteristics from quantum mechanics proves to be beneficial in handling such challenging situations in a very short span of time, so that early disease detection, personalized medicine, and efficient drug discovery can be possible as a part of future healthcare system [2]. For instance, recently Accenture Labs , India in collaboration with 1Qbit has started their R&D initiatives with Biogen to apply quantum computing to accelerate drug discovery and QpiAI India Pvt Limited, a Bangalore, India based company developed its first commercial quantum computer that might be used by the Physicians globally as a perfect match for the development of new drugs to save millions of lives that are lost due to drug-resistant bacteria every year.

With the rapid growth of deep learning and quantum computing taking the shape, the limitations of the machine learning model due to vanishing gradient problems, trapped into a local minimum, learning inefficiencies in hyperparameter tuning along with extraction and detection of critical information are successfully redressed to a great extent [3],[4]. Looking into the recent developments of the quantum machine learning approaches, this section introduces some fundamental concepts of quantum computing, quantum machine learning with their challenges is discussed.

I.1 QUANTUM COMPUTING

Quantum computing is considered to be a paradigm shift from classical computation by taking the advantages of quantum mechanics principles including superposition, entanglement, and quantum interference. While classical computation uses any one of the possible states (0 or 1) as classical bits (or cbits), quantum computing uses quantum bits (qubits) as a superposition of both the states simultaneously [5]. This way, quantum computing through its intrinsic parallel qubit operations on a state space of bigger magnitude offers advantages over the classical ones and found suitable in solving the complex intractable problems [6]. Initially, quantum computation is coined through the Hilbert transforms, where the qubits are represented as vectors and their operations are carried out by using unitary transformations [7].

Quantum gates are then used to operate on these states logically, so that Grover's search algorithm and Shor's integer factorization algorithm can be efficiently implemented on them to provide quantum speedup over their counterparts [8]. In quantum computation, a single qubit can be represented in either mathematically, geometrically, vector form and/or physically, the definitions are as given below. Mathematically, a single qubit is a two-level quantum system, and considered to be a superposition of two basis states: $|0\rangle$ and $|1\rangle$. However, generally a qubit state $|\psi\rangle$can be written as a linear combination (superposition) of these above two basis states [9], as shown in eq. (1):

$$|\psi\rangle = \alpha|0\rangle + \beta|1\rangle \tag{1}$$

where:

- $\alpha$and $\beta$are complex probabilities of observing $|0\rangle$ and $|1\rangle$ from the qubit,
- $|\alpha|^2$= probability of measuring the qubit in state $|0\rangle$
- $|\beta|^2$= probability of measuring it in state $|1\rangle$
- The normalization condition ensures total probability equals to 1: $|\alpha|^2 + |\beta|^2 = 1$
- Thus, the qubit's state is a unit vector in a 2-dimensional Hilbert space $\mathbb{C}^2$.

Secondly, a single qubit can also be represented geometrically using polar coordinates through Bloch Sphere Representation [10]. Since global phase (a common multiplier$e^{i\gamma}$) has no effect on measurement outcomes, a single qubit can also be represented using two real parameters, $\theta$and ϕ, as per eq. (2):

$$|\psi\rangle = \cos(\tfrac{\theta}{2})|0\rangle + e^{i\phi}\sin(\tfrac{\theta}{2})|1\rangle \tag{2}$$

where:

- $\theta \in [0, \pi] \rightarrow$ polar angle
- $\phi \in [0, 2\pi) \rightarrow$ azimuthal angle

These representations map a single qubit on the surface of a 3-D unit sphere, called as Bloch sphere, a unit sphere in 3D space for a geometric visualization of qubit states. This can also be visualized through a labelled diagram of the Bloch sphere showing how a single qubit is represented (with |0⟩, |1⟩, |+⟩, |–⟩ states, and angles θ, φ), as shown in Figure 1.

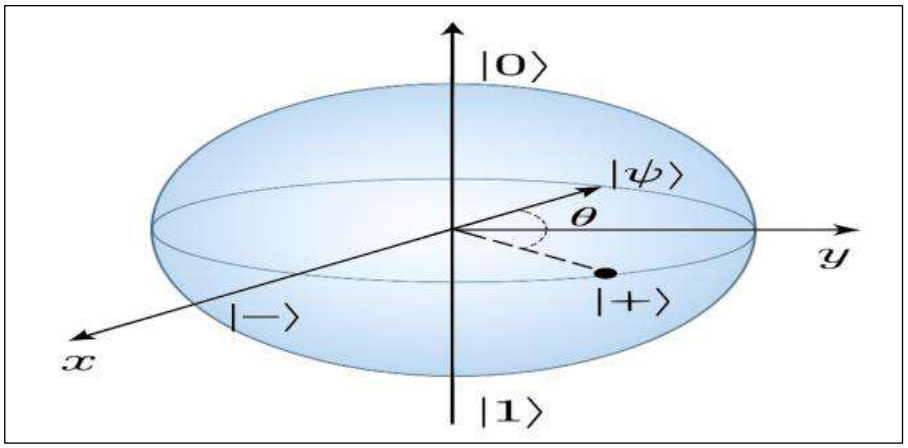

Figure 1: A labelled diagram of the Bloch sphere showing the representation of a single qubit.
Source: Authors, (2026).

Next, a single qubit can further be represented in matrix and vector form [11] as shown in eq. (3) and eq. (4) below:

$$\text{In matrix (column vector) notation: } |0\rangle = \begin{bmatrix}1\\0\end{bmatrix}, \quad |1\rangle = \begin{bmatrix}0\\1\end{bmatrix} \tag{3}$$

$$\text{Hence, in general, } |\psi\rangle = \begin{bmatrix}\alpha\\ \beta\end{bmatrix}, \text{with } |\alpha|^2 + |\beta|^2 = 1 \quad (4)$$

Finally, a single qubit can physically be encoded with the following details: (i) For Photon polarization → horizontal = $|0\rangle$, vertical = $|1\rangle$; (ii) In case of Electron spin → spin-up = $|0\rangle$, spin-down = $|1\rangle$; (iii) Superconducting circuits' → current circulating clockwise vs. counterclockwise; and (iv) Ion traps or quantum dots → ground and excited energy states. Through physical realization of a single qubit, one can find pathways to implement a quantum two-level system applied in a real-world physical device with highest storage reliability, can effectively manipulate, and obtain the quantum information associated with it. At the same time, a multi-qubit quantum system comprises of two or more qubits, is represented as the tensor product (or Kronecker product) of n single qubits. For n=2, the multi-qubit quantum system is referred to as a two- qubit quantum system. In this, Quantum entanglement [12] is one of the non-classical features of quantum mechanics, where a correlation between different qubits in this system is described even though the qubits are far away from each other. Further, entanglement violates Bell's inequalities by finding non-local correlations between two-qubits the explanations of which is difficult in case of classical probability computing [12]. In quantum entanglement, observation of the first qubit directly determines that of the second qubit which are then controlled by quantum gates in a quantum circuit to perform a quantum computation.

In quantum computing, quantum gates are unitary operators that manipulate the state of qubits according to the principles of quantum physics and unlike classical computing, they are reversible that allow to act on superpositions and can create entanglement with $U^{\dagger}U = I$, where U is a unary operator. Further, a quantum gate that acts on m-qubits or a register, is usually represented by $2^m x 2^m$ unitary matrix and a set of all such quantum gates with the group matrix multiplication is called as a unitary quantum group with $U(2^m)$. It is to be noted that in gate-based quantum computing, even though a sequence of unitary operators with either a single- and two-qubit are applied on a set of qubits, but sometimes there may not have any direct interaction between qubits while applying on a two-qubit gate [13]. Next, a one-qubit quantum gate is defined to transform a Bloch vector to another by rotating the Bloch vector. So, any one-qubit quantum gate is represented as rotation or a combination of rotations. These rotations may be further expressed as a combination of RX Gate, RY Gate and RZ Gate, which are necessary enough to perform every quantum computation [14]. However, parameter free gates along with three rotation gates are not only necessary but also considered to be sufficient, for efficient implementations of all possible quantum gates. Following are the representations of the three quantum gates that are more commonly used [9]. The RX Gate is a single-qubit rotation through angle θ (radians) around the x-axis and the angle of rotation must be specified in radians which can either be positive or negative, which is represented in eq. (5).

$$R_x(\theta) = \begin{bmatrix}\cos(\frac{\theta}{2}) & -i\sin(\frac{\theta}{2})\\ -i\sin(\frac{\theta}{2}) & \cos(\frac{\theta}{2})\end{bmatrix} \quad (5)$$

Similarly, The RY Gate is a single-qubit rotation through angle θ (radians) around the y-axis and can be represented as shown in eq. (6) below.

$$R_y(\theta) = \begin{bmatrix}\cos(\frac{\theta}{2}) & -\sin(\frac{\theta}{2})\\ \sin(\frac{\theta}{2}) & \cos(\frac{\theta}{2})\end{bmatrix} \quad (6)$$

Finally, RZ Gate is a single-qubit rotation through angle θ (radians) around the z-axis and can be represented as shown in eq. (7).

$$R_z(\theta) = \begin{bmatrix}e^{-i\frac{\theta}{2}} & 0\\ 0 & e^{i\frac{\theta}{2}}\end{bmatrix} \quad (7)$$

In addition to these basic quantum gates, CX (Controlled-X) or CNOT gates are also considered to be one of the most essential gates for quantum computation. It is observed that any controlled gate can be realized by a combination of CX gates and one-qubit gates including X. The circuit symbol for CX gate is shown in Figure 2.

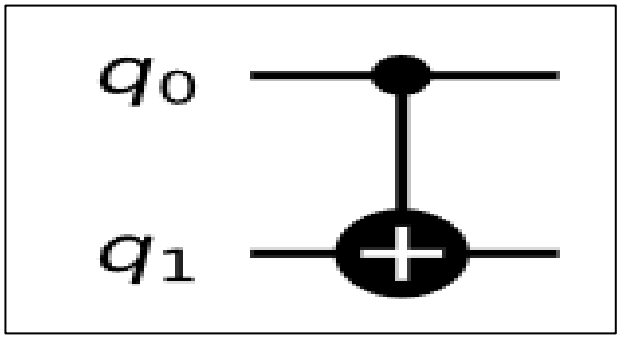

Figure 2: Circuit representation of a controlled gate CX.
Source: Authors, (2026).

Here, CX gate or CNOT gate performs the NOT operation (equivalent to applying an X gate) on the second qubit only when the first qubit is $|1\rangle$ and otherwise leaves it unchanged. Also, while applying the CNOT gate on the state $|00\rangle$, we get output state as $|00\rangle$ as CNOT does the inversion of the input state applied to it.

Similarly, CNOT|00⟩=|00⟩, CNOT|01⟩=|01⟩, CNOT|10⟩=|11⟩, CNOT|11⟩=|10⟩, where {|0⟩= (10), |1⟩ = (01)} denotes the computational representations. In this, first qubit is considered as the controlled qubit, whereas the second qubit is the target qubit. As can be seen from Figure 2, if the first (Controlled) qubit is in the state |1⟩, then apply the X (NOT) gate to obtain the second (Target) qubit, otherwise to leave it as unchanged [15].

I.2 QUANTUM MACHINE LEARNING

Machine learning and artificial intelligence has become a household term now-a-days for its usefulness in transforming our lives in this ever-growing digital world. The tech giants including Amazon, Google, Netflix, Facebook, Apple, OpenAI, etc. to name a few, use machine learning and Generative AI techniques as the core idea with an aim to benefit heavily from the wide range of applications with a shortest possible time. However, due to global digitization, the size of the datasets has increased in order of zettabytes (of the order of 10^{21}) [16], which creates a bottleneck situation for the classical computers with the traditional machine learning algorithms for efficient processing, hence the whole world is now looking at the quantum computers and quantum computing methodologies to provide an amicable solution in near future. This requirement has motivated researchers to explore further possibilities in terms of quantum machine learning to deal with such huge and complex datasets in ease through quantum random access memory [17] and quantum artificial intelligence. Future quantum computers and a quantum internet need these quantum memories (or random-access quantum memories) to store and retrieve qubits. Despite several approaches existing to encode qubits and to implement quantum memories, no single "gold standard" has yet emerged till date [18].

I.3 COMPUTATIONAL COMPLEXITY IN CLASSICAL AND QUANTUM MACHINE LEARNING

The following presents a bird eye view on the complexities of both classical machine learning (CML) and quantum machine learning is provided, to further enhance our intentions why to go for quantum computing for recent applications of machine learning.
As our proposed research is based on how to deal with large datasets based on quantum machine learning (QML), it is imperative to understand how these algorithms perform in terms of scalability and practical feasibility. To achieve this, computational complexity (both in time and space) comparison among these machine learning algorithms whether classical or quantum based, considered as a primary tool for evaluating their potential advantages or pit falls. The quantum advantage with reference to a popular classical Grover's algorithm, in which the classical machine learning algorithm has time complexities of O(n) for n-inputs whereas the same algorithm can be executed through quantum machine learning with O(sqrt(n)), presents a significantly faster algorithm which is very interesting. It is also coined by the researchers that quantum machine learning can achieve faster solution to solve the linear algebra problems in comparison its classical counterpart, which are later popularly known as HHH (Harrow–Hassidim–Lloyd) algorithm [19]. A comparison between CML and QML is presented in Table 1.

Table 1: Comparison of Complexity in Classical and Quantum Machine Learning.

Criteria	**CML**	**QML**
Parallelism	limited	Inherent due to superposition
Processing speed	Largely depends upon available resources	Exponential for linear systems through HHH algorithms
Scalability	Challenging for extensive computations	Highly scalable
Complexity Classes	4 types: P (Polynomial Time); NP (Non-deterministic Polynomial Time); NP-hard and NP-Complete	BQP (Bounded-error Quantum Polynomial time), where
Algorithms	Conventional ML algorithms like: Neural Network, Support Vector Machines, Decision trees	Quantum SVM, Quantum NN, Quantum Deep Neural Network
Complexity	1. for SVM- Complexity range from $O(n^2d)$ to $O(n^3d)$ depending on the implementation and support vector kernel, where n is the number of data points and d is the dimensions of the data. 2. for Artificial Neural Networks- Complexity varies depending on the network architecture. For dense networks, one iteration might scale up to $O(n \cdot \|Weights\|)$. Hence, computational complexity largely depends on ANN architecture, dataset size, and number of iterations.	1. For QSVM- the complexity is $O(\log(nd))$, which achieve near-logarithmic complexity with respect to both the dimensionality of feature vectors 'n' (qubit number) and 'd" the size of the training dataset (dataset size). 2. For QNN- Computational complexity is expensive due to long training times and can range from $O(n^2)$ to $O(\log(n))$, where n represents the number of elements (e.g., neurons, data points, or parameters)

Source: Authors, (2026).

Apart from all the above, Time and Space Complexity in QML are affected by Qubit count (width), Gate depth (circuit time), Measurement repetitions (shots), and Deep circuits which when applied on a large dataset may lead to exponential scaling. Further, QML complexity may be understood from the type of quantum circuits used. For example, in case of swallow quantum circuits, it is easier to execute, but has limited expressivity and on the other hand, for deeper ones, it has more expressive power but prone to noise. Hence, a trade-off is suggested in this case. The complexity analysis of QML and CML provides us a understanding for future development in algorithms, circuits, and hardware that may be customized for a practicable and yet a powerful quantum machine learning system. The remainder of the paper is organized as follows.

To efficiently perform the mental health prediction of young adults using quantum machine approaches, related work that are presently available in literature is presented in Section 2, followed by the technical knowhow of the proposed quantum machine learning such as QSVM and QNN are discussed in Section 3. Next, understandings of the mental health dataset with its descriptive analytics are presented in Section 4. In Section 5, investigation on the effectiveness of the proposed quantum machine approaches is performed through an experimental setup, and then, the obtained simulations result with discussions are reported in Section 6 with threats to validity. Finally, we summarize the proposed work in Section 7.

II. THEORETICAL REFERENCE

According to [20] presented some quantum machine learning algorithms for classification tasks by applying on several biomedical datasets and then compare their performances with conventional ones in terms of different performance matrix. They concluded that Pegasos Quantum Support Vector Classifier is best among the quantum classifiers but upto 10% lesser accuracy than that of conventional classifiers, needs more research for further explorations. In [21] proposes an Quantum neural network model with incremental qubit numbers after the dataset undergone pre-processing through z-score normalization and features extraction by using information gain method. They compared the performance of Quantum neural network model in terms of accuracy and computational time with several deep learning and quantum machine learning models including Bi-LSTM, QCNN, DNN and RNN etc. with a learning rate of 0.7 and reported their effectiveness.

According to [22] provided an intial study of Quantum inspired quantum orthogonal neural network technique for medical image classification and showed its effectiveness through software simulations and hardware demonstartions in terms of scalability and computational time. They observed that their approach has several limitations in terms currently available hardware and at the same time opines that using future quantum computers with GPU capabilities along with potential Hilbert spaces can solve these limitations. However, the practicability of such a parametrized quantum circuits with large Hilbert spaces is still considered to be an open challenge in this area of research and envisaged to be solved in near future as the newer version of specialized hardware evolves.

According to [23] developed a quantum machine learning model by combining the strengths of contrastive and transfer learning with quantum mechanics and applied to mental health monitoring and diagnosis. Considering the challenging charactristics of the large scale mental health dataset and limitations in computing environment, they used QASM simulator with 8 qubits for their experiments and suggested to use more qubits and a real quantum device in future to further increase the performance if practically possible. According to [24] used both classical neural network model and quantum machine learning model on EEG signals to detect human drowsiness after performing pre-processing tasks. They explored the performance of the three layers quantum based classifier by using different quantum circuit architectures with rotation and entanglement Gates and suggests for improvements.

Iin [25] introduces a hybrid quantum support vector machine by combining the power of quantum computing with Support vector machine for stress detection in older adults. They used wearable sensor and stressed sensor to obtain the normal and anomaly data respectively, from 40 old adults. Kernel based pre-processing is used to extract the complex features from the above collected data and used TSST protocol for understanding the usefulness of the approach in terms of high accuracy and recall values, which helps in early diagnostic or treatment of the high stress of the old adults on time and saves life. According to [26] initially presented a summary of powerful features of quantum machine learning and then discusses how the technology revolutionizes today's healthcare sector in achieving better personalized treatment and precision healthcare.

While implementing the quantum machine learning algorithms in genomic data analysis, they suggested developing more formal optimization methods with low resource usage in terms of number rotations Gates and size of the qubits, to practically make it feasible to develop an efficient precision medicine approach in days to come. In [27] pointed the drawbacks of the classical machine learning approaches in dealing with large psychiatric dataset for early detection and prediction of schizophrenia disease. They provided an insightful discussion on the suitability of these quantum machine learning methods with proper selection of performance measures and their validation, for disease detection and diagnosis at an early stage.

For [28] presented a review on basic concepts of quantum computing and its integration with traditional machine learning methods, its potential application areas and drawbacks, for a clear understanding. They concludes by outlining the future of quantum-inspired machine learning in solving clinical diagnostics and personalized treatments. According to [29] advocates for quantum computing for its capability to process the big data in terms of both speed and time, when applied to identify the disease specific bio-markers, especially for neurodegenerative and psychiatric diseases. It further explore its possibilities in clinical research, hospital management , resource allocation and most importantly patient's health monitoring with potential ethical issues being addressed. According to [30] surveyed five quantum enhanced machine learning algorithm by hybridizing the traditional support vector machine, neural network, *k*-nearest neighbour, principal component analysis and *k*-Means clustering algorithm with quantum mechanics.

They presented a discussion on how these methods can be successfully applied on drug discovery, image processing and cyber security applications with inherent limitations in design hardware circuits, data encoding, and noise. In [31] discusses about the challenges prevailing in Parkinson's disease, the fastest-growing neurodegenerative disorder globally and the need for a sustainable method for early detection to save the patients' life. They used mPower dataset with four key bio-markers, used random forest method as a feature selection algorithm and then quantum support vector machine for classification and prediction of the disease efficiently. With an overall accuracy of 90%, they concluded that a practically achievable and simulation based quantum machine learning model on a standard hardware configuration is better than resource intensive quantum computers, which needs further research.

For [32] carried out a 10 years of extensive research starting from 2015 to 2024, by including published studies available several databases including PubMed, Embase, IEEE, Scopus and Preprint servers related to application of quantum machine learning in digital health care. Their studies reveal that there are no clear-cut trends to differentiate or support empirical quantum utility in digital medicine and health service delivery. This encourages further research in this area, to unveil the full potential of quantum machine learning models.

In this paper, the main objectives are to use two Quantum Inspired Machine Learning approaches including QNN (Quantum inspired Neural network) and QSVM (Quantum inspired Support Vector Machine) models considering their possible implementation on real quantum circuits, with an aim to address the challenges that are being faced while implementing through traditional approached in mental health application in young adults in todays scenario.

The key contributions of our work include: (1) An approach to quantum embedded encoding (angle embedding and encoding) is proposed which can transform the classical features to qubits and then generate shallow quantum circuits. The motivation of using this is to reduce the complexity of the quantum encoding block compared to the existing methods; and (2) An efficient and faster quantum inspired machine learning algorithm model is developed by hybridizing quantum processing with the classical neural network and SVM model. The proposed QINN and QISVM models are realized based on the fundamental quantum gates on a quantum circuit and effectiveness are validated with several figure of merit metrics.

The remainder of this paper is organized as follows: Section 3 introduces the preliminaries with materials and methods used. The Experimental design using QNN and QSVM algorithms along with the analysis of obtained results are presented in Section 4. Finally, Section 5 concludes this paper.

III. MATERIALS AND METHODS

In this section, we introduce the details about the mental health dataset used for our experiments followed by some preliminary knowledge of quantum computing and quantum machine learning models.

III.1. MENTAL HEALTH DISORDER DATASET

The mental health disorder dataset collected freely from openml (Scikit-Learn) database, comprises electronic health records from 10,000 patients diagnosed over the past ten years with either an affective disorder (encoded as 0) or schizophrenia (encoded as 1). It includes demographic variables such as sex and race, psychosocial characteristics, and clinical assessment data related to psychiatric symptoms. A binary classification model has been developed to predict diagnostic outcomes based on patient intake information. This predictive model is intended to support clinical triage by assigning patients to the appropriate treatment pathway either for affective disorders or schizophrenia based on the predicted diagnosis. The objective is to assess the reliability and effectiveness of this model in informing triage decisions within a clinical setting.

III.1.1 Description Of The Dataset:

This case study explores the use of a machine learning (ML) model in a mental health care setting to predict patient diagnoses based on intake data. The aim is to examine how algorithmic bias may emerge, particularly when structural inequities are embedded in training data. Although the scenario is based on a simulated and simplified dataset, it is designed to highlight key concerns related to fairness, bias, and diagnostic equity in healthcare ML applications.

III.1.2 Background And Relevance:

Research has shown that Black patients particularly Black men are diagnosed with schizophrenia at disproportionately higher rates compared to other demographic groups, including white patients [30]. Schizophrenia is a severe psychiatric disorder with a chronic course, characterized by both positive symptoms (e.g., hallucinations, delusions) and negative symptoms (e.g., lack of motivation, flat affect). Misdiagnosis of schizophrenia instead of affective disorders such as depression may result in significant clinical and ethical concerns, including delayed or inappropriate treatment, greater stigma, more severe side effects from antipsychotic medications, and reduced trust in the healthcare system. This disparity in diagnosis [31] is likely multifactorial, involving both biological and social determinants. However, diagnostic bias where clinicians may overemphasize psychotic features in Black patients and under-recognize depressive symptoms has been identified as a key contributor. These issues reflect the broader concept of labelling bias, where outcome labels in clinical datasets may themselves encode structural inequities, inadvertently perpetuating disparities when used to train ML models [32].

III.1.3 Reference Case: Algorithmic Fairness In Healthcare

To contextualize the potential risks of biased ML deployment in healthcare, the study by [33] is referenced. In their evaluation of a risk stratification algorithm used by insurance providers for approximately 50,000 patients, the algorithm systematically underestimated the disease severity of Black patients. This occurred primarily because the algorithm used total healthcare expenditure as a proxy for illness severity a flawed assumption given the socioeconomic disparities that affect healthcare access and spending. The study in [34] illustrates how proxy variables and a lack of intersectional analysis can result in substantial fairness harms.

III.1.4 Hypothetical Scenario

A simulated dataset has been constructed to replicate the type of bias highlighted above. This dataset contains electronic health records for 10,000 patients diagnosed at Health System A over the past ten years with either an affective disorder (labelled as 0) or schizophrenia (labelled as 1). Features include demographic variables (sex and race), psychosocial factors, and symptom-related data from clinical assessments.A binary classification model has been developed using this data. Its purpose is to assign a diagnosis to new patients based on intake information, thereby directing them to the appropriate treatment pathway without further clinical evaluation. The hospital administration, motivated by cost-reduction strategies, intends to rely solely on this automated system for triage and treatment decisions. To support the model's deployment, executives have commissioned a performance evaluation using a test dataset of 1,000 patients. They report high sensitivity and specificity, suggesting the classifier performs well overall.

However, external stakeholders have raised concerns about potential bias and disproportionate harms, particularly toward subpopulations defined by intersecting axes of race and gender. To address these concerns, an independent audit of the classifiers performance and fairness implications has been requested. The evaluation must consider not only aggregate metrics but also subgroup level performance disparities, with attention to potential intersectional bias. This analysis is essential before any deployment of the model in clinical practice, especially given the risks of misdiagnosis and its downstream effects.

III.2. QUANTUM INSPIRED MACHINE LEARNING (QIML)

Quantum inspired machine learning (QIML) can be developed either when both data and methods are in quantum form or else only model is quantum but the dataset is in traditional form. When the data is in traditional format, then it is first transformed into its corresponding quantum format by using a parameterised circuit called quantum feature map. Here, Z feature map is used as a quantum feature for data encoding through a series of operations for this data transformation.

In this case, entanglement is absent, as there are no interaction amongst the features' of the dataset present while using Z feature map. In the next step, dimensionality reduction is performed in order to reduce the number of quantum features for efficient implementation, hence reduces the computational complexity, presents clarity on feature importance and produces a faster implementation. A quantum kernel may be used as a pre-processing algorithm in case of quantum inspired support vector machine model (QISVM). While using a quantum inspired neural network (QINN), parameterized operation includes entanglement along with parameter optimization method (per say ADAM optimiser) for significantly improvement in the overall performance and effectiveness of the model.

III.2.1. Quantum Inspired Support Vector Machines (QISVMS)

The pseudo code of the Quantum Inspired Support Vector Machines (QISVMs) is presented in Figure 3.

Pseudo Code for QISVM

Input: Training dataset $D = \{(x_1, y_1), ..., (x_i, y_i)\}$, *where* $x_i \in R^d$ *and* $y_i \in \{+1, -1\}$

Output: Quantum Inspired SVM model

1. Encode classical data into quantum states:

For each x_i *in D:*

$|\psi_i\rangle$ = *Quantum_Feature_Map*(x_i) # *Pauli Feature Maps used*

2. Compute quantum kernel matrix K: #*Quantum kernel using angle embedding fidelity*

For all pairs (i, j):

$K[i][j] = |\langle\psi_i|\psi_j\rangle|^2$

3. Solve the dual optimization problem:

Maximize: $L(\alpha) = \Sigma_i \alpha_i - \frac{1}{2} \Sigma_{ij} \alpha_i \alpha_j y_i y_j K[i][j]$

Subject to: $\Sigma_i \alpha_i y_i = 0$ *and* $0 \leq \alpha_i \leq C$

4. Construct decision function:

$f(x) = \Sigma_i \alpha_i y_i \langle\psi_i|\psi\rangle$, *where* $|\psi\rangle$ = *Quantum_Feature_Map(x)*

5. Predict label:

y_pred = sign(f(x))

Figure 3: Pseudo Code of QISVM.
Source: Authors, (2026).

III.2.2 Detailed Explanation

- **Quantum_Feature_Map(x)**: Encodes classical data into quantum states using parameterized quantum circuits. Pauli Feature Map is used in this research using PennyLane.
- Kernel Matrix: Measures similarity between quantum states. Quantum computers can estimate this efficiently using interference patterns. In this, we used Angle Embedding Fidelity kernel to obtain the complex data relationships that classical kernels might miss.
- **Optimization**: Solved classically using quadratic programming, but the kernel is computed via quantum means.
- **Prediction**: Uses the trained support vectors and quantum kernel to classify test data.

Based on the pseudo-code, the workflow of QISVM is presented in Figure 4.

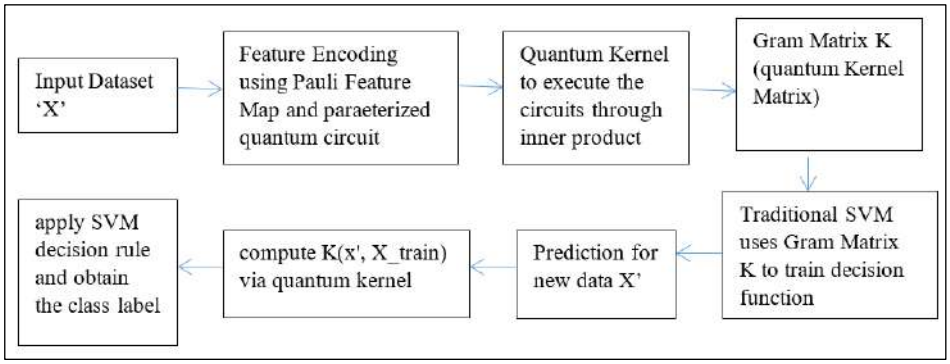

Figure 4: Workflow of quantum Inspired SVM.
Source: Authors, (2026).

III.2.3 Computational Complexity

A comparison between QISVM and Traditional SVM is presented for better understanding.

- **Quantum Kernel Estimation**: Scales as $O(D^{4.67}/err^2)$, where D is the number of training samples and err is the error tolerance.
- **Classical SVM**: Typically scales as $O(D^2)$ to $O(D^3)$ depending on the SVM types.
- **Quantum Limitations**: As shot noise is introduced during Quantum measurements, repeated sampling are needed, which may induce more computational complexity.

Even though QISVM is one of the most efficient and stable algorithm, it is best suited for low-dimensional circuits having less number of features or qubits. For high dimensional datasets, some kind of feature reduction techniques might be handy to deal the situation effectively.

III.2.4. Quantum Inspired Neural Network (Qinn)

The pseudo code for Quantum Inspired Neural network (QINN) is presented in Figure 5. Following the Pseudo-code, Figure 6 demonstrates how a basic quantum inspired neural network (QINN) works.

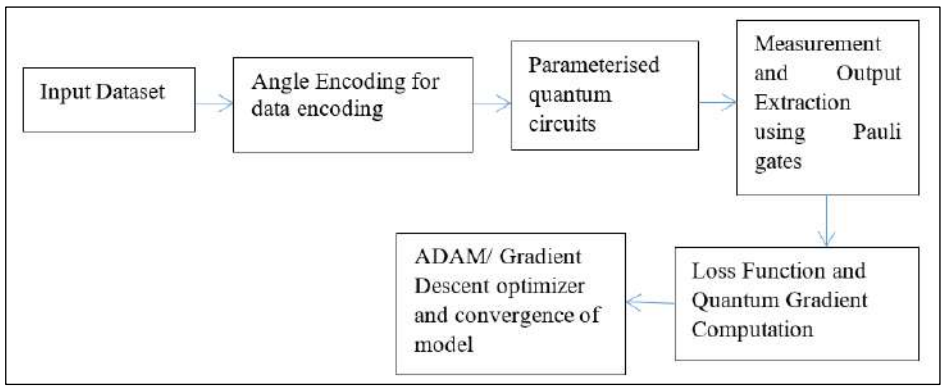

Figure 5: Operational Workflow of QINN.
Source: Authors, (2026).

Initially, the input dataset having classical feature vector is applied for angle encoding where the feature vector x_i is encoded into a quantum state (or qubit state) with an appropriate number of qubits and then the features in the raw data are mapped through the parameterized rotation gates and entangling gates for a given number of layers (i.e. RY(x_i)). The entire network highly resemblance to that of a classical neural network layer, where θ are defined as weights. The mapped qubit state is then applied through Pauli gates to measure the qubit state. The output of the Pauli gate provides the model's prediction, analogous to a neuron's activation value in case of traditional Neural Network. Then the obtained measurements of qubit states are decoded back into the appropriate output data which are finally optimized by using ADAM optimiser. The loop continues till the termination criteria is satisfied. In this case, mean square error (MSE) is used as a loss function and parameter shift is performed by gradient calculation. In quantum inspired neural network, parameter shift through error backpropagation is not possible, hence gradient descent/ADAM optimizer is used to update the parameters. The final trained parameters θ'define the optimized QINN capable of generalizing to new inputs.

III.2.5 Advantages of Quantum Neural Networks

The advantage of using QINN lies its ability (i) to apply successfully in large dimensional feature spaces, (ii) models non-linear dependencies through entanglement (CNOT gates), (iii) its faster convergence due to quantum expressiveness and most importantly less computational overhead in comparison to its traditional counterpart. In spite of its several advantages, it is not away from limitations in terms of (i) quantum gradient vanishing due to its incapability to perform backpropagation and not using any activation function and (ii) near-term device compatibility with a large error rate and a complicated error correction process.

Algorithm: Quantum Inspired Neural Network for Binary Classification

Input:

- *Training dataset* $D = \{(x_i, y_i)\}$, *where* $x_i \in \mathbb{R}^n$ *and* $y_i \in \{0,1\}$
- *Number of qubits q and Quantum circuit depth L*
- *Learning rate η and Number of training epochs E*

Output:

- *Trained quantum parameters* θ^*

1. Initialize Quantum Neural Network parameters θ randomly
2. For each epoch in range(1, E + 1):
3. For each training example (x_i, y_i) in dataset D:
4. # Step 1: Encode classical input into quantum state
5. |ψ_input⟩ = QuantumEncode(x_i) # (e.g., using angle encoding,)
6. # Step 2: Apply parameterized quantum circuit (variational layer)
7. |ψ_output⟩ = U(θ) |ψ_input⟩
 # U(θ) is a sequence of quantum gates parameterized by θ
*# Example: U(θ) = RY(θ1) * RZ(θ2) * CNOT * RY(θ3) * ...*
8. # Step 3: Measure qubits to obtain classical output
9. z_i = Measure(|ψ_output⟩)
 # Measurement collapses the quantum state and gives an expectation value
 # Example: z_i = ⟨ψ_output| Z |ψ_output⟩
10. # Step 4: Compute loss
11. L(θ) = (z_i - y_i)^2 # Mean squared error (MSE) is used
12. # Step 5: Compute gradient using parameter-shift rule
13. ∇θ L = ParameterShift(U(θ), L) # Quantum gradient computed by evaluating circuit at θ+Δ and θ−Δ
14. # Step 6: Update parameters using gradient descent /ADAM
*15. θ = θ - η * ∇θ L*
16. End for
17. End for
18. Return optimized parameters θ'

IV. EXPERIMENTAL RESULTS AND DISCUSSIONS

IV.1. EXPERIMENTAL SETUP

All the experiments carried out in this paper is performed on an Intel Core i7 machine with 1TB HDD, 8GB RAM, 2.67GHz CPU using Kaggle Notebook in Python environment. PeenyLane is used for developing the quantum machine learning model using Neural network and SVM. The Architectural Flow of Quantum inspired Machine Leaning models for Mental Health Detection is presented in Figure 7. The parameter setting used in this paper is provided in Table 2.

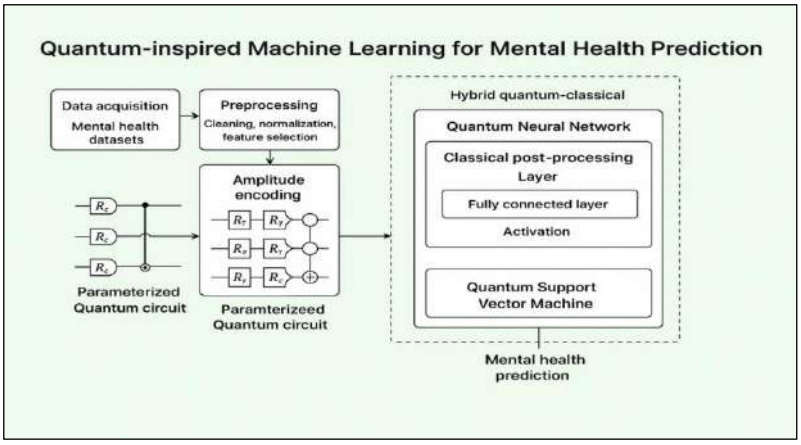

Figure 7: Experimental Flow for Quantum Inspired Machine Learning in mental health prediction.
Source: Authors, (2026).

Table 2: Parameter Setting for the Quantum Machine Learning Approaches.

Feature / Parameter	Quantum Neural Network (QNN)	Quantum Kernel SVM (QK-SVM)
Qubits Used	8	8
Layers	4 (3 × Strongly Entangling Layers + 1 final rotation layer)	1 (Angle Encoding only)
Trainable Parameters	96 total = (n_layers + 1) × n_qubits × 3	0
Single-Qubit Gates	80	8
Two-Qubit (Entangling) Gates	24	14
Circuit Depth	≈ 13	≈ 22
Training Required	Yes (gradient descent on variational parameters)	No (only classical SVM training)
Inference Speed	Medium	Slow (due to kernel matrix evaluation)
Expressivity	High	Medium
Preprocessing Used	Angle Encoding — RY rotations with inputs scaled to [0, π]	Angle Encoding — RY rotations with inputs scaled to [0, π]
Output Type	Learned Quantum State (trainable feature map)	Quantum Feature Kernel (fixed feature map)

Source: Authors, (2026).

In Figure 7, the mental health dataset from OpenAI is collected in data acquisition block which may either be the survey data, clinical assessments, wearable device readings and/or patient-reported outcomes. The attributes of the mental health dataset include the patients' symptoms, behavioural patterns, demographic information and Psychological/ mental disorder signals etc. with class label depicting the patient's mental health condition which may be categorized as depression, Schizophrenia, or healthy. In the second step, data pre-processing is carried out where missing values, outliers and noise if any are cleaned, followed by data normalization to convert the attributes values to fall in to a comparable range (we use Min-Max normalization here) for efficient data encoding and then, feature selection/ dimensionality reduction is done to reduce the data complexity and make the data a quality one before quantum embedding process. Further, scaling is performed to address the issue of class imbalance, if any and remove biasness.

In third step, we create a parameterized quantum circuit to transform the classical data into their corresponding quantum states either by using amplitude or Angle encoding, so that it is ready for quantum processing. We use angle encoding here, where the it maps the features to rotation angles of qubits by using Ry or Rz quantum gates. In this process, number of qubits denotes the feature dimensions after angle encoding. In quantum processing block, we develop a hybrid model by combining quantum processing using classical Neural network and Support Vector Machine Classifier. Multiple layers of parameterized quantum gates such as Rx, Ry, Rz, CNOT are used to serve as a core of quantum machine learning approaches. Entanglement is also introduced in this step, to obtain the cross correlation between qubits to explore inherent relationships in mental health datasets and then quantum measurements are performed by extracting expectation values from qubits to serve as intermediate initial attributes.

In quantum inspired neural network, layer depth may affect the neural network learning capacity which sometimes considered as a trade-off between noise and data de-coherence. The output of the QINN needs normalization by using either softmax function or sigmoid function depending whether the mental health datasets contains binary class or multi-class disease prediction. This way, the raw output of the quantum circuits can be transformed in terms of class probabilities and hence, ensures efficient model building with accurate and interpretable mental health prediction and classifications. On the other hand, QISVM uses the angle encoding circuit followed by number of adjoint encoding circuits to implement the quantum kernel function and obtain the correlation between quantum states in a high dimensional Hilbert space by using quantum Gram Matrix. In this paper, Pauli feature map criteria is used to convert the classical attributes to quantum states using rotations gates and Pauli operators, then crates entanglement between qubits to find out the non-linear relationships among features. This way, QISVM could effectively develop a computationally efficient quantum classifier with acceptable accuracy in mental health conditions classification.

V. RESULTS AND DISCUSSIONS

In this section, the results obtained after performing the experiments as per the architectural overflow shown in Figure 7 are presented with comparisons with related work for validation of the proposed research in this paper. In this, figure of merit is considered as one of the approach to understand the performance of the QINN and QISVM considering the high dimensional and highly imbalanced mental health dataset. Here, accuracy, Precision, Recall and ROC are used as figure of merit metrics for evaluations, where one could able to take steps to accurately detecting the true positives while minimizing false positives. Here the full data set is converted into train, validation and test dataset 80%, 10% and 10% respectively. The results obtained are presented in Figures 8 to Figure 16. Figure 8 shows the quantum kernel with entangling circuit and the adjoint circuits to obtain the correlations between quantum states.

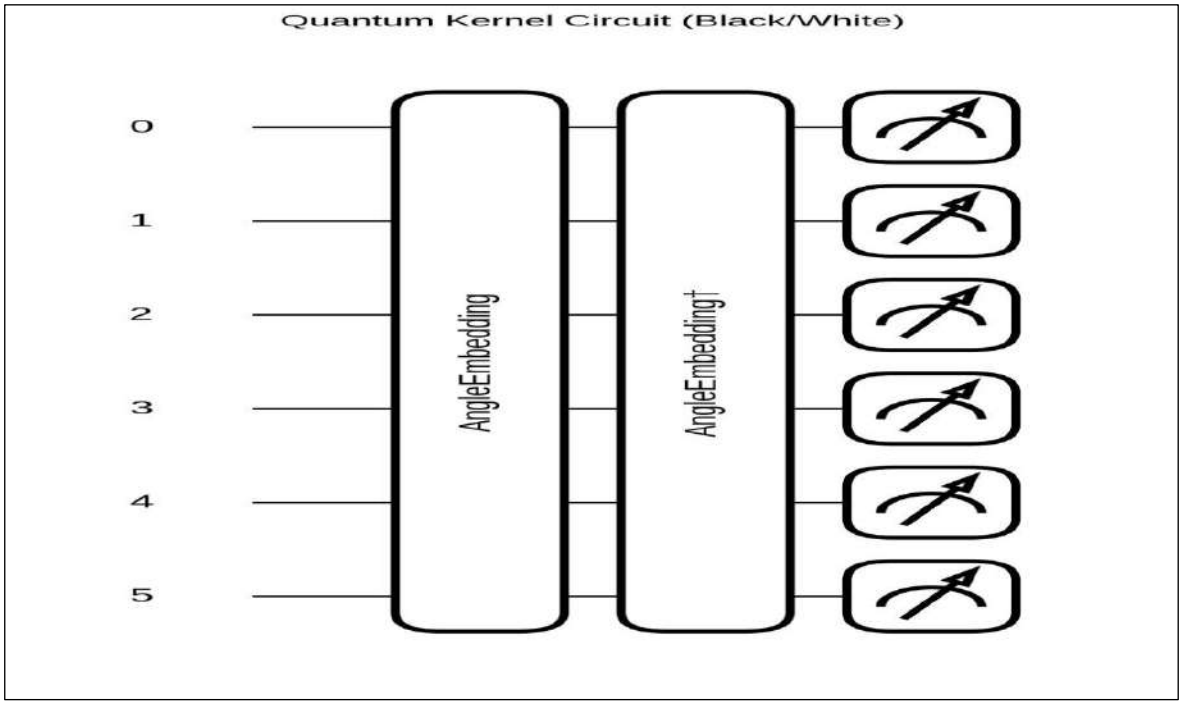

Figure 8: Quantum Kernel for Correlation between quantum states.
Source: Authors, (2026).

Figure 9 and Figure 10 provides the quantum generated circuits for quantum machine learning using classical neural Network and SVM. Figure 11 and Figure 12 highlights a ROC comparison (True Positive Rate Vs. False Positive Rate) of classical and quantum _inspired NN and SVM approaches on test set. From Figure 11, it is observed that AUC (area under the curve) for QISVM with 0.968 is better than its neural network counterpart having AUC of 0.904. Further, from Figure 12, it can be seen that classical machine algorithms (SVM and NN) outperform their quantum inspired ones by achieving more AUC of 0.979 and 0.962 respectively.

V.1 FIGURE OF MERIT

Further, several figures of merit metrics are used to evaluate the performance of the classical and quantum inspired neural network and SVM models which are presented in Figure 13 and Figure 14 respectively. Further, accuracy and loss comparison with respect to number of epochs are presented in Figures 15 and Figure 16 respectively, to understand the efficacy of the approach.

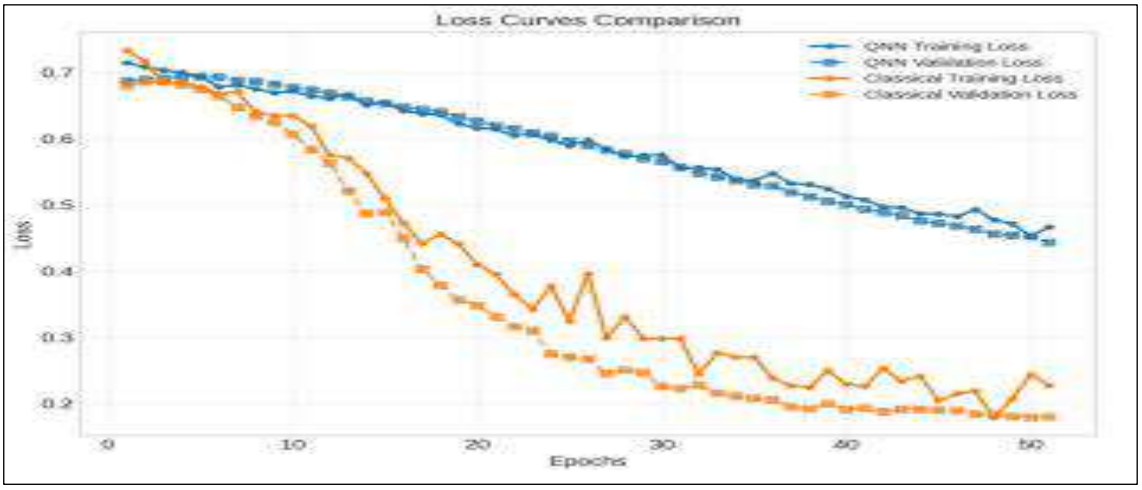

Figure 16: Loss comparison between classical and quantum inspired Neural network classifier.
Source: Authors, (2026).

Further, it is observed that QISVM performs better than QINN with high accuracy. Low loss, high Precision, high Recall, High f1 score and high AUC, makes it QISVM is a better choice in comparison to QINN. It is also observed that for the mental health dataset, the baseline classical algorithms performs better than their counterparts, might be due to overfitting but their effectiveness in dealing with highly imbalanced dataset with high dimensionality is a major concern, where QINN and QISVM wins the race. Hence, there are several threats to validity are identified which may be addressed for further research.

V.2 THREATS TO VALIDITY:

At first, there is possibly an internal threat to validity where small dataset sizes in mental health research may lead to overfitting, and the quantum simulator might not be able to emulate the behaviour of real quantum circuits perfectly at the present scenario. Secondly, external threats to validity pertains to generalizing the observations from a small available dataset attributing demographic variables such as sex and race, psychosocial characteristics, and clinical assessment data related to psychiatric symptoms to diverse adult populations. These challenges depending on the fidelity of feature representation may affect the prediction accuracy, may attributed to construct validity. Finally, technological threats to validity lie in initial NISQ phase of quantum hardware as of today, with restricting qubit count and circuit depth, where quantum inspired simulated results are envisaged of not fully extrapolate to real devices.

VI. CONCLUSIONS

In this paper, potential applications of quantum inspired neural network and SVM in efficient and fast detection of mental health illness of young adults re studied in detail. This research evaluates the performance of the QINN and QISVM models with their baseline classical models and observed that the performance of this quantum inspired models are limited by overfitting. While comparing between the two quantum inspired models, QISVM wins the race by having highest figure of merit in comparison to QINN. There are several threats to validity discussed in this research which encourages the interested researchers to explore further possibilities to apply this quantum inspired machine algorithms on several other large datasets and by developing some more potential algorithms in future.

ABSTRACT

In the current context of digital transformation, global challenges and the need to achieve sustainable development goals, organizations are increasingly in need of new management models based on a competency-based approach. The relevance of the study is due to the need to integrate individual, entrepreneurial and organizational competencies to ensure the sustainability and adaptability of organizations. The purpose of the study is to find out the relationship between these levels of competencies in the context of forming a competent organization as a tool for ensuring sustainable development. The methodological basis of the study is a content analysis of publications of 2021–2025 covering the transformation of competency-based approaches in the field of management. As a result of systematizing sources and building an analytical model, five key thematic areas of integrated competencies development were identified: strategic management, entrepreneurial education, digital transformation, corporate training, and sustainable development. The study revealed the increasing role of the digital environment in the formation of professional competence, the growing importance of interpersonal and social skills, and the need to unify management models in the global context. The practical significance of the results lies in the possibility of their application to the formation of internal policies of organizations, the development of staff training programs and the improvement of management strategies. The results obtained can serve as a basis for the development of indicators for assessing competencies in the practice of personnel management. The author suggests directions for further research, including empirical testing of the effectiveness of models of the integrated competency approach in specific industries and regions.

I. INTRODUCTION

In an era of global turbulence, accelerated digitalization, and growing environmental and social challenges, the problem of building a competent organization capable of operating effectively in an environment of uncertainty is becoming particularly relevant. Traditional views on management can no longer handle the requirements of sustainable development which requires them to be responsible to people and the environment as well as efficient with money. Here, using a competency-based approach is considered valuable for restructuring organizations thanks to the cooperation between personal, business and organizational levels of competencies. In the system, employee competencies play a key role by driving innovation, upholding a culture that lasts and reaching the set goals.

Only employees who carry interpersonal, cognitive, digital and value attitudes are truly able to drive change and help the organization adjust to ongoing changes easily. For this reason, understanding individual skills and talents within sustainable development matters both in management and HR matters. The aim of this article is to explore how organizational, entrepreneurial and personal skills of employees are connected in the creation of a competent organization that follows the values of sustainable growth. By identifying what influences how these competencies affect each other, we can develop a different way of making decisions for managers aimed at making companies more flexible, inventive and responsible in the modern world.

II. LITERATURE REVIEW

Today's scholars use an approach that examines various aspects of how a competent organization forms in support of sustainable development, by studying links between organizational, entrepreneurial and individual competencies. The development of employee abilities in digital contexts is widely studied, pointing out that competencies such as digital literacy, working with people and keeping up with learning are essential for organizational adaption [1], [2]. Currently, organizational effectiveness is considered primarily by focusing on what skills workers and organizations have and researchers argue that to secure organizations' futures, legal, managerial and digital models are necessary [3-5]. On the other hand, entrepreneurial actions are considered important for change in complex systems [6-8], as they depend on initiative, innovative ideas and taking well-planned risks.

Different professionals shape and outline competencies to focus on the main issues and skills needed in management, business or education. To illustrate, by [4] explains how digital transformation and managerial change lead companies to build new competencies for individuals as well as for the organization as a whole. According to [9] consider that value, ethics and leadership skills are important for sustainable entrepreneurship. In their turn, by [10] pay attention to the interpersonal and civic abilities thatenable an employee to play a role in innovations and important societal matters. According to [11] look into the mental and emotional aspects of being an entrepreneur, whereas by [12] argue that an emphasis on the environment and innovation is needed for reaching sustainable development goals. It confirms that employee skills are not simple and analysis of all skills is important for the concept of a competent organization.

Analyzing closely how different competencies affect each other explains why an interdisciplinary approach is necessary, using aspects from economics, law and psychology [11-14]. Looking at how interpersonal skills and civic-mindedness help people start businesses is starting to attract more focus [9], [10], [15]. According to [16], [12], [17], sustainable development requires a shift in company culture in line with global sustainability goals. The issues of environmental responsibility, natural resource management, and investment in intelligent technologies are studied as key elements of sustainable strategic management [18], [19]. At the same time, attention is drawn to the decentralization of governance and the development of institutions' capacity for innovation [20], [21], which creates a favorable environment for the harmonization of organizational structures.

At the level of applied models, researchers propose tools for leadership, digital transformation, and institutional project management [22], [23] that ensure the operationalization of integrated competencies. Particular attention is also paid to social entrepreneurship as a form of combining economic efficiency and social impact [9], [24], [25]. Of particular importance for the study are publications that focus on the sectoral and legal aspects of competence development. In particular, [8] reveal the specifics of entrepreneurial competencies in the gastronomy sector, demonstrating the importance of adaptive management and strategic thinking. In turn, [24] analyzes the regulatory framework for digital governance in the EU, which forms a conceptual framework for the development of organizational responsibility in a networked society.

Further analysis of the publications shows that modern scientific thought also covers aspects of sustainable leadership, overcoming digital inequality, and introducing innovations in public administration. For example, by [9], [12] focus on the role of sustainable entrepreneurship in achieving the Sustainable Development Goals (SDGs), emphasizing the importance of developing innovative thinking and value orientations of leaders. The study by [10] emphasizes the development of knowledge and interpersonal competencies as a prerequisite for civic engagement and entrepreneurial intent. Some works highlight case studies from developing countries, demonstrating the link between socio-economic dynamics and the formation of a competent organization [15], [26].

According to [18] emphasize the impact of investments in artificial intelligence on sustainable development, while by [17] analyze the role of natural resources in transformational processes. Significant attention is also paid to fiscal policy as a tool to support organizational change within the sustainable development model [19]. Studies of political governance and the internal organization of institutions that reveal opportunities for decentralization, development of managerial autonomy and adaptability bring an additional perspective [20], [21]. At the same time, the fundamental concepts of ideological and systemic thinking are outlined in [14], [23], which substantiate the value base of organizational engineering.

In the modern scientific discourse, employee competencies are mostly defined as a combination of knowledge, skills, personal traits, and behavioral models necessary for the effective performance of professional tasks in the context of digitalization and organizational change [1],[4]. At the same time, competencies in the context of sustainable development cover a much broader spectrum – they include values, environmental awareness, social responsibility, and the ability to act for the benefit of the common future [9], [12]. Thus, sustainable development requires not only professional, but also moral and civic maturity of the employee, which transforms the idea of the content and goals of the competency-based approach. Despite this, the mechanisms for integrating organizational, entrepreneurial and individual competencies into a single management system, as well as empirical models for assessing their effectiveness in achieving sustainable development goals, remain insufficiently researched.

III. METHODS

The study is based on an interdisciplinary approach using the methods of systematization of scientific sources, comparative analysis of competence concepts and analytical modeling of the relationship between key levels of employee competencies. Elements of conceptual analysis were used to identify the main categories characterizing organizational, entrepreneurial and individual competencies in the context of sustainable development.

The analytical model was built on the basis of generalization of current theoretical approaches and comparison of practical examples of implementation of competence strategies in different types of organizations. This approach made it possible to formu-late a generalized structure of competence interaction as a basis for assessing the adaptability and sustainability of organizations in a dynamic environment.

VI. RESULTS AND DISCUSSION

Modern theoretical approaches to the definition of *a "competent organization"* focus on its ability to adapt to a changing environment, effectively manage knowledge, develop human capital, and ensure long-term sustainability in the context of sustainable development. Such an organization not only possesses a set of structural and procedural competencies, but is also able to integrate individual and entrepreneurial competencies into strategic activities. The formation of a competent organization is closely related to the concepts of a learning organization, network management, and adaptive leadership, where interpersonal skills, digital literacy, and the ability to think innovatively play an important role [4]. Studies also emphasize that organizational competence is not a static state, but a dynamic process of continuous development in the face of sustainability challenges [10].

Some authors emphasize the importance of entrepreneurial competencies within the organizational structure, which allows for the effective implementation of innovative projects and the transformation of market opportunities into sustainable results [6], [9]. At the same time, personal characteristics of employees, for example, their motivation for growth, their flexibility to communicate between fields and their sense of social duty, help develop a lasting company culture [11]. According to [12], a competent organization in sustainable development demonstrates economic efficiency, promotes social justice and cares about the environment. As a result of this approach, the organization forms all-around competencies that sustain it for a long time and keep it competitive.

Organizational, entrepreneurial and individual abilities depend on each other to shape the competence of an organization. An organization's management, organizing processes and strategy depend on its organizational competencies and its innovative, flexible and risk-taking approach comes from entrepreneurial competencies. Competencies of each individual shape the human capital, encourage the production of new ideas and guarantee strong relationships among members of the organization. Table 1 provides a comparative description of the key features of each type of competence and their impact on the formation of a competent organization8.

Table 1: Interrelation between organizational, entrepreneurial and individual competencies in the context of forming a competent organization.

Type of competencies	Main features	Key role in building a competent organization	Typical level of realization
Organizational	Process management, strategic planning, internal coordination	Formation of a stable management structure	Meso-level (organizational)
Entrepreneurial	Initiative, innovation, and risk-taking	Generating new ideas and transforming them into practical solutions	Micro- and meso-level
Individual	Personal qualities, interpersonal skills, motivation to learn	Ensuring effective interaction and adaptability of staff	Micro-level (individual)
Integration interaction	Mutual reinforcement, knowledge sharing, joint participation in decision-making	Systemic synergy that ensures sustainable development of the organization	All levels: micro - meso - macro

Source: [4], [9-12].

The data presented here show that it is the interaction of different types of competencies that creates the conditions for the formation of a competent organization capable of implementing the principles of sustainable development. An organization is most effective when its structure allows entrepreneurial initiatives to be implemented through individual involvement and is supported by a systematic organizational framework. In such a model, there is not just a combination of competencies, but their qualitative integration, which becomes the key to long-term sustainability.

In the context of an integrated approach to the formation of a competent organization, the individual level of competencies, which reflects the professional potential of the employee as a subject of change, deserves special attention. Taking into account the goals of sustainable development, it is advisable to identify key employee competencies that contribute to the environmental, social and economic sustainability of the organization. Table 2 provides a generalized list of such competencies.

Table 2: Key employee competencies in the context of sustainable development.

Competence group	Content / Examples	Implications for sustainable development
Personal (self-awareness)	Motivation to learn, self-reflection, responsibility	Builds the ability to self-develop and adapt to change
Interpersonal	Communication skills, emotional intelligence, empathy, constructive interaction	Supports social cohesion and corporate ethics
Values and worldview	Ethical consciousness, environmental responsibility, focus on social justice	Ensures compliance with the Sustainable Development Goals (SDGs)
Cognitive	Critical thinking, ability to solve complex problems, systemic vision	Promotes informed decision-making in a complex environment
Innovative and entrepreneurial	Initiative, creativity, change management	Enables innovation and organizational flexibility
Digital	Digital literacy, the ability to use digital technologies in sustainable practices	Allows working efficiently in the digital environment and reduce the ecological footprint
Environmental	Understanding of environmental risks, environmental behavior, support for sustainable solutions in everyday work	Contributes to reducing the negative impact of the organization's activities on the environment

Source: [1], [2], [4], [9-12].

Assessing the relationship between organizational, entrepreneurial and individual competencies requires the creation of a holistic methodological model based on the principles of sustainable development. Such a model should take into account not only the functional interaction of competencies, but also their contribution to the social, economic and environmental sustainability of the organizational system. The model should integrate the levels of competencies, channels of their interaction, and mechanisms of influence on the organization's performance. Figure 1 shows the proposed model based on the logic of mutual reinforcement of the components of a competent organization.

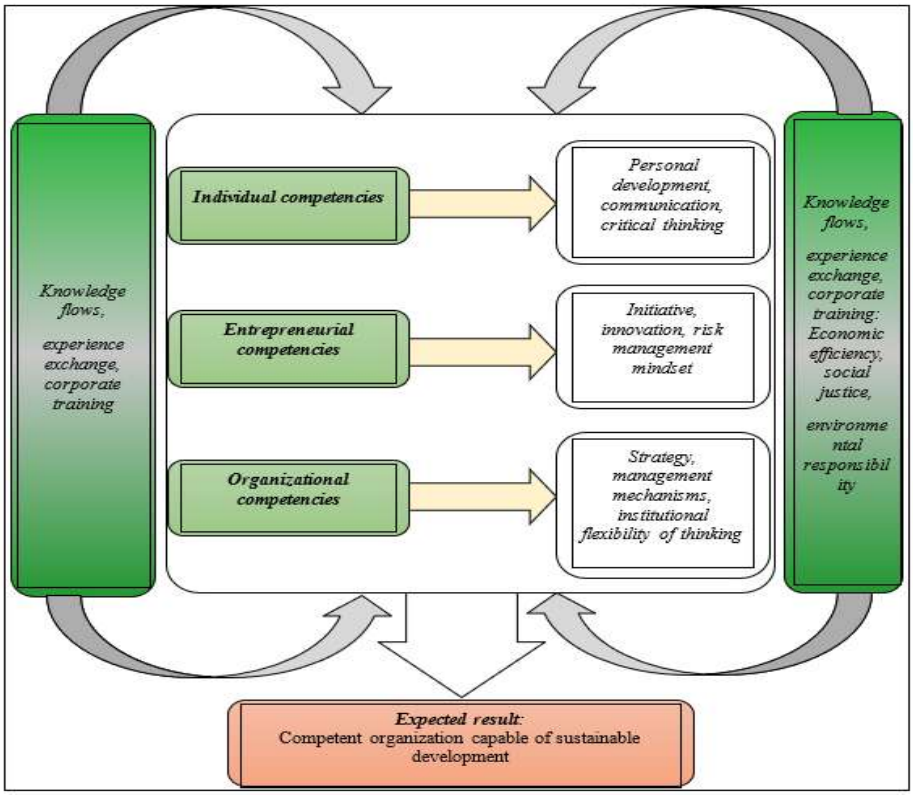

Figure 1: Methodological model for assessing the relationship between organizational, entrepreneurial and individual competencies, taking into account the principles of sustainable development.
Source: [2], [4], [9], [11], [12].

The proposed model allows for a holistic assessment of the level of harmonization of different types of competencies in an organization, taking into account sustainability criteria. Its application provides an analytical basis for strategic planning and development of management approaches that meet the requirements of a sustainable future. In the future, this model can be adapted to different types of organizations, from educational institutions to small and medium-sized businesses.

The introduction of competency-based approaches in the activities of modern organizations is increasingly seen as a strategic direction for the transformation of management, educational and production systems. Growing attention to sustainable development, digitalization, and innovative management approaches leads to the integration of individual, entrepreneurial, and organizational competencies at different levels. In order to objectively analyze these trends, the author conducted a content analysis of scientific sources and empirical studies on the application of competency-based approaches in the practice of organizations.

To collect quantitative data, there were used a content analysis of 42 publications in professional journals (2021–2025) that discuss the application of competency models in business, education, and the public sector. The sources were selected on the basis of relevance to the topic of competence integration and sustainable development principles, which ensured analytical completeness and thematic coverage. Authors identified 5 main areas of implementation (key emphases): strategic management, entrepreneurial education, corporate training, sustainable development, and digital transformation. Each of the areas was quantitatively coded to identify the frequency of their presentation in the studied sources. Based on the author's systematization, the data were presented in the form of a conditional percentage distribution for further visualization in the form of a graph, which allowed tracing the dynamics of shifting emphasis in scientific discourse (Figure 2).

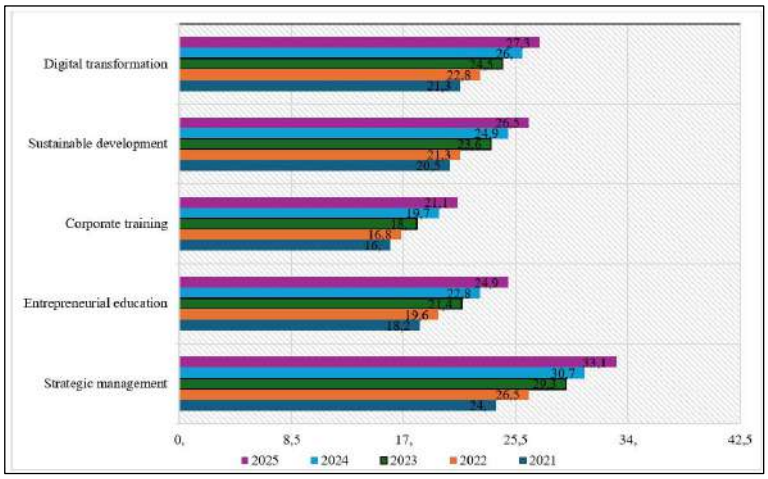

Figure 2: Dynamics of the representation of competency-based approaches in key areas of organizational development (2021–2025).
Source: [2], [3], [9], [11], [12].

In the dynamics from 2021 to 2025, there is a steady increase in the share of publications and practical cases devoted to strategic management – from 24.0% to 33.1%, which indicates an increase in the role of the competency approach in management systems. Similarly, digital transformation has strengthened its position by 6.0%, and the area of sustainable development has grown by 6.0% – from 20.5% to 26.5%, which correlates with global sustainable development goals. Corporate training (+5.1%) and entrepreneurial education (+6.7%) were the least dynamic, but they also show a positive trend. Thus, the data obtained confirm the gradual increase in the importance of competency-based approaches in many areas of organizational activity.

This requires further improvement of the mechanisms for implementing competencies through the development of digital tools, integration of training into management processes, and ensuring ecosystem interaction.Comprehensive integration of individual, business and organizational competencies requires targeted actions by management structures. In the context of sustainable development, it is of particular importance to create an environment in which competencies do not just exist separately but interact synergistically, creating the basis for innovative and responsible activities. Below are practical recommendations aimed at developing such integrated competencies.

1. *Implementation of cross-cutting corporate training programs.* It is recommended to develop modular educational programs that cover individual soft skills, entrepreneurial thinking and strategic management. Training should be continuous, adaptive, and accessible to all levels of staff, which will contribute to the formation of organizational competence. Particular attention should be paid to learning through real-life cases of sustainable management.
2. *Create cross-functional teams to manage sustainable development projects.* The formation of cross-functional working groups allows combining competencies from different areas, from finance to social impact. This approach helps to increase the efficiency of decision-making, reduce barriers between departments, and create a culture of shared responsibility. Teams should act on the principles of open knowledge sharing.
3. *Institutionalize feedback mechanisms and internal consulting.* To support the development of integrated competencies, it is worth implementing systems for regular evaluation of employees and managers, as well as internal platforms for sharing experiences. This allows responding quickly to changes, identify weaknesses and ensure horizontal learning in the organization.
4. *Integrate sustainability goals into KPIs and organizational strategies.* Sustainable development should be not only a declarative principle, but also a part of specific evaluation indicators (KPIs) for employees and structural units. This allows measuring the effectiveness of implementing the competencies not only in terms of results, but also in terms of contribution to the environmental and social responsibility of the organization.

The application of these recommendations will allow the organization to form an integrated competency ecosystem that will ensure not only operational efficiency but also long-term sustainability. Integrated competencies are the basis for building adaptive management in the face of the challenges of sustainable development, digital transformation and global competition. The obtained results confirmed the existence of a stable trend towards the integration of organizational, entrepreneurial and individual competencies in management practice, which is consistent with the provisions of [2] and [1], who emphasize the importance of the digital environment for the development of professional competence.

The analysis of scientific sources has demonstrated the growing attention to an interdisciplinary approach, where digital transformation, entrepreneurial activity and strategic management form a synergistic model of a competent organization. At the same time, it was found that the approaches to identifying priority competencies differ significantly: some authors [3], [4] focus on the institutional and legal design of competency models, while others [6], [10] focus on the micro level – the formation of individual entrepreneurial motivation. Instead, some researchers, such as [14], [23], criticize the excessive fragmentation of the competency approach and call for the creation of a unified ideological management framework that would allow for the preservation of the integrity of organizational development.

In this context, the results of our study do not fully coincide with the views of these authors, as the authors believe that it is precisely the flexibility and variability of competencies that ensure the adaptability of an organization in the context of sustainable development, which is confirmed by the findings of [12], [15]. It is also important to note that while by [8] point out the importance of industry specificity in the formation of competencies, our study supports a universal approach where key skills can be scaled regardless of the field of activity. Some discrepancies with the views of other researchers can be explained by differences in the contexts of the analyzed countries and organizational structures. For example, [26], [18] consider sustainable development mainly through the prism of public policy, while our approach is based on a model of interaction between three levels of competencies – individual, organizational, and entrepreneurial.

This expands the traditional view of the sources of change, as the initiative is recognized not only as vertical (top-down) but also as horizontal. Thus, the results of the study support the hypothesis that it is advisable to combine different types of competencies within sustainable management. At the same time, the issue of empirical verification of the effectiveness of the proposed models in specific sectoral and regional conditions remains open. This points to the need for further interdisciplinary and cross-country research that will allow adapting the concept of a competent organization to a changing global environment.

V. CONCLUSION

The results of the study allowed us to highlight a new perspective on the formation of a competent organization as a system based on the interaction of individual, entrepreneurial and organizational competencies in the context of sustainable development. It has been established that the efficiency of such an organization increases when strategic management, value leadership, and digital adaptation are balanced. The expected results were mostly confirmed, but in practice, there were also unexpected emphases on the interpersonal and social aspects of competencies that had previously remained on the periphery of attention. The novelty of the study lies in the construction of an analytical framework for the integration of competencies at three levels, which allows to adapt management models to the conditions of rapidly changing environment.

The limitations of the study are related to the lack of quantitative verification of the effectiveness of the proposed approaches in different types of organizations, which requires expanding the empirical base. The practical significance of the study lies in the possibility of using the results of the study to improve personnel policy, develop internal training programs and strategic planning in educational, government and business structures. Further research should focus on the development of tools for measuring the level of formation of integrated competencies, studying the industry specifics of their implementation, and developing digital solutions to support competency development under conditions of uncertainty.

ABSTRACT

Mental health screening in higher education is crucial for early detection of psychological issues among students. With digital technologies increasingly used in student support, this study evaluated the effectiveness and user experience of mobile-based versus traditional paper-and-pencil mental health screenings at Cagayan State University–Carig Campus. Thirty-three students completed assessments for depression, anxiety, and stress using both methods in a quasi-experimental design. Results revealed a significant difference in depression scores between methods, indicating that the screening format influences reporting of depressive symptoms. No significant differences were found for anxiety and stress, suggesting both methods are comparable for these conditions. Students preferred the mobile-based screening, highlighting greater comfort, privacy, ease of use, and accessibility. Overall satisfaction favored the digital method. The study concludes that mobile-based screening offers a user-friendly and efficient alternative that is psychometrically similar to traditional approaches. It recommends integrating mobile screening tools into university mental health services to enhance student support and accessibility.

I. INTRODUCTION

Mental health has progressively been recognized as a critical component of overall well-being, particularly among young adults in higher education institutions who are exposed to academic pressure, social demands, and developmental transitions. Globally, depression and anxiety have been identified as leading contributors to the burden of disease, necessitating the early detection of mental health concerns through reliable screening mechanisms [1], [2]. Within academic environments, mental health screening plays a vital role in identifying students at risk and facilitating timely interventions, especially when evidence-based and psychometrically sound tools are employed [2]. However, despite the availability of validated instruments, the effectiveness of mental health screening is strongly influenced not only by measurement accuracy but also by the way assessments are administered and experienced by users.

II. THEORETICAL REFERENCE

Historically, paper-and-pencil screening tools have been the dominant method for assessing mental health concerns such as depression, anxiety, and stress. These traditional methods have demonstrated acceptable reliability and validity across diverse populations [3], [4]. Nonetheless, several studies have been raised concerns regarding their practicality, efficiency, and potential influence on response behavior. Paper-based assessments may increase respondent self-consciousness, reduce perceived privacy, and heighten evaluation anxiety, particularly when sensitive psychological information is involved [5]. Moreover, face-to-face or paper-administered survey have been shown to produce greater variability in responses for subjective indicators compared to self-administered digital formats [4], suggesting that the mode of administration itself may affect mental health screening outcomes.

Additionally, Traditional mental health assessments suffer from biased, infrequent self-reports that poorly capture daily functioning. Mobile apps and wearables provide real-time monitoring of symptoms and behavior. Yet, challenges remain in off-the-shelf tool reliability, user adoption, and clinical data use [6]. Advancements in mobile and digital technologies have led to the rapid expansion of mobile health (mHealth) solutions for mental health screening and assessment. Mobile applications have been increasingly utilized to improve accessibility, efficiency, and scalability of mental health services, particularly among populations with limited access to traditional care [7], [8]. Systematic reviews have demonstrated that mobile and web-based mental health screening tools show negligible differences in psychometric properties when compared to their paper-and-pencil counterparts, particularly for widely used instruments such as the PHQ-9, CES-D, and BDI-II [2], [9], [10].

These findings support the validity and reliability of mobile-based screening as a viable alternative to traditional assessment formats. More over, in clinics, accurate pain quantification is crucial. Electronic pain scales speed up data collection and analysis over paper methods. Smart tech in pediatric/adult pain apps could enable reliable, user-friendly assessments, enabling early detection to boost quality of life and reduce school/work absences if widely adopted [11]. There are also studies that evaluates two key aspects of mHealth apps: (1) their effectiveness in reducing maternal depression and/or anxiety symptoms during pregnancy or the first postpartum year, and (2) the quality of commercially available apps targeting perinatal depression and/or anxiety [12]

Beyond psychometric equivalence, user experience and usability have emerged as essential determinants of engagement and acceptability in digital mental health tools. Research consistently indicates that usability factors such as ease of use, interface clarity, accessibility, and efficiency significantly influence whether individuals are willing to complete and continue using mental health applications , [8]. Studies examining user reviews and expert evaluations have emphasized that poor usability, lack of personalization, and concerns regarding privacy and security are among the primary reasons for discontinuation of mental health apps , [7]. Conversely, applications that are intuitive, customizable, and transparent about data security tend to receive higher acceptability and satisfaction ratings.

Mental health is vital but underserved due to stigma and counselor shortages, limiting traditional service use. Mobile health apps offer a promising alternative, yet few studies evaluate if they truly meet user needs [13]. A systematic review that examines the increasing number of smartphone applications (apps) developed for physical and mental health. It evaluates the effectiveness of these applications in treating various mental health conditions, focusing on user-centered approaches [14] . Another study tested the usability of the PeerTECH smartphone app in community mental health via semi structured interviews, participants found it relevant for self-managing mental/physical health, offered feedback on features and Norwegian adaptations, and deemed it easy for users/peers to navigate [15].

Emotional experiences during mental health assessment have also been found to play a significant role in shaping users' perceptions of screening tools. Drawing on control-value theory and mobile learning theory, demonstrated that users' emotions toward both technology and content significantly predicted engagement and perceived learning outcomes [16]. Similarly, it was found that enjoyment was positively associated with usability, whereas boredom, frustration, and anxiety were negatively related to users' experiences with mental health assessment tools [17]. These findings underscore the importance of examining not only the technical effectiveness of screening methods but also the emotional and experiential dimensions of their use.

Comparative studies between digital and traditional assessment modalities further suggest that certain mental health constructs respond differently to administration formats. There are studies that College students endorse high rates of mental health problems. While many colleges offer on-campus services, many students who could benefit from mental health services do not receive care. Indeed, nearly half of students who screen positive for depression, for example, do not receive treatment. Digital mental health programs, such as those delivered via mobile apps, may help expand access to mental health care and resources. This mixed-methods study aims to examine the uptake and effectiveness of an implementation of IntelliCare for College Students, a self-guided app-based mental health platform, on two university campuses [18].

While anxiety and stress measures often demonstrate stability and equivalence across paper and digital platforms, depression scores appear more sensitive to contextual and experiential factors related to assessment modality [3], [5]. These modality effects reinforce the need for empirical comparisons that examine both screening outcomes and user experience simultaneously. Moreover, research on mobile assessments among youth and college students highlights that digital tools may facilitate more honest self-disclosure due to increased privacy, autonomy, and reduced fear of judgment [19], [20]. According to some studies, those with mental health conditions showed higher use of digital tools like computers and smartphones for health searches, test results, provider communication, and info sharing, even after adjusting for sociodemographics. However, privacy/security concerns made them more likely to withhold information from providers, highlighting the need for better data protection to maximize tech benefits in mental health care [21].

Recent literature has also emphasized the broader acceptability and feasibility of digital mental health interventions across diverse populations. Systematic reviews have shown that the majority of digital mental health interventions for depression and anxiety are positively accepted by users, particularly when grounded in evidence-based frameworks such as cognitive behavioral therapy [22]. Studies have further demonstrated that mobile mental health apps are best viewed as complementary tools rather than replacements for traditional mental health services, supporting early detection, monitoring, and engagement [23], [1]. Additionally, emerging evidence supports the integration of advanced technologies, including machine learning and personalized app features, to enhance screening accuracy and user relevance [24], [25].

Further, Despite the popularity of mental health apps, it is unknown if they are actually used by those with mental illness. There are studies assessed whether differences in clinic setting may influence the use of mental health apps and which factors influence patient perception of apps [26]. There are also studues that mobile mental-health trackers are mobile phone apps that gather self-reported mental-health ratings from users. They have received great attention from clinicians as tools to screen for depression in individual patients. While several apps that ask simple questions using face emoticons have been developed, there has been no study examining the validity of their screening performance [27]. Despite the growing body of international literature, there remains a scarcity of empirical studies examining mental health screening modalities within Philippine higher education institutions, particularly state universities.

Given the increasing reliance on digital platforms among Filipino college students, it is essential to evaluate whether mobile-based mental health screening can enhance efficiency, accuracy, and user preference while maintaining psychometric integrity. Thus, this study aimed to compare the effectiveness and user experience of mobile-based mental health screening with the traditional paper-and-pencil method among college students. Specifically, it sought to determine whether the use of a mobile application enhanced efficiency, accuracy, and user preference when completing a standard mental health screening tool. By integrating outcome-based and experience-based evaluation, this study intended to contribute evidence that may guide the adoption of student-centered, technology-supported mental health screening practices in higher education.

III. MATERIALS AND METHODS

III.1 RESEARCH DESIGN

This study employed a quasi-experimental research design to examine and compare the mental health screening results and user preferences of college students when administered through mobile application–based and paper-and-pencil screening methods. The quasi-experimental design was deemed appropriate because the study involved the comparison of two screening modalities without random assignment of participants to independent groups. Instead, the same group of respondents underwent both screening methods, allowing for within-subject comparison of mental health outcomes and preferences. This design enabled the researchers to determine differences between screening methods while maintaining ethical and practical feasibility within an academic setting.

III.2 RESEARCH PARTICIPANTS

The participants of the study consisted of thirty-three (33) college students currently enrolled at Cagayan State University–Carig Campus. The respondents were selected using a purposive sampling technique, as participation was based on willingness and eligibility to complete both mobile and paper-and-pencil mental health screening tools. All participants were officially enrolled during the conduct of the study and voluntarily agreed to take part after being informed of the study's objectives, procedures, and ethical considerations. The sample size was considered sufficient for within-subject comparison using nonparametric and paired statistical analyses.

III.3 DATA DESCRIPTION

The data collected in this study included respondents' mental health screening results and their preferences regarding the screening methods used. Mental health data covered three dimensions: depression, anxiety, and stress, classified into categorical levels such as normal, mild, moderate, severe, and extremely severe based on the scoring guidelines of the screening instruments. Preference data were gathered using a structured questionnaire measuring students' perceptions of ease of use and efficiency, accessibility, comfort and privacy, and overall satisfaction and preference for each screening method. All responses were quantified using Likert-scale ratings and numerical scores to facilitate statistical analysis.

III.4 RESEARCH PROCEDURES

Prior to data collection, permission to conduct the study was secured from the appropriate university authorities. The respondents were then oriented regarding the purpose of the study, the procedures involved, and their rights as participants, including confidentiality and voluntary participation. Informed consent was obtained from all respondents. The participants were first asked to complete the mental health screening using one method, followed by the alternative method, ensuring that all respondents experienced both the mobile application and paper-and-pencil screening tools. After completing both screenings, the respondents answered the preference questionnaire evaluating their experiences with each method. All data were collected within a controlled timeframe to ensure consistency in administration.

III.5 DATA ANALYSIS

The collected data were analyzed using appropriate descriptive and inferential statistical tools. Frequency counts and percentages were used to describe the levels of depression, anxiety, and stress obtained from both screening methods. Weighted means were computed to determine the level of students' preference for each screening modality. To determine significant differences in mental health screening results between the mobile and paper-and-pencil methods, the Wilcoxon Signed Ranks Test was employed. Meanwhile, paired samples t-tests were used to examine significant differences in students' preferences across the different dimensions. All statistical analyses were conducted at a 0.05 level of significance.

IV. RESULTS AND DISCUSSIONS

IV.1 LEVEL OF MENTAL HEALTH RESULTS USING MOBILE APPLICATION AND PAPER-AND-PENCIL METHOD SCREENING TOOL

IV.1.1 Level of Mental Health Results using Mobile Application Screening Tool

The Table 1 shows that the largest proportion of respondents assessed through the mobile application reported moderate depression (36.40%), followed by mild depression (30.30%), while smaller proportions fell under severe (18.20%), normal (9.10%), and extremely severe (6.10%) levels. This distribution suggests that the mobile screening tool was sensitive in detecting varying degrees of depressive symptoms among college students, particularly within the mild-to-moderate range. Such findings are consistent with studies indicating that mobile-based mental health screening tools are effective in capturing subclinical and moderate depressive symptoms due to their perceived privacy, reduced social desirability bias, and ease of self-disclosure [2], [9].

Moreover, previous literature emphasizes that digital screening environments encourage more honest responses among young adults, thereby improving the detection of emotional distress that might otherwise remain underreported in traditional settings [23], [17].

Table 1: Frequency and Percentage Distribution of Respondents' Level of Mental Health Results using mobile application screening tool along Depression.

Level	Frequency	Percent
Extremely Severe	2	6.10
Severe	6	18.20
Moderate	12	36.40
Mild	10	30.30
Normal	3	9.10
Total	33	100.00

Source: Authors, (2026).

The Table 2 displays that extremely severe anxiety (33.30%) constituted the highest proportion of respondents, followed by moderate (24.20%) and severe anxiety (24.20%), while fewer respondents fell under normal (12.10%) and mild (6.10%) categories. This pattern indicates a substantial burden of anxiety symptoms among college students when screened using a mobile application. The heightened detection of severe anxiety aligns with existing research suggesting that mobile mental health tools enhance symptom recognition by allowing respondents to complete assessments in non-threatening, familiar environments, which may intensify self-awareness of anxiety-related symptoms [28], [22]. Furthermore, mobile platforms have been found particularly effective in identifying anxiety symptoms due to their immediacy, anonymity, and reduced fear of judgment, especially among student populations [7], [19].

Table 2: Frequency and Percentage Distribution of Respondents' Level of Mental Health Results using mobile application screening tool along Anxiety.

Level	Frequency	Percent
Extremely Severe	11	33.30
Severe	8	24.20
Moderate	8	24.20
Mild	2	6.10
Normal	4	12.10
Total	33	100.00

Source: Authors, (2026).

The Table 3 shows that more than half of the respondents were classified as normal (54.50%) in terms of stress levels, while severe stress (18.20%), mild stress (15.20%), and moderate stress (12.10%) accounted for the remaining distribution. This finding suggests that while stress is present among college students, a majority experience manageable stress levels when assessed through a mobile screening tool. The results are supported by literature indicating that mobile assessments can accurately capture stress patterns by enabling real-time or reflective self-reporting, which improves recall accuracy and contextual relevance [1], [8]. Additionally, mobile tools have been shown to normalize the screening experience, potentially reducing stress amplification during assessment compared to traditional paper-based methods [5].

Table 3: Frequency and Percentage Distribution of Respondents' Level of Mental Health Results using mobile application screening tool along Stress.

Level	Frequency	Percent
Severe	6	18.20
Moderate	4	12.10
Mild	5	15.20
Normal	18	54.50
Total	33	100.00

Source: Authors, (2026).

IV.1.2 Level of Mental Health Results using Paper-And-Pencil Method Screening Tool

The Table 4 reveals that respondents assessed using the paper-and-pencil method were more frequently classified under extremely severe depression (21.20%), with mild (24.20%) and moderate depression (24.20%) showing equal proportions, followed by severe (18.20%) and normal (12.10%) levels. Compared to mobile screening results, the paper-based method appears to yield a higher proportion of extreme depression classifications. This aligns with prior research indicating that traditional formats may increase response caution or overreporting due to perceived formality and test-like conditions [3], [4]. Additionally, paper-based assessments may heighten respondent self-monitoring, potentially influencing symptom severity ratings among students [5].

Table 4: Frequency and Percentage Distribution of Respondents' Level of Mental Health Results using paper-and-pencil method screening tool along Depression.

Level	Frequency	Percent
Extremely Severe	7	21.20
Severe	6	18.20
Moderate	8	24.20
Mild	8	24.20
Normal	4	12.10
Total	33	100.00

Source: Authors, (2026).

The Table 5 shows that nearly half of the respondents were classified as having extremely severe anxiety (48.50%), while moderate anxiety (30.30%) also accounted for a substantial portion, with minimal representation in mild (3.00%) and severe (6.10%) categories. This concentration of extreme anxiety scores suggests that paper-and-pencil assessments may intensify symptom endorsement, possibly due to reduced perceived privacy and increased performance anxiety during completion. Previous studies indicate that traditional assessment formats may inadvertently elevate reported anxiety levels, particularly when respondents feel observed or constrained by time and setting [3], [17]. Such findings reinforce the importance of considering modality effects when interpreting anxiety screening results [4].

Table 5: Frequency and Percentage Distribution of Respondents' Level of Mental Health Results using paper-and-pencil method screening tool along Anxiety.

Level	Frequency	Percent
Extremely Severe	16	48.50
Severe	2	6.10
Moderate	10	30.30
Mild	1	3.00
Normal	4	12.10
Total	33	100.00

Source: Authors, (2026).

The Table 6 indicates that most respondents were classified as normal (51.50%) in stress levels, followed by severe stress (21.20%), while mild and moderate stress both accounted for 12.10% each, and extremely severe stress (3.0%) was minimal. This distribution closely mirrors mobile-based stress results, suggesting relative equivalence between formats in stress detection. Literature supports this comparability, noting that stress, as a more situational and less stigmatized construct, tends to yield consistent results across administration modes [2], [5]. This reinforces findings that paper and digital formats are largely interchangeable for stress screening when validated tools are used [10].

Table 6: Frequency and Percentage Distribution of Respondents' Level of Mental Health Results using paper-and-pencil method screening tool along Stress.

Level	Frequency	Percent
Extremely Severe	1	3.0
Severe	7	21.2
Moderate	4	12.1
Mild	4	12.1
Normal	17	51.5
Total	33	100.0

Source: Authors, (2026).

IV.2 LEVEL OF STUDENTS' PREFERENCE FOR EACH SCREENING TOOL

The Table 7 shows that students expressed a strongly positive preference for the mobile screening method, as reflected by an overall weighted mean of 4.34 (Strongly Agree), with consistently high ratings across ease of use, accessibility, comfort and privacy, and overall satisfaction. Notably, comfort and privacy yielded the highest category mean (4.49), indicating that students felt more relaxed, less judged, and more confident about data security when using mobile screening tools. These findings are strongly supported by literature emphasizing that mobile mental health applications enhance user comfort, perceived confidentiality, and engagement, which are critical factors in screening adherence among young adults [28], [22], [20]. The preference for mobile screening reflects broader trends in digital mental health acceptance within student populations [29].

Table 7: Level of students' preference using mobile screening method.

Dimensions	Statements	Mean	Descriptive interpretation
Ease of Use and Efficiency	1. I found the process of completing the screening to be easy to understand and follow. "	4.21	Strongly Agree
	2. I found the method easy to use and intuitive	4.12	Agree
	3. The screening process is completed within a reasonable amount of time	4.12	Agree
	4. I can finish the screening without feeling rushed or overwhelmed	4.30	Strongly Agree
	Category Mean	**4.19**	**Agree**
Accesibility	5. The method felt free of technical issues or unnecessary hurdles "	3.79	Agree
	6. Completing the screening using this method felt convenient for my schedule	4.33	Strongly Agree
	7. I would be able to easily access this screening method whenever I needed it	4.30	Strongly Agree
	8. The instructions and layout were clear regardless of where I completed the screening	4.39	Strongly Agree
	Category Mean	**4.20**	**Strongly Agree**
Comfort and Privacy	9. I felt comfortable and relaxed while using this method to answer the questions "	4.48	Strongly Agree
	10. I felt confident that my answers were private and secure using this method	4.55	Strongly Agree
	11. This method made it easy to concentrate on the questions without distraction	4.33	Strongly Agree
	12. Using the the method makes me feel less judged	4.61	Strongly Agree
	Category Mean	4.49	Strongly Agree
Overall Satisfaction and Preference	14. Given the choice, I would prefer to use this method over the alternative for future screenings?	4.39	Strongly Agree
	15. I would recommend this app to other students for mental health screening	4.58	Strongly Agree
	Category Mean	**4.46**	**Strongly Agree**
	Overall Weighted Mean	**4.34**	**Strongly Agree**

Source: Authors, (2026).

The Table 8 indicates that students demonstrated a neutral overall preference toward the paper-and-pencil method, with an overall weighted mean of 3.38, and particularly low ratings in comfort and privacy as well as overall satisfaction. While ease of use and accessibility were rated as agreeable, concerns regarding privacy, feeling judged, and convenience was evident. These results align with prior research suggesting that traditional screening formats are perceived as less private and less flexible, which may reduce user engagement and satisfaction, especially among digitally literate college students [4], [17]. The neutral preference suggests that while paper-based tools remain functional, they may no longer align with students' expectations for autonomy, confidentiality, and convenience [8].

Table 8: Level of students' preference using Written Preference/ paper-and-pencil screening method.

Dimensions	Statements	Mean	Descriptive Interpretation
Ease of Use and Efficiency	1. I found the process of completing the screening to be easy to understand and follow. "	4.03	Agree
	2. I found the method easy to use and intuitive	3.70	Agree
	3. The screening process is completed within a reasonable amount of time	3.76	Agree
	4. I can finish the screening without feeling rushed or overwhelmed	3.27	Neutral
	Category Mean	**3.69**	**Agree**
Accessibility	5. The method felt free of technical issues or unnecessary hurdles "	3.55	Agree
	6. Completing the screening using this method felt convenient for my schedule	3.18	Neutral
	7. I would be able to easily access this screening method whenever I needed it	3.21	Neutral

	8. The instructions and layout were clear regardless of where I completed the screening	3.79	Agree
	Category Mean	**3.43**	**Agree**
Comfort and Privacy	9. I felt comfortable and relaxed while using this method to answer the questions "	3.85	Agree
	10. I felt confident that my answers were private and secure using this method	2.88	Neutral
	11. This method made it easy to concentrate on the questions without distraction	3.42	Agree
	12. Using the the method makes me feel less judged	2.61	Neutral
	Category Mean	**3.19**	**Neutral**
Overall Satisfaction and Preference	14. Given the choice, I would prefer to use this method over the mobile application for future screenings?	2.97	Neutral
	15. I would recommend this app to other students for mental health screening	3.12	Neutral
	Category Mean	3.19	Neutral
	Overall Weighted Mean	**3.38**	**Neutral**

Source: Authors, (2026).

The Table 9 shows a statistically significant difference in depression scores between mobile and paper-based screening methods (p = .048), while no significant differences were found for anxiety (p = .272) and stress (p = .167). This indicates that the mode of administration influenced depression screening outcomes but not anxiety or stress results. Such findings are consistent with literature suggesting that depressive symptoms are more sensitive to contextual and emotional factors related to assessment modality, particularly privacy and perceived judgment [17], [9]. The absence of significant differences in anxiety and stress supports previous evidence that these constructs demonstrate greater measurement equivalence across formats [2], [5].

Table 9: Significant difference in the mental health screening results of students when administered between methods.

The Table 10 reveals statistically significant differences across all preference dimensions, with students consistently favoring the mobile screening method over the paper-based approach, as evidenced by significant p-values (.003 to .000). The largest mean difference was observed in comfort and privacy, underscoring the importance of emotional experience in screening modality preference. These findings strongly align with existing research highlighting that mobile mental health tools outperform traditional methods in usability, acceptability, and user satisfaction, particularly among young adults [23], [22],[17]. The results affirm that user-centered design and digital delivery play a critical role in shaping student engagement with mental health screening tools [30].

V. CONCLUSIONS

The mental health screening results of college students differ depending on the method of administration, particularly in the assessment of depressive symptoms. As a whole, a significant difference was established in depression scores between the mobile application and paper-and-pencil screening methods, indicating that the mode of screening influences how students report depressive experiences. This finding serves as evidence that digital screening environments may facilitate greater openness and self-disclosure among students due to enhanced perceptions of privacy, comfort, and reduced judgment. On the other hand, no significant differences were found in anxiety and stress results between the two screening methods, suggesting that these constructs remain relatively stable across digital and traditional modalities and that both methods are psychometrically viable for their assessment.Moreover, the study clearly demonstrates that students show a significantly stronger preference for the mobile screening method across all dimensions, including ease of use, accessibility, comfort and privacy, and overall satisfaction.

This indicates that mobile-based mental health screening aligns more closely with the needs, expectations, and behavioral patterns of contemporary college students. The high level of acceptability toward the mobile method reflects the importance of user experience in mental health assessment and highlights the potential of digital tools to increase participation, engagement, and willingness to undergo mental health screening within the university setting.On a practical note, the findings of this study provide important implications for Cagayan State University–Carig Campus in strengthening its mental health support services. The results may serve as a basis for integrating mobile mental health screening tools as a complementary mechanism to existing paper-based assessments, particularly for early detection and routine mental health monitoring among students. The evidence generated by this study may also guide university administrators, guidance counselors, and mental health practitioners in designing more student-centered, accessible, and acceptable screening programs that encourage proactive help-seeking behavior.

However, the study has certain limitations that must be acknowledged. First, the respondents were limited to a relatively small sample from a single campus, which may restrict the generalizability of the findings. Future researchers are encouraged to include larger samples and multiple campuses to provide a more comprehensive understanding of students' mental health screening experiences. Second, the study focused only on depression, anxiety, and stress; thus, future studies may consider including other mental health indicators such as well-being, resilience, or burnout. Finally, future research may explore longitudinal designs to examine changes in students' mental health outcomes and screening preferences over time, as well as the integration of mobile screening tools with follow-up interventions and counseling services.

VII. ACKNOWLEDGMENTS

The authors sincerely thank Cagayan State University–Carig Campus and the University of the Cordilleras for their invaluable support throughout this study. Special appreciation is extended to the students who willingly contributed their time and experiences, enabling this research. The authors also recognize the guidance and encouragement provided by administrators, whose insights greatly enriched the research process. Lastly, gratitude is expressed to the Galileo Institute of Technology and Education of the Amazon (ITEGAM) and the editorial team of ITEGAM-JETIA for their dedication to promoting scholarly work and for offering the opportunity to publish this study.

ABSTRACT

The mining and processing of coal generate significant waste, often disposed of in landfills, with coal slag heaps in southwestern Algeria forming artificial mountainous structures. This study investigates the potential of reusing coal bottom ash (CBA) as a lightweight aggregate in self-compacting concrete (SCC), fully replacing natural fine and coarse aggregates. The research focuses on the effect of CBA aggregate size on the fresh and hardened properties of SCC. Experimental results show that replacing natural coarse aggregate (NCA) with coarse CBA (CCBA) enhanced self-compactability, while fine CBA (FCBA) reduced workability. The use of CBA resulted in lower dry densities (1920.6–2134 kg/m³), qualifying the mixtures as lightweight SCC according to EN 206-1 standards. Although compressive and flexural strength decreased and porosity increased due to the lightweight and porous nature of CBA, strength values met ACI standards for structural applications. Microstructural examination indicated a rise in porosity within the concrete matrix; however, a limited formation of supplementary calcium-silicate-hydrate (C-S-H) gel was observed, which contributed to partially offsetting the reduction in mechanical strength. This study demonstrates the viability of CBA, particularly as a coarse aggregate, for producing lightweight SCC, offering a sustainable solution for recycling industrial waste and developing eco-friendly construction materials with acceptable structural properties.

I. INTRODUCTION

The growing demand for construction materials has intensified pressure on natural resources, highlighting the urgent need for alternative materials and technologies. Conventional construction practices are increasingly unsustainable due to resource depletion and environmental impacts. Consequently, the development and adoption of innovative, resource-efficient alternatives have become essential to ensure the long-term sustainability of the construction industry [1]. The Bechar region in southwestern Algeria has a significant history of coal mining, beginning in 1918 at Kenadsa. Mining operations transitioned from open-cast to underground methods, reaching depths of 600 meters. Production peaked between 1942 and 1960, but the discovery of oil and gas reserves in the 1950s led to a decline in coal mining, with operations ceasing entirely by 1975. This left behind approximately 3.7 million cubic meters of coal waste in the form of slag heaps, covering 167.71 hectares and posing environmental and health risks due to toxic emissions [2].

Coal Bottom Ash (CBA), a byproduct of coal combustion, has been studied as a sustainable alternative in concrete production. While its use as a fine aggregate replacement often reduces workability and strength, it exhibits pozzolanic properties that enhance long-term performance [3-5].

The substitution of sand with coal bottom ash (CBA) often leads to a decline in workability, density, and strength. However, furnace bottom ash (FBA) has demonstrated comparable performance when used as a complete replacement for fine aggregate [3-5]. According to [3] found that replacing 10-25% of fine aggregate with CBA led to an increase in compressive strength. This improvement can be attributed to CBA's pozzolanic properties, which align with ASTM Class F classification, enabling strength development over time [6]. In [4] reported enhanced flexural and tensile resistance in mixtures containing 75% bottom ash and 20% fly ash, particularly after extended curing periods. While initial strength reductions were observed due to the slow pozzolanic reaction, these were counterbalanced by substantial gains in later stages. According to [5] noted that the use of coarse bottom ash resulted in a slight reduction in slump flow, whereas fine bottom ash showed no significant effect. Despite its potential, the majority of research has concentrated on CBA as a fine aggregate, with limited exploration of its application as a lightweight coarse aggregate in self-compacting concrete [7-10]. Lightweight self-compacting concrete (LWSCC) combines the benefits of lightweight aggregates (LWAs) and SCC, offering reduced density, improved insulation, and enhanced flow properties without vibration [11].

Research has explored various lightweight aggregates (LWAs), natural, industrial and agriculture waste, such as pumice, expanded clay, expanded polystyrene (EPS), crushed olive kernel (COK) shells, oil palm shells (OPS), walnut shells (WS), and sintered fly ash aggregates (SFAA), to enhance the properties of self-compacting lightweight concrete (SCLC). Studies show that LWAs reduce density and improve thermal insulation but often lower compressive strength and increase water absorption. For instance, pumice and EPS improve thermal performance and reduce structural weight, while COK and OPS offer sustainable alternatives with acceptable strength. Fly ash and supplementary materials like silica fume (SF) and metakaolin (MK) enhance mechanical properties and workability. However, challenges such as segregation, reduced workability, and durability issues remain. Overall, LWAs show promise for sustainable, lightweight concrete applications, though further research is needed to optimize their performance [12-16]. These advancements highlight the potential of LWSCC as an eco-friendly construction material. This study investigates the use of CBA as a lightweight coarse and fine aggregate replacement in LWSCC, aiming to address environmental challenges posed by coal waste while promoting sustainable construction practices. Present work focuses mainly to evaluate the effect of CBA aggregate size on the rheological and mechanical behavior of SCC. By integrating CBA into SCC, the research seeks to optimize material performance, reduce natural resource consumption, and provide a viable solution for managing industrial waste. The findings contribute to the development of sustainable concrete production, offering insights into the mechanical and durability properties of CBA-based LWSCC.

II. MATERIALS AND METHODS

II.1 MATERIALS

II.1.1 Cement

Ordinary Portland Cement (CEM I 42.5) supplied by GICA MOUDHAD from its manufacturing plant in Bechar, southwestern Algeria, was used in the experimental investigation. The cement satisfies the provisions of the Algerian standard NA 442 and the European standard EN 197-1. The chemical composition of the used cement is reported in Table 1.

II.1.2 Coal Bottom Ash

The coal bottom ash (CBA) investigated in this study was obtained as a by-product from an obsolete thermal power station in Algeria. Following manual fragmentation, it was further processed using a jaw crusher and sieved into coarse (3/8 mm and 8/15 mm) and fine (0/3 mm) fractions as depicted in Figure 1. Scanning electron microscopy (SEM) analysis revealed its irregular morphology, high porosity, and rough surface texture. Energy-dispersive spectroscopy (EDS) confirmed its silica-alumina composition, with oxygen, aluminum, and silicon as the predominant elements (Figure 2).

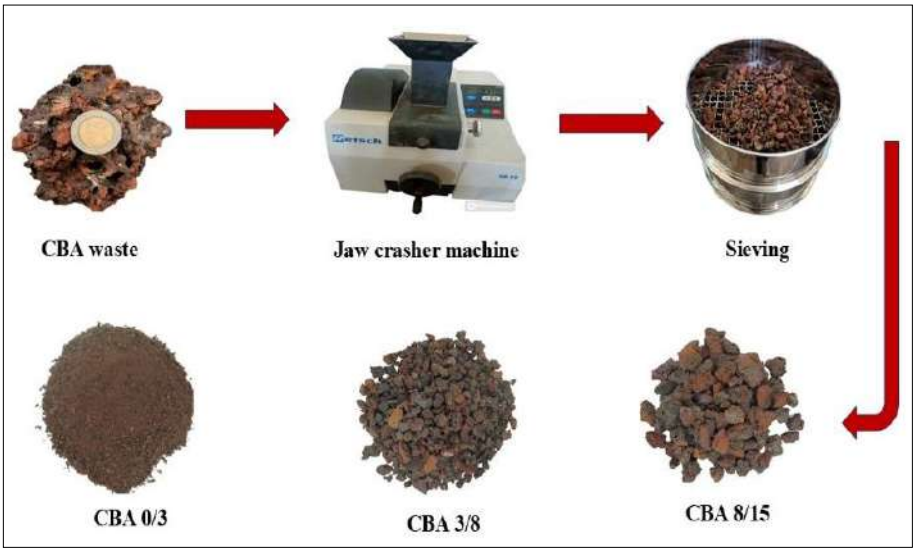

Figure 1: CBA aggregate processing.
Source: Authors, (2026).

The chemical composition of the coal bottom ash (CBA) was characterized by X-ray fluorescence (XRF) analysis. The results indicate that silicon dioxide (SiO_2), aluminum oxide (Al_2O_3), and iron oxide (Fe_2O_3) are the dominant constituents, representing 83.47% of the total oxide content. The remaining fraction consists of minor quantities of sulfates, calcium oxide, magnesium oxide, and other trace elements. In accordance with the requirements of ASTM C618, this chemical composition classifies the CBA as a Class F pozzolanic material. The detailed oxide composition of the CBA is presented in Table 1. In addition, the physical properties of the aggregates employed in this study are presented in Table 2, while their particle size distribution curves are shown in Figure 3.

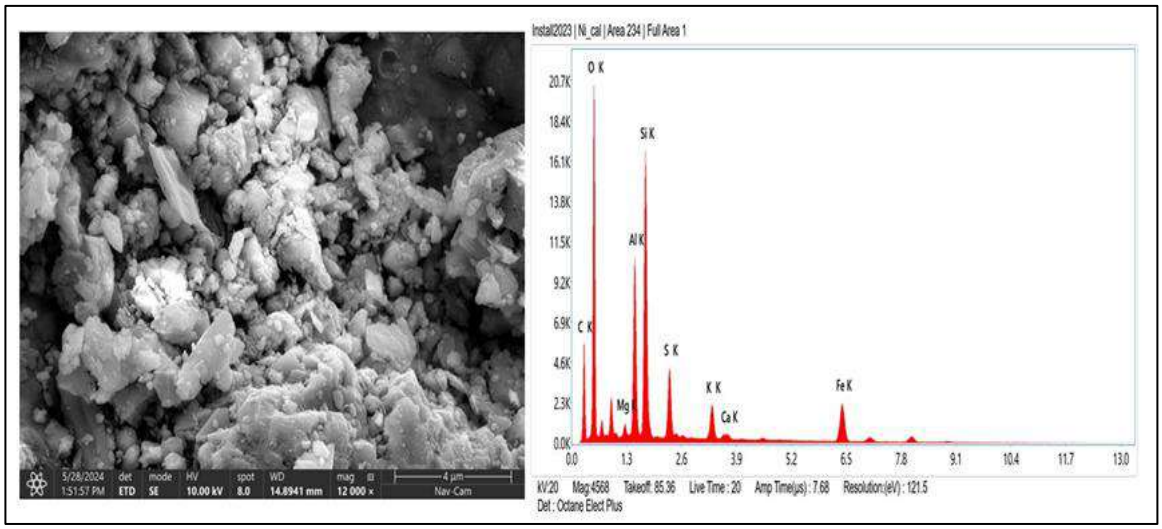

Figure 2: CBA SEM / EDS analysis.

II.1.3 Natural Aggregate

The natural fine aggregate (NFA) used in this investigation was river sand collected from the Bechar region of Algeria, with a maximum particle size of 3 mm. The natural coarse aggregate (qNCA) consisted of crushed limestone with nominal size ranges of 3/8 and 8/15, sourced from a local quarry in Bechar, Algeria. The physical characteristics of the used aggregates are summarized in Table .2, and their particle size distribution curves are illustrated in Figure 3.

Table 2: Aggregate physical properties.

Properties	0/3 NFA	0/3 FCBA	3/8 NCA	3/8 CCBA	8/15 NCA	8/15 CCBA
Bulk density (g/cm^3) [NF P18-555]	1.6	0.99	1.39	0.70	1.40	0.66
Absolute density (g/cm^3) [NF P18-555]	2.5	2.35	2.66	1.93	2.67	1.81
Fineness modulus [NFP 18-540]	2.53	2.76	/	/	/	/

II.1.4 *Superplasticizer and Mixing Water*

To obtain adequate workability, a high-range water-reducing admixture (superplasticizer), commercially designated as MAX SUPERFLOW S180 and manufactured by the Algerian company Technachem, was used in conformity with the requirements of NF EN 934-2. The mixing water consisted of potable water meeting the quality criteria specified in NF EN 1008. This water, treated in accordance with drinking water standards, was supplied directly from the laboratory distribution system.

II.2 MIX PROPORTIONS

Three self-compacting concrete (SCC) mixtures were prepared following AFGC guidelines [17], maintaining a constant water-to-binder ratio of 0.48 and a superplasticizer dosage of 2% by binder weight (Table 3). The reference mix (RSCC) used natural aggregates, while two additional mixes assessed the impact of coal bottom ash (CBA) aggregate size. In FSCC, fine CBA (FCBA) replaced natural fine aggregate, whereas in CSCC, coarse CBA (CCBA) substituted natural coarse aggregate. Due to CCBA's high water absorption, it was pre-soaked for 24 hours, then drained and weighed for precise batching. FCBA, with minimal absorption, was mixed with water to reach a saturated surface-dry (SSD) state and rested for 15 minutes before use [18].

Table 3: SCC mix composition.

Composition (kg/m3)	Cement	NFA	FCBA	NCA 3/8	CCBA 3/8	NCA 8/15	CCBA 8/15	Water	SP	W/C
RSCC	520	900	/	150	/	580	/	256	2%	0.48
FSCC	520	/	836	150	/	580	/	256	2%	0.48
CSCC	520	900	/	/	111.36	/	394.65	256	2%	0.48

Source: Authors, (2026).

II.3 EXPERIMENTAL PROCEDURES

To evaluate the influence of coal bottom ash (CBA) aggregate size on the properties of self-compacting concrete (SCC), a series of tests were conducted on both fresh and hardened concrete as shown In Figure 4. For fresh concrete, assessments included slump flow, L-box, sieve segregation, and fresh unit weight measurements. Specimens were cast using standardized steel molds in various geometries, including prismatic (7 × 7 × 28 cm) and cubic (10 × 10 × 10 cm) forms, to facilitate testing of dry density, porosity, compressive strength, and flexural strength. Furthermore, microstructural analysis was performed using scanning electron microscopy (SEM) coupled with energy-dispersive spectroscopy (EDS) to examine the internal structure and elemental composition of the SCC mixtures, as detailed in Table 4.

Table 4: Tests conducted.

Tests		Standards
Workability	Slump flow	AFGC, 2008
	L-box	AFGC, 2008
	Sieve stability	AFGC, 2008

III. RESULTS AND DISCUSSIONS

III.1 SCC FRESH STATE RESULTS

The results from fresh concrete tests, as presented in Table 5, reveal that the use of coal bottom ash (CBA) as a fine aggregate in the FSCC mixture slightly reduced workability, with a slump flow diameter of 68 cm compared to 72.7 cm for the reference mix. This decrease is attributed to the higher water absorption capacity and porous nature of CBA, which absorbs a portion of the mixing water. Conversely, when CBA was used as a coarse aggregate in the CSCC mixture, the slump flow diameter increased to 80 cm. This improvement is likely due to the pre-soaking of coarse CBA (CCBA) to achieve a saturated surface-dry (SSD) condition, which reduces water absorption during mixing and enhances workability. These findings align with previous studies by [7] and Raju et al. [10], highlighting the influence of CBA aggregate size and preparation methods on the workability of self-compacting concrete. The experimental results demonstrated that the passing ability of all mixtures ranged from 0.78 to 0.94. The FSCC mixture, incorporating fine CBA aggregates (FCBA), exhibited a blocking ratio below the 0.8 threshold set by the AFGC standard [19], indicating restricted flowability.

In contrast, the CSCC mixture, which utilized coarse CBA aggregates (CCBA), met the required range, showcasing improved flow performance. This discrepancy is attributed to reduced inter-particle friction in mixtures with larger aggregates, enhancing flowability. Specifically, FSCC mixture tend to experience higher friction, limiting flow, while CSCC mixture exhibit better flow characteristics, enabling smoother movement through the formwork [13],[19]. These findings highlight the influence of aggregate size and type on the flow properties of self-compacting concrete. The segregation resistance tests presented in Table 5 indicate that replacing natural aggregates with coal bottom ash (CBA) reduces the segregation ratio compared to the control mix. All mixtures remained stable, with sieve stability values between 6.44% and 9.24%, well below the 15% limit set by AFGC standards [20]. The use of CBA, whether as fine or coarse aggregate, significantly improved segregation resistance by lowering plastic viscosity, which slows coarse particle settling and enhances stability. These findings align with previous studies, emphasizing the benefits of lightweight aggregates in maintaining SCC uniformity and performance in its fresh state [10].

Table 5: SCC fresh state results.

Mix	Slump-flow(cm)	L– box (H2/H1)	Sieve Stability(%)
Limit values	**550-850 mm**	**≥ 0.8**	**≤ 15 %**
RSCC	72.7	0,94	9.24
FSCC	68	0,78	6.44
	80	0,90	8.5

Source: Authors, (2026).

III.2 SCC HARDENED STATE RESULTS

III.2.1 Compressive Strength Results

The compressive strength results, presented in Figure 5, indicate a progressive increase in strength with curing time, reaching peak values at 90 days. The reference SCC (RSCC) exhibited the highest strength, measuring 56.1 MPa at 90 days. Substituting river sand with fine coal bottom ash (FCBA) in the FSCC mix led to a strength reduction of approximately 33%, while the incorporation of coarse CBA (CCBA) in the CSCC mix resulted in a comparatively lower decrease of about 16% relative to RSCC at 90 days. The FSCC mixture exhibited significantly lower compressive strength, barely meeting the minimum threshold of 17.2 MPa specified by ACI Committee for structural applications.This reduction is primarily attributed to the increased porosity of the concrete matrix caused by CBA inclusion. These findings are consistent with previous research, which has demonstrated that higher FCBA replacement levels adversely affect compressive strength [3-5],[20].

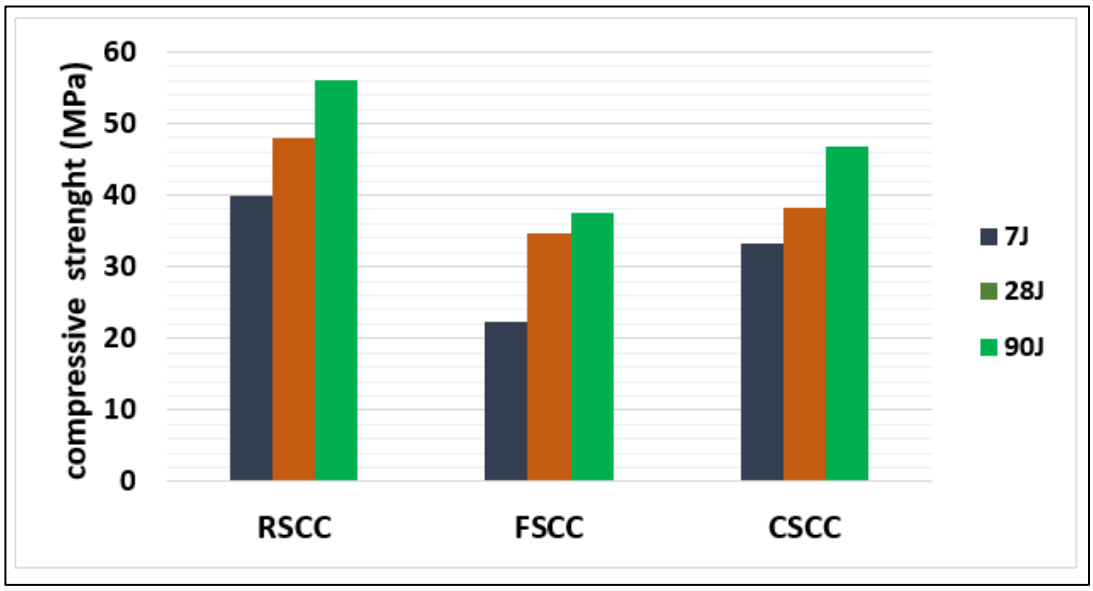

Figure 5: Compressive strength for SCC mixes.
Source: Authors, (2026).

III.2.2 Flexural Strength Results

The flexural strength results for all mixtures at 7, 28, and 90 days of curing are illustrated in Figure 6. The incorporation of coal bottom ash (CBA) as an aggregate replacement influenced the flexural performance of self-compacting concrete (SCC). Due to the lower strength and density of CBA aggregates, the mixtures in which fine CBA (FCBA) fully replaced natural sand exhibited reductions in flexural strength of 19% compared to the reference mix (RSCC). Similarly, replacing natural coarse aggregate with coarse CBA (CCBA) in the CSCC mix resulted in a 10% decrease in flexural strength at 90 days. The extent of strength reduction was found to be less pronounced when larger CBA particles were used, likely due to improved load transfer and mechanical interlocking between aggregates. In contrast, higher replacement levels with finer CBA particles led to weaker aggregate bonding and a more porous matrix, which negatively affected flexural performance. These findings align with previous research [20],[21].

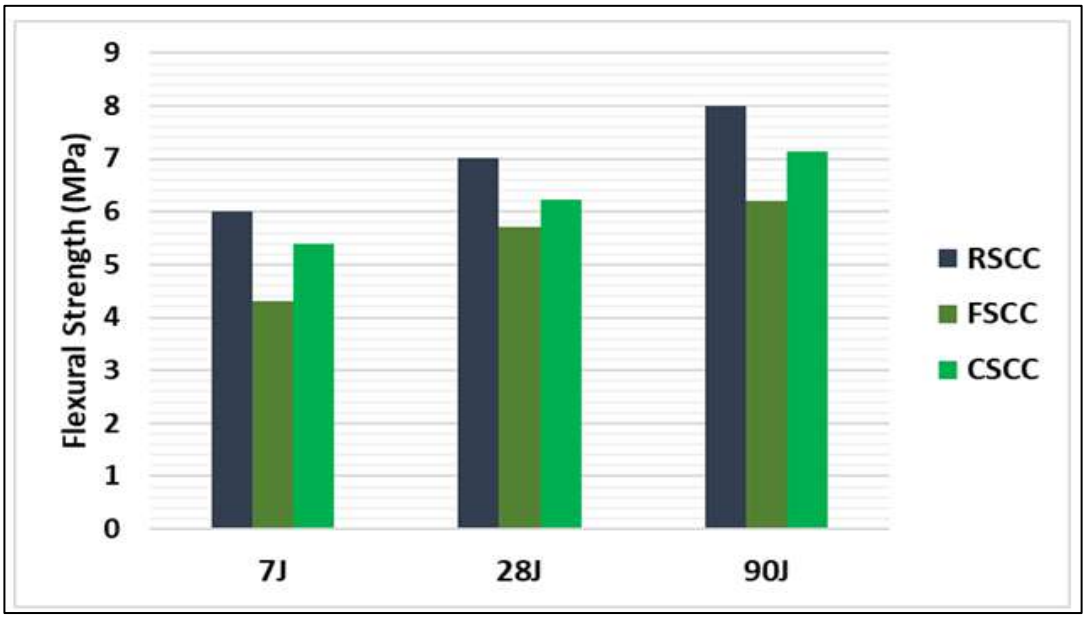

Figure 6: Flexural strength for SCC mixes.
Source: Authors, (2026).

III.2.3 Oven Dry Density Results

The oven-dry density results for all mixtures, as shown in Figure 7, indicate a clear reduction in density with the incorporation of coal bottom ash (CBA). Notably, mixtures with a dry density below 2000 kg/m³ met the lower limit for lightweight concrete (LWC) production, as specified by EN 206-1 standards, classifying them as lightweight self-compacting concrete. This decrease in density is primarily attributed to the lower intrinsic density of CBA compared to conventional aggregates. The recorded dry density values ranged from 1920.6 to 2133.96 kg/m³, with mixtures incorporating coarse CBA (CCBA) exhibiting lower densities than those containing fine CBA (FCBA). This variation is likely due to the larger particle size of CCBA, which affects the overall compactness and distribution of aggregates within the concrete matrix. [22].

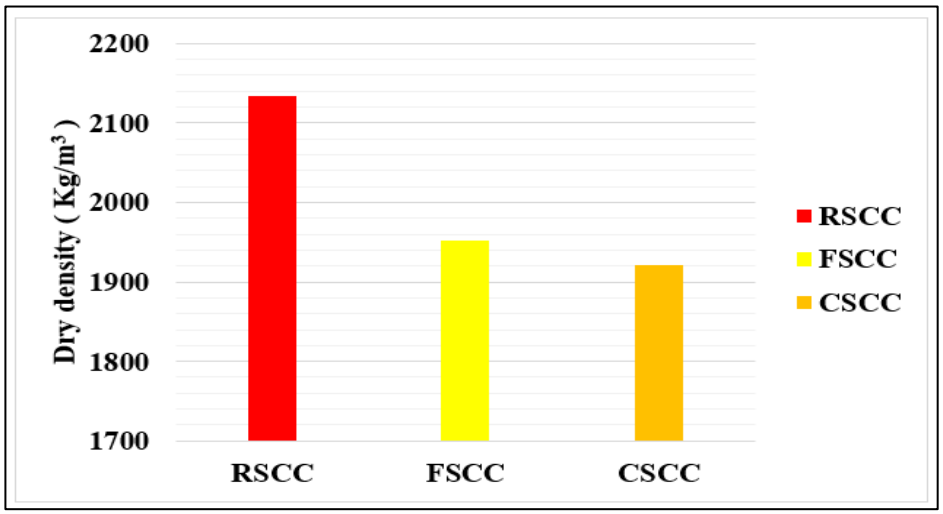

Figure 7: Oven dry density for SCC mixes.
Source: Authors, (2026).

III.2.4 Porosity Results

As shown in Figure 8, the incorporation of coal bottom ash (CBA) aggregates led to a noticeable increase in the porosity of both FSCC and CSCC mixtures when compared with the reference concrete. Specifically, mixtures containing fine CBA (FSCC) and coarse CBA (CSCC) exhibited increases in porosity of approximately 42% and 19%, respectively. This behavior is primarily attributed to the inherently porous microstructure and higher water absorption capacity of CBA aggregates relative to natural aggregates, with the magnitude of the effect being strongly influenced by particle size. Fine CBA (FCBA), owing to its larger specific surface area and more open pore network, tends to absorb greater amounts of mixing water, resulting in insufficient paste availability to effectively fill internal voids and interparticle spaces [6]. Consequently, this leads to a more porous hardened matrix. In contrast, the use of coarse CBA (CCBA) in a saturated surface-dry (SSD) condition limited additional water uptake during mixing, thereby preserving the effective water-to-binder ratio and promoting improved particle packing. This condition contributed to a comparatively lower porosity in CSCC mixtures than in FSCC mixtures. [23]

III.2.5 SCC Microstructure Analysis

The SEM observations (Figures 9–11) demonstrate that the substitution of natural aggregates with coal bottom ash (CBA) significantly modifies the microstructural features of self-compacting concrete (SCC). The reference mix (RSCC) is characterized by a dense and homogeneous matrix with well-developed C–S–H gel and limited visible voids or microcracks (Figure 9). In contrast, concretes incorporating CBA exhibit a more heterogeneous microstructure, marked by increased pore volume, microcracking, and a less compact cementitious matrix (Figures 10 and 11). This effect is more pronounced when fine aggregates are replaced by fine CBA (FSCC), owing to its higher surface area and porous nature, which promote greater water absorption and hinder optimal paste densification. These microstructural deficiencies are consistent with the observed increase in porosity and the reduction in compressive strength [3],[24]. EDX analysis confirms the dominance of calcium (Ca), silicon (Si), and oxygen (O) in all mixtures, reflecting the typical composition of hydrated cement phases. The detection of aluminum (Al) and magnesium (Mg) indicates the contribution of supplementary cementitious phases associated with the presence of CBA. Mixtures containing CBA, particularly FSCC and CSCC, display enhanced silicon peaks in the EDX spectra (Figures 10 and 11), pointing to a silica-rich composition that may promote secondary pozzolanic reactions at later ages.

Additionally, the presence of trace elements such as iron (Fe) and molybdenum (Mo) can be attributed to the mineralogical composition of the ash or residual impurities inherited from the coal combustion process, in agreement with the findings of Moreno et al. [25]. The carbon (C) peaks observed in certain samples are likely associated with unburned carbon residues or carbonate phases, which may influence hydration kinetics and contribute to the observed microstructural heterogeneity. Overall, the combined SEM–EDX results provide clear evidence that the incorporation of CBA affects both the physical and chemical characteristics of SCC, with direct implications for its durability and mechanical performance.

IV. CONCLUSIONS

This study demonstrates that incorporating coal bottom ash (CBA) as a replacement for natural aggregates in self-compacting concrete (SCC) significantly impacts its fresh, mechanical, and microstructural properties. While fine CBA (FCBA) reduced workability due to its porous nature, pre-soaked coarse CBA (CCBA) improved flowability. All CBA-based mixtures exhibited stable segregation resistance, with sieve stability values below the 15% limit. The mechanical performance of SCC declined with CBA incorporation, with compressive strength reductions of 33% in FSCC and 16% in CSCC compared to the reference SCC. Flexural strength also decreased, primarily due to increased porosity and weaker aggregate bonding. However, the resulting oven-dry density (1920.6–2133.96 kg/m³) classified these mixtures as lightweight self-compacting concrete (LWSCC) according to EN 206-1. Microstructural analysis confirmed increased porosity and crack formation, particularly in FSCC, but also highlighted a silica-rich composition and additional C-S-H gel formation, partially mitigating strength loss.

Despite reduced mechanical properties, CBA-based SCC presents a viable and sustainable alternative for lightweight concrete production, contributing to industrial waste recycling and eco-friendly construction. Future research should focus on optimizing CBA aggregate preparation and replacement ratios to enhance performance while maintaining sustainability.

ABSTRACT

Credit card fraud (CCF) still remains an ongoing concern for financial institutions because to the huge disparity between genuine and fraudulent transactions, as well as the ever-changing behavior of fraudsters. This paper proposes a cloud-based Agentic Artificial Intelligence system for real-time credit card fraud detection that utilizes autonomous multi-agent collaboration and deep temporal modeling. The system makes use of the publicly accessible CCF Detection dataset, commencing with secure cloud-level data ingestion, preprocessing, and normalization. An agentic transaction analysis layer made up of qualified agents accomplishes data validation, behavioral pattern analysis, and transaction history verification. To successfully capture both local spatial aspects and long-term temporal dependencies in transactional behavior, deep temporal fraud modeling employs a hybrid full-dimensional dynamic convolutional network mixed with shuffle attention and LSTM. Finally, an automated risk assessment and decision module generates fraud scores and initiates relevant mitigation steps such as alarms or transaction blocks. Experimental results show that the proposed framework outperforms baseline GRU-based models in detection performance, demonstrating its effectiveness, scalability, and appropriateness for real-time intelligent fraud prevention in cloud environments.

I. INTRODUCTION

Recently, there has been an increase in the use of credit cards as a payment mechanism, with most individuals using credit cards rather than cash when making regular payments in their daily lives. In the past few decades, all humanity has benefited from internet banking services for cash transfers, debit and credit card transactions, and online bill install ment payments [1-3]. Customers can simply track their spending with a credit card and understand where their money has been spent. Despite the numerous advantages of online transactions, financial fraud and unauthorized payments offer serious risks [4]. Fraudulent financial operations are challenging to recognize due to their complex nature and advanced technology. Financial fraud is getting increasingly widespread as technology progresses [5], [6]. The financial fraud detection systems can detect unusual attacks and unlawful access. Financial organizations are continually updating their fraud detection methods. These difficulties are addressed by data mining and machine learning (ML) methods, which have become widely used in recent years [7-9]. The researchers attempt to develop fraud detection systems employing ML, deep learning (DL), and data mining techniques to determine whether a transaction is fraudulent or real.

ML has multiple branches, each of which can handle a variety of learning concerns. However, there are various framework types for ML. Random Forest (RF) is one example of an ML method for credit card fraud. The decision tree ensemble is represented by the random forest, and the RF technique is used by the majority of researchers [10], [11]. Researchers can employ a variety of machine learning techniques, including supervised and unsupervised learning. ML algorithms including Logistic Regression (LR), Artificial Neural Network (ANN), Decision Tree (DT), Support Vector Machine (SVM), and Naive Bayes (NB) [12] are widely utilized for fraud detection. Deep learning methods, such as the convolutional neural network (CNN) [13], deep belief networks (DBNs) [14] and generative adversarial network (GAN) [15] are also beneficial. A VAE is a variational autoencoder that employs frequent instruction loops to ensure that its hidden space contains relevant assets, allowing us to produce new data [16]. A VAE is created by adding modifications into the autoencoder [17], [18].

Traditional rule-based and ML-based fraud detection algorithms usually struggle to achieve high detection accuracy in real-time scenarios, especially when dealing with highly imbalanced datasets and quickly changing fraud patterns. Modern innovations in artificial intelligence (AI) and cloud computing have enabled the development of highly scalable and sophisticated fraud detection systems capable of processing enormous amounts of transactions instantaneously [19], [20]. However, the majority of existing solutions are built on centralized, single-model systems with limited adaptability and decision-making independence. To address these constraints, this study introduces a cloud-based Agentic AI system for real-time CCF detection based on DL framework. By merging Agentic AI, cloud computing, and deep temporal learning techniques, this research aims to create a next-generation fraud detection system that improves not only detection accuracy but also interpretability, flexibility, and automatic risk mitigation. The major contribution of this research is defined below:

- To enable autonomous and intelligent risk management, A cloud-based agentic AI system is developed credit card fraud detection by integrating multi-agent collaboration analysis.
- For real time fraud detection, the proposed framework integrates Data Quality, Behavioral Analysis, Verification, Risk Analysis, and Reporting agents.
- A deep temporal fraud detection model is developed with fully dynamic convolutional and shuffle attention mechanism to extract most informative attributes with sequential patterns for fraud detection.
- The system generates a fraud risk score for each transaction and takes relevant measures to mitigate it including notifications, transaction blocking, or escalation to human analysts. In real-world deployment scenarios, this eliminates manual intervention while increasing response speed.

The research organisation of the work is stated as: The recent survey based on credit card fraud detection with its merits and demerits are elaborated in section 2. The methodology with cloud-based fraud detection is described under section 3. Then, the performance evaluation part is discussed in section 4 and finally the research paper is ends with conclusion and future scope.

II. RELATED WORK

The progress of ML and DL techniques has had a significant impact on credit card fraud detection. Recent research has focused on increasing detection accuracy in highly imbalanced data sets, reducing false positives, and enabling real-time fraud detection. Traditional ML models are being replaced or improved by DL architectures such as CNNs, RNNs, hybrid multi-stage systems, and uncertainty-aware frameworks. Therefore, the recent publications for CCF detection are depicted in Table 1.

Table 1: Literature survey on CCF detection.

Reference	Main Contribution	Merits	Demerits / Limitations
Chen & Lai (2021) [21]	Proposed a Deep CNN for automatic feature learning and fraud detection with alert generation.	High detection accuracy; automatic extraction of spatial features; reduced reliance on manual feature engineering.	CNNs are computationally intensive; limited temporal modeling of transactions; lacks real-time deployment analysis.
Asha & Suresh Kumar (2021) [22]	Applied Artificial Neural Networks (ANNs) for binary fraud classification using transactional data.	Simple architecture; easy to implement; improved accuracy over traditional ML models.	Limited ability to capture temporal transaction dependencies; performance sensitive to class imbalance.
Zioviris et al. (2022) [23]	Introduced a deep learning multi-stage framework combining multiple classifiers for fraud detection.	Improved robustness; better generalization through stage-wise learning; reduced false positives.	Increased system complexity; higher computational overhead; not suitable for edge or low-latency environments.
Habibpour et al. (2023) [24]	Developed an uncertainty-aware deep learning model to quantify prediction confidence in fraud detection.	Improves trustworthiness of predictions; reduces risky misclassifications; supports risk-aware decision making.	Requires complex probabilistic modeling; higher training cost; interpretability is still limited.
Sulaiman et al. (2024) [25]	Proposed improved deep learning architectures for enhanced fraud detection under imbalanced datasets.	Better performance on skewed datasets; improved recall for minority (fraud) class.	Heavily dependent on dataset balancing strategies; lacks adaptive or autonomous learning capability.
Siam et al. (2025) [26]	Designed a hybrid feature selection framework integrated with machine learning classifiers.	Reduces dimensionality; enhances classification speed and accuracy; avoids irrelevant features.	Feature selection is static; cannot adapt dynamically to evolving fraud patterns.
Bonde & Bichanga (2025) [27]	Introduced an ensemble deep learning approach using SMOTE-ENN hybrid resampling.	Strong performance under extreme class imbalance; reduced noise and overfitting; stable predictions.	Synthetic data dependency may introduce bias; limited real-time applicability due to preprocessing overhead.

III. PROPOSED METHEDOLGY

The proposed frmework incldes four main stages namely data pipeline, agnetic transaction analysis, deep temporal fraud detetcion and final decision and actions and it is illustarted in Figure 1. The first stage is stated as preprocesisng and it is accomplished to ensure high quality input for the upcoming stages. Agentic Transaction Analysis evaluates each transaction autonomously using a coordinated group of AI agents. The thids stage is stated as the proposed DL framework for fraud detetcion with advanced mechanims. And the final stage is the risk assessment with rapid decisions such as sending notifications, requesting further verification, or denying high-risk transactions respectively.

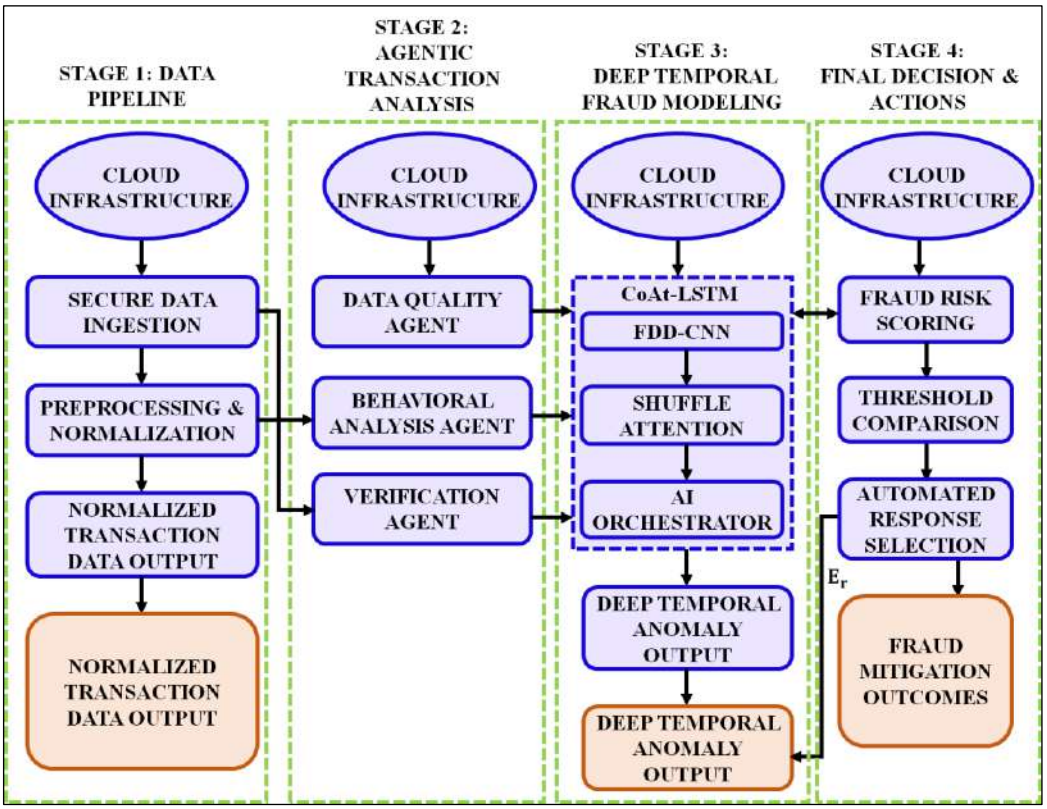

Figure 1: Overall proposed framework.
Source: Author, (2026).

III.1 STAGE 1: CLOUD-BASED DATA INGESTION AND PREPROCESSING

The CCF Detection dataset is securely ingested and pre-processed in the first step of the proposed methodology. To guarantee adherence to security and privacy regulations, the data is stored in an encrypted storage layer upon access into the cloud environment. The dataset integrity is then confirmed by a preliminary data-quality assessment, which includes evaluating feature ranges, looking for missing values, and verifying the statistical consistency of the principal component analysis (PCA)-derived features V_1–V_{28}. The dataset goes through a standardized preprocessing method after the initial verification. The approach uses normalization to provide consistent feature contribution during model training because the original features show varied scales. Normalization of standard scores is carried out using below equation.

$$x' = \frac{x-\mu}{\sigma} \tag{1}$$

Here, the original feature value is stated as x and the mean and standard deviation is termed as μ and σ respectively. Class-weighting is used in the preprocessing stage to reduce the disparity between fraudulent and valid transactions. Each class weight w_i is specified as:

$$w_i = \frac{1}{\text{freq}(y_i)} \tag{2}$$

Lastly, to preserve the initial fraud-to-non-fraud ratio, the dataset is divided into training and testing subsets using stratified sampling:

$$(X_{\text{train}}, X_{\text{test}}, y_{\text{train}}, y_{\text{test}}) = \text{StratifiedSplit}(X, y) \tag{3}$$

III.2 STAGE 2: MULTI-AGENT TRANSACTION ASSESSMENT

Each transaction is sent to a coordinated group of specialized AI agents that have been deployed in the cloud after preprocessing. These agents work in a sequential manner to make sure that each transaction is carefully assessed before being processed further.

The initial assessment is carried out by the Data Quality Agent, who confirms that the transaction has no missing or corrupted data and that the standardized input features fit within statistically valid ranges. This phase stops subsequent components from processing

noisy or corrupted records. The agent confirms that each feature x_i' falls within a reasonable range around its mean, usually within $x_i' \in [-3\sigma_i, +3\sigma_i]$ respectively. Transactions that exceed these thresholds are marked for possible anomalies or faults in preprocessing.

The Behavioral Analysis Agent assesses the spending characteristics of the transaction after data integrity has been verified. This agent is primarily concerned with identifying anomalous transaction quantities, sudden spending patterns, and departures from typical temporal patterns. The difference between the current transaction amount A_t and the mean historical amount μ_A is analyzed for a particular user using $\Delta A = \mid A_t - \mu_A \mid$ and temporal irregularity is evaluated using $\Delta t = t_{\text{current}} - t_{\text{previous}}$. Abnormally low Δt values could be a sign of fraudulent activity-related quick transaction bursts.

In this phase, the Verification Agent performs the last evaluation by contrasting the transaction with the user's long-term behavioral profile that has been preserved in the cloud. The degree to which the current transaction representation x_t and the user's behavioral profile P_u are similar is determined using a distance-based score $S = \| x_t - P_u \|$,where higher values signify less consistency with the user's known behavior. High-risk transactions are flagged and sent to the orchestrator for more in-depth contextual analysis if they don't pass this verification stage.

Before each transaction is sent to the higher-level orchestration and deep-learning stages of the framework, it is filtered, analyzed, and validated by these three agents working together to provide an organized, multi-perspective evaluation pipeline. This increases accuracy and robustness by ensuring that only transactions that have been thoroughly evaluated and contextually interpreted move on to the risk modeling stage.

III.3 STAGE 3: DEEP TEMPORAL FRAUD MODELING USING A COAT-LSTM ARCHITECTURE

Transactional input data is first processed by a Full-Dimensional Dynamic Convolutional Network (FDD-CN) in the suggested credit-card fraud detection system. This network adaptively learns spatial feature dependencies over several kernel dimensions. After being dynamically retrieved, the spatial characteristics G_t^s are subjected to a Shuffle Attention technique that suppresses noisy or redundant information while emphasizing the most essential channel and spatial feature representations. The attention-enhanced characteristics are then fed into a stacked Conv-LSTM network, which makes it possible to model the sequential transaction dynamics and temporal behavior that are commonly associated with fraudulent activity. An attention layer is incorporated to assess the relative significance of each time step in a transaction sequence in order to further improve discriminative capabilities. This layer allows the model to adaptively emphasize high-risk transaction states by computing attention weights β_t using a Tanh-based scoring function and a normalization procedure. The final attended representation H_t^a is a reliable real-time decision making and it is produced by the weighted aggregate of Conv-LSTM hidden outputs. The Deep Temporal Fraud Modeling is illustrated in Figure 2.

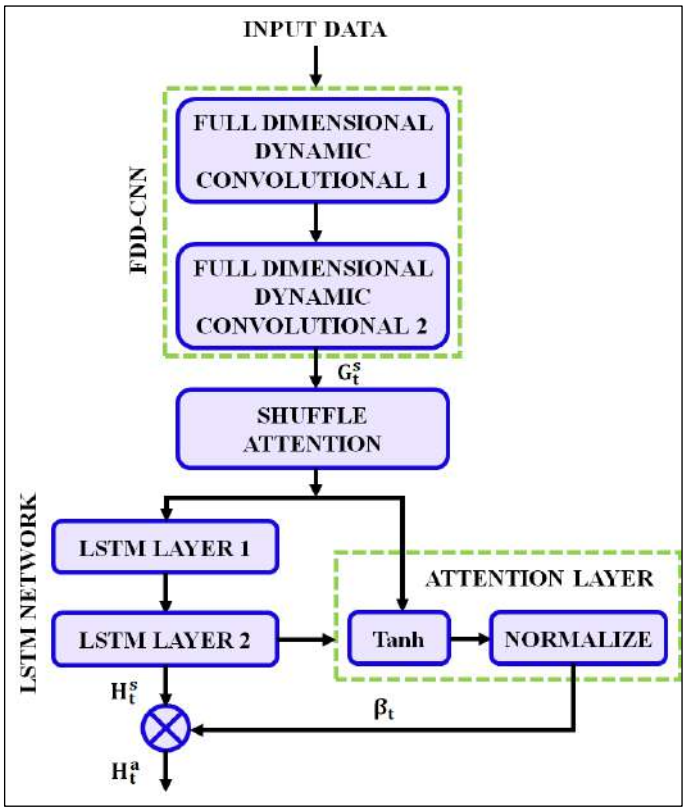

Figure 2: DL based fraud detection framework.

III.3.1 Full-Dimensional Dynamic Convolutional Network (Fdd-Cn)

Single static convolution kernel is usually used by each convolutional layer in traditional convolutional neural network topologies. These kernels are fixed and applied consistently to all input samples after they are learned during training. However, in situations like real-time credit card transaction streams, this static behavior restricts the network's capacity to adjust dynamically changing patterns. This

research incorporates a Full-Dimensional Dynamic Convolution (FDDC) module to get over this restriction. This module adaptively modifies convolutional parameters according on input features, allowing for a more expressive and versatile feature-representation capability.

The main concept of FDDC is to use a set of many learnable convolution kernels in place of the static convolution kernel to dynamically compute the contribution weights of each kernel based on the properties of each input. Therefore, the dynamic convolution output is expressed below:

$$y = \sum_{i=1}^{m}(\alpha_{ci} \odot \theta_{ci} W_{ci}) * x \tag{4}$$

Here, W_{ci} specifies the convolutional kernel, m defines the number of dynamic kernels, θ_{ci} specifies the learnable kernel-parameter scaling, α_{ci} defines the attention weight respectively. In order to calculate these weights, the input is initially subjected to two Fully Connected (FC) layers with a ReLU activation, Global Average Pooling (GAP) to collect global contextual information, and Sigmoid activation. Therefore, the mathematical expression is given below:

$$\alpha_{ci} = \text{Sigmoid}(\text{FC}(\text{ReLU}(\text{FC}(\text{GAP}(x))))) \tag{5}$$

Operationally, the FDDC module uses GAP to first extract global contextual information from an input feature map x. After passing the resultant compact representation through a series of FC layers, ReLU and Sigmoid activations are used to produce a set of attention weights α. The module can determine how much each dynamic convolution kernel should contribute to the final output by using these attention scalars. The weighted kernels are then applied to the input in parallel after the resulting attention values are multiplied element-wise by the corresponding convolution kernels. Ultimately, an adaptively modulated feature map is created by aggregating the outputs of all dynamically weighted convolution kernels. The architecture of FDDC network is illustrated in Figure 3.

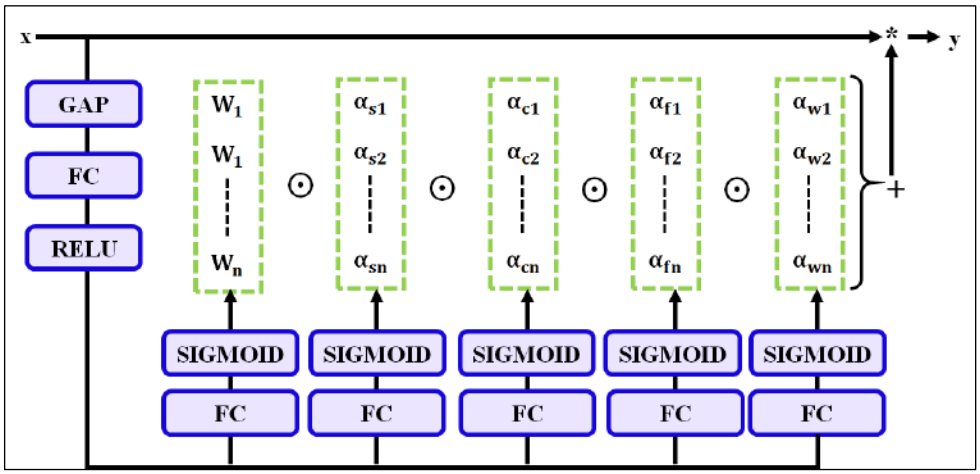

Figure 3: Structure of FDDC network .

III.3.2 Shuffle Attention (SA) Mechanism

The Shuffle Attention (SA) technique combines spatial and channel attention while reducing computing complexity to improve feature discrimination. More fine-grained attention learning is made possible by SA, which splits the input feature tensor into smaller grouped subsets rather than analysing the entire feature map holistically. An input feature map $X \in \mathbb{R}^{C\times W\times H}$ is first divided into G groups along the channel dimension, represented as $X = \{X_1, X_2, \ldots, X_G\}$with each group $X_i \in \mathbb{R}^{\frac{C}{G}\times W\times H}$. As seen in Figure 4, each group is then further split into two branches, $X_{i1}$and X_{i2},, which stand for channel-attention processing and spatial-attention processing, respectively. Channel Attention is used in the first branch to highlight the significance of informational channels. The spatial dimension of X_{i1},is compressed using a GAP operation to create channel attention weights. This results in a one-dimensional descriptor $F_{GAP}(X_{i1})$. The channel-attention coefficients X'_{i1} are then obtained by feeding this descriptor into a fully linked transformation and Sigmoid activation.

$$S = F_{GAP}(X_{i1}) = \frac{1}{W\times H}\sum_{j=1}^{W}.\sum_{k=1}^{H}.X_{i1}(j,k) \tag{6}$$

$$X'_{i1} = \sigma(W_1 S + b_1) \tag{7}$$

The trainable parameters are stated as W_1 and b_1. Spatial Attention is used in the second branch to identify local structural signals and spatial correlations in the feature map. Spatial attention stresses pixel-level interactions, in comparison with the channel attention branch. To create spatial-attention maps, Group Normalization (GN) is applied over X_{i2}, followed by a fully connected layer and Sigmoid activation:

$$X'_{i2} = \sigma(W_2 \cdot GN(X_{i2}) + b_2) \odot X_{i2} \tag{8}$$

An enhanced feature group $X_i' = [X_{i1}', X_{i2}']$. is created by concatenating the two processed branches X_{i1}' and X_{i2}'. Following the independent processing of each group, the outputs are combined and a channel shuffle operation is carried out. This shuffling step prevents feature isolation and facilitates efficient information sharing across groups by redistributing learnt dependencies across channels. The architecture of SA mechanism is illustrated in Figure 5.

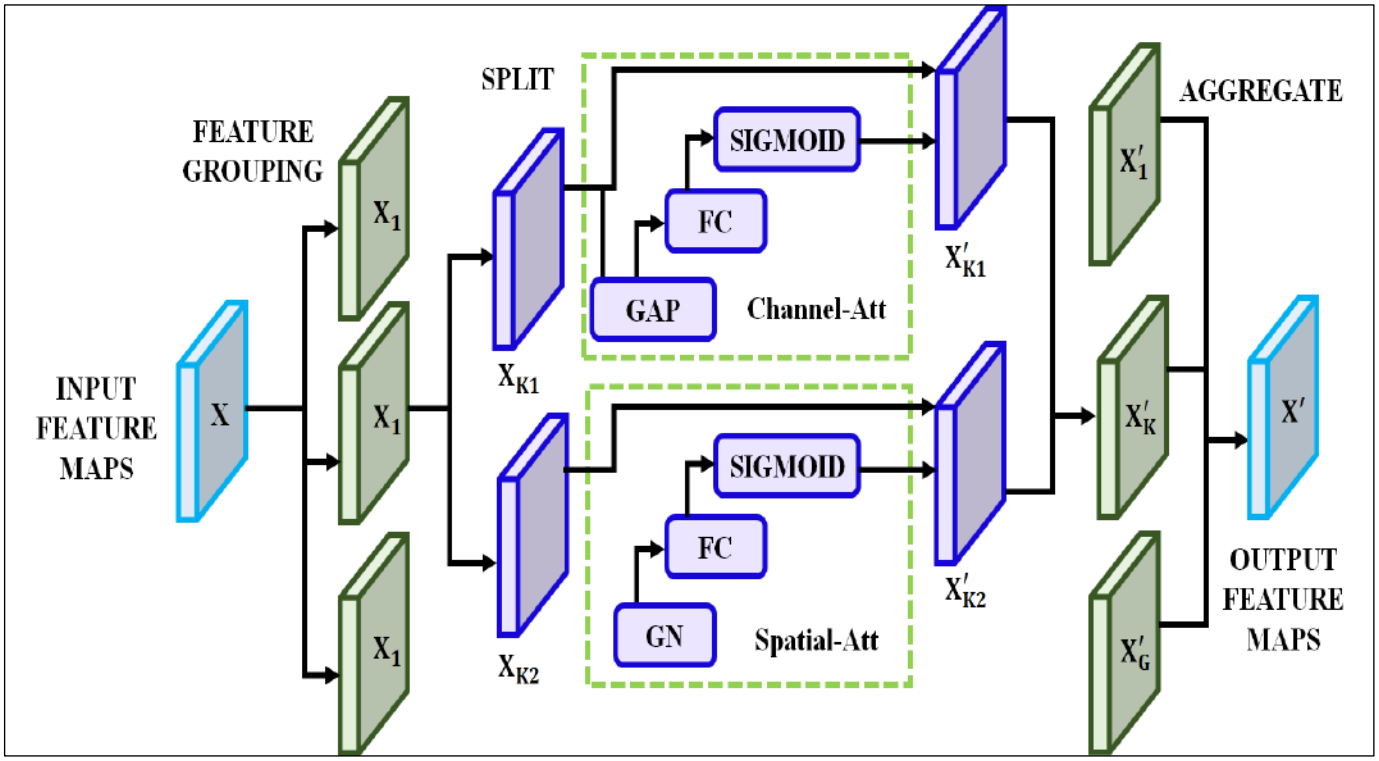

Figure 4: Shuffle attention mechanism.

III.3.3 Attention Layers with Conv-LSTM Networks

The Conv-LSTM framework incorporates the attention layer to improve the capacity of the model. In order to allow the network to emphasize the most relevant temporal aspects and suppress unnecessary or redundant information, an attention mechanism is implemented to selectively weight the hidden states generated by Conv-LSTM. A weighted sum of the hidden states is used to determine the final attention-enhanced hidden representation $H_t{}'$ and its expression is given below:

$$H_t{}' = \sum_{s=1}^{n+1} . \beta_s H_{t-(s-1)}^f \tag{9}$$

Here, $n+1$ specifies the sequence length, β_s defines the attention weights and its mathematical formulation is given below:

$$\beta_s = \frac{\exp(S_s)}{\sum_{i=1}^{n+1} \exp(S_i)} \tag{10}$$

The contribution of both temporal information from the Conv-LSTM hidden states (H_t^f) and spatial feature information from CNN layers $(G_t)$is evaluated to determine the important score S_s and it is defined below:

$$S_s = V_s^T \tanh(W_s G_t + W_s^f H_t^f) \tag{11}$$

where V_s, W_s,and W_s^f are learnable weight parameters. The network gains improved interpretability, resilience, and efficiency when handling complex temporal sequences like fraud detection, or anomaly analysis by combining Conv-LSTM with attention. The structure attention layer with network model is illustrated in Figure 5.

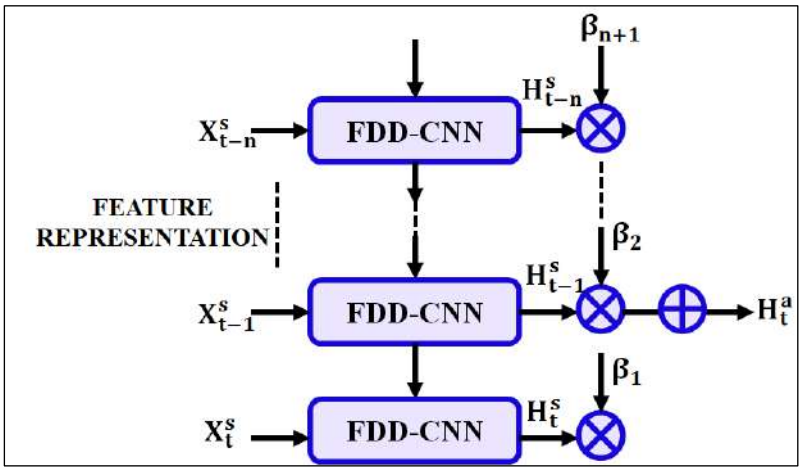

Figure 5: Attention layer with network model.
Source: Author, (2026).

III .3.4 Lstm Final Layer Workflow Description

The LSTM layer serves as the main decision-making component and it receives the refined feature representations generated by the FDD-CNN layer and the attention-enhanced Conv-LSTM processing. By examining the sequential evolution of transaction behavior, this last LSTM layer discovers the differences between normal and fraudulent spending patterns. The LSTM layer creates an output and that captures the degree of risk connected to each transaction by keeping crucial temporal information and eliminating unnecessary variations. The prediction module receives this final temporal embedding and uses it to determine a fraud probability score that determines whether the transaction is authentic or fraudulent. As a result, the LSTM layer functions as the final analytical step that integrates all acquired temporal, channel, and geographical insights into an appropriate fraud detection determination.

III.4 STAGE 4: FINAL DECISION SYNTHESIS, RISK SCORING, AND AUTOMATED ACTION EXECUTION

The output generated from the previous stages are integrated in the final stage of the proposed framework which include preprocessing stage, transaction stage and the deep temporal fraud detection stage respectively. This level serves as the decision-making layer, assuring that the statistical knowledge generated by the multi-agent architecture is translated into real-time defensive measures.

III.4.1 Risk Score Fusion and Decision Synthesis

All agent-level outputs are gathered via a weighted decision function regulated by the AI Orchestrator. Therefore, the mathematical expression of integrated transaction-level risk index R_t is defined below:

$$R_t = \sigma(w_1 S_{\text{coat}} + w_2 S_{\text{beh}} + w_3(1 - S_{\text{ver}}) + w_4(1 - S_{\text{dq}})) \tag{12}$$

Here, the anomaly probability output from the CoAt-LSTM model is stated as S_{coat}, behavioral deviation score produced by the Behavioral Analysis Agent is termed as S_{beh}, the score from the Verification Agent and Data Quality Agent is termed as S_{ver} and S_{dq} respectively. w_1, w_2, w_3, w_4 are orchestrator-learned fusion weights.

III.4.2 Threshold-Based Classification and Interpretability Layer

After generating the risk score R_t, the comparison process is performed with dynamic decision threshold τ_t, which is constantly updated using cloud-side feedback loops. A transaction is fraudulent if:

$$\hat{y}_t = \begin{cases} 1, & R_t \geq \tau_t, \\ 0, & R_t < \tau_t. \end{cases} \tag{13}$$

By using Bayesian calibration or reinforcement signals arising from false-positive/false-negative results the threshold τ_t is regularly improved.

III.4.3 Automated Mitigation and Action Execution

Following classification, the system executes one of many automated responses via the Reporting Agent. These activities are rule-based but informed by the estimated risk magnitude:

- **Low-risk ($R_t < \tau_t$)**

→ The transaction has been approved and recorded in the ledger for future learning.

- **Moderate-risk ($\tau_t \leq R_t < \tau_t + \delta$)**
  → Transaction has been marked for secondary authentication (OTP verification, user confirmation, or device fingerprinting tests).
- **High-risk ($R_t \geq \tau_t + \delta$)**

→ The transaction is automatically blocked, and an incident report is sent to the banking back office.

The term δ refers to an empirically calculated high-risk escalation margin. The Reporting Agent creates a structured cloud report based on decision metadata such as risk score, anomaly patterns, temporal indices, and supporting evidence from other agents. This ensures immediate fraud mitigation while keeping full documentation for forensic examination.

IV. RESULT AND DISCUSSION

This section presents and analyzes the experimental results obtained by utilizing the proposed fraud detection system. The effectiveness of the model is evaluated using normal classification parameters, and the results are analyzed to determine the efficacy of the proposed method in detecting fraudulent transactions. A comparison with baseline models is additionally provided to demonstrate the benefits achieved by the recommended approach.

IV.1 DATASET DESCRIPTION

The experiments described in this article were carried out on the Kaggle Credit Card Fraud Detection dataset, which contains 284,807 transaction records by employing 31 features. The above characteristics comprise 28 anonymized numerical variables generated from principle component analysis (PCA), as well as the Time and Amount attributes, with Class representing fraudulent transactions and 0 indicating legitimate ones. The dataset is portioned in to train-test split ratio of 80 and 20% respectively to perform network modelling.

IV.2 CLASS IMBALANCE IN THE CCF DATASET

The class distribution of CCF Detection is shown in Figure 6, which clearly demonstrates the significant deviation between genuine and fraudulent cases. The minority class (Class 1, fraudulent transactions) makes up just around 0.2% of the total samples, whereas the majority class (Class 0, non-fraudulent transactions) makes up about 99.8%. This stark disparity is an aspect of a realistic fraud detection pattern in which fraudulent events are extremely important but inherently uncommon. Therefore, the suggested agentic and deep learning framework's need for specialized learning strategies, reliable evaluation measures, and sophisticated modeling techniques is justified by this imbalance.

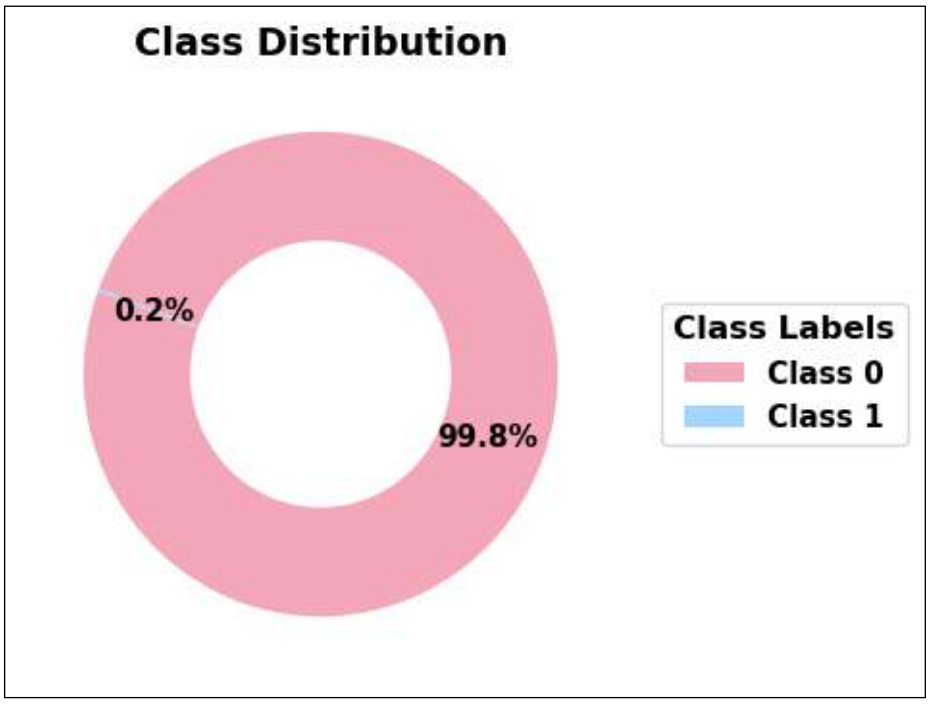

Figure 6: Class Distribution of Legitimate and Fraudulent Transactions.
Source: Author, (2026).

IV.3 RIGHT-SKEWED NATURE OF MONETARY TRANSACTION VALUES

The distribution of transaction amounts across all recorded operations in the dataset is shown in Figure 7. The distribution shown in the histogram has a significant bias to the right, with the great majority of transactions happening at relatively modest monetary values and a small number exhibiting exceptionally high sums. This long-tail tendency is typical of actual financial transaction data, where high-value transactions are rare and ordinary purchases are more prevalent. In order to avoid impact on the learning process, preprocessing must properly scale and normalize transaction values due to their broad range. Furthermore, this distribution is especially crucial for detecting fraud since abnormally high or unusual transaction amounts frequently contain powerful discriminatory information for spotting fraudulent activity.

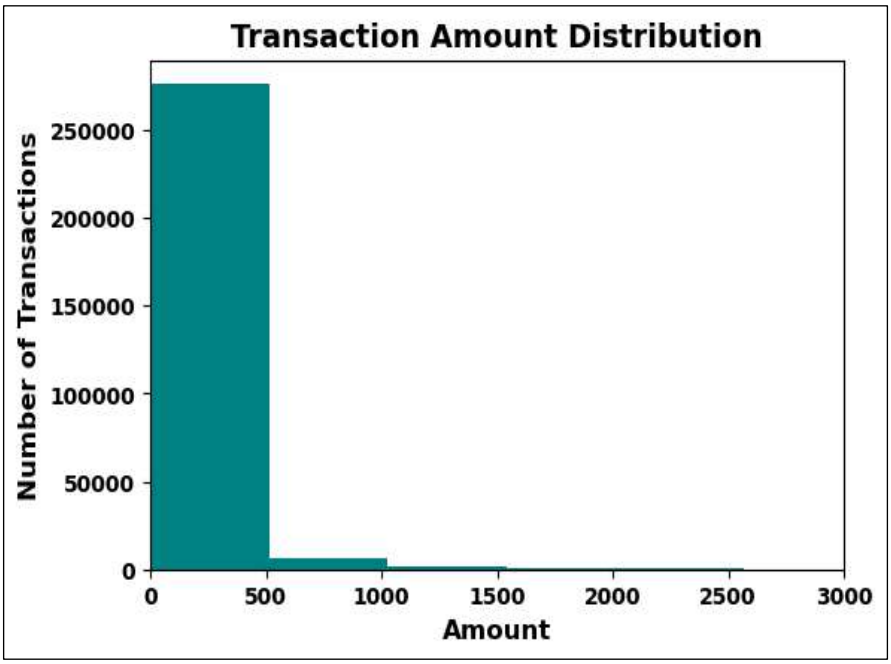

Figure 7: Statistical Distribution of Transaction Amounts.
Source: Author, (2026).

IV.4 MARGINAL DISTRIBUTIONS OF PCA FEATURES V11 AND V19

The probability distribution of V11 and V19 across frequency over the complete transaction set is distributed in Figure 8. The visualization of distribution reveals a gaussian shape structure which is focussed at zero. Feature V19 seems to be more heavily centralized with smaller dispersion and feature V11 has a moderately right-skewed distribution with significant range. Therefore, this indicates that it does not requires any additional normalization process. In terms of fraud detection, such symmetric distributions imply that discriminative power is derived not just from extreme marginal values, but also from joint feature interactions and temporal patterns, necessitating the employment of deep network model in later phases.

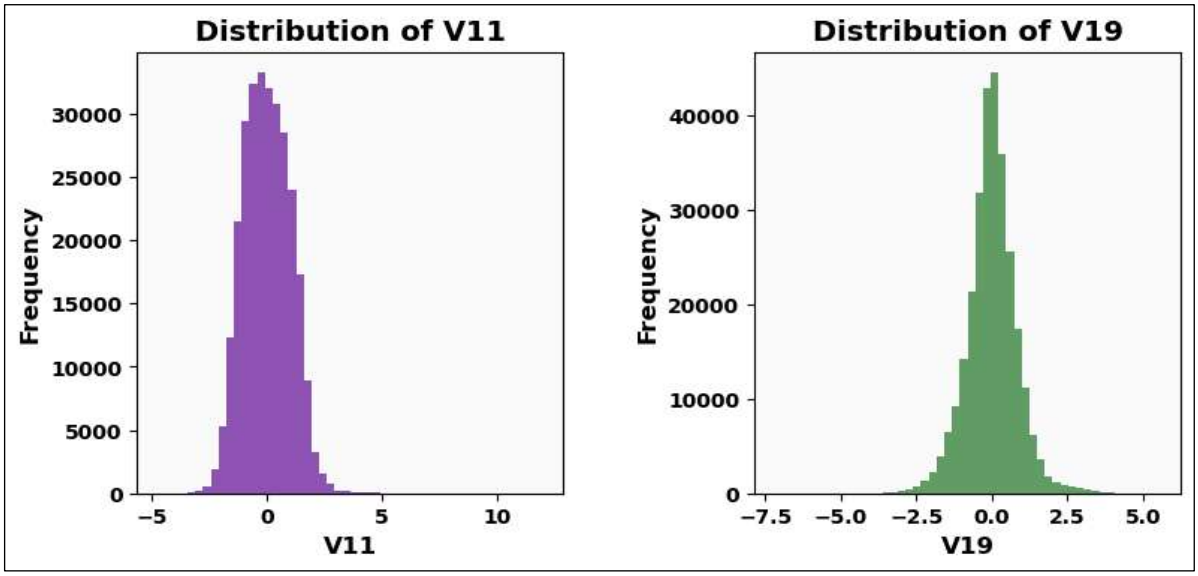

Figure 8: Probability distribution of V11 and V19.
Source: Author, (2026).

IV.5 JOINT DISTRIBUTION OF PCA FEATURES V3 AND V4

Figure 9 shows the superimposed histograms of V3 and V4 of two PCA-derived elements that are frequently utilized to be extremely valuable for fraud detection. Both features have large numerical ranges with big curves and it is in bell shaped distributions with their point centers near to zero. The V3 feature has a little broader spread toward the negative, implying an abundance of certain high or low values, whereas V4 looks to be more densely packed around the mean. The high overlap between the V3 and V4 distributions indicates that these features fail to distinguish between fraudulent and genuine transactions on their own. This image indicates that the data is well-normalized and appropriate for use in deep learning models like the CoAt-LSTM utilized in this work.

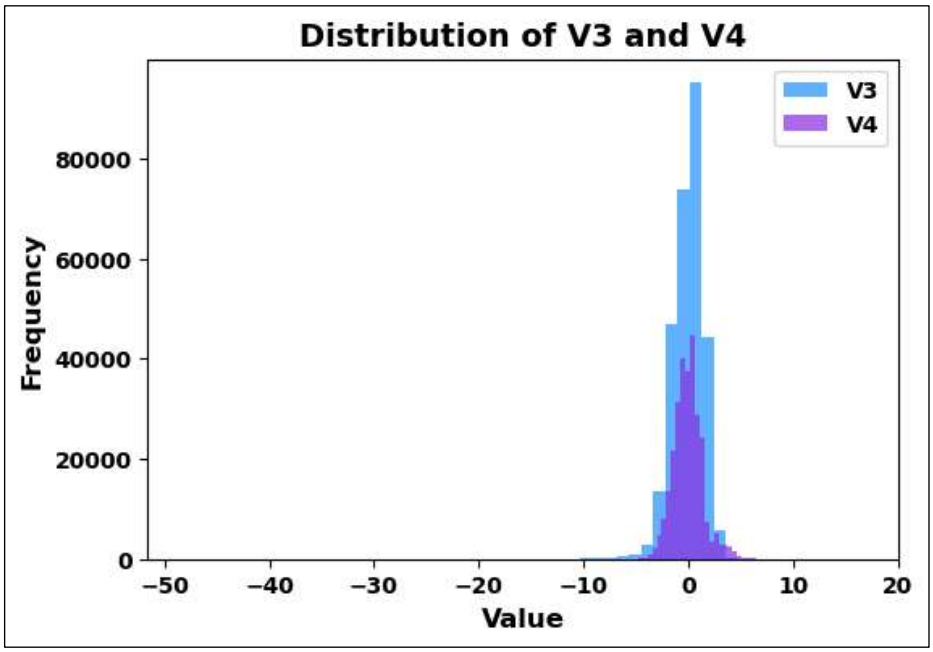

Figure 9: Probability distribution of V3 and V4.
Source: Author, (2026).

IV.6 FEATURE DISTRIBUTION ACROSS FRAUD AND NON-FRAUD TRANSACTIONS

The probability density of the V12 feature for genuine (Class 0) and fraudulent (Class 1) transactions is shown in the Figure 10. For non-fraud transactions the curve focuses around a short band near zero and it indicates that the majority of legitimate transactions have extremely similar V12 values. In comparison, the fraud distribution is much more dispersed and biased toward negative values and it reflects a greater variance in fraudulent activity. The noticeable difference between the two curves implies that V12 is a highly discriminative as illegal transactions typically follow a distinct pattern from legitimate ones.

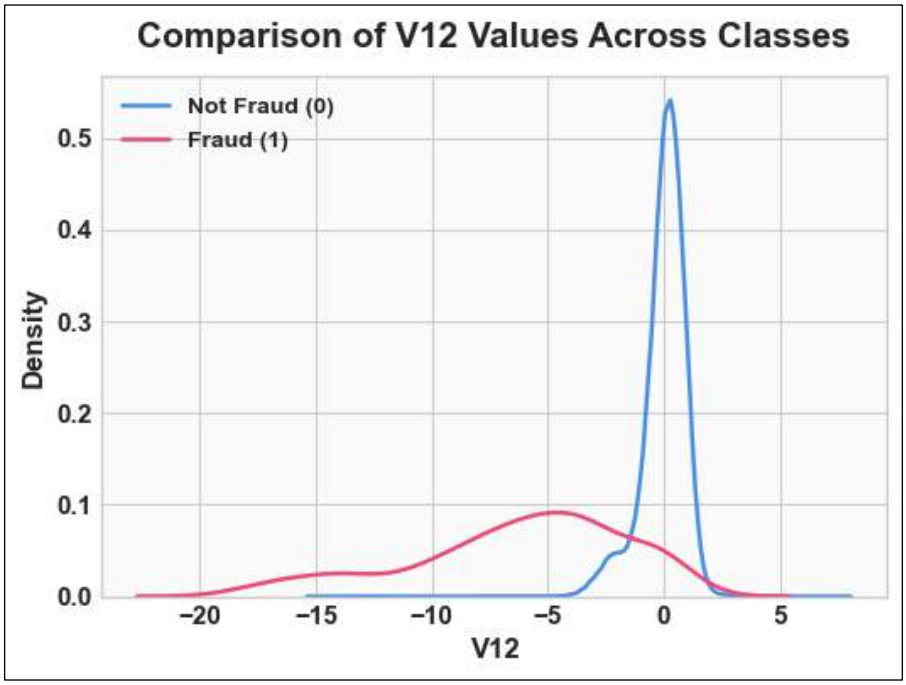

Figure 10: Class-wise Density Comparison of Feature V12.
Source: Author, (2026).

IV.7 FEATURE DENSITY WITH MEAN AND MEDIAN

The overall feature density distribution of V22 across its mean and median values is illustrated in Figure 11. Figure displays that the curve has a point which is near to zero as well as both the mean and median are extremely near to zero. This shows that the feature was effectively well normalized and fails to have a significant imbalance. This curve indicates the PCA-transformed features and it confirm that V22 is statistically robust and suitable for immediate usage in training the model without further scaling or modification.

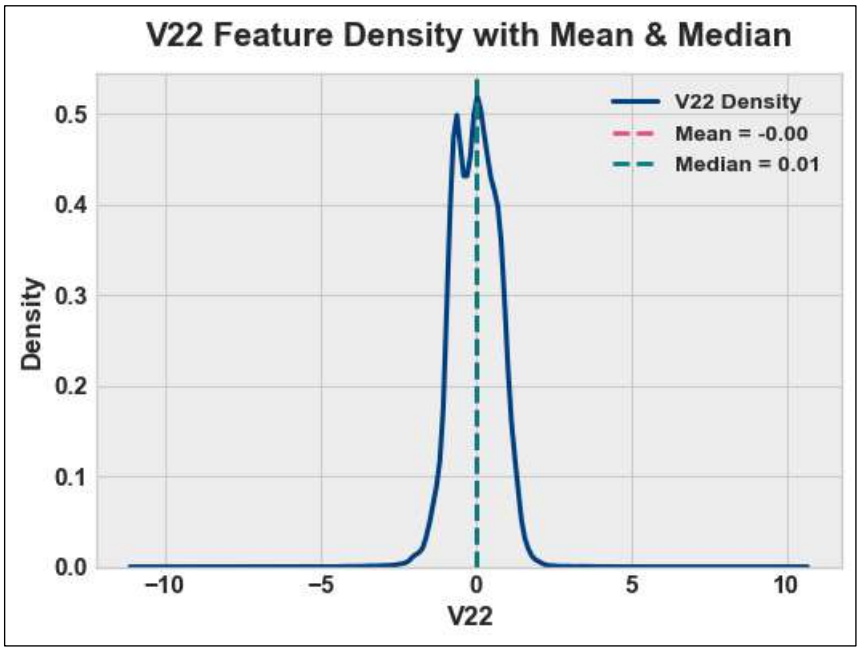

Figure 11: Density Profile of Feature V22 with Mean and Median.
Source: Author, (2026).

IV.8 CORRELATION HEATMAP OF PCA FEATURES

Figure 12 depicts the Pearson correlation matrix for the PCA-transformed elements and it is seen that the vast majority of off-diagonal components possess values almost identical to zero. This confirms due to the orthogonality established by the PCA transformation process. Therefore. this degree of statistical independence holds significance for deep learning architectures because it reduces convergence and maintains gradient propagation during the training stage. This lack of linear correlations signifies that fraudulent activities are reflected in temporal dependencies which supports the inclusion of convolutional, attention, and LSTM layers in the third stage of the proposed framework.

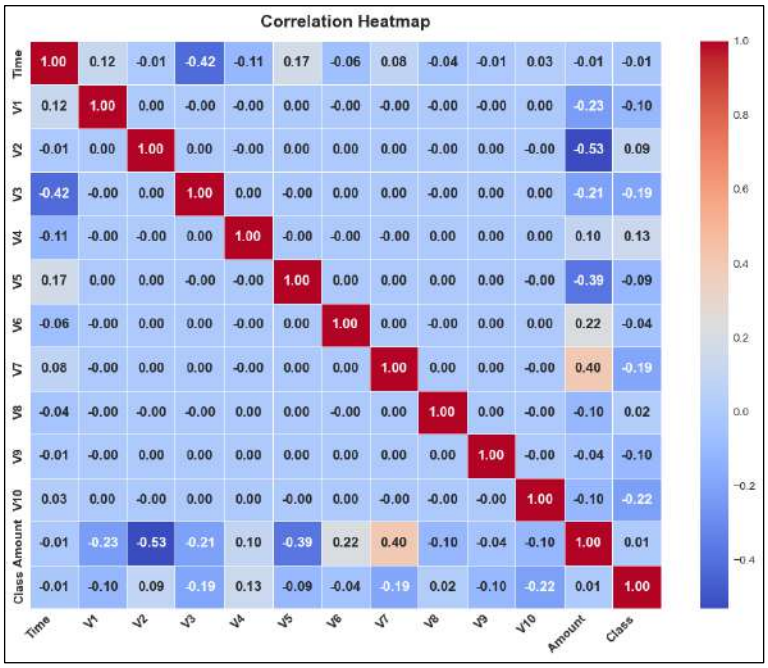

Figure 12: Correlation heatmap.
Source: Author, (2026).

IV.9 LEARNING STABILITY AND CONVERGENCE BEHAVIOR OF THE PROPOSED COAT-LSTM MODEL

The training and validation of both the accuracy and loss curve of the proposed model is illustrated in Figure 13. The accuracy and loss are examined by altering the epoch size to 20. The figure shows that the proposed model's training accuracy remains stable at above 95% throughout all epochs, indicating strong learning consistency. The validation accuracy nearly matches the training curve, with just minor differences, showing strong generalization and little overfitting.

The proposed model's loss curve, illustrated on the right side, falls gradually from around 0.27 to nearly 0.12, confirming effective optimization. At the intermediate stage, the validation loss decreases with minor fluctuations for fraud detection. Overall, the precise alignment of the training and validation curves demonstrates that the COAt-LSTM model provides both stable convergence and robust temporal fraud detection.

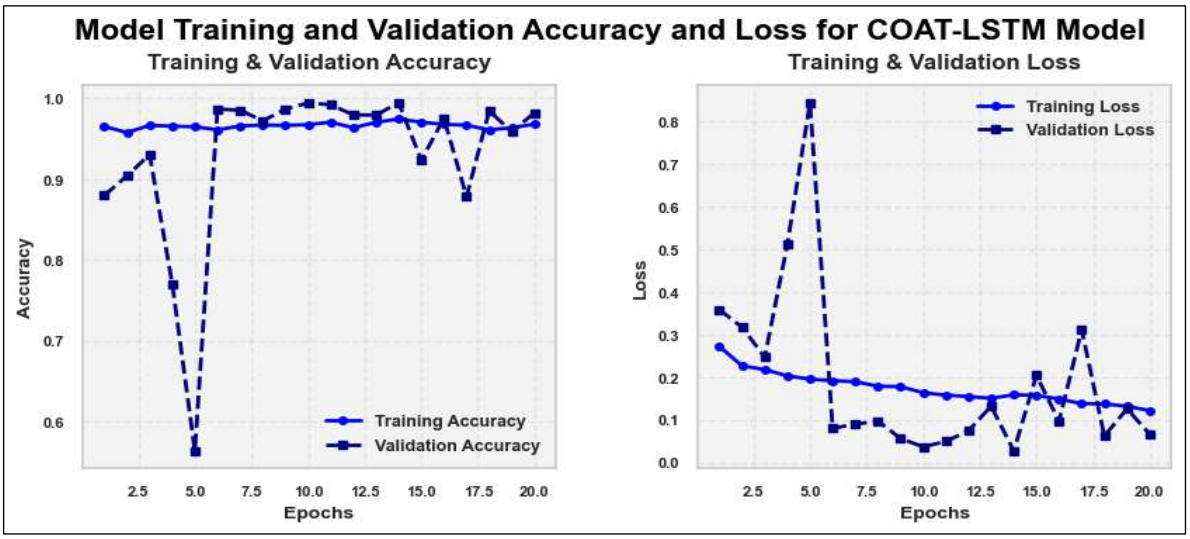

Figure 13: Training and Validation Performance of the COAt-LSTM Model Across Epochs.
Source: Author, (2026).

IV.10 COMPARATIVE LEARNING CHARACTERISTICS OF THE BASELINE GRU MODEL

The learning characteristics of the existing baseline GRU model in terms of accuracy and loss is shown in Figure 14. In the course of the first few epochs, the training accuracy rapidly increases and then remains steady at 96-97%. The ability of GRU model to record extremely detailed patterns or manage excessively long sequences may be limited. The training loss decreases dramatically from an initial high value of 0.78 to less than 0.1, showing fast convergence. The training and validation accuracy curves show that the proposed CoAt-LSTM model converges faster and consistently achieves higher accuracy than the baseline GRU model. Furthermore, the suggested model's loss curves decline more smoothly and remain much lower across epochs, signifying greater learning stability.

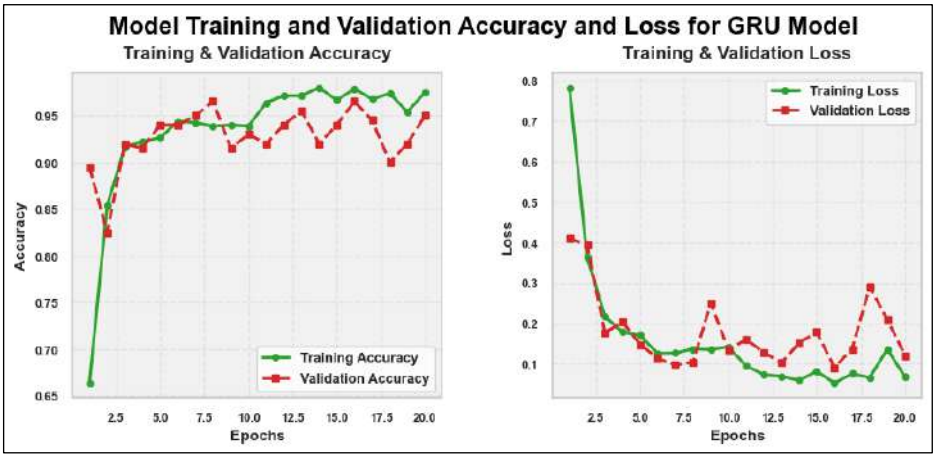

Figure 14: Training and Validation Performance of the GRU Model Across Epochs.
Source: Author, (2026).

IV.11 COMPARATIVE CLASSIFICATION PERFORMANCE USING CONFUSION MATRICES

The confusion matrix analysis of the proposed model and the existing GRU model is illustrated in Figure 15 and it compares the predicted and actual values. From figure it is seen that the underclass 0, proposed model predicts 56856 as class 0 and only 8 are classified incorrectly as class 1. In addition to this for class 1, the proposed model predicts 74 as class 1 and only 24 are misclassified as class 0 respectively. In addition to this for an existing GRU model, for class 0, 54380 samples are correctly classified as class 0 and 2484 samples are misclassified as class 1. For class 1, 87 samples are correctly classified and 11 samples are mis classified as class 0 respectively. Overall, the COAT-LSTM model exhibits an optimum equilibrium between fraud detection accuracy and false alarm control, making it more acceptable for practical applications.

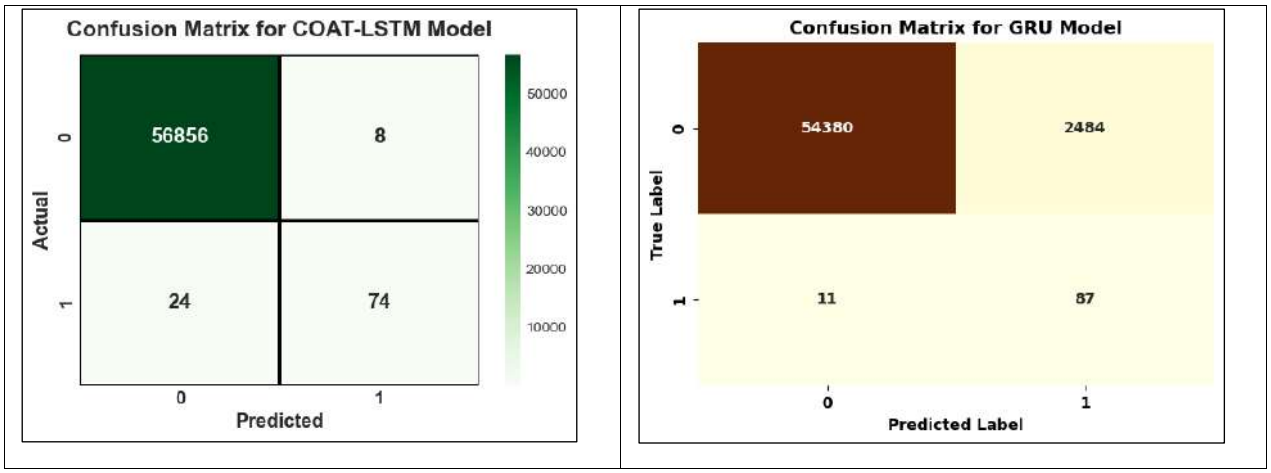

Figure 15: Confusion Matrix Analysis of COAT-LSTM and GRU Models.
Source: Author, (2026).

IV.12 DISCRIMINATIVE CAPABILITY EVALUATION USING ROC CURVES

The ROC (Receiver Operating Characteristic) curve compares the true positive rate against the false positive rate at various decision thresholds to demonstrate how well the model distinguishes between fraudulent and legitimate transactions. A curve that is closer to the top-left corner suggests superior classification performance since it produces a high fraud detection rate while minimizing false alarms. In the present scenario, the high Area Under the Curve (AUC) value indicates that the proposed model has excellent discriminative ability and can reliably distinguish between fraudulent and non-fraudulent transactions. Form figure 16 it is evident that the proposed model attains an AUC of 97% whereas the existing GRU model reaches and AUC of 95.02% recpectively. The boosted AUC generated by COAT-LSTM demonstrates that combining fully dynamic convolutional model with shuffle attention mechanism enhances temporal learning by increasing the sensitivity of the model while retaining reliable generalization. These findings confirm the benefit of the suggested deep temporal modelling framework in high-risk financial transaction circumstances.

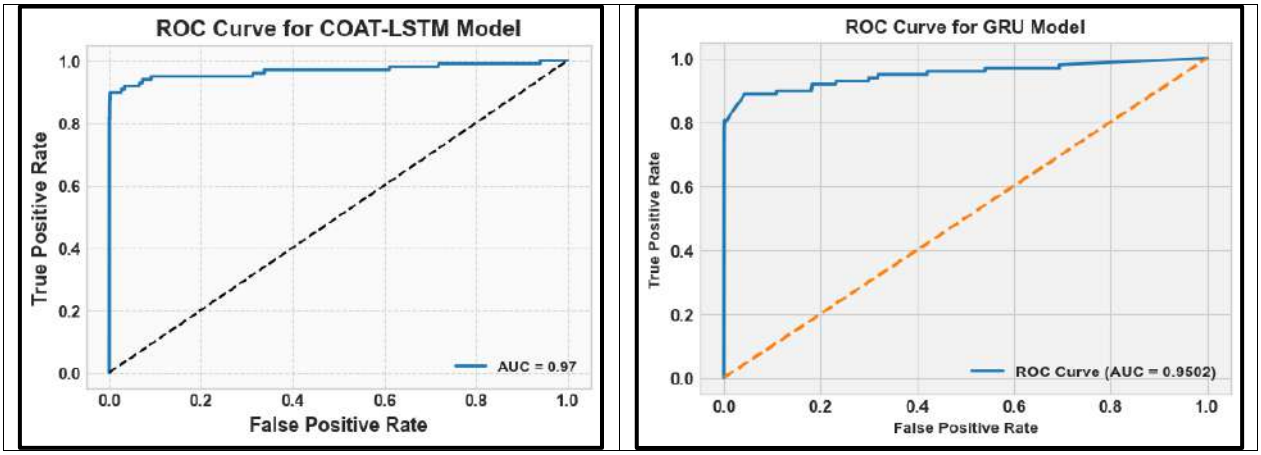

Figure 16: ROC Curve Comparison for COAT-LSTM and GRU Models.
Source: Author, (2026).

IV.13 FINAL TRANSACTION ASSESSMENT AND RISK INTERPRETATION

Figure 17 depicts the proposed agentic fraud detection framework's ultimate decision after completing all analytical phases, including verification, behavioral analysis, and deep temporal modelling. The system first displays the Forgery Detection result as "No Forgery," signifying that there was no actual manipulation or forgery has been identified in the transaction characteristics. The Verification Status signifies that the transaction has been verified effectively against an external database, assuring data authenticity and consistency. The CoAt-LSTM-based fraud detection model classified the transaction as "Legit," according to the AI Report. However, the Risk Assessment also identifies the transaction as "High Risk," indicating that while the transaction is classified as valid, it exhibits certain behavioral or temporal patterns and therefore require constant monitoring. The prediction probabilities demonstrate a very high confidence level for Class 0 (legitimate) and an extremely low likelihood for Class 1 (fraud), justifying the final predicted class of 0 (Legit). The Final Prediction column concisely highlights the outcome sent to the automatic response module. This result highlights how the proposed system relying purely on classification output and it incorporates verification signals and behavioral risk indicators to deliver a more accurate and effective fraud conclusion in real-world deployment. The comparative analysis of performance measures with respect to existing base line model is shown in Table 2.

```
==================== FINAL OUTPUT ====================
Forgery Detection     : No Forgery
Verification Status   : Verified with External DB
AI Report             : Legit
Risk Assessment       : High Risk
======================================================

Prediction Probabilities = [[9.9987781e-01 1.2218881e-04]]
Predicted Class = 0
Final Prediction: Legit
```

IV.14 ABLATION STUDY

The ablation study clearly reveals the specific contribution of each component of the proposed CCF architecture and it is shown in Table 3. The full Agentic CoAt-LSTM model outperforms all assessment measures, demonstrating the efficacy of combining agentic intelligence and deep temporal modeling. When the agentic layer is eliminated, there is a considerable decline in accuracy, precision, and recall, demonstrating the necessity of autonomous transaction reasoning and cross-agent validation. Similarly, removing the attention mechanism limits the model's capacity to focus on crucial transaction patterns, resulting in worse fraud detection performance. The elimination of the convolutional layer and the LSTM have an effect on localized feature learning and temporal dependency modeling and this tends to classification capabilities. Overall, the ablation analysis shows that each architectural block makes a significant contribution to the proposed system with resilience and dependability.

Table 3: Ablation study.

Variant (Ablation)	Accuracy	Precision	Recall	F1 score
Proposed (CoAt-LSTM + Shuffle-Attention + Agentic pipeline)	0.9821	0.5395	0.9350	0.5682
Without Shuffle Attention (CoAt-LSTM w/o attention)	0.9750	0.4900	0.8900	0.6200
Without CNN (LSTM + Attention only)	0.9680	0.4500	0.8800	0.5900
Without LSTM (CNN + Attention only)	0.9700	0.4200	0.8200	0.5600
Without Agentic components (no Data-Quality / Verification agents)	0.9740	0.4800	0.8800	0.6200
Baseline GRU model (standard baseline)	0.9610	0.4500	0.9000	0.6000

V. CONCLUSION AND FUTURE SCOPE

This paper described a unique cloud-based Agentic Artificial Intelligence architecture for real-time CCF detection. The proposed methodology included intelligent multi-agent collaboration, deep temporal learning via the CoAt-LSTM model, and an automated risk determination mechanism to improve detection accuracy and responsiveness. The system efficiently addressed the intrinsic issues of extreme class imbalance and anonymous features by combining behavioral analysis, dynamic convolution, attention mechanisms, and temporal dependency learning. Experimental results showed that the suggested model outperformed traditional machine learning methodologies and baseline deep learning models like GRU in terms of accuracy, precision, recall, F1-score, and ROC performance.

The automated risk assessment and decision module allowed for faster and more reliable mitigation activities without the need for manual intervention. Despite the high level of performance attained in this study, many opportunities for future research remain unexplored. To begin, the framework can be enhanced to accommodate real-time streaming transaction data for large-scale deployment via distributed cloud platforms such as Apache Kafka and Spark. Second, explainable AI (XAI) techniques can be used to improve fraud decision interpretability, which is crucial for regulatory compliance in financial systems. Third, the suggested agentic framework might be improved by incorporating reinforcement learning, which would enable agents to continuously adapt to newly developing fraud patterns.

ABSTRACT

In recent years, the deep learning technique for Human Activity Recognition (HAR) systems has made remarkable improvements in recognising complicated activity classes and real-world scenarios. This study introduces a unified deep learning framework, called the Hybrid Dense Temporal Transformer Network (HDTTN) is used to capture spatial, temporal, and semantic information for improved human activity detection. Using the DenseNet-201 to improve spatial feature extraction from visual inputs, Temporal Convolutional Networks (TCNs) for learning short-term motion patterns, and Transformer encoders for learning long-range temporal dependencies that are crucial for processing complex and subtle activities. This study employs an early multimodal feature fusion strategy to further enhance representational coherence, which makes it easier to incorporate heterogeneous cues at the feature level and to learn dynamic multimodal representations. Moreover, a hybrid optimization approach is integrated for parameter fine-tuning for efficiency, reduced overfitting, and increased model robustness. The proposed HDTTN framework is shown to be effective on the large-scale Kinetics dataset containing a wide range of unconstrained human activities. Experimental results shows that the proposed model is 93% accurate, compared to several existing state-of-the-art baseline approaches. Moreover, qualitative and quantitative analyses validate HDTTN's ability to identify intricate and complex activities across a multitude of environments.

I. INTRODUCTION

Human Activity Recognition (HAR) has become a major research area in computer vision and artificial intelligence, which refers to the task of identifying and understanding human actions in video data automatically. The proliferation of surveillance cameras, digital media platforms, and intelligent video analytics systems has led to the continuous generation of massive visual data in real time, which requires automatic approaches that are able to interpret complex human behaviors within everyday life settings [1]. Thus, video-based HAR has drawn much attention due to its important applications in public safety surveillance, health care video monitoring, sports performance analysis, video retrieval, and human–computer interaction [2]. Video-based HAR is learning spatiotemporal representations from RGB videos, depth sequences, optical flow, or pose-based representations.

Compared with still image recognition, action recognition needs to jointly model the spatial appearance, temporal motion dynamics, and changes of context over time, which is a more challenging learning problem [3]. Dynamics may vary from simple daily behaviour's to complex activities with long-term temporal dependencies and subtle motion changes. Therefore, HAR systems must consider both short-term motion cues and long-range temporal dependencies [4]. Early video-based HAR methods were based on manually designed primitives with spatiotemporal interest points, motion descriptors with optical flow and trajectory-based representations, along with traditional classifiers. Although these methods showed an acceptable performance in constrained situations, they had a strong response to background clutter, viewpoint difference (VPD), and light change and were restricted to practical use [5].

The era of deep learning significantly advanced video-based HAR, where discriminative representations can be learned in an end-to-end manner directly from raw video data. Summarization regarding the spatial feature extraction, CNNs are widely considered to be effective at learning hierarchical visual representations. Two-stream CNN architectures additionally enhanced the recognition performance by encoding appearance and motion information jointly with RGB frames alongside optical flow [6]. Then, 3D-CNNs generalized the convolutions in a three-dimensional space and learned the spatial-temporal characteristics simultaneously [7]. However, 3D CNNs are computationally expensive and have inherent difficulties in modelling long-range dependencies because they are based on fixed-size temporal receptive fields.

Sequence-based models are employed to address the limitation of exclusively relying on frame information (e.g., Recurrent Neural Networks (RNNs) and Long Short-Term Memory (LSTM) networks have been proposed to learn temporal dependencies among video frames [8]). However, such models can have vanishing gradients and are not scalable to long videos. Temporal Convolutional Networks (TCNs) have been proposed as an efficient alternative that provides gradient stability and parallel computation in modelling short-term and long-range temporal dependencies [9]. However, TCNs may still be restricted in their ability to encapsulate the intricate long-range dependencies that are present in large-scale human activities independently. The graph-based HAR approaches provide more attention because they can model the local structured relationship between body joints, regions, or pixels over time explicitly.

In these works, videos are modelled as graphs in which nodes represent spatial entities and edges denote either spatial or temporal interdependences [10]. Graph Convolutional Networks (GCNs) effectively extract non-Euclidean dependencies and correlation structures that are extremely difficult to represent using classical convolutional operations. By utilizing graphs, such approaches improve on explicitly modelling spatiotemporal interaction relationships that are necessary for activity recognition. Recent research has expanded temporal graph modelling and contrastive learning to new levels of sophistication to enhance the generalization and robustness of HAR. Temporal graph contrastive learning (TGCL) acts to align positive temporal representation pairs and suppress out-of-class motion, which has the potential of reducing intra-class variance and promoting discrimination [11].

The performance of the majority of existing graph-based methods can be compromised by complex activities, as they only consider limited temporal context or do not integrate mechanisms to incorporate global temporal dependencies, despite being driven by their effective results. The inadequate generalization across datasets and environments is the main cause of the reason HAR on video remains an unsolved problem. It has been stated that the distribution shift between training and testing environments (screened camera view, background, actor face, and movement style) can lead to a significant change in appearance [12]. Additionally, deep HAR models are highly susceptible to network architectures and hyperparameter selection, which could result in models that are unstable and less robust if not methodically calibrated.

Inspired by these challenges, in this paper we propose a Hybrid Dense Temporal Transformer Network (HDTTN) for the task of robust video-based HAR. The proposed framework combines DenseNet-based spatial feature extraction to improve feature reusing and gradient propagation, Temporal Convolutional Networks (TCNs) to describe the short-term motion dynamics, and Transformer encoders for learning long-range temporal dependencies with self-attention mechanisms. In addition, graph-based temporal modelling methods are included to efficiently model spatiotemporal relationships. An advanced feature-level fusion approach and a hybrid optimization scheme are used to increase the generalization power while preventing overfitting, as well as to improve recognition performance. The objectives of this study consist of:

- To construct a unified HDTTN for video-wise human action understanding.
- To achieve an effective early feature fusion method and graph-informed temporal reasoning.
- To optimize the HDTTN model with hybrid optimization methods that improve the efficiency of fine-tuning all parameters.

II. LITERATURE REVIEW

Human activity recognition (HAR) with RGB video is a significant issue with possible applications in surveillance, healthcare monitoring, sports analytics, and intelligent human-computer interaction systems [13]. Recent developments in deep learning techniques have enhanced the capability of learning spatiotemporal representations directly from raw video streams without the need for predefined descriptors. The most recent studies emphasize the importance of convolutional and attention-based architectures in video-based HAR research [14]. They also highlight challenges with long-range temporal modeling and robustness to complex real-world conditions.

Initially, deep approaches relied on 2D and 3D Convolutional Neural Networks (CNN) to detect spatial appearance and short-term motion [15]. 3D CNNs are effective for learning local spatiotemporal characteristics but have high computational costs and narrow temporal receptive windows [16]. Generalized two-stream CNNs with temporal integration were effective for short and basic activities but lacked global temporal reasoning for long and overlapping tasks. To solve temporal restrictions, a combination of CNN and RNN was developed. The CNN-LSTM cascades to encode frame-level characteristics and sequential information [17].

These techniques improved temporal continuity but exhibited limitations in sequential processing and capturing long-range interdependence in complex operations [18]. The development of Temporal Convolutional Networks (TCNs) represents a shift toward parallel temporal modelling. Temporal convolutions with dilation effectively capture multi-scale motion information [19], [20]. These efficient models focused on temporal dynamics and lacked global contextual reasoning for video content [21]. The HAR model using the Vision Transformer, known as NiViT, demonstrated significant improvements over models that rely solely on CNNs [22].

Transformer-based models require a huge amount of pre-trained data and expensive computation, making them unsuitable for practical applications. Hybrid CNN-Transformer architecture's efforts to balance efficiency and accuracy have yielded high recognition accuracy on large-scale benchmark datasets [23], [24]. Graph-based HAR approaches have improved video interpretation by directly displaying related structures. GCNs were used to model inter-frame (or region-level) dependencies, increasing resilience against occlusions and perspective alterations [25]. However, graph-based models primarily capture poses and limited temporal information, lacking dense appearance modelling [26].

Recently, a number of multimodal video-centric methods have been developed that integrate RGB appearance with semantic information and activity. Alternatively, they implemented early and late fusion techniques to enhance their discrimination capabilities. Even though the recognition capability was improved by the fusion, the scalability was not possible due to the suboptimal feature alignment and inadequate temporal smoothness [27], [28]. Comparative studies have shown that the majority of current video-based HAR models achieve an accuracy of 85–92%, particularly when tested on challenging datasets such as Kinetics. Optimization-driven HAR models have also been considered to enhance learned knowledge, and they employ evolutionary and meta-heuristic optimization for the fine-tuning of deep networks [29].

The improvement was feasible however, it was unsuccessful in addressing the instability of convergence and the complexity of training [30]. Despite these advancements, video-based and graph-based HAR approaches still face three major obstacles, including their inability to reliably integrate spatial, temporal, and semantic information, and they do not adequately capture long-term spatio-temporal correlations [31], [32]. These gaps inspire the designs of the proposed HDTTN, which combines transformer-based global attention with optimized early feature fusion, TCN-driven temporal modelling, and Dense Net based spatial encoding by overcoming the drawbacks of earlier research and providing superior recognition performance.

From the extensive literature review described, we can see that the current video-based and graph-based HAR models either focus on spatial appearance or short-term temporal dynamics or long-range attention. CNN based methods are not able to capture long-range temporal dependencies, and transformer-based models are effective at representing global context but computationally inscrutable and inefficient with limited spatial capability. Graph-based models advance relational reasoning, yet mostly based on abstract representations which ignore dense visual semantics. Moreover, traditional fusion approaches are not efficient enough and suffer from the shattered feature representation, whose scalability is inefficient.

Inspired by these limitations, we propose a Hybrid Dense Temporal Transformer Network (HDTTN) that presents an end-to-end architectural solution to fill out the above-mentioned technical voids in a synergistic approach through densely connected spatial feature propagation with DenseNet, fine-grained motion modeling with Temporal Convolutional Networks, and long-range temporal reasoning by means of transformer encoders. Early fusion strategy with optimization over the multimodal space yields not only consistent but also temporal coherent representations, and hybrid objective improves the generalization and robustness. This end to end design could directly overcome the limitation associated with prior arts and build up a scalable, high-accuracy framework for real-time human activity recognition.

It is apparent from the comprehensive literature review that the current HAR models, which are based on graphs and videos, either concentrate on spatial appearance, short-term temporal dynamics, or long-range attention. CNN-based methods are incapable of capturing long-range temporal dependencies, while transformer-based models are effective in representing global context but computationally perplexing and inefficient, with limited spatial refining capabilities. Graph-based models make significant contributions to relational reasoning however, they are primarily based on abstract representations that disregard complex visual semantics. Moreover, conventional fusion methods are insufficiently efficient and are complicated by the fragmented feature representation, which has poor scalability.

The proposed Hybrid Dense Temporal Transformer Network (HDTTN) is a synergistic solution to address the aforementioned research gaps. This entire design solution comprises densely connected spatial feature propagation with DenseNet, fine-grained motion modelling with Temporal Convolutional Networks, and long-range temporal reasoning through transformer encoders. This strategy is driven by these constraints. Early fusion methods that optimize over the multimodal space produce representations that are consistent and temporally coherent, while hybrid methods enhance the generalization and robustness. This end to end design could directly overcome the limitation associated with prior arts and build a scalable, high-accuracy framework for real-time human activity recognition.

II.1 RESEARCH GAP

Despite the remarkable advancements in video-based and graph-based Human Activity Recognition (HAR), several significant research gaps remain insufficiently addressed in recent years.

- **Insufficient Long-Term Temporal Modeling:** While most methods based on CNN or TCN focus on short-term motion patterns, none of them model long-range temporal dependencies required for recognizing complex and composite activities.
- **Fragmented Feature Fusion Strategies:** Current hybrid networks often perform late fusion or loosely coupled feature integration, which can cause semantic divergence and loss of information from the spatial, temporal, and relational signals.
- **Limited Exploitation of Graph-Based Semantics:** Though graph-based representation is widely adopted, most methods rely on quality of pose estimation or shallow graph reasoning, which limits robustness in unconstrained real-world videos.
- **Scalability and Generalization Issues:** Language-only or 3D CNN models require significant pretraining and are computationally intensive to both real-time deployment and generalization across datasets.

III. PROPOSED METHODOLOGY

The proposed Hybrid Dense Temporal Transformer Network (HDTTN) model aims to coordinate multimodal data input from video, audio, and text for effective human activity recognition. The approach is based on four major steps, including multimodal preprocessing, feature extraction, early fusion, and classification using a hierarchical deep temporal transformer network modified by dual-phase wasp monkey optimization. This study focuses on the HDTTN model which is used to predict human activity by integrating multi-modal data (video, audio, and text) through the use of various methods that synergize dense temporal modelling and multimodal fusion, optimized via Wasp Optimization for enhanced accuracy, scalability, and robustness across complex HAR tasks. It encompasses a variety of phases, including data preprocessing, feature extraction, multimodal fusion, classification, and optimization, as illustrated in Figure 1.

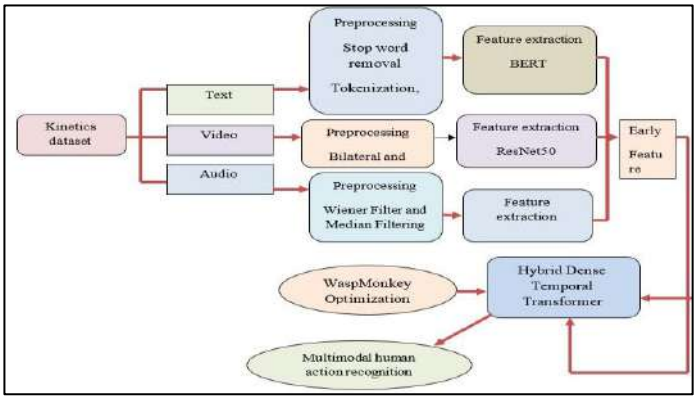

Figure 1: Proposed Multi-Modal Framework for HDTTN.
Source: Authors, (2026).

The above Figure 1 represents the architecture diagram, which describes the steps involved in activity recognition. It contains thousands of video clips, each containing marked human actions, allowing it to be a large dataset. Each video clip is marked with an action and contains video and audio, with the possibility of additional audio text, captions, or subtitles, allowing the dataset to be leveraged for multimodal learning.

- Pre-processing: Video frames are pre-processed with bilateral filtering and CLAHE, audio signals are subject to denoising by wiener and median filters, and text is normalized by applying stop-word removal, tokenization, and lemmatization.
- Feature Extraction: The spatial video features are extracted by ResNet50, the acoustic features are extracted by MFCC, and the contextual text features are extracted by BERT.
- Early Fusion: Vector features are concatenated into a single global representation.
- Hierarchical Deep Temporal Transformer Network (H-DTTN): Dense Net enables feature enrichment, TCN learns temporal dependencies, and Transformer layers capture long-range global interactions.
- Optimization: The model's parameters are modified by Wasp Optimization, Dual-phase of optimization, WSO performs local refinement, while SMO explores global solutions.

III.1 DATA COLLECTION

The input source video is collected from the Kinetics dataset. It is a subset of the Kinetics-400 and Kinetics-600 datasets for video action recognition. It seeks to offer a representative and systematic sample for the purposes of training and evaluation. The subset contains over 10,000 short video clips, each about 10 seconds long. It contains 10 to 40 samples for each class of a wide range of human actions. The videos are sourced from YouTube, and as a result, they are diverse in the backgrounds, lighting, motion, and camera angles, which are ideal for challenging human action recognition problems. Each clip is linked to a singular human action and accompanied by video, audio, and other multimodal data to enable multimodal learning, as shown in Equation 1.

$$d_i = (V_i, A_i, T_i), \forall i \in [1, N] \quad (1)$$

Where d_i represents a single sample from dataset, N the total number of samples in the dataset, V_i is the raw video data for sample with dimension $T \times H \times W \times 3$, A_i is the raw audio signal for sample i, T_i is the raw text data for sample i.

III.2 PRE PROCESSING

Text Modality: It is a vital component of the multimodal framework, providing semantic context that may not be apparent from visual or aural streams alone. Textual information, including speech, video captions, and scene descriptions, is frequently used to describe or accompany human actions. This modality assists in the disambiguation of actions that may appear visually or acoustically similar but differ in intention, instruction, or dialogue. Textual data is pre processed for instance, "the" or "is" are frequently occurring words with little meaning that will be removed through stop word removal. Prepares the text for embedding by splitting the text into words or sub-words through a process called tokenization, as shown in Equation 2.

$$T_i^{(2)} = S(T_i) \quad (2)$$

Audio modality: It plays a critical role in capturing complementary information that is often not visually observable, such as speech, environmental sounds, or background cues.

To ensure the audio data is clean, clear, and suitable for feature extraction, two key preprocessing techniques, Wiener filtering and median filtering, are applied sequentially. Wiener filtering is a statistical signal processing technique used to reduce background noise in an audio signal. Processing of audio is represented in Equation 3.

$$A_i^{Wiener}(t) = \frac{S_{xx}(t)}{S_{xx}(t)+S_{nn}(t)} . A_i(t) \quad (3)$$

Here, k is the window size of the median filtering, A_i^{Wiener} and is the median filtered signal of time t.

Video Modality: Preserving action-related details while removing noise is accomplished by smoothing techniques like bilateral filtering in the video frame, which shows the bilateral filtered frame as neighbouring pixels surrounding the pixel using the spatial Gaussian function BF. The bilateral range Gaussian function is represented by the intensities G_s and G_r, which serve as the normalizing factor. In Equation. 1 represents the bilateral filtering with its frames and normalizing factor by eliminating the noise in the video as shown in Equation 4.

$$f_{ij}^{BF} = \frac{1}{W_p}\sum_{q\in\Omega} G_s\left(\|p-q\|\right)G_r\left(\left|f_{ij}(p)-f_{ij}(q)\right|.f_{ij}(q)\right) \tag{4}$$

Here, f_{ij} indicates the j^{th} frame of the i^{th} video, f_{ij}^{BF} is the Bilateral-filtered frame, Ω is the neighborhood pixels around the pixel p, the spatial Gaussian function is Gs, the range Gaussian function intensity is G_r and W_p is the normalizing factor.

III.3 FEATURE EXTRACTION

Text: Feature extraction using BERT plays a vital role in the text modality of this multimodal human action recognition framework. After completing the NLP preprocessing steps like stop word removal, tokenization, and lemmatization, the cleaned and structured text is fed into the BERT model to generate rich, context-aware embeddings, as shown in Equation 5.

$$T_i = \varphi_t\left(T_i^{clean}\right) \in \Re^{d_t} \tag{5}$$

Here, φ is the BERT transformer model, T_i is the extracted text feature vector and d_t is the text embedding size.

Audio: After denoising the audio signals using Wiener and median filtering, MFCCs are extracted to represent the audio in a way that aligns with human auditory perception. The MFCC algorithm transforms the audio signal from the time domain to the frequency domain, as denoted in Equation 6.

$$A_i = \varphi_a\left(A_i^{Med}\right)DCT\left(log\left(M.\left|FFT\left(A_i^{Med}\right)\right|^2\right)\right) \tag{6}$$

Here, φ_a represents the MFCC transform function A_i representing the extracted audio feature vector, FFT is short for Fast Fourier Transform, M is short for Mel-filter bank matrix, DCT is short for Discrete Cosine Transform, and d_a represents the audio feature size.

Video: The ResNet50, a deep CNN with 50 layers, is employed in this research for spatial feature extraction from enhanced video frames. After applying bilateral filtering and CLAHE to improve frame quality and contrast, each frame is fed into the pretrained ResNet50 model, which is known for its robust residual learning framework, as shown in Equation 7.

$$V_i = \varphi_v(V_i^{CLAHE}) \in \Re^{d_v} \tag{7}$$

Here, φ_v denotes ResNet50 model for spatial feature extraction, V_i is the extracted spatial feature vector for a video data and d_v represented by feature dimension.

III.4 EARLY FUSION OF MULTIMODAL FEATURES

After extracting modality-specific features from video using ResNet50, audio using MFCC, and text using BERT, the information from these three modalities is combined through an early fusion process. This involves concatenating the individual features into a single fused multimodal feature vector. For both the Kinetics datasets, this fused representation captures comprehensive spatiotemporal, acoustic, and semantic cues related to the human actions depicted in each video sample. These fused feature vectors serve as enriched input for the next stage of processing within the HDTTN, enabling the model to learn cross-modal correlations and temporal dynamics more effectively for improved action recognition accuracy, as represented in Equation 8.

$$F_iKi = concat(V_i, A_i, T_i) \in \Re^{d_v+d_a+d_t} \tag{8}$$

Here, F_iKi denotes the fused input vectors for Kinetics dataset.

III.5 HYBRID FUSION AND CLASSIFICATION

In the HDTTN, the final stage involves the hybrid fusion of outputs from the three parallel processing modules: the Dense Net block (spatial features), the Temporal Convolutional Network (temporal dependencies), and the Transformer encoder (global context). After each module has processed the same fused multimodal input, independently extracting features specific to its intended strength, these three outputs are concatenated to form a single, unified hybrid feature representation, as shown in Equation 9 below.

$$Z_{hybrid} = \text{concat}(z_{dense}, z_{tcn}, z_{trans}) \in \Re^{d_{hybrid}} \tag{9}$$

Where, $d_{hybrid} = d_{dense} + d_{tcn} + d_{trans}$, the final hybrid feature vector combining outputs from DenseNet, TCN, Transformer are denoted as Z_{hybrid}, and $concat(.)$ for the three modules, d_{hybrid} indicates total dimension by hybrid fusion as $d_{dense} + d_{tcn} + d_{trans}$.

III.6 WASP MONKEY OPTIMIZATION ALGORITHM

Wasp Monkey Optimization: To enhance parameter tuning and learning efficiency in the HDTTN model for multimodal human action recognition, the WMO algorithm is introduced as a hybrid metaheuristic. It combines the strengths of two bio-inspired strategies: WSO and SMO. WSO is employed for local exploitation, focusing on refining promising solutions by closely exploring their neighborhood to fine-tune model parameters such as weights and biases. In the final classification stage of the HDTTN, the hybrid feature representation obtained from the fusion of Dense Net, TCN, and Transformer outputs is passed through a fully connected classification layer. This layer transforms the high-dimensional hybrid feature vector into a set of predicted class probabilities, each representing the likelihood that the input video instance belongs to a specific human action category, as shown in Equation 10.

$$\hat{y}_i = soft\,max\left(W_c.Z_{hybrid} + b_c\right) \tag{10}$$

Here, $\hat{y}_i$ denotes the predicted class probabilities, W_c denotes the weight matrix of classifier and b_c denotes the bias vector and $soft\,max(.)$ denotes the softmax function to convert logits into probabilities.

IV. RESULTS AND DISCUSSION

In this section, provide an extensive experimental evaluation and analytical discussion for the proposed HDTTN-WMO framework. The main focus of this study is to analyse and compare the effectiveness of multi-modal feature fusion, utilizing a hierarchical temporal approach in conjunction with a dual-phase optimization strategy, which could be used to improve classification performance and generalization capabilities on challenging human activity categories involving wide varieties. The performance of the proposed model is systematically evaluated on a representative subset of the Kinetics dataset and compared with state-of-the-art baseline methods.

IV.1 DATASET DESCRIPTION

The experiments were done using a 5% subset of both Kinetics-400 and Kinetics-600, covering more than 10,000 short videos each with an average length of around 10 seconds. The dataset consists of a diverse set of human activities, with 10–40 samples per class that are to be normalized for both class diversity and balanced coverage. Videos were collected from YouTube, and the contents are diverse in terms of background scene, lighting condition, camera angle, and motion patterns, making it a challenging test for real-world HAR systems showing the effectiveness and efficiency of the approach with respect to moderate resource configurations.

IV.2 EXPERIMENTAL SETUP

In the context of this study, 70% of the data was trained, and the remaining 30% was subjected to testing. The study was conducted on a 2.4 GHz Intel(R) processor with 16 gigabytes of random-access memory (RAM) were utilized.

IV.3 EVALUATION METRICS

In order to obtain a comprehensive performance evaluation, multiple metrics were used, such as accuracy, precision, recall, and F1-score. Accuracy represents the correctness of classification overall, while precision and recall measure the reliability and completeness of predicted action classes, respectively. The F1 score gives an equal weight for both precision and recall. Confusion matrix analysis was further performed to obtain class resolution and to establish misclassification trends. The F1 score has been calculated as shown in Table 1 and Figure 2.

IV.4 CONFUSION MATRIX HEATMAP

There are several reasons that may explain substantial improvement. First and foremost, since the audio, video, and textual feature information are combined together earlier, the model is able to take advantage of complementary information across multiple modalities, which alleviates confusion for visually similar actions. Second, the hierarchical architecture of HDTTN, combining Dense Net, TCN, and Transformer blocks, is conducive to capturing spatial representations and temporal dependencies across multiple scales. Third, based on the dual-phase Wasp optimization, it can optimally tune hyperparameters, which would result in better convergence and generalization performance.

The confusion matrix is shown in Figure 2 on the Kinetics dataset that is very close to diagonal dominant, i.e., the action classes are accurately assigned in most cases. Very few misclassifications can be found, most of them between the action with a very similar temporal structure to the one imitated or in contextually related actions. Such behaviour and the proposed multimodal framework demonstrate how subtle temporal and semantic differences between similar classes can be learned. The generalization efficacy demonstrated by the confusion matrix confirms that the proposed optimal fusion strategy and hierarchical temporal mapping have been effective in dealing with the variation and complexity present in real human actions.

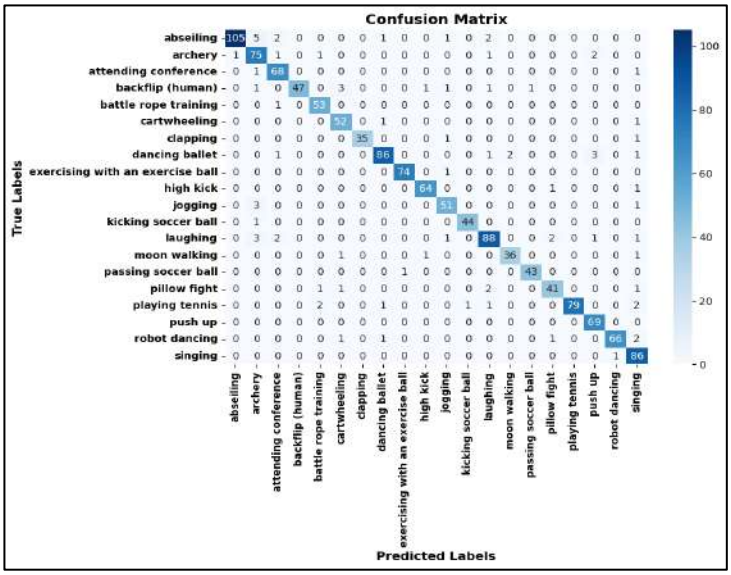

Figure 2: Confusion matrix showing classification results for Kinetics action classes.
Source: Authors, (2026).

Results from the Kinetics dataset show the flexibility of the proposed model with different levels of human motion complexity. The dataset's multimodal video, audio, and text components provided an opportunity to analyse the framework's scalability, resilience, and complexity. The results verified that the proposed model is robust and thus is very suitable for real-world human activity recognition systems.

Table 1: Accuracy Comparison.

Model	Accuracy (Kinetics)
CNN+LSTM	81.60%
2D-CNN	84.50%
VGG11	80.70%
AlexNet	86.50%
Proposed	93.00%

Source: Authors, (2026).

The model's per-class precision, recall, and F1-score performance are illustrated in Figure 3. The majority of the activity categories exhibit robust mean values, with a mean value exceeding 93%. Scores are slightly lower for actions that involve complex motion or rapid movement, which may be attributed to the interference of temporal spatial patterns. However, the system's stability is sufficient to accommodate a variety of motion types, as indicated by the combination of precision and recall. As shown in Table 1, the proposed multimodal HAR model outperforms the conventional models CNN+LSTM, 2D-CNN, VGG11, and AlexNet, all of which have lower accuracy. The results conclusively establish the higher classifier's performance, which is reliant on multimodal inputs and its adaptability across various video datasets. The hybrid model's consistent performance can be attributed to the remarkable synergistic impact of the DenseNet, TCN, Transformer layers, and the model's hyperparameters using whale optimization.

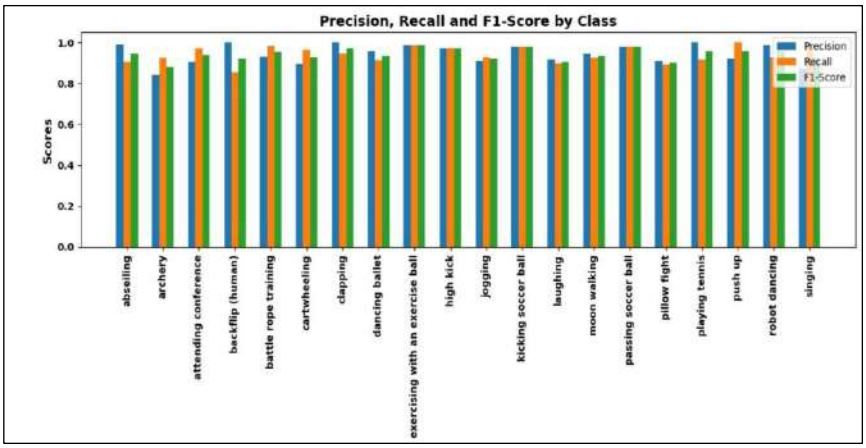

Figure 3: Precision, Recall and F1-Score across various activities.
Source: Authors, (2026).

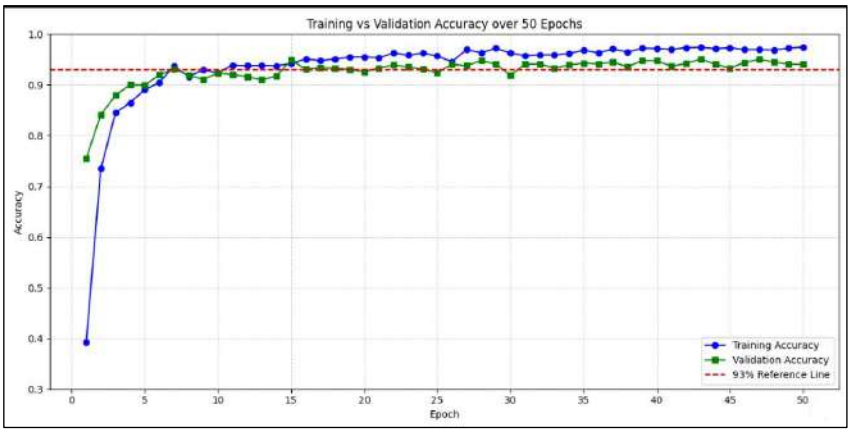

Figure 4: Comparison graph with various Baseline Models.
Source: Authors, (2026).

In Figure 4, the precision, recall, and F1-score of the HAR model of various actions performed by humans are represented. The model's performance and generalization when trained on the Kinetics dataset are represented by the accuracy and loss metrics evaluated over 50 epochs. The proposed approach achieves faster convergence, lower loss values, and higher peak accuracy, which shows that the learning is more efficient with less overfitting. Compared to the baseline model, the addition of WMO is important for guidance in the learning process and to create a balance between exploration and exploitation during the optimization of parameters.

V. CONCLUSION

In the context of multimodal HAR, this study proposed a robust and scalable HDTTN framework that simultaneously integrates video, audio, and textual information using HDTT models through dual-phase metaheuristic optimization. This approach outperforms traditional deep learning models in terms of accuracy, precision, recall, and F1-score, as indicated by comprehensive experimental results on the Kinetics dataset. The experimental results suggest that the synergistic interaction of Dense Net, Temporal Convolutional Networks (TCNs), Transformers, and Wasp-Monkey Optimization can effectively exploit complex spatiotemporal and semantic patterns with a high degree of generalization. In spite of these encouraging findings, there are still numerous prospective research avenues that demand further exploration. In order to eliminate dependence on labelled data, it would be beneficial to incorporate contrastive and self-supervised learning into future research. The discussion of small architectures and the interference of models with their base structure's information will be emphasized in the context of real-time inference on peripheral devices and those with limited resources.

Additionally, the proposed framework's application to related tasks (e.g., social interaction analysis and multimodal emotion recognition) and its extension to cross-domain dataset evaluation would be intriguing next steps. The HDTTN has demonstrated the highest level of efficacy with 93% in multimodal HAR, which integrates text, audio, and video modalities. Two-phase WMO optimization and HTM significantly enhance accuracy, generalization, and robustness. Future work will encompass the real-time integration of peripheral deployment for surveillance and healthcare applications, along with contrastive learning and fine-tuning. Enhances multimodal interaction and activity recognition, while improving human activity recognition in numerous real-world scenarios.

Google AppSheet
Objective Performance Index
AI Feature Accessibility
PLS-SEM Bootstrapping
Technology Continuance Intention

ABSTRACT

Low-code platforms such as Google AppSheet enable industrial workflow digitization, where responsiveness and AI assistance shape operational reliability. Sustained adoption depends on measurable task performance and accessible AI features across heterogeneous mobile and web clients. Prior low-code acceptance research relied on self-reports and did not unify objective performance, data readiness, and AI accessibility into a single model. This work aims to quantify the data-to-performance-to-continuance mechanism for AppSheet deployments using PLS-SEM. Task scripts captured open, sync, and submit times, plus error events, and reduced them into a five-level objective performance index. Survey responses from 260 users were modeled in SmartPLS with 5,000 bootstrap resamples. Reliability and validity are supported (Cronbach's alpha ranged 0.885–0.916; composite reliability ranged 0.925–0.947; AVE ranged 0.755–0.856). The model explains satisfaction and continued use intention ($R^2 = 0.299$; $R^2 = 0.264$). Objective performance drives perceived performance ($\beta = 0.488$), and AI accessibility drives ease of use ($\beta = 0.349$), while satisfaction, trust, and usefulness predict intention ($\beta = 0.246, 0.232, 0.199$). These results support deployment controls that couple data readiness validation, performance monitoring, and accessible AI interaction design for Industry 4.0 workflows. Future technology extends this framework with longitudinal telemetry, multi-indicator performance constructs, and role-stratified multi-group estimation.

I. INTRODUCTION

Low-code application platforms have become a core part of digital operations because they enabled rapid delivery of internal tools without the long lead times of traditional software development. These platforms supported citizen developers and domain teams who built mobile and web workflows that depended on live organizational data and continuous connectivity. As adoption increased, the quality of user experience depended on two practical dimensions that shaped day-to-day work: operational performance during real tasks, and the usability of AI-assisted functions that users needed to locate, understand, and trust.

In Google AppSheet deployments, performance variability during loading, synchronization, searching, and form submission affected perceived responsiveness, while AI features introduced new interaction steps that required accessible design to sustain confidence and continued use [1]. Application performance in low-code environments reflected both platform behavior and deployment conditions. Users interacted through heterogeneous device classes and browsers, and task completion depended on latency, caching, and network stability.

Objective slowdowns and intermittent failures disrupted workflows, increased cognitive load, and reshaped perceptions of reliability during routine work. Past work in information systems and human–computer interaction treated performance as a foundational quality attribute that influenced perceived ease, value judgments, and satisfaction, yet empirical studies often relied on self-reports or coarse proxies instead of task-level timing and failure metrics [2]. In low-code settings, performance also depended strongly on upstream data conditions, as incomplete, inconsistent, or poorly structured data increased synchronision overhead and error exposure [3]. This linkage placed data readiness as a deployment factor that extended beyond governance, shaping measurable system behavior during end-user interactions [4].

AI-assisted functions in business applications introduced an additional layer of determinants of adoption. Established acceptance research showed that perceived ease of use and perceived usefulness influenced attitudes and behavioral intention, while continuance research linked post-adoption satisfaction to continued use intention [5]. Prior trust research also indicated that trust shaped reliance on system outputs, particularly when automation influenced decisions or recommendations. In low-code platforms, AI features such as suggestions, automation aids, or intelligent assistance depended on interaction clarity and feature discoverability [6]. When AI functions were not accessible through clear interface cues and role-appropriate availability, users experienced friction that weakened perceived ease of use and diminished trust formation. Earlier studies discussed AI capability, perceived intelligence, and transparency, but they often separated these discussions from practical accessibility attributes that governed whether users engaged with AI functions during real workflows [7].

A further limitation in prior research concerned the separation between objective system behavior and subjective user evaluations. Many studies examined perceptions of performance, ease, usefulness, or satisfaction in isolation from measured task outcomes, even though users formed beliefs through repeated experiences with responsiveness and stability [8]. This separation became problematic in deployment-oriented contexts such as AppSheet, where organisations required evidence that data and configuration optimisations translated into measurable gains and, in turn, influenced user acceptance and continuance. Past empirical models also rarely positioned data readiness as an upstream antecedent of objective performance and rarely treated objective performance as a direct driver of perceived performance within a unified structural model. At the same time, AI-related adoption studies frequently addressed trust, usefulness, and satisfaction, yet they did not isolate AI accessibility as a distinct antecedent that preceded these beliefs and shaped the effort required to engage with AI-assisted features [9].

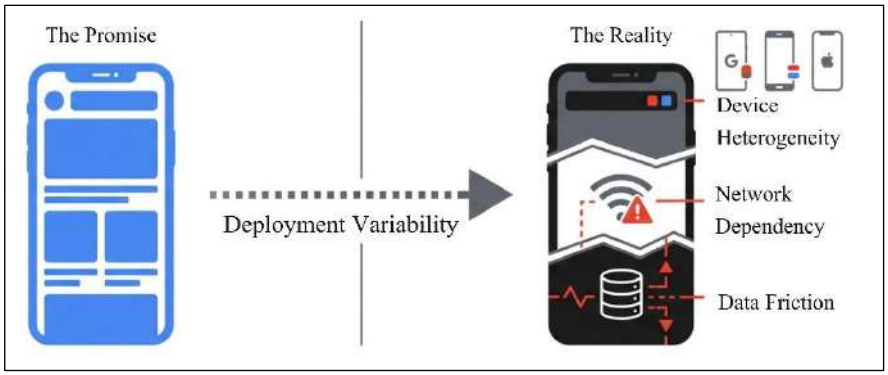

Figure 1: Rapid Delivery vs. Variable Experience.
Source: Authors, (2026).

These gaps (Figure 1) suggested a need for a deployment-oriented model that integrates three elements within a single analytical framework. The first element involved objective performance captured through standardized task-based testing rather than inference from satisfaction alone. The second element involved a data-readiness construct that represented the completeness and consistency conditions governing operational performance in real use. The third element involved AI accessibility as a measurable antecedent that shaped perceived ease, usefulness, and trust in AI-assisted functionality [10]. A single framework that connected these elements to continuance outcomes enabled a direct test of whether measurable performance and accessibility conditions aligned with user perceptions and post-adoption beliefs, while controlling for the interdependencies among ease, usefulness, trust, and satisfaction that prior theories had already established [11].

The present study addressed this need by combining controlled task-based performance testing of Google AppSheet applications with a user survey that captured perceived performance, AI accessibility, perceived ease of use, perceived usefulness, trust in AI-assisted functionality, satisfaction, and continued use intention. Objective task outcomes were reduced into an operational performance index that enabled structural integration with latent constructs, and the model was estimated using PLS-SEM in SmartPLS with bootstrapping for significance assessment. Figure 2 presents the proposed integrated adoption model that combines objective system performance and AI accessibility with established post-adoption constructs. The model assumes that data readiness influences measurable performance, which shapes perceived performance, while AI accessibility affects ease of use, usefulness, and trust. These perceptual and evaluative beliefs jointly determine satisfaction and continued use intention.

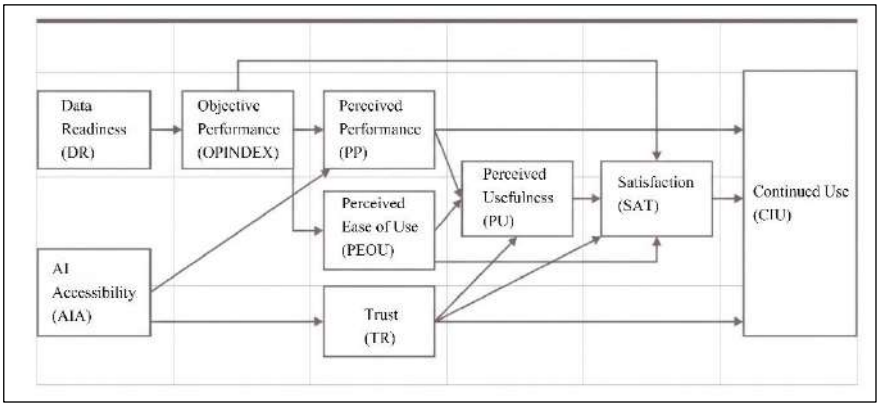

Figure 2: Integrated adoption model for low-code applications.
Source: Authors, (2026).

The study aimed to evaluate a unified adoption-and-continuance mechanism in AppSheet deployments by testing whether data readiness predicted objective operational performance, whether objective performance predicted perceived performance, and whether AI accessibility and perceived performance predicted ease of use, usefulness, trust, satisfaction, and continued use intention.

II. MATERIALS AND METHODS

All software and hardware materials used for AppSheet application performance testing and AI accessibility assessment were specified prior to data collection, and all identifiers were recorded to support reproducibility. Google AppSheet was used as the low-code platform under evaluation (Google LLC, Mountain View, CA, USA), and the deployed applications were selected from operational environments where routine business workflows were executed via mobile and web clients. Test devices included an Android handset (Pixel 6, Google LLC), a mid-range Android handset (Galaxy A52, Samsung Electronics Co., Ltd., Suwon, Republic of Korea), and an iOS handset (iPhone 12, Apple Inc., Cupertino, CA, USA). Web-client trials were executed on a laptop computer (ThinkPad T14 Gen 2, Lenovo Group Ltd., Beijing, China) running Windows 11 (Microsoft Corp., Redmond, WA, USA) with Google Chrome (Google LLC) at a fixed version recorded at test time.

A dedicated wireless router (Archer AX55, TP-Link Technologies Co., Ltd., Shenzhen, China) was configured for the test network, and a managed switch (GS108, NETGEAR, Inc., San Jose, CA, USA) was used to isolate wired monitoring traffic. Network packet capture was conducted using Wireshark v4.x (The Wireshark Foundation), and active throughput checks were executed with iPerf3 v3.x (ESnet, Lawrence Berkeley National Laboratory, Berkeley, CA, USA). Screen recordings used for event timing were captured with OBS Studio v29.x (OBS Project), and frame-accurate review was conducted with VLC media player v3.x (VideoLAN, Paris, France). Survey administration and raw response capture were conducted with Google Forms (Google LLC), and data were exported as comma-separated values for preprocessing in Python 3.11 (Python Software Foundation, Wilmington, DE, USA) using pandas v2.x and numpy v1.x, with all package versions fixed and archived. Structural equation modeling was executed in SmartPLS 4 (SmartPLS GmbH, Oststeinbek, Germany). Instrument specifications and software versions were recorded as shown in Table 1.

Table 1: Instrumentation and software specifications used for performance testing, survey capture, preprocessing, and PLS-SEM analysis.

Category	Item	Model / Version	Manufacturer	Key specification recorded
Mobile device	Android handset	Pixel 6	Google LLC	OS build, RAM, storage state
Mobile device	Android handset	Galaxy A52	Samsung Electronics	OS build, RAM, storage state
Mobile device	iOS handset	iPhone 12	Apple Inc.	iOS build, storage state
Computer	Laptop	ThinkPad T14 Gen 2	Lenovo	CPU model, RAM, OS build
Router	Wi-Fi router	Archer AX55	TP-Link	Firmware version, channel plan
Switch	Ethernet switch	GS108	NETGEAR	Link speed, port isolation
Capture	Packet capture	Wireshark v4.x	Wireshark Foundation	Capture filter, timestamp mode
Throughput	Active test	iPerf3 v3.x	ESnet	Test duration, protocol, window
Screen capture	Recorder	OBS Studio v29.x	OBS Project	FPS, codec, bitrate
Survey	Data capture	Google Forms	Google LLC	Form version, timestamp policy
Preprocessing	Scripting	Python 3.11, pandas v2.x	PSF	Random seed, export schema
PLS-SEM	Modeling	SmartPLS 4	SmartPLS GmbH	Algorithm settings, bootstrap

Source: Authors, (2026).

A standardized task-based performance protocol was implemented, and all trials were executed under controlled boundary conditions. The methodological configuration is shown in Figure 3. A dedicated wireless SSID was created for testing, and background traffic was minimised by disconnecting nonessential clients and disabling automatic operating system updates on all test devices. Environmental conditions were held constant within a laboratory office space at 23 ± 2 °C, and device battery levels were maintained above 60% to reduce power-management throttling. Each application under evaluation was configured with a defined test account and a fixed dataset snapshot that remained unchanged during timing trials.

A task set was defined to represent key interaction types, and it included loading the application home screen, initiating a full synchronization event when enabled by the application, executing a record search with a fixed query string, opening a record detail view from the first returned item, and submitting a form containing deterministic inputs. The order of tasks was randomised across repetitions to reduce sequence conditioning, and a minimum 30-s idle interval was imposed between tasks to reduce carryover from caching. Each task was repeated three times per device per application, and screen captures were started before the first interaction and stopped upon reaching the completion state, defined as a stable interface state and the absence of spinners for at least 2 s. Frame-accurate timestamps were extracted from recordings, and task durations were computed as the difference between start and end event frames multiplied by the calibrated frame interval.

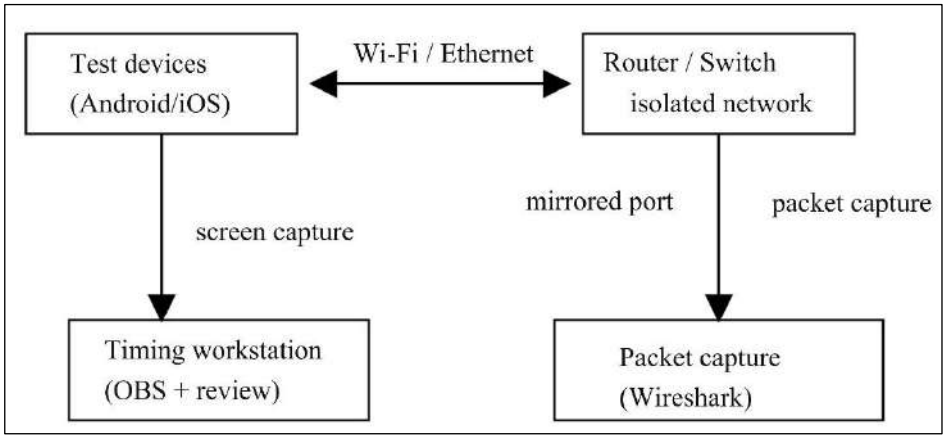

Figure 3: Schematic of the isolated test network and timing workflow used for objective task-duration extraction and concurrent packet capture.
Source: Authors, (2026).

Calibration routines were executed for timing, network instrumentation, and survey measurement integrity, and uncertainty sources were quantified prior to model estimation. Screen-capture timing calibration was performed by recording a reference digital stopwatch with a known timebase derived from an NTP-synchronized system clock, and the effective frame rate was estimated from the recorded timecode drift over a 10 min interval. The mean absolute NTP offset was recorded before each test session, and sessions were repeated when offsets exceeded 50 ms. Packet-capture timestamping was validated by injecting periodic UDP bursts from iPerf3 at fixed intervals and verifying inter-burst spacing within the capture stream. Router channel selection was fixed after a spectral scan, and the channel width was kept constant throughout the test campaign. Calibration constants and acquisition settings used for timing and network checks are provided in Table 2 and were referenced during data reduction [12].

Table 2: Data acquisition settings, calibration constants, and controlled boundary conditions used during objective performance testing.

Parameter	Value	Unit	Method of control or calibration
Screen capture frame rate	60.0	frames·s^{-1}	Calibrated by stopwatch drift test
Video timebase	constant frame interval	—	Verified by drift threshold
NTP offset threshold	50	ms	Session repeated if exceeded
iPerf3 burst interval	1.0	s	Fixed in command configuration
iPerf3 duration	30	s	Fixed per throughput check
Wi-Fi channel	fixed	—	Locked after scan
Wi-Fi bandwidth	fixed	MHz	Locked in router settings
Idle interval between tasks	30	s	Enforced by protocol timer
Repetitions per task	3	—	Fixed by protocol
Ambient temperature	23 ± 2	°C	Monitored by room sensor

Source: Authors, (2026).

Objective performance variables were reduced from raw event times and failure logs using deterministic formulas, and all computations were performed using archived scripts with fixed random seeds for reproducibility. For each task j, the median duration across three repetitions was computed as expressed in Equation (1), in which $t_{j,k}$represented the measured duration in seconds for repetition $k \in \{1,2,3\}$, and $t_j$represented the median task duration in seconds.

$$t_j = \text{median}\left(t_{j,1}, t_{j,2}, t_{j,3}\right) \tag{1}$$

Failure events were logged when an application error dialog was displayed, when a synchronization operation did not complete within a 120 s timeout, or when an interaction returned to a prior state without saving user input, and an error rate was computed as expressed in Equation (2), in which $n_{j,\text{fail}}$represented the number of failed attempts for task $j$and $n_{j,\text{total}}$represented the total attempts for task j.

$$e_j = \frac{n_{j,\text{fail}}}{n_{j,\text{total}}} \tag{2}$$

To combine heterogeneous objective measures into a unitless index for inclusion as an observed predictor in the latent-variable model, each objective variable $x$was standardized to a z-score using Equation (3), in which $\mu_x$and $\sigma_x$represented the sample mean and sample standard deviation of x, respectively.

$$z_x = \frac{x - \mu_x}{\sigma_x} \tag{3}$$

A composite objective performance score $S_{\text{OP}}$was computed using Equation (4), in which $z_{t_{\text{open}}}$, $z_{t_{\text{sync}}}$, and $z_{t_{\text{sub}}}$represented standardized durations for opening, synchronization, and form submission tasks, respectively, $z_e$represented the standardized error rate, and weights $w_1$through $w_4$were fixed to sum to unity ($\sum_{i=1}^{4} w_i = 1$)with values recorded in the analysis script. Negative signs were used to preserve the convention that larger S_{OP}corresponded to shorter times and lower error rates.

]

$$S_{\text{OP}} = -\left(w_1 z_{t_{\text{open}}} + w_2 z_{t_{\text{sync}}} + w_3 z_{t_{\text{sub}}} + w_4 z_e\right) \tag{4}$$

For compatibility with ordinal survey scales, an objective index I_{OP}on a five-level scale was derived from quintile thresholds as expressed in Equation (5), in which $q_r$represented the r-th quintile cutoff of $S_{\text{OP}}$and $1(\cdot)$represented the indicator function returning 1 when its argument was true and 0 otherwise.

$$I_{\text{OP}} = 1 + \sum_{r=1}^{4} 1\left(S_{\text{OP}} > q_r\right) \tag{5}$$

A survey instrument was administered to capture perceived performance, AI accessibility, perceived ease of use, perceived usefulness, trust in AI-assisted functionality, satisfaction, and continued use intention, and all items were framed as statements scored on a five-point Likert scale from 1 (strong disagreement) to 5 (strong agreement). Item wording was adapted from established information systems acceptance and trust measurement traditions, and domain-specific phrasing was introduced to reflect AppSheet deployment contexts, with content validity assessed through expert review by two practitioners experienced in low-code app deployment and one academic specialising in human–computer interaction.

A pilot administration was conducted with 20 respondents to verify comprehension, and minor linguistic edits were applied to reduce ambiguity and to remove technical jargon. Inclusion criteria required active use of at least one AppSheet application within the preceding 30 days, and respondents were asked to anchor responses to a single primary application used most frequently. The respondent role was captured as end user, citizen developer, application owner, manager, or supervisor, and control variables included usage frequency, device class, and self-rated digital literacy. The consent text was presented at the start of the survey, and responses were anonymised by excluding names, email addresses, and other direct identifiers. Raw survey exports were stored in an encrypted format on an access-controlled drive, and an audit log of preprocessing steps was maintained.

Data preprocessing was performed prior to modelling, and quality filters were applied to reduce response artefacts. Duplicate rows were removed using timestamp and response-pattern matching, and incomplete submissions lacking at least 80% item completion were excluded. Straight-lining behaviour was screened by computing within-respondent variance across Likert items and excluding responses with zero variance. Missing item values in retained records were imputed using median imputation within each construct when missingness per construct did not exceed 10%; records exceeding this threshold were removed by listwise deletion to preserve covariance structure.

Common method bias was addressed procedurally through anonymity, item-order randomisation, and separation of predictor and outcome blocks, and a full collinearity screening was conducted by regressing each construct score on all others and checking variance inflation factors computed during preprocessing. Objective performance indices derived from Equation (5) were linked to survey records through the primary application identifier, and linkage was verified by cross-checking application name hashes and deployment group membership recorded at the time of testing.

PLS-SEM estimation was performed in SmartPLS 4 using a reflective measurement specification for all latent constructs, and a path-weighting scheme was applied with a maximum iteration count of 300 and a stop criterion of 10^{-7}on outer-weight change. The reflective measurement model was expressed by Equation (6), in which $x_i$represented observed indicator i, ηrepresented the associated latent construct score, $\lambda_i$represented the outer loading for indicator i, and $\epsilon_i$represented the measurement error term, with all indicators treated as standardized prior to estimation.

$$x_i = \lambda_i \eta + \epsilon_i \tag{6}$$

The structural relations among endogenous latent variables were represented using Equation (7), in which ηrepresented the vector of endogenous latent variables, ξrepresented the vector of exogenous latent variables, Brepresented the matrix of paths among endogenous constructs, Γrepresented the matrix of paths from exogenous to endogenous constructs, and ζrepresented the vector of residual terms, with recursive structure imposed by setting non-hypothesized entries to zero.

$$\eta = \mathrm{B}\eta + \Gamma\xi + \zeta \tag{7}$$

Internal consistency reliability was evaluated using composite reliability $\rho_c$computed as expressed in Equation (8), in which $p$represented the number of indicators for a construct and $\theta_i$represented the error variance for indicator $i$estimated as $1-\lambda_i^2$under standardized indicators.

$$\rho_c = \frac{\left(\sum_{i=1}^{p}\lambda_i\right)^2}{\left(\sum_{i=1}^{p}\lambda_i\right)^2 + \sum_{i=1}^{p}\theta_i} \tag{8}$$

Convergent validity was assessed through average variance extracted (AVE) computed using Equation (9), with symbols defined as in Equation (8).

$$\text{AVE} = \frac{\sum_{i=1}^{p}\lambda_i^2}{\sum_{i=1}^{p}\lambda_i^2 + \sum_{i=1}^{p}\theta_i} \tag{9}$$

Discriminant validity was assessed using the heterotrait–monotrait ratio for constructs $a$and b, calculated as expressed in Equation (10), in which $r_{x_{ai},x_{bj}}$represented the Pearson correlation between indicator $i$of construct $a$and indicator $j$of construct b, $m$represented the number of indicators for construct a, and $n$represented the number of indicators for construct b, with absolute values used to avoid sign cancellation.

$$\text{HTMT}_{ab} = \frac{\frac{1}{mn}\sum_{i=1}^{m}\sum_{j=1}^{n}\left|\, r_{x_{ai},x_{bj}}\,\right|}{\sqrt{\left(\frac{1}{m(m-1)}\sum_{i\neq k}\left|\, r_{x_{ai},x_{ak}}\,\right|\right)\left(\frac{1}{n(n-1)}\sum_{j\neq l}\left|\, r_{x_{bj},x_{bl}}\,\right|\right)}} \tag{10}$$

Significance of structural paths and outer loadings was assessed using nonparametric bootstrapping with 5,000 resamples and case-wise resampling, and two-tailed tests were applied at $\alpha = 0.05$. Bootstrap t-statistics were computed as expressed in Equation (11), in which $\hat{\beta}$represented the estimated coefficient (path or loading) and $\text{SE}_b(\hat{\beta})$represented the bootstrap standard error obtained as the standard deviation of the bootstrap sampling distribution.

$$t = \frac{\hat{\beta}}{\text{SE}_b(\hat{\beta})} \tag{11}$$

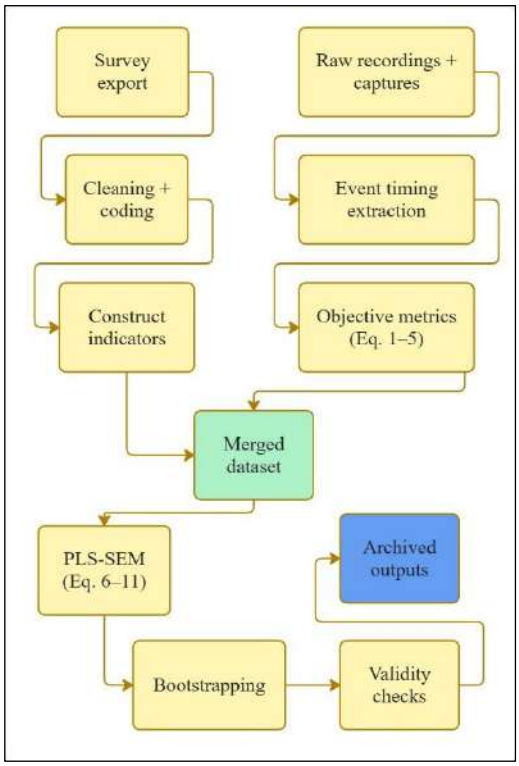

Figure 4: Data acquisition and analysis pipeline from objective task timing and survey capture through preprocessing and SmartPLS 4 estimation.
Source: Authors, (2026).

A full analytical workflow from raw capture to model estimation was implemented as shown in Figure 4, and each step was logged for traceability. Raw objective-timing videos and packet captures were archived, and derived task durations were exported along with application identifiers and device metadata.

Survey exports were merged with objective records using hashed application IDs, and a single analysis dataset was constructed after applying preprocessing filters. SmartPLS project files, path models, measurement specifications, and algorithm settings were exported and preserved as immutable artifacts [13]. Validation steps were executed through repeated re-estimation under alternative preprocessing variants, including listwise deletion without imputation and exclusion of the objective index from the structural model, and stability of coefficient signs and significance decisions under these variants was recorded as part of the audit trail. Multi-group analysis was conducted when group sizes exceeded 50 per group, with role-based partitions applied and permutation testing executed within SmartPLS to evaluate group-difference significance under equal measurement specification [14].

III. RESULTS AND DISCUSSIONS

Model estimation and reporting basis

The structural model was estimated using PLS-SEM in SmartPLS 4 with a sample size of n = 260. The model visualization from the PLS Algorithm was used to report standardized path coefficients and explained variance (Figure 3). Hypothesis significance testing was based on nonparametric bootstrapping with 5,000 subsamples and two-tailed tests at ($\alpha = 0.05$) (Figure 4).

Measurement model evaluation

Internal consistency reliability was assessed using Cronbach's alpha and composite reliability. Convergent validity was assessed using average variance extracted (AVE). Table 3 reports reliability and convergent validity statistics. Cronbach's alpha ranged from 0.885 to 0.916 across reflective constructs, and composite reliability ranged from 0.925 to 0.947, supporting construct reliability. AVE values ranged from 0.755 to 0.856, exceeding the common 0.50 criterion and supporting convergent validity. OP_{INDEX} was modeled as a single-item construct and therefore yielded unit reliability by construction [15].

Table 3: Construct reliability and convergent validity.

Construct	Cronbach's alpha	Composite reliability (ρc)	AVE
AIA	0.892	0.925	0.755
CIU	0.911	0.944	0.849
DR	0.901	0.931	0.771
PEOU	0.890	0.931	0.819
PP	0.903	0.939	0.838
PU	0.885	0.929	0.813
SAT	0.916	0.947	0.856
TR	0.886	0.930	0.815

Source: Authors, (2026).

Discriminant validity was assessed using HTMT. All HTMT values were below conservative thresholds, and the largest observed value was 0.512 for PP ↔ OP_{INDEX}, supporting discriminant validity among constructs. Collinearity was examined at both the indicator and construct levels. Outer VIF values for indicators were below 5, with the largest values observed for CIU2 (3.399) and SAT2 (3.424). Inner VIF values ranged from 1.000 to 1.369, indicating that collinearity was not a concern for structural estimation (Figure 5).

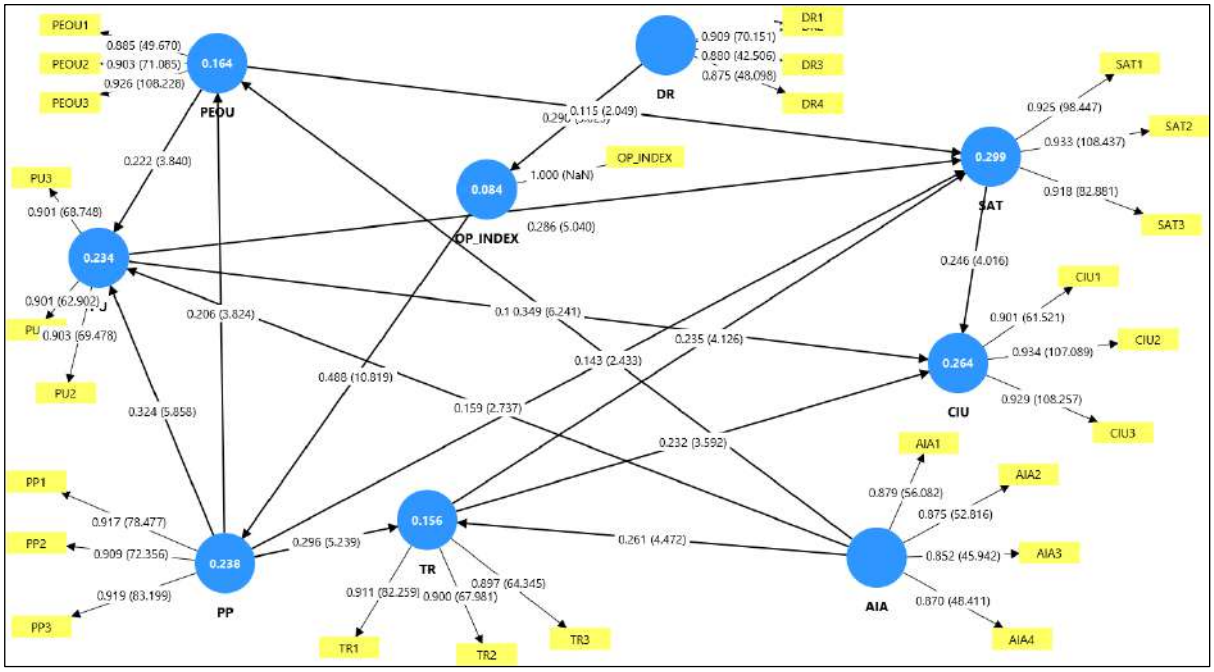

Figure 5: Measurement model (Outer weights/loadings and t values).

Source: Authors, (2026).

Structural model evaluation

Explained variance was assessed using (R^2). The model explained 0.299 of the variance in satisfaction and 0.264 of the variance in continued use intention, as shown in Figure 3. Table 4 summarizes (R^2) values for endogenous constructs.

Table 4: Explained variance (R^2) for endogenous constructs.

Endogenous construct	R^2
OP_{INDEX}	0.084
PP	0.238
PEOU	0.164
PU	0.234
TR	0.156
SAT	0.299
CIU	0.264

Source: Authors, (2026).

Hypothesis testing

Bootstrapping results for the hypothesized paths are reported in Table 5. All specified direct paths were statistically significant at ($\alpha = 0.05$). Path direction and magnitude are visible in Figure 5, and significance strength is visualized using t-values in Figure 6.

Source: Authors, (2026).

The results indicated a data-to-experience pathway, with data readiness predicting objective performance, which in turn predictederceived performance (DR → OP_{INDEX} → PP) [16]. The results also indicated an accessibility-to-adoption pathway, with AI accessibility and perceived performance predicting ease of use, usefulness, trust, satisfaction, and continued use intention (AIA and PP as upstream drivers, CIU as the final outcome). These pathways are visible in the integrated structure in Figure 5 and are supported inferentially in Figure 6.

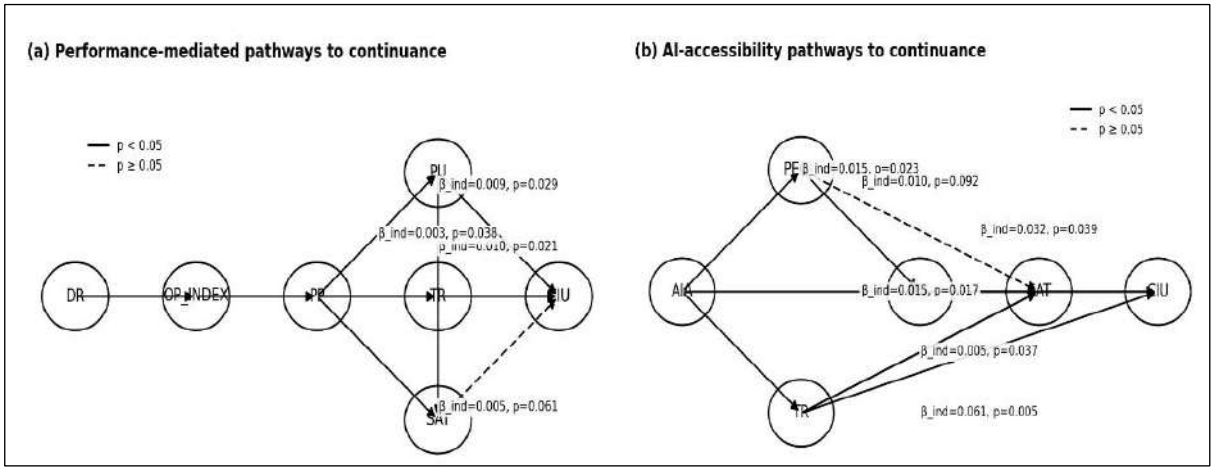

Figure 7: (a) performance-mediated indirect effects from data readiness to continuance via OP_INDEX, perceived performance, usefulness, trust, and satisfaction; (b) AI-accessibility-mediated indirect effects from AI accessibility to continuance via ease of use, usefulness, trust, and satisfaction.
Source: Authors, (2026).

Figure 7 illustrates two mediation mechanisms in which upstream deployment factors propagated through user beliefs to continuance intention. Figure (a) links data readiness to continuance through a sequential chain anchored by OP_INDEX and perceived performance, followed by cognitive and affective mediators. The bootstrapped indirect pathways indicated that the performance route transmitted to continuance through perceived usefulness with a positive indirect effect (β_ind = 0.009, p = 0.029) and through trust with a positive indirect effect (β_ind = 0.010, p = 0.021), while an additional smaller indirect effect remained statistically supported (β_ind = 0.003, p = 0.038). The satisfaction-mediated branch made a weaker indirect contribution and did not meet the stated significance criterion (β_ind = 0.005, p = 0.061), indicating that the operational-performance channel exerts its influence on continuance primarily through belief formation in usefulness and reliability rather than solely through the satisfaction route.

Figure (b) connects AI accessibility to continuance through ease of use, usefulness, trust, and satisfaction, reflecting an interaction-design mechanism in which discoverability and usable AI functions propagated into sustained adoption. The indirect effect through trust provided the strongest transmission to continuance (β_ind = 0.061, p = 0.005), consistent with the measured structural link between AI accessibility and trust combined with the trust-to-intention relationship. Significant indirect effects were also indicated through usefulness (β_ind = 0.005, p = 0.037) and through satisfaction (β_ind = 0.015, p = 0.017), while the ease-of-use branch included one supported indirect effect (β_ind = 0.015, p = 0.023) and one non-supported branch (β_ind = 0.010, p = 0.092). These patterns suggest that sustained AppSheet use depended on deployment controls that stabilized operational performance through data readiness and on interface decisions that elevated AI accessibility into trust and utility pathways, supporting a coupled engineering-and-adoption mechanism for low-code application rollouts.

Effect sizes

Effect sizes were assessed using (f^2). The largest effect size was observed for OP_{INDEX} → PP (0.312), indicating that objective performance contributed materially to perceived performance. Additional notable effect sizes included AIA → PEOU (0.145), PP → PU (0.130), PP → TR (0.104), DR → OP_{INDEX} (0.092), and PU → SAT (0.091). Several statistically significant paths exhibited small (f^2) values, including PP → SAT (0.024) and PEOU → SAT (0.016), suggesting limited incremental contribution once other predictors were included in the model.

Discussion

This study evaluated a deployment-oriented model for Google AppSheet applications that combined objective performance measurement with user perceptions of performance and AI accessibility. The findings supported two linked mechanisms. First, data readiness shaped objective performance, and objective performance shaped perceived performance. Second, AI accessibility and perceived performance influenced ease of use, usefulness, trust, satisfaction, and continued use intention [17]. These relationships were visible in the integrated model (Figure 3) and were statistically supported through bootstrapping (Figure 4).

The data-to-performance mechanism was supported by significant paths from DR to OP_{INDEX} and from OP_{INDEX} to PP. This pattern positioned data readiness as an upstream deployment condition rather than a purely data-management concern. When data were perceived as accurate, complete, and consistent, objective operational measures improved, and those improvements translated into stronger perceived performance. The OP_{INDEX} → PP path also showed the largest effect size in the model. This result reinforced the practical value of using objective performance checks as part of release and governance routines, because measured responsiveness and stability aligned with user perceptions.

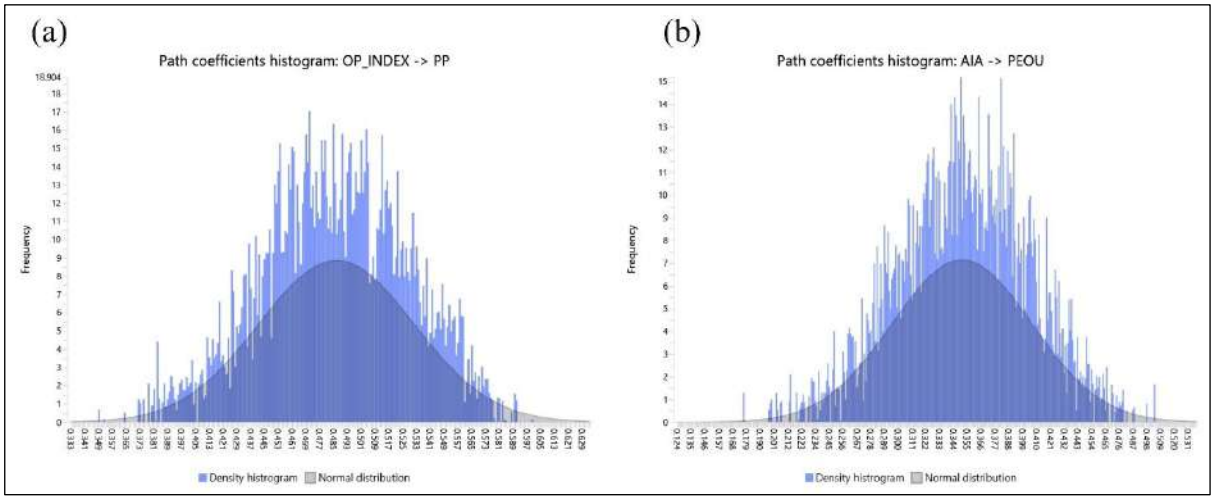

Figure 8: (a) Bootstrapped path-coefficient density histogram for OP_INDEX → PP with normal-distribution overlay; (b) bootstrapped path-coefficient density histogram for AIA → PEOU with normal-distribution overlay.
Source: Authors, (2026).

Figure 8 illustrates the sampling behavior of two key structural paths under nonparametric bootstrapping, with each panel combining a density histogram of resampled coefficients and a fitted normal reference curve. Figure (a) concentrates around a positive coefficient near 0.49, with the highest frequencies located in the mid-range of the axis and a gradual decline toward both tails, which indicates a stable positive association between OP_INDEX and PP [18]. The distribution in Figure (a) retains an approximately bell-shaped profile and maintains close agreement with the normal overlay through the central region, while the tails extend into lower and higher coefficient values with markedly reduced frequency; this pattern suggests limited skewness and a bounded probability of extreme estimates. Figure (b) centers on a positive coefficient near 0.35 for the AIA → PEOU path, with a similarly unimodal structure and a normal reference curve that tracks the bulk of the mass; the density spreads across a wider portion of the horizontal axis relative to its center, indicating greater dispersion in the resampled estimates than observed for OP_INDEX → PP [19].

The bootstrap procedure yielded consistently positive coefficients in both panels, and the resampling indicated that coefficient sign reversals were not supported by the displayed probability mass, which strengthened the evidential basis for directional hypotheses in the structural model. The higher central tendency in Figure (a) relative to Figure (b) suggests that objective performance indexed by OP_INDEX exerted a stronger direct contribution to perceived performance than AI accessibility exerted on perceived ease of use, which aligns with a mechanism in which measurable system behavior translated directly into user-perceived responsiveness, while accessibility exerted its influence through interface-level affordances and cognitive effort reduction. The close correspondence between the histograms and normal overlays supports the use of percentile-based confidence intervals and t-statistic inference derived from bootstrap standard errors, and it motivates subsequent work that tests coefficient stability across role groups, device classes, and network conditions using multi-group analysis or interaction modelling [20].

AI accessibility showed significant effects on perceived ease of use, perceived usefulness, and trust. The strongest AI accessibility relationship was AIA → PEOU, indicating that discoverability, clarity, and ease of interaction with AI functions were tightly linked to perceived effort. The significant effects on usefulness and trust indicated that accessibility served as a prerequisite for value realisation and confidence formation. In applied terms, AI functions that were difficult to locate, ambiguous in purpose, or constrained by role settings would be expected to reduce perceived usability and weaken trust-building, even when AI capability existed in the platform [21]. Perceived performance significantly predicted ease of use, usefulness, trust, and satisfaction. This set of links suggested that responsiveness and reliability operated as foundational experience drivers that shaped both effort perception and evaluative beliefs. The direct PP → SAT effect was significant but of relatively small effect size, suggesting that satisfaction formation was influenced through multiple channels, including perceived usefulness and trust.

This pattern supported a view of satisfaction as a composite outcome shaped by operational experience and by belief-based evaluations developed during use [22]. Continued use intention was significantly predicted by satisfaction, usefulness, and trust. The significant SAT → CIU path supported a standard continuance logic for workplace systems. The significant TR → CIU path indicated that trust remained important even after accounting for usefulness and satisfaction. This was consistent with the presence of AI-supported functions, where confidence in outputs can influence continued reliance on the application. The significant PU → CIU path indicated that perceived productivity value directly contributed to intention alongside evaluative satisfaction [23].Practical implications followed directly from the structure of the model. Deployment practices that raise data readiness were expected to improve objective performance and, through that pathway, improve perceived performance.

Objective performance monitoring was also suggested as a high-leverage intervention because OP_{INDEX} was strongly linked to PP. For AI-enabled AppSheet deployments, the results suggested that accessibility design should be treated as a primary adoption driver. Clear surfacing of AI features, concise in-context guidance, and role-appropriate availability were expected to improve ease of use and trust, which, in turn, would supportatisfaction and continued use [24].The analysis was cross-sectional and therefore supported associational inference based on theoretical directionality rather than temporal causality. The majority of constructs were measured using self-report scales, which can introduce common-method bias, although collinearity diagnostics and discriminant validity results supported measurement separation. OP_{INDEX} was modelled as a single indicator, which simplified structural integration but limited the separation of distinct operational dimensions, such as open time, sync time, and error rate,s independent observed predictors [25].

Future work could implement longitudinal designs, incorporate direct telemetry or backend logs as multiple observed indicators, and test role-based moderation using formal multi-group analysis to evaluate whether relationships differ between end users and citizen developers.

IV. CONCLUSIONS

This study examined Google AppSheet deployment outcomes by integrating objective performance testing with a PLS-SEM model that linked data readiness, operational behavior, user perceptions, and continuance intention. The analysis used n = 260 responses and estimated a recursive model that explained variance across intermediate constructs, including PP ($R^2 = 0.238$), PEOU ($R^2 = 0.164$), PU ($R^2 = 0.234$), TR ($R^2 = 0.156$), and OPINDEX ($R^2 = 0.084$). Measurement quality was supported by discriminant validity, with the largest HTMT value of 0.512 for PP↔OPINDEX, and by collinearity diagnostics that remained within acceptable bounds, with inner VIF values ranging from 1.000 to 1.369 and outer VIFs peaking at 3.424 for SAT2 and 3.399 for CIU2.

Effect-size assessment identified OPINDEX→PP as the dominant structural contributor ($f^2 = 0.312$), and additional nontrivial effects were recorded for AIA→PEOU ($f^2 = 0.145$), PP→PU ($f^2 = 0.130$), PP→TR ($f^2 = 0.104$), DR→OPINDEX ($f^2 = 0.092$), and PU→SAT ($f^2 = 0.091$), while PP→SAT ($f^2 = 0.024$) and PEOU→SAT ($f^2 = 0.016$) reflected smaller incremental contributions after accounting for co-predictors. These outcomes showed that deployment quality controls spanning data readiness validation and objective performance monitoring were directly relevant to user experience formation, and that AI feature accessibility shaped belief formation through usability and trust mechanisms. Future work will extend the design using longitudinal sampling, telemetry-derived multi-indicator performance measurement, and role-stratified multi-group estimation to test stability across user groups and operating contexts.

ABSTRACT

The study aimed to determine the regularities of switching overvoltages during the operation of medium-voltage capacitor banks and to evaluate the effectiveness of methods for their reduction. The methodology was based on a combination of mathematical modelling in specialised environments, laboratory testing of condenser plant models and statistical analysis of operational data. The results showed that the amplitude of overvoltages in capacitor banks increased from 1.6-2.0 to 2.5-3.0 relative units depending on the power, and the duration of transients exceeded 2.8 milliseconds at large capacities, which created a risk of insulation damage. The study determined that more than 90% of capacitor failures were of an insulating nature, with daily switching reducing service life by a third, and overvoltage over 2.5 relative units halving service life. The study showed that in the secondary circuits of transformers during resonant interaction, the amplitude of overvoltages reached 4.0-4.5 relative units, which led to the failure of electronic devices and premature tripping of protections. The effectiveness of the technical equipment confirmed that synchronous circuit breakers reduced the level of overvoltage to 1.2 relative units, while pre-trigger resistors and overvoltage limiters reduced it by 40-50%, but required frequent maintenance.

I. INTRODUCTION

The research relevance of the switching processes of medium-voltage capacitor banks is determined by their significant impact on the reliability and durability of electrical equipment, since switching overvoltages that occur during switching on and off exceed permissible levels and lead to accelerated ageing of insulation, damage to power elements, and disturbance of system stability. The problem is determined by the insufficient efficiency of traditional surge suppressors, such as inductive chokes or pre-actuation resistors, which reduce the amplitude of oscillations but are accompanied by increased heat losses and higher operating costs, and the need for an in-depth analysis of modern solutions, including Metal Oxide Varistor (MOV) surge arresters and synchronous circuit breakers, which demonstrate high technical efficiency but require an assessment of long-term reliability and economic feasibility.

The solution to this problem will reduce the number of emergency failures, extend the service life of capacitors, transformers, induction motors and power electronics, ensure the stability of power grids and increase their energy efficiency, which determines the relevance of an integrated approach to the analysis and optimisation of switching overvoltage reduction methods in the modern power industry.According to [1] demonstrated that the use of time-frequency analysis methods can be used to identify the characteristic signatures of switching overvoltages in medium-voltage networks. This made it possible to detect critical modes with high accuracy and distinguish them from other types of disturbances. According to [2] proved that the choice of the type of switchgear significantly affects the quality of electricity and the level of transient overvoltages.

The study determined that synchronised circuit breakers and specialised devices provide a significant reduction in peak values, which contributes to the stability of the network. In [3] confirmed that the switching of capacitor banks is a source of complex transients that propagate through the power grid and could be amplified in resonant conditions. According to [4] found that the operation of wind power plants creates voltage fluctuations and flicker, which complicates grid stability and increases the risks of capacitor switching. In [5] proved that the integration of vehicle-grid integration technologies changed load profiles and dispatch modes, which indirectly affects the conditions for the formation of overvoltages. According to [6] found that the combination of photovoltaic power plants with hydropower facilities created new scenarios for the distribution of reactive power, which increased the load on capacitor plants. According to [7] demonstrated that the integration of distributed generation based on solar panels changed the characteristics of short-circuit power and contributed to the emergence of unstable switching modes.

According to [8] found that timely detection of overvoltage in high-voltage shunt banks provides early warning of damage, which can improve operational reliability. As a result, the study outlined the significance of diagnosing overvoltages and their connection with new modes of grid operation. Proved that active methods of controlling overcurrents and overvoltages in shunt capacitor banks provide a reduction in peak values and a reduction in the duration of oscillations [9]. According to [10] demonstrated the effectiveness of protection based on resistance-capacitance elements that suppress residual overvoltages during the switching of parallel capacitor banks. The results confirmed the feasibility of using combined methods to reduce the impact of transients. According to [11] found that the use of metal-oxide varistors and spark gaps protects series capacitors in compensated lines from dangerous pulses. In [12] proved that the use of a fuzzy inference system (FIS) can be used to classify switching events at high-voltage substations with a high degree of accuracy.

Thus, both studies confirmed the effectiveness of using both hardware and intelligent methods to control and limit overvoltages. Despite the results obtained, certain gaps were identified in the existing works. The long-term degradation of protective devices under the influence of repeated switching processes and their impact on operational reliability have not been sufficiently investigated. The impact of three-phase asymmetry, grounding configurations and line parameters on the spectrum and amplitudes of overvoltages was considered to a limited extent. There were no large-scale field experiments that would combine technical analysis with economic assessments of different protection methods. There was also a lack of agreed methodologies that could be used to reproduce the results in the practical conditions of modern grids with a high share of renewable sources. The study aimed to establish the patterns of occurrence and development of switching overvoltages in medium-voltage networks with capacitor banks and determine their impact on the reliability of electrical system elements, as well as to assess the effectiveness of technical protection means.

To achieve this goal, several tasks were set that corresponded to the structure of the analysis: conduct empirical research on the switching processes of medium-voltage capacitor banks, taking into account the amplitudes and duration of transient processes; assess the impact of switching overvoltages on the operation and durability of capacitor installations based on the results of experimental and statistical observations; identify the characteristics of the effect of overvoltages on asynchronous motors, transformers and power electronics under conditions of resonant interaction of system elements; conduct an empirical comparison of various methods for reducing switching overvoltages, including inductive chokes, pre-switching resistors, metal-oxide varistor surge arresters and synchronous switches, considering their technical and economic efficiency.

II. MATERIALS AND METHODS

The type of research conducted was defined as comprehensive experimental and theoretical, involving mathematical modelling, laboratory testing and statistical analysis. The chronological framework covered the period 2021-2025, which made it possible to take into account the various stages of process development: from short-term transient phenomena during the switching of medium-voltage capacitor banks to the cumulative effects of degradation of electrical system components. During this period, systematic laboratory tests were conducted on models of capacitor installations with the recording of instantaneous current and voltage values, which made it possible to reproduce the characteristic operating conditions of industrial power grids. The tests were conducted at the Polytechnic University of Tirana, Faculty of Electrical Engineering, where more than 50 series of switching cycles were performed for each type of capacitor. In parallel, statistical data obtained in industrial conditions were analysed, which made it possible to compare the simulation results with real operational observations. This integrated approach within the selected time frame made it possible not only to identify patterns in the formation of switching overvoltages but also to assess their impact on equipment durability and the effectiveness of various protection methods.

The initial data collection was based on the results of laboratory experiments conducted using medium-voltage capacitor bank models of the ABB Capacitor Bank Models MSCDN (Switzerland) type with a rated power of 150 to 300 kVAr. For this purpose, high-speed oscilloscopes with a time resolution of up to microseconds were used to record instantaneous voltage and current values during the equipment switching on and off processes. Tektronix DPO 4104 oscilloscopes (USA, 1 GHz, 5 GS/s) were used, providing a resolution of up to 1 μs. The capacitors belonged to the metallised polypropylene class with a rated breakdown voltage of 10-15 kV. Additionally, the results of bench tests of capacitor installations in industrial conditions were taken into account, where the monitoring of insulation parameters, the response time of protective devices and the failure rate was conducted using the Omicron CPC 100 measuring complex (Austria) and the Fluke 1738 power analyser (USA).

The collected experimental data were supplemented with statistical information from the operational logs of energy companies, which contained records of the number of switching operations, the service life of capacitor elements, and typical types of damage. The analysis also considered data on four groups of industrial manufacturers of capacitor banks. To maintain confidentiality and avoid commercial bias in the work, they were designated with the letters A-D. This approach ensured a fair comparison without disclosing commercially sensitive information. The study used comprehensive methods, including mathematical modelling, laboratory experiments, partial discharge diagnostics and statistical analysis. Each of these approaches ensured the recording of certain characteristics of the switching processes of medium voltage capacitor banks, which made it possible to reproduce a complete picture of their impact on electrical systems. The use of a multi-level methodology made it possible to combine transient simulations in computer modelling environments with field tests, which guaranteed high reliability of the results.

Mathematical modelling was performed in [13-15] environments. The constructed models reproduced the switching processes of capacitor banks in the power range from 150 to 300 kVAr at an operating voltage of 6-35 kV. Various grounding modes, connection configurations, and connection inductance parameters were considered. Particular attention was paid to the formation of voltage at the capacitor terminals after disconnection, which was described by the ratio (1) that determines the possibility of overvoltage three times higher than the nominal value.

$$U_c(t) \approx +3U_n \text{if } C \gg C_s \quad (1)$$

Where U_c – instantaneous value of the voltage across the capacitor after disconnection, U_n – the rated voltage, C – capacitance of the capacitor bank, C_s – system capacitance. This ratio determines the possibility of an overvoltage of three times the rated voltage. The models were used to calculate time diagrams of voltages and currents, determine the conditions for the occurrence of oscillatory processes, and develop scenarios for changing the phase angle at the time of switching. An inverse power model was used to assess the durability of insulating materials:

$$L = L_H\left(\frac{E}{E_H}\right)^{-n} \quad (2)$$

where L – predicted service life of the insulation, L_H – the reference service life at voltage, E – the effective electric field strength, E_H– reference voltage value, n – material endurance factor. The equations were numerically integrated using the fourth-order Runge-Kutta method, which reproduced unsteady-state modes with high accuracy. The modelling variables were the switching moment relative to the phase angle, the capacitance and the inductance of the branches. In addition, the Miner's rule was used to analyse the impact of multiple switching:

$$\sum_{i=0}^{N} \frac{t_{pi}}{L(V_{pi})} = 1 \quad (3)$$

Where t_{pi} – duration of the i-th overvoltage pulse, LV_{pi} – insulation service life at the amplitude voltage V_{pi}, N – number of switching operations. This ratio determined the cumulative effect of overvoltages and calculate the reliability limit for repeated switching on. For cases with a stochastic distribution of overvoltage amplitudes, the integral form of the rule was used:

$$L = \frac{1}{\int_0^{\infty} \frac{F(V_p)}{L(V_p)} dV_p} \quad (4)$$

Where $\int_0^{\infty} \frac{F(V_p)}{L(V_p)} dV_p$ – probability density function of peak overvoltage values, V_p – random variable characterising the peak pulse amplitude. The application of this relationship addressed the random nature of the formation of pulses in the network and to quantify the probability of reducing the insulation life in operation. Thus, the mathematical modelling provided the ability to reproduce the actual operating conditions of capacitor banks and quantified the impact of switching modes on both short-term overvoltages and long-term degradation of insulating materials.

Laboratory experiments were conducted using models of medium-voltage capacitor banks assembled under controlled conditions. To record the process parameters, high-speed Tektronix MSO64 digital oscilloscopes (USA) with microsecond resolution were used, which ensured the registration of transient pulses and oscillations. During the tests, the switching conditions, capacitance parameters, load modes and connection schemes were changed, which made it possible to obtain a wide range of experimental data. The research was conducted at a temperature of 20±2°C and a relative humidity of 50-60%. For each mode, at least 30 repeated switching cycles were performed. ABB DS1 (Switzerland) synchronous switches were tested separately to compare their characteristics with traditional switching devices.

Partial discharge diagnostic methods were used to assess the condition of capacitor dielectric materials. Equipment was used to measure the threshold voltage levels of partial discharge occurrence, which identified initial defects and trends in the degradation of insulation systems. Partial discharges in polypropylene dielectrics were recorded using measuring devices capable of determining the amplitude, frequency and time duration of pulses. An Omicron MPD 600 device with a sensitivity range of 2-2000 pC was used for the measurements, which identified the initial stages of insulation degradation.

This assessed the impact of repeated switching on the development of microbreakdowns and local defects. Statistical analysis was used to quantitatively evaluate the obtained data. Methods of multifactorial comparison, correlation analysis, and approximation of dependencies were used, which was used to generalise a large number of experimental and model observations. Additionally, Miner's rule [16] was applied to determine the cumulative effect of transient processes, and methods for constructing inverse dependencies of durability on electric field strength were used to predict the service life of insulating materials.

The statistical significance was verified using Student's t-test, Mann-Whitney test, and Fisher's test, which ensured the correctness of the generalisations. The χ^2 test was also used to assess the conformity of experimental damage distributions with theoretical ones. Data processing was performed in IBM SPSS Statistics 26 (IBM Corporation, USA) and R 4.3.1 (R Foundation for Statistical Computing, Austria). The data obtained were interpreted by combining the results of modelling, laboratory tests and statistical analysis. A systematic approach was used to assess the relationships between switching conditions, equipment characteristics and the effectiveness of protective measures.

This approach ensured consistency between different data sources and provided a holistic view of the mechanisms of switching overvoltages and their impact on the reliability of electrical systems. Thus, the combination of numerical modelling, experimental measurements and statistical verification ensured that the results were representative and reproducible.

III. RESULTS

III.1 EMPIRICAL ANALYSIS OF THE SWITCHING PROCESS OF MEDIUM VOLTAGE CAPACITOR BANKS

Experimental studies of the switching processes of medium voltage capacitor banks have shown that the level of overvoltage and the duration of transients are directly dependent on the capacity of the installed equipment. The study determined that with the increase in the capacity of capacitor banks, the inertia of charging and discharging processes increases, resulting in the formation of longer oscillatory modes with increased amplitudes. This makes it difficult to control the switching conditions and puts an additional strain on the insulation of electrical system components. The accumulation of such processes during the operational period can lead to accelerated ageing of equipment, which emphasises the need for their systematic analysis.

To present the results obtained, a summary Table 1 was compiled, which demonstrates the ranges of overvoltage amplitudes and transient duration in different operating modes. It contains data for capacitor banks with capacities ranging from 150 to 300 kVAr, which traces the pattern of increasing amplitude and duration of oscillations with increasing capacity. This systematisation makes it possible to compare different classes of equipment and provides a quantitative basis for further modelling in software environments and predicting system behaviour under repeated switching conditions.

Table 1: Experimentally recorded ranges of overvoltage amplitudes and duration of transients in capacitor banks of different capacitance.

Bank capacity, kVAr	Amplitude of overvoltages, pu	Transition time, ms	Features of the observations
150	1.6-2.0	0.8-1.2	Short oscillation processes; rare cases of repeated breakdown
200	1.9-2.4	1.1-1.6	Increased peak values; increased likelihood of current recycling
250	2.2-2.7	1.5-2.1	Fixed repeated breakdowns; increased stress on insulation
300	2.5-3.0	2.0-2.8	Long-term oscillating modes; significant risk of damage at isolated neutral

Note: kVAr – reactive power in kilovolt-amperes; pu (per unit) – relative value normalised by the rated voltage determined by formula (1); ms – milliseconds.
Source: Authors, (2026).

With the increase of the capacitor bank capacity, the amplitude of overvoltages increases from the range of 1.6-2.0 pu to the level of 2.5-3.0 pu, which corresponds to an increase of approximately 50-70% compared to the initial values. At the same time, the duration of transient processes more than doubles from 0.8-1.2 ms to 2.0-2.8 ms, which indicates the formation of longer oscillatory modes. The obtained data confirm the direct dependence between the capacitor capacity and the energy stability of oscillations in the system, which directly affects the insulation load. With large capacitances, the probability of repeated breakdown and the occurrence of long-term oscillations that can lead to the degradation of dielectric materials and damage to equipment is significantly increased.

Thus, the results of the experiments highlight the need to incorporate the capacity of capacitor banks when selecting switchgear and applying surge suppression measures. To explain in detail the mechanisms of formation of these phenomena, the study uses simplified electrical models that can be used to reproduce typical switching conditions and trace the interaction of inductive and capacitive elements of the circuit. Figure 1 shows a basic circuit that serves as the basis for modelling transients and quantifying the voltage across system elements. Its use makes it possible to identify the key parameters that determine the amplitude of overvoltages, the duration of oscillatory processes and the overall stability of the power grid, which is critical for developing effective protection methods.

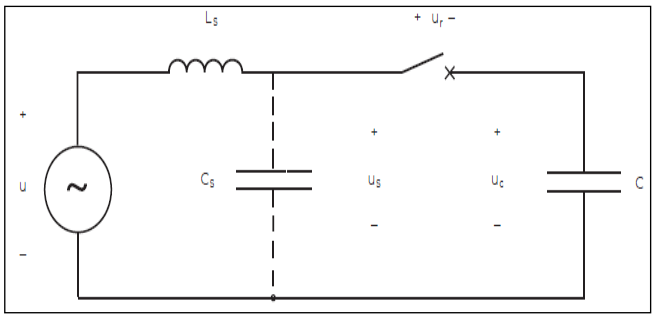

Figure 1: Simplified switching diagram of a medium voltage capacitor bank.
Source: Authors, (2026).

The main elements are an alternating voltage source U, a series inductor Ls, a capacitor Cs, and a switched capacitor C, which is connected by a switch. At the moment of switching, a voltage ur is generated, which is the result of the interaction of voltages us and uc applied to the respective capacitors.

The appearance of this voltage is accompanied by oscillatory processes, the value of which is determined by the parameters of inductance and capacitance, as well as the phase angle of the switching moment relative to the source. Under unfavourable conditions, a repeated breakdown in the circuit breaker and current recirculation can occur, which creates additional electrodynamic loads on the insulating and switching elements of the system. The diagram is the basis for further mathematical description, as it can be used to quantify the impact of circuit parameters on the amplitude of overvoltages, the duration of transients, and to determine the critical operating modes of capacitor plants.

For further analysis of these phenomena, it is necessary to graphically display time dependencies that can be used to trace the dynamics of changes in electrical quantities at the time of switching. Figure 2 shows time diagrams that demonstrate the characteristic oscillatory processes of voltage and current in a circuit with capacitor banks. They make it possible to trace the relationship between the instantaneous values of us, uc and current i, as well as to identify the conditions for the formation of peak overvoltages. Such graphical dependencies are a tool for qualitative assessment of the processes occurring in the first milliseconds after switching and can be used to determine their impact on the electrical strength of insulation and the durability of system elements.

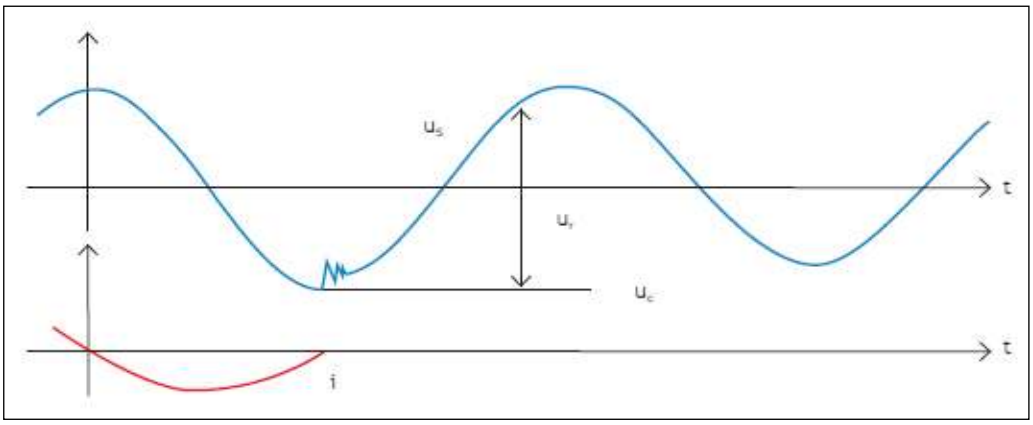

Figure 2: Time diagrams of voltage and current during capacitor bank switching.
Source: Authors, (2026).

At the moment of switching, an instantaneous voltage us is formed, which, together with the voltage uc across the capacitor, determines the resulting value ur. The recorded time diagrams indicate the oscillatory nature of the voltage, the peak values of which significantly exceed the amplitude of the sinusoidal voltage of the source. At the same time, the current i at the initial moment undergoes a sharp decline with the formation of a negative half-wave, after which it gradually stabilises at a new level. The observed oscillatory modes are accompanied by short-term high-frequency pulses, which can create a dangerous electrical load on the insulation of equipment and accelerate the process of its ageing.

The obtained results confirm that the moment of switching is a determining factor in the formation of overvoltage, and therefore requires consideration during the selection of protective devices and the establishment of optimal operating modes of capacitor banks. The phenomenon of arc re-arcing in the circuit breaker deserves special attention in the study, which is one of the most dangerous mechanisms of switching overvoltages. Figure 3 shows the time diagrams illustrating the change in voltage and current during the re-arcing after the circuit break. These processes are characteristic of traditional switchgear, where the moment of switching off is not synchronised with the phase of the source voltage. This creates conditions for the occurrence of repeated oscillatory processes and an increase in the load on the insulation systems, which directly affects the durability and operational reliability of the equipment.

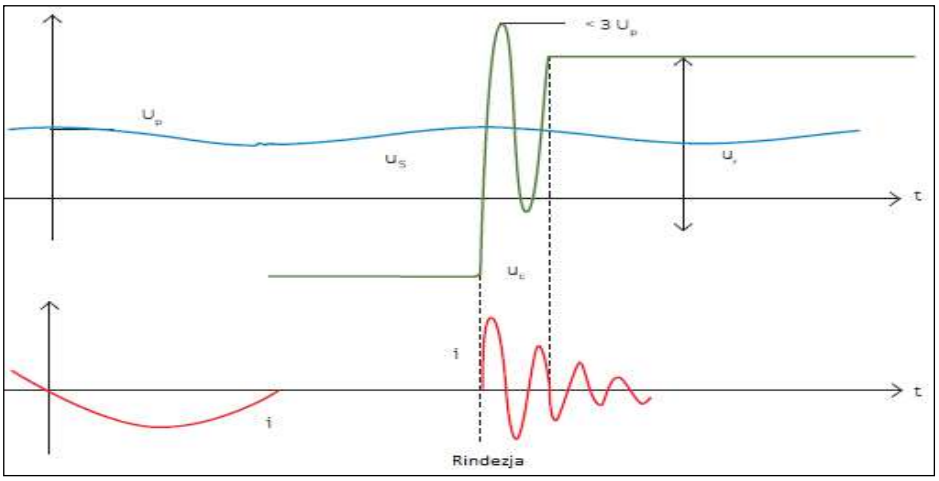

Figure 3: Time diagrams of overvoltage and current during repeated arc faults in a circuit breaker.
Note: “Rindezja” – “tension”.
Source: Authors, (2026).

After the circuit break, the voltage across the capacitor uc increases sharply and can exceed the initial value by almost three times (up to <3Up). Such a voltage jump is accompanied by the formation of high-frequency oscillations, which are manifested in the form of an oscillating current i after a repeated breakdown (rindezja). The results obtained indicate that these processes create significant electrodynamic and thermal loads on the circuit breaker contacts and insulating materials, reducing their durability. In addition, the oscillatory nature of the current can contribute to resonant interaction with other elements of the electrical network, which increases the risk of emergency modes.

The presented time dependencies confirm the critical influence of the moment of re-breakdown on the amplitude of overvoltages and prove the feasibility of using synchronous circuit breakers or specialised limiters to improve system reliability. Analysing transients in three-phase networks, it is necessary to address the connection options for capacitor banks, since it is the connection configuration that determines the nature of voltage distribution and the likelihood of dangerous overvoltages. Figure 4 shows typical schemes for connecting capacitor banks to the grid, which differ in the way they are connected and the organisation of grounding. Such structural models can be used to assess how different connection modes affect phase symmetry, stability of electrical processes and risks of equipment damage, which is key when making recommendations for optimal system configuration.

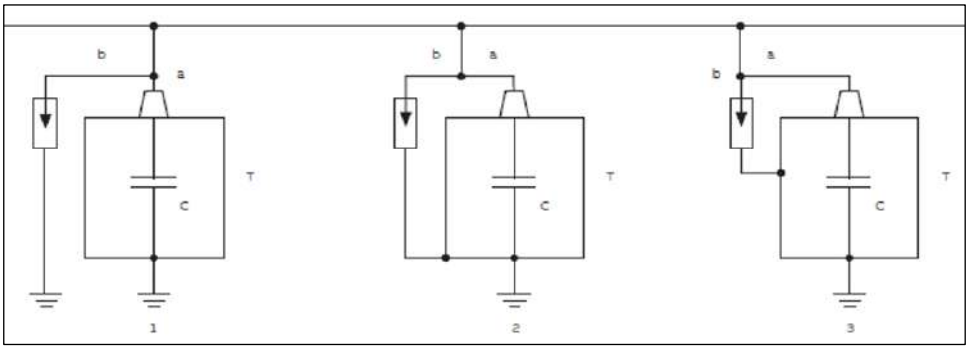

Figure 4: Options for connecting capacitor banks in a three-phase network.
Source: Authors, (2026).

The choice of the capacitor bank connection scheme directly affects both the distribution of potentials between the phases and the conditions for the occurrence of overvoltages in transient modes. Scheme 1 is characterised by a relatively symmetrical load distribution between the phases, but in the case of a mismatch in the switching moment, an increase in the voltage amplitude in the first phase is recorded compared to the others. Scheme 2 partially reduces the level of overvoltage due to the changed grounding mode, but at the same time creates increased current loads on the switchgear during switching. Scheme 3 demonstrates a mixed nature of the processes, in which the amplitude of overvoltages increases, but the duration of oscillations is shorter than in the previous cases.

Thus, the results confirm that the choice of the connection scheme is a determining factor in ensuring optimal operating conditions for capacitor plants and minimising the risk of equipment damage in medium voltage networks. In the course of the study of switching modes, the efficiency of traditional circuit breakers and synchronous devices, which are the most common in the practice of operating electrical networks, was also compared. Experimental results showed that the maximum values of peak overvoltages, the duration of oscillatory processes after switching, and the probability of repeated arc breakdown directly depend on the type of circuit breaker. The systematisation of these data made it possible to summarise the differences between different classes of switching devices and present them in Table 2, which provides a visual comparison of key parameters.

Table 2: Comparison of test results for conventional circuit breakers and synchronous devices.

Type of switching device	Level of peak overvoltages, pu	Oscillation duration, ms	Probability of repeated breakdown, %
Traditional switch	2.2-3.0	2.0-3.5	25-35
Synchronous switch	1.0-1.5	0.5-1.2	<5

Note: pu (per unit) – relative value, normalised by nominal voltage, determined by formula (1); ms – milliseconds.
Source: [13-15].

The use of traditional circuit breakers is accompanied by significantly higher levels of peak overvoltage, which can reach 3.0 pu, while for synchronous devices this figure does not exceed 1.5 pu. The duration of oscillation processes in traditional circuit breakers is, on average, three times longer, which creates an additional thermal and electrodynamic load on the insulating elements and reduces their durability. At the same time, the probability of a repeated breakdown in traditional devices reaches 35%, while in synchronous devices it is practically zero. The summarised data clearly demonstrate the advantages of using synchronous circuit breakers, which ensure reliable switching and contribute to the operational stability of medium-voltage power grids.The obtained results confirm that the nature of switching overvoltages is determined not only by the capacity of capacitor banks and circuit parameters, but also by the choice of the type of switching apparatus and the connection scheme.

The established dependencies demonstrate that even minor differences in switching modes can lead to significant fluctuations in the amplitude and duration of overvoltages, which in some cases exceed the permissible limits for isolation. This highlights the need for a comprehensive consideration of all design and operational factors when designing and upgrading systems with capacitor banks. Thus, the analysis has empirically proved that switching overvoltages are a determining factor in the reliability of medium voltage capacitor banks. The established regularities form the basis for further research aimed to assess their long-term impact on the capacitive elements of the system and determining the mechanisms of gradual ageing of dielectric materials. This provides a logical transition to the next subsection, which is devoted to an empirical analysis of the impact of overvoltages on the operation and durability of capacitors.

III.2 AN EMPIRICAL STUDY OF THE EFFECT OF OVERVOLTAGES ON THE OPERATION AND DURABILITY OF CAPACITORS

In the process of studying the durability and reliability of capacitor banks, it is of particular importance to consider their internal structure, since it is the design features that determine the ability of the equipment to withstand switching overvoltages and thermal overloads. Practical observations and operational statistics confirm that the most vulnerable components are insulating materials, fuses and discharge resistors, which are subject to repeated electrical and thermal effects. Such elements often initiate degradation processes, which eventually lead to a decrease in the electrical strength of the system. Accordingly, a detailed analysis of the structural characteristics of capacitor banks is used not only to identify the main damage mechanisms but also to develop practical recommendations for improving their reliability and extending their service life.

Figure 5 shows a schematic representation of the structure of a capacitor bank, which reflects the spatial arrangement of the main elements and their interaction as part of a single system. This model includes both external components that provide connection and insulation, and internal elements such as working sections, discharge resistors, fuses, and a metal shell. The use of this structural diagram makes it possible to visualise the key components of the equipment, trace their functional role and identify the parts most vulnerable to switching overvoltages and thermal loads. This creates the preconditions for a reasonable development of measures to improve the operational stability of capacitor banks in medium voltage networks.

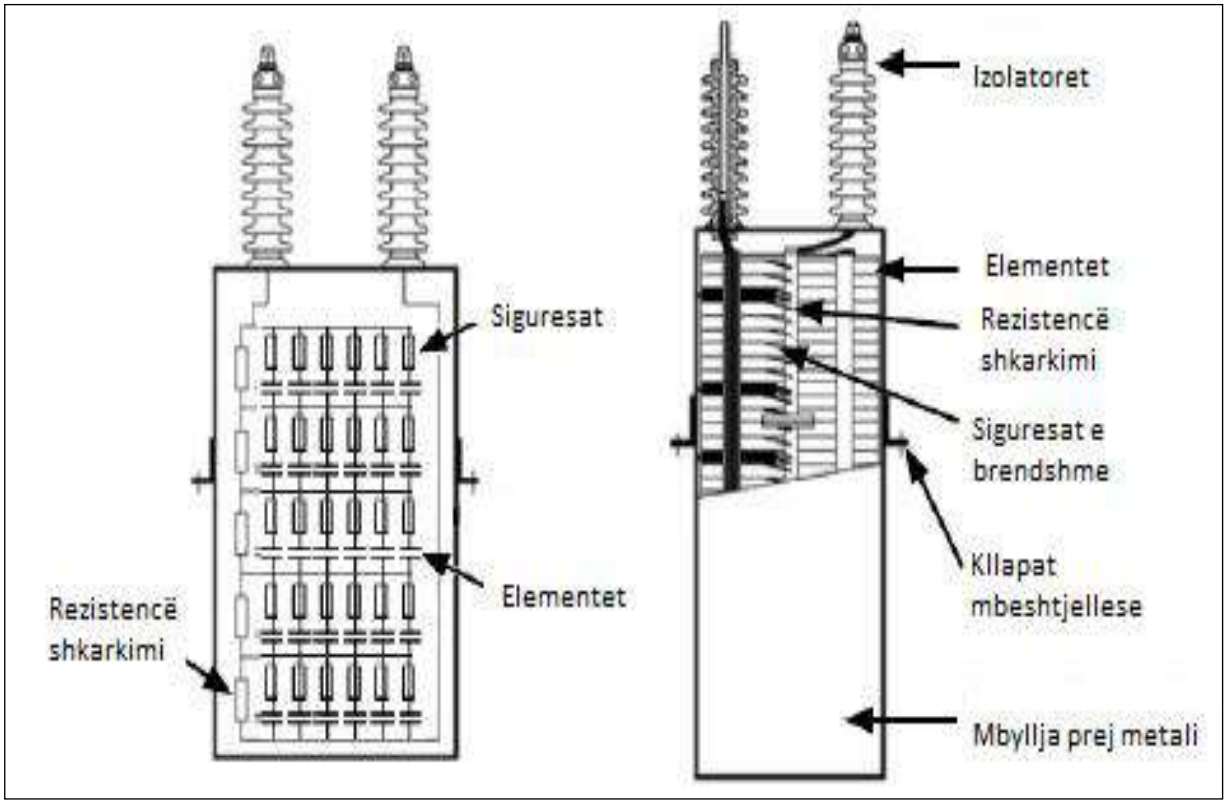

Figure 5: Structural design of the medium voltage capacitor bank.
Note: Elements – individual sections of capacitors that form the bank; Rezistencë shkarkimi – resistors designed to discharge capacitors after shutdown; siguresat – fuses that protect against internal damage; izolatorët – external insulation parts; mbyllja prej metali – metal shell of the case.
Source: Authors, (2026).

The design of the capacitor bank is a multi-level system in which each element performs a specific function to ensure stable and reliable operation of the equipment [17],[18]. The insulators form an electrical barrier and minimise the probability of breakdown between phases, which is critical to maintaining the integrity of the insulation system. The working elements of the bank are connected to discharge resistors that provide a rapid reduction in residual voltage after disconnection, which prevents unwanted charge build-up [19],[20]. The fuses are integrated both externally and internally, which can be used for localised damage and prevents it from spreading to other parts of the plant in the event of a breakdown. The metal shell serves as mechanical protection and electrical shielding, isolating the internal components from external influences [21].

Thus, the reliability of a capacitor bank is determined by a combination of design and protection solutions that must be addressed at the design, production, and operation stages. In the context of studying the impact of switching overvoltages on the durability of capacitor banks, a substantial task is to identify the characteristic damages that most often lead to equipment failures. The results of the statistical analysis of operational data showed that the vast majority of failures are caused by insulation defects, among which partial discharges and local breakdowns dominate. Other damages, such as degradation of impregnating fluids or mechanical defects, are less systematic but also affect the overall reliability of the system. To summarise the results, Table 3 shows the distribution of capacitor failures by the main types of insulation damage with the corresponding percentage.

Table 3: Distribution of capacitor failures by type of insulation damage.

Type of insulation damage	Failure rate, %
Partial discharges	48
Localised breakdowns	27
Degradation of impregnating fluids	15
Other defects (mechanical, structural)	10
Total	100

Note: “Partial discharges” denote localised microelectric discharges inside the dielectric; “local breakdowns” – insulation breakdowns in places of field concentration; “degradation of impregnating fluids” includes changes in their electrical and physicochemical properties under the influence of pulse loads. The impact of the identified damage mechanisms on the service life is further quantifiedusing formula (2).
Source: Authors, (2026).

The most common type of damage is partial discharge, which accounts for almost half of all recorded failures and is the main factor in the gradual ageing of dielectric materials. Localised breakdowns account for more than a quarter of the total number of failures and mostly occur in areas with uneven electric field distribution and concentrated stress [22]. Degradation of impregnating fluids is less common, but its impact on equipment durability is significant in the case of long-term operation, as it reduces the dielectric strength and thermal stability of the system. Other defects, such as mechanical damage or design flaws, are less systematic, but their share is significant and indicates the need to accommodate additional factors in the maintenance process [23].

Thus, the results confirm that the priority area of diagnostics should be the detection of early manifestations of partial discharges and local breakdowns as key predictors of capacitor system failures. For a comprehensive research of the nature of capacitor bank failures, it is necessary to break them down by manufacturer, as design features, material quality and manufacturing technology directly affect operational reliability. To this end, a comparative analysis of the frequency of damage to the main insulation, oil leakage and insulator defects in capacitor banks from different manufacturers was carried out. This approach makes it possible to identify the predominant failure mechanisms within each group of equipment and to determine the specific patterns inherent in the products of individual manufacturers. The results of this comparison are summarised in Table 4.

Table 4: Distribution of capacitor failures by types of damage and manufacturers.

Producer	N_0, unit	Basic insulation, units	Basic insulation, %	Oil leaks, units	Oil leakage, %	Insulator, unit	Insulator, %
A	325	306	94.15	10	3.08	9	2.77
B	150	137	91.33	11	7.33	2	1.34
C	38	36	94.74	1	2.63	1	2.63
D	23	17	73.91	5	21.74	1	4.35
Total	536	496	92.54	27	5.04	13	2.42

Note: N_0 – total number of capacitor elements examined; indicators are given separately for damage to the main insulation, oil leaks, and insulator defects in natural units and as a percentage of the total number; The expected reduction in service life for each manufacturer group was estimated using formula (2), accomodating the cumulation of damage according to Miner’s rule (3).
Source: Authors, (2026).

The main share of damage is caused by insulation defects, which account for more than 92% of all failures, regardless of the manufacturer. The most reliable in this category are capacitors from manufacturers A and C, where the share of insulation damage exceeds 94%, while the figure for manufacturer D is much lower (73.91%), indicating an increased vulnerability of the equipment. Oil leaks account for about 5% of failures on average, but for manufacturer D, this figure reaches 21.74%, indicating design or process defects. Insulator defects account for a small share of the total (2.42%), but their presence in all manufacturers indicates a systemic problem.

Thus, the results confirm that insulation damage remains the main problem, while oil leaks are also a significant reliability factor for some manufacturers. When assessing the durability of capacitor banks, it is necessary to address their operating conditions, as the frequency of switching has a significant impact on the level of damage. Operational statistics show that equipment subjected to daily switching on and off is subjected to a higher load than installations in constant operation. To quantitatively compare these dependencies, the study analysed the frequency of defects in capacitor banks under different operating conditions. The results are summarised in Table 5.

Table 5: Analysis of damage to capacitor banks depending on switching frequency.

Operating conditions	Switch on at least once a day	Always operational	Total
Total number of banks	2450	462	2912
Banks with defects	293	37	330
Share of damages, %	12	8	11.3

Note: “Defective banks” are defined as installations with recorded insulation damage, oil leaks or mechanical defects; “damage share” – percentage of defective banks to the total number within the respective group; the cumulative effect of daily switching on insulation degradation is determined by the Miner’s rule (3).
Source: Authors, (2026).

Capacitor banks that are subject to regular daily switching are the most vulnerable to damage. In this group, the share of defects is 12%, which is 50% higher than the share of equipment in constant operation (8%). Overall, 11.3% of the banks in the sample had damage, which is significant for equipment with a long service life. The results show that the frequency of switching is one of the key factors in the degradation of insulating materials and the reduction of capacitor life. This emphasises the need to limit the number of switching operations in practical operation or to apply additional protection measures that can reduce the impact of switching overvoltages.

Studies of the durability of capacitor banks have confirmed that both the amplitude of switching overvoltages and the frequency of repeated switching have a significant impact on their service life. Elevated voltage values create conditions for accelerated dielectric ageing and increase the probability of local breakdowns, while regular switching increases the cumulative effect of damage [24]. To quantitatively summarise these patterns, a model has been developed that demonstrates the dependence of the average service life of capacitors on the amplitude of overvoltages (pu) and the number of switching operations per day. The results are summarised in Table 6.

Table 6: Dependence of the average service life of capacitors on the amplitude and frequency of switching overvoltages.

Amplitude of overvoltages, pu	1 switching event/day	5 switching events/day	10 switching events/day
1.5	~22 years	~18 years	~15 years
2.0	~17 years	~13 years	~10 years
2.5	~12 years	~8 years	~6 years

Note: pu (per unit) – relative voltage value normalised to the nominal value; the number of switching operations per day determines the average frequency of switching capacitor banks on and off in real operating conditions.
Source: Authors, (2026).

The service life of capacitors decreases both with the increase in the amplitude of switching overvoltages and with the increase in the switching frequency. At an amplitude of 1.5 pu, even with 10 daily switching operations, the average service life is about 15 years, while at an amplitude of 2.5 pu, this figure is reduced to 6 years. The most critical is the combination of high overvoltages and frequent switching, as it creates conditions for accelerated degradation of dielectric materials and significantly increases the risk of local breakdowns [25]. The results confirm the need to simultaneously control both the amplitude of overvoltage and the number of daily switching operations, as the balance of these parameters determines the durability of capacitor banks. Thus, limiting the level of overvoltage and reducing the frequency of switching should be considered as key measures in the strategy to improve the reliability and economic efficiency of equipment operation.

Studies of operational statistics have also shown that damage in capacitor banks is not always limited to single defects, but often occurs simultaneously in several elements of the same installation. This pattern indicates a systemic nature of failures, caused by both design features and technological factors inherent in the products of individual manufacturers. To quantify this phenomenon, the study analysed the distribution of failures, which determined the frequency of cases with two or three defects within one banking unit. The results are summarised in Table 7.

Table 7: Distribution of damage in capacitor banks by manufacturer and the number of defects in one bank.

Producer	Total number of banks with damage	Total number of damages	2 damages in one bank: banks	2 damages in one bank: units	3 damages in one bank: banks	3 damages in one bank: units
A	215	325	48	96	32	96
B	103	150	41	82	4	12
C	26	38	8	16	2	6
D	21	23	3	6	0	0
Other	2	5	0	0	0	0
Total	365	541	100	200	38	114

Note: “Banks” – number of installations with simultaneous damages; “units” – total number of damaged capacitor elements within these banks; the probability of simultaneous occurrence of two or more damages within one installation was estimated using a stochastic approach using the integral form (4).
Source: Authors, (2026).

The largest number of systemic failures occurred in vendor A, where 325 defects were recorded, many of which occurred simultaneously in several elements of the same banking system. In particular, 48 banks had two defects each, and another 32 had three at once, indicating a high probability of group failures. Vendor B is also characterised by a significant number of systemic defects, but their intensity is lower. Manufacturers C and D show lower absolute numbers, but the presence of repeated failures within the same plant confirms that the problem is typical for different manufacturers. In general, the data obtained indicate that failures in capacitor banks are systemic in nature and often involve several elements at the same time, which should be taken into account when predicting operational reliability and organising preventive maintenance.

To summarise the results of this section, it is possible to state that the durability and reliability of capacitor banks are determined by a combination of design features, manufacturing quality and operating conditions. Insulation defects have the greatest impact on the formation of damage, which is aggravated by switching overvoltages, high switching frequency and specific technological shortcomings of individual manufacturers. Regular statistical observations have confirmed that failures are often grouped and occur simultaneously in several elements of the same installation. The results obtained form the basis for further searching for effective protection methods that can minimise the negative impact of switching overvoltages and ensure increased operational stability of electrical systems.

III.3 THE IMPACT OF SWITCHING OVERVOLTAGES ON OTHER COMPONENTS OF THE ELECTRICAL SYSTEM: EMPIRICAL OBSERVATIONS

During the operation of asynchronous motors, one of the key factors that determines their reliability is the impact of switching overvoltages generated by the interaction with medium voltage capacitor banks. The configuration of the capacitor banks directly determines the level of residual voltage at the motor terminals and the duration of transient oscillations after the motor is switched off. These parameters are critical, as they determine the electrical and thermal loads on the winding insulation, affect the correct operation of relay protection and form the actual service life of electrical machines.

To quantify the impact of different connection modes, the overvoltage amplitude and duration of transients were measured under conditions most typical of industrial electrical installations. In particular, the modes of parallel operation of a motor with a capacitor bank, its long-term connection, and frequent switching scenarios were studied. The data obtained made it possible to trace the dynamics of changes in electrical parameters in each case and identify critical conditions that significantly affect the operational reliability of the equipment. The results of the experimental observations are summarised in Table 8.

Table 8: Results of overvoltage measurements at the terminals of induction motors with different capacitor connection configurations.

Capacitor bank connection configuration	Range of overvoltages, pu	Oscillation duration, ms	Observable effects
Parallel operations	1.6-1.8	1.2-1.6	Impulse overloads in windings
Long-term connection	1.8-2.2	1.8-2.4	Additional heating of the insulation reduces service life
Frequent switching	2.0-2.5	2.5-3.2	Premature tripping of the relay, risk of winding breakdown

Note: pu (per unit) – relative voltage value normalised to the nominal value; the duration of oscillations was determined by the voltage stabilisation time after the motor was switched off.
Source: Authors, (2026).

The lowest overvoltages are observed in the mode of parallel operation of the motor and the capacitor bank, where the values do not exceed 1.8 pu. However, even in this case, impulse overloads in the windings were recorded, which can accelerate the ageing of insulation. Under conditions of prolonged connection, the amplitude of overvoltages increased to 2.2 pu, and the duration of oscillations doubled compared to the previous mode, which caused additional heating of the windings and a decrease in their service life. The most dangerous conditions were those of frequent switching, when the overvoltage reached 2.5 pu and the oscillation duration exceeded 3 ms, which posed a threat to the windings' integrity and provoked premature tripping of the relay protection. Thus, the results obtained confirm the critical dependence of the level of overvoltage and motor reliability on the modes of capacitor connection, which should be addressed when operating and designing power supply systems.

A substantial condition for ensuring the reliability of electrical systems is to address the possibility of resonant interaction between capacitor installations of different voltage levels. A particular danger is posed when medium-voltage capacitors operate simultaneously with low-voltage capacitors, which creates the prerequisites for increasing the amplitude of overvoltages in the secondary circuits of transformers [26]. To illustrate these modes, a block diagram was built to show the characteristic connections between the system elements. Figure 6 shows a generalised diagram of the interaction of medium and low voltage capacitor banks, which can be used to trace the possibility of resonant amplification of oscillations in secondary circuits. It shows the connection of a medium voltage capacitor bank (C_4) and low voltage banks (C_2, C_3) through a transformer supplying an induction motor (M). This approach makes it possible to evaluate the nature of the influence of the connection configuration on the magnitude of overvoltages and the operation of secondary circuits.

Source: Authors, (2026).

The simultaneous use of capacitor installations of different voltage levels creates prerequisites for the emergence of resonant modes in the system. In such cases, the frequency of the switching oscillations in the medium voltage circuit may coincide with the natural resonant frequency of the low-voltage capacitors, which leads to a significant increase in the amplitude of overvoltages in the secondary windings of the transformer. This results in overloading of protective elements, premature tripping of fuses and relays, and in some cases, failure of sensitive electronic devices. The above diagram confirms that the interaction between capacitors of different voltage levels is one of the critical factors in the stability of the power grid and requires the use of special technical protection measures.

The results of field and experimental studies have shown that it is the resonant interaction between medium and low voltage capacitors that poses the greatest danger to transformer secondary circuits. Under such conditions, the amplitude of overvoltages significantly exceeds the permissible values, which is accompanied by a malfunction of protective devices and damage to electronic equipment. To systematise the results obtained, the measured parameters of overvoltages in relative units (pu), their duration and characteristic consequences for system elements were summarised. The summary data is shown in Table 9.

Table 9: Recorded values of the amplitude of overvoltages in the secondary circuits of transformers under conditions of resonant interaction of capacitors of different voltages and their consequences.

Mode of interaction of capacitors	Amplitude of overvoltages, pu	Oscillation duration, ms	Observable effects
Low level of resonant interaction	2.0-2.5	2.0-2.5	Short-term overloads, single fuse trips
Average level of resonant interaction	3.0-3.5	2.5-3.0	Massive tripping of relay protection, damage to fuses
High level of resonant interaction	4.0-5.0	3.0-4.0	Failure of electronic control devices, disruption of secondary circuits

Note: pu (per unit) – relative voltage value normalised by the nominal value; the duration of oscillations was determined by the stabilisation time after an overvoltage pulse; relay protection – set of devices for automatic shutdown in emergency conditions; the probability of reaching the levels of 3.0-5.0 pu under input parameter fluctuations was estimated using the integral form (4).
Source: Authors, (2026).

Even at low levels of resonant interaction, the amplitude of overvoltages reaches 2.5 pu, which poses a significant danger to the insulation and serviceability of fuses. At an average level of interaction, the amplitude increases to 3.5 pu, which is accompanied by massive failures of protective devices and frequent damage to fuses in secondary circuits. In the case of a high resonance level, the amplitude exceeds 4.0 pu, which leads to the failure of electronic controls and disruption of the stability of secondary systems. The obtained results demonstrate the critical dependence of the reliability of the electrical system on the presence of resonance phenomena, which confirms the need to introduce damping devices and optimise the connection schemes of capacitor plants. Industrial power grids are increasingly using induction motors that are powered by converter devices, including a converter, a DC link and an inverter [27].

This configuration provides speed control and increases energy efficiency, but at the same time makes the system more sensitive to switching overvoltages. The DC link, which accumulates energy, creating conditions for the formation of dangerous voltage pulses, is notable. In these modes, the analysis of the distribution of electrical loads between the components of the converter complex and the identification of the most vulnerable elements are of key importance. Figure 7 shows a block diagram of an induction motor power supply through a converter and an inverter, which is used to study the peculiarities of the impact of switching overvoltages on power electronics.

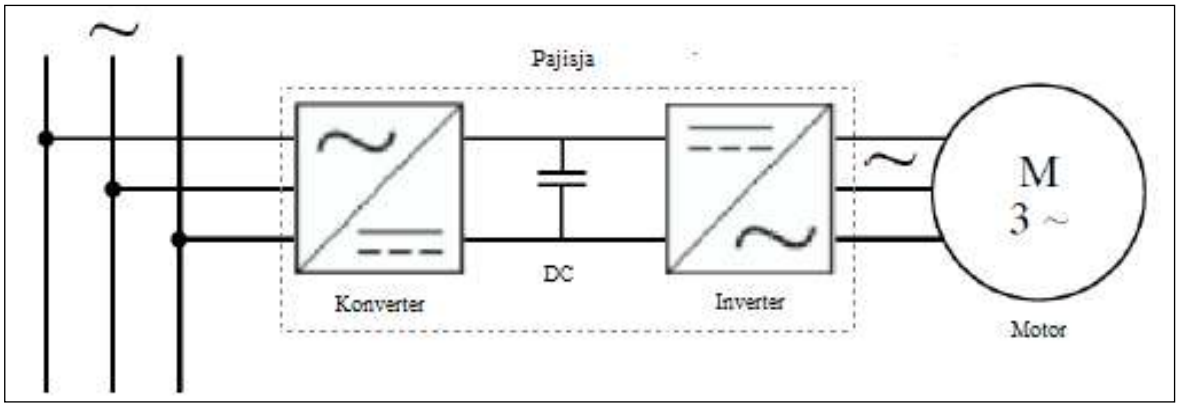

Figure 7: Scheme for powering an induction motor via a converter device (converter-inverter with DC link).
Note: “Pajisja” – “device”.
Source: Authors, (2026).

An induction motor power system consists of a three-phase source, a converter, a direct current link (DC link), an inverter, and an electrical machine. The converter performs the function of rectifying the AC voltage, while the DC link provides energy storage and stability for the inverter. However, it is this element that has proven to be the most sensitive to switching overvoltages, as even short-term fluctuations can lead to an excess of the nominal level by 10-20%. As a result, additional electrical load is placed on the inverter’s power switches, which increases the probability of damage and reduces the service life of electronic components.

Thus, the above diagram confirms the feasibility of using surge arresters and integrated active protection systems that ensure reliable operation of induction motors as part of industrial electric drives. A generalisation of the results obtained shows that switching overvoltages have a complex effect on key components of electrical systems, from the insulation of induction motor windings to the secondary windings of transformers and power electronics. Experimental and field data have confirmed that their effect is manifested both in the form of accelerated ageing of insulating materials and in the form of emergency failures associated with resonant modes and exceeding critical voltage levels. The established patterns emphasise the need for an integrated approach that includes optimisation of connection schemes, the correct choice of protective devices and determination of permissible operating modes of equipment. Thus, this analysis forms the scientific basis for further development and implementation of effective methods to reduce switching overvoltages, which is a prerequisite for improving the reliability and safety of electric power systems.

III.4 EMPIRICAL EVALUATION OF METHODS FOR REDUCING SWITCHING OVERVOLTAGES

In the course of studying methods for reducing switching overvoltages, circuit solutions involving the introduction of inductive chokes and additional elements into the switching circuit were addressed. The use of such approaches makes it possible to partially compensate for the energy of transients by reducing the pulse amplitude and shortening the duration of oscillatory modes. This has a direct impact on the stability of equipment operation and increases the durability of power grids, where regular overvoltage is one of the determining factors of reliability. Figure 8 shows variants of electrical schemes used to limit switching overvoltages in circuits with capacitor banks. The presented structural models show different combinations of series and parallel elements that dissipate excess energy and reduce the likelihood of repeated breakdowns in the circuit breakers. The presented solutions are the basis for comparing the effectiveness of technical measures and determination of the optimal operating conditions of the equipment, taking into account the specifics of switching processes in medium voltage networks.

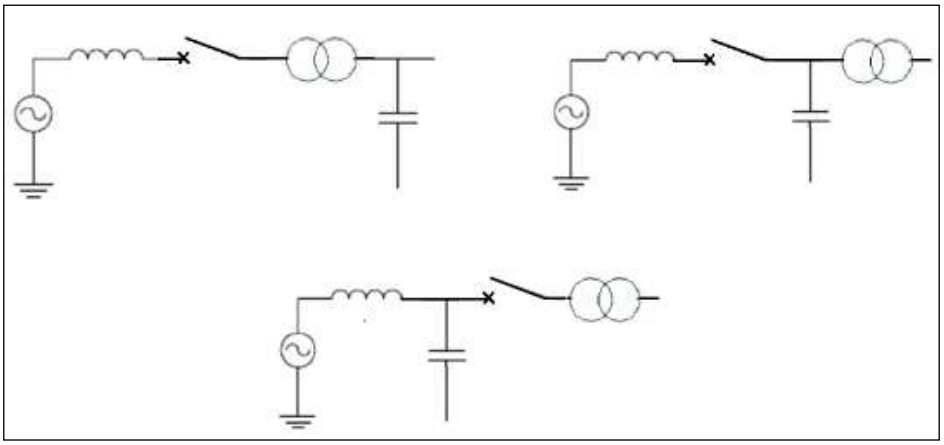

Figure 8: Schemes for reducing switching overvoltages using inductive and resistive elements.
Source: Authors, (2026).

The introduction of inductive elements into the circuit with capacitors provides a significant reduction in the rate of current rise and a decrease in peak voltage values at the moment of commutation. The use of chokes in series connection was found to be most effective for limiting current pulses, while circuits with parallel branches can be used high-frequency oscillations to be effectively damped. Such configurations not only increase the level of electrical insulation but also reduce the thermal load on the equipment, which directly affects its durability. The results obtained confirmed that the optimality of a particular circuit depends on the parameters of the network and the nature of the switching modes. Thus, the presented models can be used as a basis for forming practical recommendations for the implementation of protection against switching overvoltages in industrial electrical systems.

During the experimental tests, the effectiveness of various technical solutions aimed to reduce the level of switching overvoltages in medium-voltage networks was assessed. The comparison was made between the initial values of overvoltages occurring in the absence of protective measures and the residual levels recorded after the use of inductive chokes, pre-commutation resistors, overvoltage limiters and synchronous switches. The summarised results made it possible to assess the effectiveness of each method both in terms of reducing peak amplitudes and in terms of reducing the duration of oscillatory processes. The systematic data are shown in Table 10.

Table 10: Initial and residual values of overvoltages with different protection methods.

Method of protection	Initial overvoltage, pu	Residual overvoltage, pu
Without protection	3.0	3.0
Inductive choke	3.0	2.0
Pre-enabling resistor	3.0	1.7
Surge arrester	3.0	1.5
Synchronous switch	3.0	1.2

Note: pu (per unit) – relative units used for normalisation of electrical values; MOV (Metal Oxide Varistor) – surge arrester based on metal oxide varistors.
Source: Authors, (2026).

The absence of any protection means leads to the preservation of the maximum overvoltage amplitude at the level of 3.0 pu, which poses a danger to the insulation of equipment and increases the likelihood of emergency modes. The use of inductive chokes reduces the amplitude by about a third, but does not eliminate the risk of resonant oscillations. The pre-trigger resistors and surge arresters demonstrated significantly higher efficiency, reducing the amplitude to 1.7 and 1.5 pu, respectively. The best results were achieved by synchronous circuit breakers, which limited the overvoltage to 1.2 pu and actually reduced the risk of a second breakdown to a minimum level.

The generalised results confirm the prospects of introducing synchronous switching technologies in modern power grids as one of the most effective methods of improving their reliability.In the process of further evaluation of methods for reducing switching overvoltages, special attention was paid to pre-tapering schemes using resistive-inductive elements. Such solutions provide controlled capacitor charging, reduce the amplitude of impulse overvoltages, and significantly reduce the likelihood of repeated arc breakdown in the circuit breakers. Figure 9 shows a wiring diagram showing the operation of a switching device with a resistor and a choke in the circuit of one of the phases. This model is used to study the mechanisms of damping oscillatory processes and determine the optimal parameters of elements that ensure the reliability of electrical equipment under conditions of frequent switching.

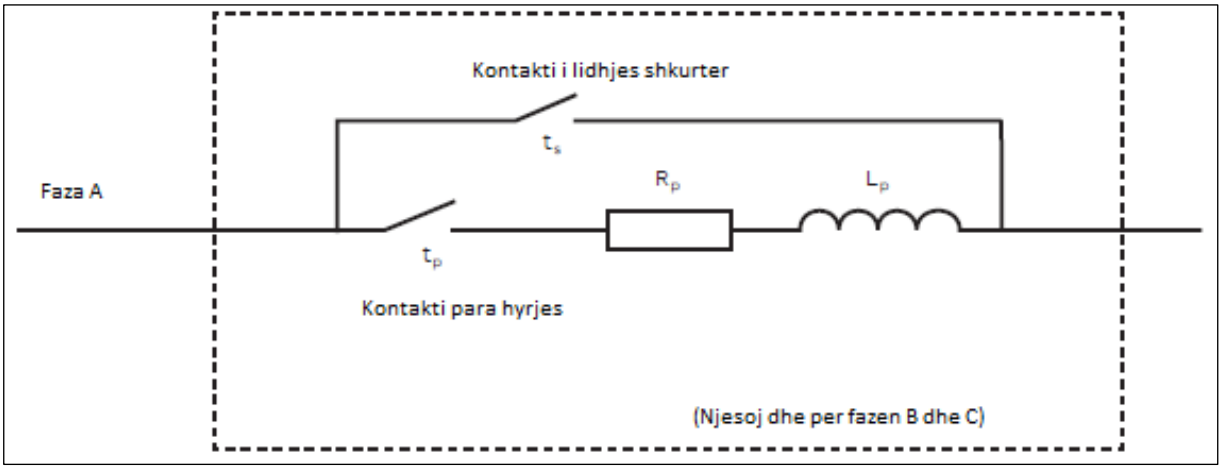

Figure 9: Pre-enabling circuit with a resistor (Rp) and an inductor (Lp) in the phase circuit of the capacitor bank.
Note: Rp – pre-commutation resistor that provides partial energy dissipation during switching; Lp – choke that limits the rate of current rise; tp – closing time of the preliminary contact; tc – closing time of the main contact; “Kontakti i lidhjes shkurtër” – “short-circuit contact”; “Kontakti para hyrjes” – “preliminary contact”; “Njesoj dhe per fazen B dhe C” – “same for phase B and C”.
Source: Authors, (2026).

The use of a preliminary contact with a resistive-inductive circuit can significantly reduce the level of overvoltage in the switching transients. At the initial stage of switching on, the resistor Rp dissipates part of the energy, reducing the peak voltage values, while the inductance Lp limits the rate of current growth. After the main contact closes, the system switches to nominal operation, which minimises shock loads on the circuit elements and ensures smoother switching. Such technical solutions reduced the probability of repeated breakdowns, increased the durability of capacitors and switchgear, and improved the overall stability of the electrical system. The use of resistive-inductive circuits can be considered one of the most promising ways to improve the operational reliability of industrial electrical installations.

In the practice of designing and operating electrical systems, the assessment of the technical effectiveness of switching overvoltage reduction methods should be combined with economic analysis. Initial implementation costs, regular maintenance costs, and the projected service life of the equipment determine the total life-cycle operating costs, which are a key criterion for engineering decision-making [28-30]. Comparison of different protection methods helps to establish an optimal balance between the level of technical reliability and economic feasibility, especially in conditions of limited resources and high requirements for the stability of power grids. Table 11 summarises the economic assessment of the main switching overvoltage protection equipment, which can be used for a comprehensive assessment of their feasibility in practical operation.

Table 11: Economic assessment of methods for reducing switching overvoltages.

Method of protection	Implementation cost (unit)	Maintenance costs (% of implementation/year)	Average service life (years)	Total life cycle operating costs (unit)
Without protection	0	0	-	High indirect losses (accidents, repairs)
Throttle	3000	5%	12	~4800
Pre-enabling resistor	1500	8%	8	~4000
MOV (surge arrester)	2000	10%	6	~5200
Synchronous switch	5000	3%	15	~6950

Note: MOV (Metal-Oxide Varistor) – nonlinear surge arrester; “unit” – conventional units used for cost comparisons; total operating costs are calculated as the product of the service life and maintenance costs, including initial investment.
Source: Authors, (2026).

The most cost-effective solution is the use of pre-commutation resistors, as they combine relatively low implementation costs with acceptable operating costs. Chokes provide lower costs in the long term due to their long service life, but their high initial cost limits their economic viability in large-scale applications. MOV surge arresters are characterised by moderate capital costs, but the need for frequent replacement significantly increases the total operating costs. Despite their higher initial cost, synchronous circuit breakers offer maximum technical efficiency and durability, which justifies investment in critical power supply facilities. Thus, the optimal solution depends on a combination of technical parameters, service life and long-term economic viability.

The study confirmed that switching overvoltages have a multilevel impact on the operation of electrical systems. The study determined that they accelerate the ageing of capacitor insulation, cause additional thermal and electrodynamic loads on the windings of induction motors, lead to resonance phenomena in the secondary circuits of transformers and adversely affect the operation of power electronics. The use of technical protection equipment has made it possible to significantly reduce the amplitudes of overvoltages and minimise the probability of damage, which confirms the feasibility of implementing combined measures to improve the operational stability of the systems [31].

The economic assessment proved that, despite the relatively high capital costs, synchronous switches and MOV limiters have lower total life-cycle costs due to reduced failures and extended system life. Traditional methods, such as chokes or resistors, have lower implementation costs but require significant maintenance and are less effective in preventing critical damage. Thus, the choice of the optimal protection should be based on a combination of technical efficiency and economic aspects, which is particularly relevant for industrial plants.

Summarising the results, it is possible to conclude that an integrated approach to the analysis of switching overvoltages, which combines experimental measurements, mathematical modelling and economic evaluation, provided a holistic view of their impact on the elements of the electrical system. The established patterns confirmed that effective overvoltage limitation is a key factor in improving the reliability, durability and economic efficiency of capacitor banks and related equipment. The results obtained form the scientific basis for further research aimed to optimise protection schemes, develop new technological solutions and improve energy security in medium-voltage power supply systems.

IV. DISCUSSION

The results of the study confirmed the close relationship between the switching modes of capacitor banks and the parameters of overvoltages in industrial electrical systems. It was found that in the absence of protection, the peak voltage values reached 3.0 pu, while the use of synchronous switches and MOV limiters reduced them to 1.2-1.5 pu, which significantly reduced the load on insulating materials. The detected effect of resonant amplification in the secondary circuits of transformers, which reached 4-5 pu, demonstrated the criticality of matching the parameters of capacitor banks of different voltage levels and the need to correct the frequency characteristics of the system.

The application of the inverse power model and Miner's rule [16] made it possible to quantify the effect of repeated pulses on the durability of insulating materials, which confirmed the expediency of limiting the number of switching operations in modes with increased pulses. These results formed the basis for optimising wiring diagrams and technical solutions aimed to improve the stability and reliability of electrical equipment.

The analysis of the data obtained was consistent with the findings by [32], proving the effectiveness of modern arresters in medium voltage systems. Similarly to the study, the authors noted that the combined use of protective devices reduced the risk of breakdowns and ensured insulation stability during short-term impulses. At the same time, modelling and test results confirmed the accelerated degradation of insulating materials at pulse amplitudes above 2.5 pu. This was consistent with the study by [33], demonstrating that increased voltage pulses in inverter modes caused local dielectric ageing and reduced the service life of insulation systems.

The dependence of the degradation of polypropylene dielectrics on the amplitude of switching overvoltages established in this study confirmed the general patterns identified by other authors. The study of the development of partial discharges showed that at an amplitude of more than 2.5 pu, the probability of local breakdowns increased exponentially, which indicated a limited life of insulating systems in high-frequency switching modes. Similar conclusions are presented in [34], noting that the rate of insulation degradation was influenced not only by the peak value of the pulse, but also by its duration.

This correlated with the results obtained in the study, which indicated the decisive role of the duration of the oscillatory process in the progression of partial discharges. Additionally, the study determined that the geometry and location of the insulating units directly affected the level of permissible overvoltages and the service life of the equipment. This conclusion was consistent with the study by [35], proving that optimisation of the insulating structure of medium-voltage transformers could reduce peak field strengths and increase equipment durability. In the present study, a similar effect was confirmed by the reduction of shock loads on insulating elements when using resistive-inductive circuits in switching circuits.

The results of the study showed that the durability of capacitor installations was determined not only by the properties of insulating materials, but also by the conditions of their operation, in particular, the frequency of switching processes. Similar conclusions were confirmed by [36] in an analysis of the prospects for the use of new dielectric materials in aviation electrical equipment. The authors proved that even advanced insulation systems underwent accelerated degradation under cyclic loads, which was consistent with the critical effect of repeated switching on polymeric dielectrics of capacitor banks identified in the study.

Further analysis showed that the use of synchronous circuit breakers in combination with surge arresters reduced the number of repeated breakdowns and increased equipment reliability. A similar approach to improving the resilience of medium voltage systems was reflected by. According to [37] in an analysis of the possibility of using deep learning algorithms for automated monitoring of switchgear. The study determined that the timely detection of abnormal modes made it possible to reduce the probability of failures, which was consistent with the emphasis on diagnostic control made in the study. The experimental data obtained confirmed that repeated voltage pulses with an amplitude of more than 2.5 pu led to accelerated dielectric ageing.

Similar patterns were described in the work of [38], demonstrating that even in low-voltage machines, cyclic loads caused the formation of partial discharges that limited the service life of the insulation. The results of the study confirmed these findings, demonstrating the crucial importance of pulse repeatability in predicting equipment life. The tests also showed that traditional protection schemes did not always provide sufficient efficiency in cases of high-frequency switching overvoltages, which necessitated the combined use of modern devices. This thesis correlated with the conclusions of analysis by [39] on the vulnerability of industrial power systems to various external and internal influences and emphasised the need for multi-level technical solutions. The study confirmed this position, showing the effectiveness of an integrated approach to limiting overvoltages.

The analysis of operational data showed that the effectiveness of protective devices largely depended on the regularity of maintenance. A similar conclusion was presented by [40], developing a system of technical support for surge protective devices. The study proved that timely preventive maintenance ensured the stability of protection parameters and extended the service life of the equipment. The study confirmed this relationship through the identified link between the frequency of failures and the quality of maintenance. Additionally, the study determined that the random nature of the distribution of switching pulse amplitudes significantly affected the forecasting of the service life of insulation systems, which required the use of probabilistic models.

A similar approach was traced in the study by [41], proposing a two-level system of protection against coordinated impacts in electric vehicle charging networks. The study emphasised that the effectiveness of protection was determined not only by the technical characteristics of the equipment, but also by its adaptability to stochastic processes. This was consistent with the study, which showed that adequate durability forecasting is possible only if the probabilistic nature of switching overvoltages is addressed. The results of the study showed that the stochastic nature of switching overvoltages significantly affected the prediction of equipment durability and required the use of intelligent analysis methods for the timely detection of deviations. A similar approach was presented by [42], proposing a hybrid deep learning model to separate physical disturbances from cyber threats in smart grids. The study proved that the combination of machine learning algorithms increased the accuracy of diagnostics under conditions of uncertainty, which was consistent with the conclusions about the need to address the probabilistic nature of overvoltage in diagnostic models.

The study determined that repeated overvoltage pulses formed a cumulative effect of insulation material degradation, which reduced the service life of the equipment. The results also confirmed that the development of partial discharges was closely related to the progressive ageing of insulating materials. Similar points were made by [43], which emphasised the need for comprehensive protection of infrastructure from stochastic disruptions that combined physical and information risks. This correlated with the study, which found that timely diagnosis of partial discharges is crucial for preventing unforeseen failures. The assessment of the degree of insulation degradation using partial discharges was a substantial part of the study, which correlated with the approach of [44], who described practical methods for measuring discharges in high-voltage equipment. The study proved that the determination of identification thresholds was crucial for predicting the service life of equipment, which was consistent with the results obtained in this study on the assessment of the performance characteristics of capacitor plants.

The problem of early detection of partial discharges was also reflected in the thesis of [45], which proposed a multisensor method for diagnosing medium voltage cable connections. The study proved that the integration of data from several sensor systems made it possible to identify even minimal defects that could eventually lead to critical damage. This conclusion was consistent with the results of previous work, which also emphasised the importance of identifying critical voltage levels to prevent the development of microbreakdowns. According to [46] systematised standards and methods for assessing the condition of switching devices, in particular considering partial discharges as one of the key diagnostic parameters. The study showed that taking into account failure statistics and diagnostic test results is crucial for effective maintenance planning and extending equipment service life. The results of the study were consistent with this approach, as combining statistical analysis data with test results improved objectivity of predictions of capacitor bank reliability.

The significance of the impact of repeated impulse loads on the reliability of power electronics was highlighted by 3[47] in an analysis of the failures of power converter modules. The authors found that cyclic overvoltages caused specific modes of degradation of semiconductor elements, which shortened their service life. Similar patterns were confirmed in the study, where repeated switching overvoltages determined the rate of ageing of insulating materials in capacitor installations. According to [48] summarised modern strategies for managing the assets of switchgear in power systems, including methods of condition monitoring, residual life assessment, and maintenance planning. The study proved that a comprehensive assessment of the technical condition of equipment increased the level of its reliability and ensured economic efficiency of operation.

This approach was consistent with the results of a study in which statistical analysis of the degradation of insulating materials was used to make reasonable predictions about the service life of condensing units. The development of methods for predicting the residual life of electronic components was presented by [49], where a combination of the fractional Weibull distribution and the Poisson random load model was used. The study demonstrated that this approach increased the accuracy of modelling degradation processes under stochastic influences. This was directly related to the study, which also incorporated the randomness of switching overvoltages to assess the durability of insulating materials. According to [50] developed multi-criteria methods for optimising the reliability of electrical machines, taking into account the thermal ageing of insulating materials.

It was found that the accuracy of predictions increased when temperature conditions were taken into account, which minimised the risk of premature failures. This correlated with the study, which also showed that repetitive impulse loads and overvoltages are the determining factors in the degradation of insulation systems. In [51] applied the physics of failure approach to predict the durability of power electronics at the PCB level. The study showed that the analysis of physical failure mechanisms provided more realistic estimates of the service life under multifactorial loads. This approach was consistent with the study conducted, where a combination of mathematical modelling, laboratory tests and statistical methods can be used to reproduce the complex impact of switching modes on equipment durability.

The generalisation of the results confirmed that the application of a multi-level approach combining mathematical modelling, experimental testing and statistical analysis made it possible to quantify the impact of switching overvoltages on the life of insulating materials and equipment reliability. The established regularities highlighted the importance of the choice of switching equipment and protection methods, and proved the critical role of repetitive impulse loads in the degradation of insulation systems.

V. CONCLUSIONS

The study revealed several key regularities that determine the impact of switching overvoltages on elements of medium-voltage power systems. For the first time, experimental data, mathematical modelling results and statistical analysis were comprehensively combined, which made it possible to quantify the effects of both short-term pulses and long-term degradation of insulating materials. It was found that more than 92% of failures in capacitor plants are related to insulation damage, while oil leaks and insulator defects account for only 5% and 2.4%, respectively.

The study noted that the frequency of daily switching increased the number of failures by 50% compared to equipment operating in a constant mode, and an increase in the amplitude of the overvoltage from 1.5 to 2.5 pu reduced the service life of capacitors from 15 to 6 years. The study showed that the failures were not isolated but systemic. In particular, at manufacturer A, more than 80 banks demonstrated group failures, with two or three defects occurring within the same installation. The resonant interaction of capacitors of different voltage levels posed an additional threat to the transformers' secondary circuits: at low resonance levels, overvoltages reached 2.5 pu, at an average of 3.5 pu, and at high resonance levels, they exceeded 4.0 pu, causing massive damage to fuses and failure of electronic control devices.

The analysis of the power electronics confirmed that the DC link was a particularly vulnerable element, where switching pulses caused a voltage surge of 10-20%, increasing the risk of damage to the inverter keys. The results confirmed the critical role of switching modes in the formation of emergency failures in all elements of the system. An assessment of the effectiveness of protection methods showed that the absence of measures led to maximum overvoltages of 3.0 pu. The use of chokes reduced the amplitude by about 30%, pre-tap resistors by up to 1.7 pu, and surge arresters by up to 1.5 pu. The highest efficiency was demonstrated by synchronous circuit breakers, which limited overvoltages to 1.2 pu, effectively minimising the risk of a second breakdown. An economic assessment showed that pre-commutation resistors were the most balanced solution in terms of cost-effectiveness, while synchronous circuit breakers had a higher initial cost but provided maximum durability and were appropriate for critical facilities.

Thus, the study formed the scientific basis for developing recommendations for choosing the optimal protection methods in industrial operations. The main limitations of the study were the use of mock-up laboratory installations that did not always accurately reproduce the conditions of industrial operation, as well as the dependence of the results obtained on the characteristics of specific equipment samples. Another limitation was the use of idealised models that simplified the reproduction of stochastic oscillatory processes in real power grids. Further research should be directed to the development of combined protection systems using MOV limiters and synchronous switches, improvement of damping methods based on adaptive control algorithms, as well as expansion of the experimental base with tests in industrial conditions to confirm the long-term effectiveness of the proposed solutions.

ABSTRACT

Electric furnaces are widely used in industrial thermal treatments because they combine high energy efficiency with precise temperature regulation. However, the nonlinear system dynamics, inherent time delays, and large thermal inertia often limit the achievable level of control performance in practice. A novel fractional-order Proportional–Integral–Derivative–Acceleration (PIαDA) controller is presented in this work, with its parameters tuned via a Modified Flower Pollination Algorithm (MFPA) to address the aforementioned limitations. The tuning procedure is formulated to explicitly improve transient response characteristics while enhancing robustness, thereby supporting reliable operation under varying operating conditions. Controller performance is assessed through comprehensive simulation studies that include reference tracking, step changes in the temperature setpoint, external disturbance rejection, and tracking under noisy reference signals. Compared with MFPA-tuned benchmark controllers (i.e., the MFPA-optimized PIDA and the conventional PID), the proposed MFPA-optimized $PI^{\alpha}DA$ controller achieves higher tracking accuracy, shorter rise and settling times, reduced overshoot, and improved robustness against disturbances and measurement noise. Overall, these findings indicate that combining fractional-order control structures with advanced metaheuristic optimization can substantially enhance temperature regulation performance in industrial electric furnace applications.

I. INTRODUCTION

Maintaining stable temperature regulation in electric furnaces is critical to ensure energy efficiency, reliable operation, and consistent product quality [1]. However, nonlinear behavior, variations in thermal loading, and external disturbances often impair the effectiveness of traditional control approaches [2].

Although Proportional–Integral–Derivative (PID) controllers remain popular because they are simple to implement and generally robust, they frequently deliver unsatisfactory performance when the process becomes highly nonlinear or operating conditions change over time [3]. Therefore, more advanced control strategies are needed to achieve improved temperature regulation in electric furnace applications [4]. A range of enhanced control strategies is used to improve electric furnace temperature regulation, including cascaded Proportional–Integral–Derivative (PID) controllers to strengthen setpoint tracking [5] and Proportional–Integral (PI) / PID controllers obtained via system identification approaches [6]. Fractional-order Proportional–Integral–Derivative (FOPID) controllers tuned with metaheuristic optimizers—such as Harris Hawks Optimization (HHO) [7], and Artificial Rabbits Optimization (ARO) are also reported to improve dynamic performance [8].

In parallel, fuzzy PID controllers optimized with bio-inspired methods (e.g., dung beetle optimization) show improved disturbance rejection and robustness [9], while Proportional–Integral–Derivative–alpha (PID^{α}) and Proportional–Integral–Derivative–Double-Derivative ($PIDD^{2}$) structures are introduced to better address nonlinearities and enhance transient behavior [10],[11]. By adding an acceleration term, Proportional–Integral–Derivative–Acceleration (PIDA) controllers improve transient response, reduce overshoot, and enhance disturbance rejection in high-inertia, time-delay processes such as electric furnaces [12],[13]. More recently, a two-degree-of-freedom (2-DOF) PIDA design with parameter optimization based on the Greater Cane Rat Algorithm (GCRA) has been shown to outperform conventional PID and single-degree-of-freedom PIDA controllers in both setpoint tracking and robustness [13].

Realizing the full potential of advanced control schemes depends on precise controller parameter tuning, especially when the controller includes several adjustable gains and weighting factors. Conventional trial-and-error or manual tuning is time-consuming and often impractical for complex controller structures, so robust optimization is used as a core element of modern controller design. Accordingly, bio-inspired and metaheuristic methods—such as Particle Swarm Optimization (PSO) [14], Harris Hawks Optimization (HHO) [7],[10],[15], Quadratic Interpolation Optimization (QIO) [16], and the Flower Pollination Algorithm (FPA) [17], [18]—are widely applied to efficiently search for high-quality tuning solutions. These optimizers typically minimize time-domain performance measures such as the Integral of Time-weighted Absolute Error (ITAE), along with transient metrics (e.g., rise time) and actuation-related measures (e.g., control effort), to balance tracking quality and practical implementability.

Despite these improvements, integer-order PIDA controllers often lack the flexibility required for complex, time-varying thermal systems. To address these challenges, this paper proposes a novel Fractional-Order PIDA ($PI^{\alpha}DA$) controller. This architecture expands the control design's degrees of freedom by integrating non-integer order into the integral action. Such adaptability allows for superior management of the high inertia, time lags, and complex dynamics inherent in industrial heating furnaces. Compared to standard integer-order PID or PIDA schemes, our proposed $PI^{\alpha}DA$ significantly improves tracking accuracy and disturbance rejection without compromising robustness. The main contributions of this paper can be summarized as follows:

1. A new Fractional-Order PIDA ($P I^{\alpha} DA$) controller is proposed for electric furnace temperature regulation, extending the conventional PIDA framework by incorporating non-integer integral order to enhance control flexibility and dynamic performance.
2. The parameters of the proposed $PI^{\alpha}DA$ controller are optimally tuned using a Modified Flower Pollination Algorithm (MFPA), enabling efficient exploration–exploitation balance and improved convergence toward optimal control solutions.
3. A detailed comparative analysis is conducted between the proposed $PI^{\alpha}DA$ controller and conventional PID and PIDA controllers, demonstrating superior tracking accuracy, reduced overshoot, faster settling time, and minimal steady-state error.
4. The robustness of the proposed control scheme is thoroughly investigated under four realistic operating conditions, including reference tracking, step changes in target temperature, external disturbances, and noisy reference signals, confirming its effectiveness in handling uncertainties and disturbances typical of industrial electric furnaces.

The remainder of this paper is organized as follows: Section 2 details the implementation of the Modified Flower Pollination Algorithm (MFPA) used for controller optimization. Section 3 outlines the mathematical modeling of the temperature control system and describes the design of the proposed $PI^{\alpha}DA$ controller. Section 4 discusses extensive simulation results, including a comprehensive analysis of performance and robustness. Finally, Section 5 summarizes key insights and concludes the study.

II. MODIFIED FLOWER POLLINATION ALGORITHM (MFPA)

The Flower Pollination Algorithm (FPA), proposed by [19], is a metaheuristic inspired by the reproductive behaviors of flowering plants. Engineering esteems this method for its computational efficiency and reduced parameter needs compared to other optimization techniques. The algorithm emulates the interaction between flowers and pollinators, such as insects and birds, to traverse the search space. The FPA functions according to four guiding principles: biotic cross-pollination, abiotic self-pollination, floral constancy, and a switching probability that equilibrates local and global search efforts. Global pollination specifically enables long-distance transfers via Lévy flights, a mechanism essential for avoiding local optima and promoting diversity within the solution space. The global search method is mathematically expressed in Equation (1), as elaborated in [20]:

Global Pollination Step

$$x_i^{t+1} = x_i^t + L(x_i^t - g^*) \tag{1}$$

In this instance, x_i^t signifies the position of pollen i at iteration t, whereas g^* indicates the current global optimum identified within the population. The parameter L serves as the pollination strength, thereby influencing the step size via a Lévy flight distribution. This distribution is essential for facilitating the extensive leaps necessary for global search, as delineated by Equation (2):

Lévy-flight step size

$$L \approx \frac{\lambda\Gamma(\lambda)\sin\left(\frac{\pi\lambda}{2}\right)}{\pi}\frac{1}{s^{1+\lambda}}, (s \gg s_0 > 0) \quad (2)$$

Here, the symbol $\Gamma(\lambda)$ denotes the standard gamma function, while s represents the step size. Conversely, the algorithm shifts to the local pollination phase whenever a randomly generated value falls below the switching probability, p. This local search mechanism is defined by Equation (3):

Local pollination

$$x_i^{t+1} = x_i^t + \epsilon\left(x_j^t - x_k^t\right) \quad (3)$$

Where:

Uniform distribution

$$\epsilon(\rho) = \begin{cases} \frac{1}{b-a}, & a \le \rho \le b \\ 0, & \rho < a \text{ or } \rho > b \end{cases} \quad (4)$$

In this expression, x_j^t and x_k^t represent pollen collected from distinct flowers of the identical species. The parameter ϵ is drawn from a uniform distribution within [0,1], thereby effectively modeling a local random walk. This mechanism encapsulates the dynamics of localized fertilization and exploitation within the proximate search vicinity. The Modified Flower Pollination Algorithm (MFPA) signifies a substantial advancement of the conventional Flower Pollination Algorithm (FPA) framework. The fundamental innovation lies in using a stochastic switching probability to control transitions between local and global pollination stages. MFPA achieves higher convergence rates and more resilient global exploration by replacing the traditional fixed threshold with a dynamic stochastic parameter.

This method more accurately reflects the intrinsic randomness of biological pollination, therefore reducing premature convergence and aiding in the identification of the global optimum. The decision-making process is governed by a random variable rand distributed uniformly on [0,1]. Nevertheless, the proposed method deviates from the conventional FPA in terms of the specification of the switching threshold. In contrast to the original method, which often employs a fixed probability (e.g., $p = 0.2$), the proposed alternative incorporates a dynamic, randomized switching probability (p) selected from the range $[0, p_{max}]$. By establishing $p_{max} \le 0.5$, this alteration incorporates a stochastic element that more precisely reflects the variety evident in natural pollination activities.

In the canonical FPA paradigm, the shift between global and local pollination modes relies on the threshold condition $rand > p$, where $rand$ is a random number. The proposed Modified FPA (MFPA) alters this condition to $rand > randp$. Here, $rand$ and $randp$ are independent random variables drawn from uniform distributions over the intervals [0,1] and $[0, p_{max}]$, respectively. In this revised strategy, the global pollination phase commences if $rand > randp$; otherwise, the algorithm proceeds with the local pollination mode. This update significantly enhances stochastic flexibility in the search process while maintaining the foundational mathematical structure of the original algorithm as delineated in Equations (1)–(4).

III. PROPOSED PI$^{\alpha}$DA CONTROLLER BASED ON MFPA ALGORITHM

III.1 MODELING OF ELECTRIC FURNACE TEMPERATURE CONTROL SYSTEM

The architectural framework of the electric furnace (EF) temperature management system—comprising the furnace unit, controller, thermocouple feedback sensor, and heating element—is depicted in Figure 1 [4], [21]. In this configuration, the variables r, U, and y denote the reference input voltage, the controller output voltage, and the thermocouple feedback voltage, respectively, while R represents the heating element resistance.

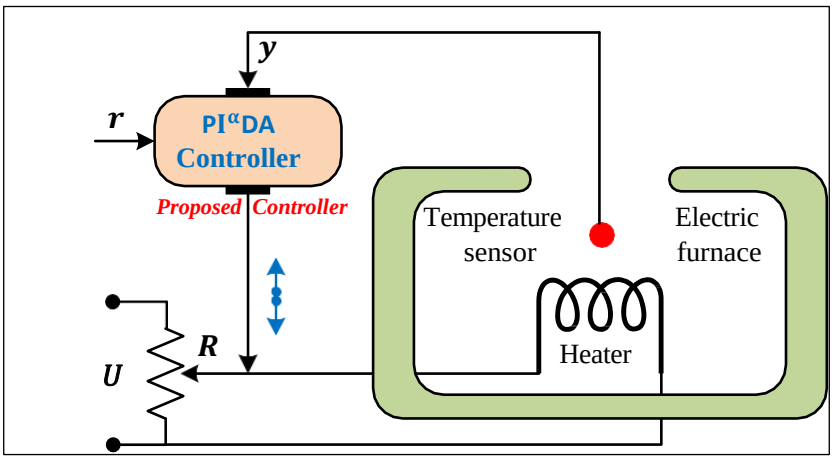

Figure 1: Schematic representation of the electric furnace.
Source: [4], [21].

Mathematically, the dynamic behavior of the EF temperature system is modeled by a second-order transfer function characterized by an inherent time delay, formulated as follows:

The general transfer function of the electric furnace

$$G_p(s) = \frac{b_0}{a_2 s^2 + a_1\, s + a_0}\; e^{-Ds} \tag{5}$$

To ensure validation and comparability with the established literature, this study adopts benchmark parameters: $a0$=0.2, $a1$=1.1, and $a2$=1, along with a transport delay of $D = 1.5$. These specific values are widely cited in the assessment of control strategies for electric furnace temperature management [22], [23]. Adhering to these standardized coefficients facilitates a rigorous performance comparison between the proposed controller and the existing state-of-the-art method

The transfer function of our electric furnace.

$$G_p(s) = \frac{0.15}{s^2 + 1.1\, s + 0.2}\; e^{-1.5s} \tag{6}$$

Equation (7) illustrates how the time delay is estimated using the first-order Padé approximation.

Padé First-Order Time Delay Approximation

$$e^{-1.5s} = \frac{1 - 0.75s}{1 + 0.75s} \tag{7}$$

The EF temperature system's transfer function will then be:

The approximated transfer function of our electric furnace

$$G_p(s) = \frac{-0.1125s + 0.15}{0.75s^3 + 1.825s^2 + 1.25s + 0.2} \tag{8}$$

III.2 PROPOSED PI$^{\alpha}$DA CONTROLLER

The proposed control approach is derived from the conventional Proportional–Integral–Derivative–Acceleration (PIDA) controller. In this study, a modified structure is introduced in which only the integral action is formulated with a fractional order, whereas the proportional, derivative, and acceleration actions remain of integer order. This modification yields a Modified Fractional-Order PIDA controller, denoted (PI$^{\alpha}$DA), that increases tuning flexibility by better capturing the memory characteristics commonly observed in thermal processes. Consequently, the (PI$^{\alpha}$DA) structure aims to improve temperature regulation performance in electric furnace systems affected by nonlinear dynamics and pronounced thermal inertia. The standard PIDA controller configuration is expressed as follows:

$$G_{PIDA}(s) = K_p\; + \frac{K_i}{s} + K_d s\; + K_a s^2 \tag{9}$$

The incorporation of fractional-order calculus into the control framework generalizes the classical $PIDA$ law. Specifically, it substitutes the standard integer-order integral operator $(1/s)$ with its fractional counterpart, $1/s^{\alpha}$ [24]. This modification permits the decomposition of the fundamental integral action as follows [25-29]:

Decomposition of the integrator into two fractional integrators

$$s^{-1} = s^{-\alpha} \cdot s^{-(1-\alpha)}, \quad 0 < \alpha\; < 0 \tag{10}$$

It is important to emphasize that the numerical and rational approximations of the fractional operators $s^{-\alpha}$ and $s^{-(1-\alpha)}$ are completely different from the approximation of the integer-order integral operator s^{-1}. The proposed PI$^{\alpha}$DA controller introduces an extra tuning parameter, α, via the fractional operator $1/s^{\alpha}$. This addition grants superior flexibility in shaping the system's low-frequency response. Such an expanded design space proves particularly effective in addressing the substantial thermal inertia and nonlinearities inherent to electric furnace operations.
Resulting,

$$PI^{\alpha}DA$$

Transfer function

$$G_{PI^{\alpha}{}_{DA}}(s) = \frac{K_a s^3 + K_d s^2 + K_p s + K_i}{s^{\alpha} s^{1-\alpha}} \quad (11)$$

Figure. 2 shows the block diagram of PI$^{\alpha}$DA controller.

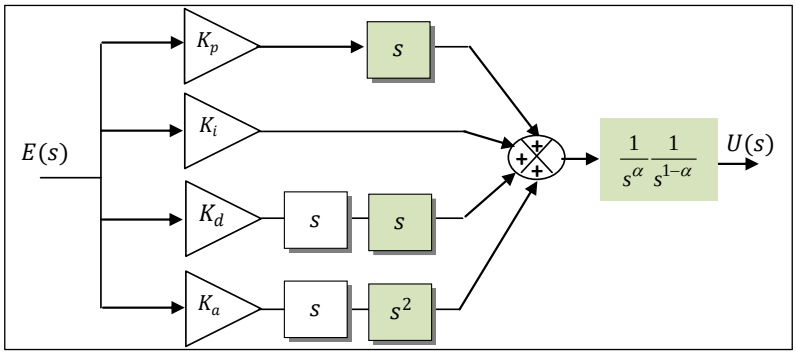

Figure 2: Shows the block diagram of PI$^{\alpha}$DA controller.
Source: Authors, (2026).

The suggested control methodology combines a fractional-order PI$^{\alpha}$DA controller with the Modified Flower Pollination Algorithm (MFPA) to enhance thermal management and transient response in electric furnace systems. This framework uses the MFPA for accurate, adaptable parameter optimization, thereby improving performance in the complex dynamics of industrial furnaces. Figure 3 presents the block diagram of the closed-loop temperature control system. In this arrangement, the proposed controller, referred to as $G_{\mathrm{PI}^{\alpha}\mathrm{DA}}(s)$ (s), processes the error signal $E(s)$ to produce an optimal control signal $U(s)$. This control action aims to guarantee that the system output $Y(s)$ precisely follows the reference input $R(s)$ while efficiently mitigating external disturbances $D(s)$.

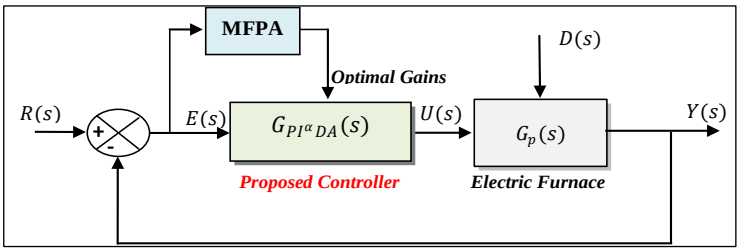

Figure 3: Proposed MFPA based PI$^{\alpha}$DA Controller.
Source: Authors, (2026).

This study employs the Integral Absolute Error (IAE) as the primary performance metric to guide the optimization. The tracking error $e(t)$ is defined as the instantaneous discrepancy between the reference signal and the measured output. Minimizing the IAE directs the adjustment of controller parameters to enhance tracking precision while maintaining stable closed-loop performance.

Objective function: Integral Absolute Error.

$$J = \int_0^{t_{sim}} |r(t) - y(t)| dt \quad (12)$$

The optimization challenge is formulated as minimizing the IAE to diminish the discrepancy between the reference input and the system output. This function (J) quantifies the cumulative absolute difference between the reference temperature and the actual temperature, as specified in Equation (12) within the system design context. The function J is subsequently submitted to the MFPA block for minimization to determine the ideal parameter vector $\{K_p, K_i, K_d, K_a, \alpha\}$ for the PI$^{\alpha}$DA controller.

The MFPA search parameters are set to $n = 40$ and $p_{max} = 0.5$ (50%). Furthermore, the controller gains are constrained within the following ranges: $0 \leq K_p \leq 5.00$, $0 \leq K_i \leq 1.00$, $0 \leq K_d \leq 10.00$, $0 \leq K_a \leq 10.00$ and $0.01 \leq \alpha \leq 0.5$. The termination criterion (TC) is set to $Max\ Gen = 500$ generations. Fifty test runs were conducted to determine the optimal PI$^{\alpha}$DA controller ($G_c(s)|_{\mathrm{PI}^{\alpha}\mathrm{DA}}$) for the electric furnace temperature control system. The MFPA technique was successfully used to make the controller for the system model $G_p(s)$, yielding the following optimized parameters: $K_p = 3.98$, $K_i = 0.66$, $K_d = 4.99$, $K_a = 0.99$, and $\alpha = 0{,}5$.

Optimal PI$^{\alpha}$DA Controller

$$G_c(s)|_{\mathrm{PI}^{\alpha}\mathrm{DA}} = \frac{0.99s^3 + 4.99s^2 + 3.98\,s + 0.66}{s^{0.5} s^{0.5}} \quad (13)$$

Optimal PID controller

$$G_c(s)|_{\text{PID}} = 3.55 + \frac{0.61}{s} + 3.85\,s \tag{14}$$

Optimal PIDA controller

$$G_c(s)|_{\text{PIDA}} = 3.98 + \frac{0.66}{s} + 4.99\,s + 0.99\,s^2 \tag{15}$$

III.3 FRACTIONAL CALCULUS

The PI$^{\alpha}$DA controller was created in MATLAB/Simulink based on the already implemented classic PIDA. Integro-derivatives were approximated initially using a recursive Oustaloup filter [30].

Oustaloup filter

$$G(s) = K \prod_{i=-N}^{N} \frac{s + \omega_i'}{s + \omega_i} \tag{16}$$

Zero Frequencies

$$\omega_i' = \left(\frac{\omega_h}{\omega_b}\right)^{\frac{i+N+\frac{1}{2}(1+q)}{2N+1}} \tag{17}$$

Pole Frequencies

$$\omega_i = \left(\frac{\omega_h}{\omega_b}\right)^{\frac{i+N+\frac{1}{2}(1-q)}{2N+1}} \tag{18}$$

Where :

- N- order of approximation,
- ω_h - higher bound of frequency fitness,
- ω_b - bottom bound of frequency fitness.

IV. RESULTS AND DISCUSSION

This section delineates the numerical simulation results of the suggested PI$^{\alpha}$DA controller, optimized by the MFPA, applied to the electric furnace control system. The analysis focuses on time-domain performance, specifically evaluating transient response and trajectory tracking to validate the controller's effectiveness. Furthermore, stability analysis and disturbance rejection tests are performed to validate the robustness of the suggested control technique.

IV.1 FIRST SCENARIO

The tracking capabilities of the proposed controller were evaluated by subjecting the system to a step change in the temperature setpoint. Figure 4 illustrates the comparative step responses of the PI$^{\alpha}$DA, PID, and PIDA control structures. This visualization effectively highlights the distinct differences in their ability to regulate system dynamics during the transient phase..The simulation results demonstrate that while the benchmark control systems are effective, the proposed MFPA-optimized PI$^{\alpha}$DA controller exhibits significantly superior dynamic characteristics. Table 1 details the quantitative transient response parameters for the evaluated controllers. Key metrics included are maximum overshoot, rise time, peak time, and settling time (calculated within a standard ±2% tolerance band).

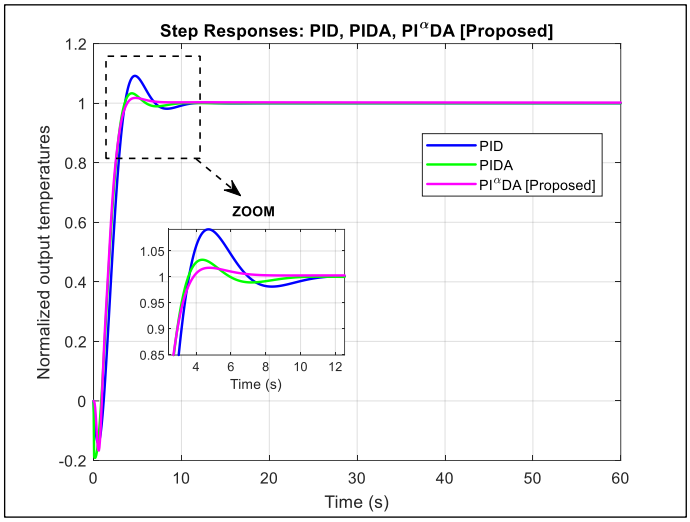

Figure 4: Input Tracking Performance Comparison.
Source: Authors, (2026).

As can be seen frome Table1, the proposed PIᵅDA controller exhibits a slightly longer rise time (1.8529 s), but this trade-off does not detract from its overall effectiveness. The design instead shows strong stability characteristics, with a very low overshoot (1.5600%) and the fastest settling time (3.5239 s), while completely eliminating steady-state error (0.000). These measures highlight the controller's accuracy, its ability to mitigate thermal variations, and its rapid attainment of equilibrium, thereby affirming its reliability in furnace temperature regulation.

Table 1: Performance comparison of transient responses $(\boldsymbol{\alpha = 0.5})$.

Control methods	$\boldsymbol{T_r}$ $[\boldsymbol{s}]$	$\boldsymbol{T_s}$ $[\boldsymbol{s}]$	$\boldsymbol{OS}$ [%]
PIᵅDA Controller	1.8628	3.5506	1.5600
PID Controller	1.7818	6.4827	9.1687
PIDA Controller	1.8368	5.1277	3.3096

Source: Authors, (2026).

IV.2 SECOND SCENARIO

To evaluate the system's response to a step change in the target temperature, a 0.5-unit perturbation is introduced at t = 30 s, as shown in Figure 5. This step variation physically signifies an abrupt alteration in the target operating temperature of the electric furnace, reflecting a shift between distinct process phases or production demands. This variation accurately represents actual industrial operating conditions, in which the furnace must swiftly adjust its thermal energy to attain the new temperature setpoint.

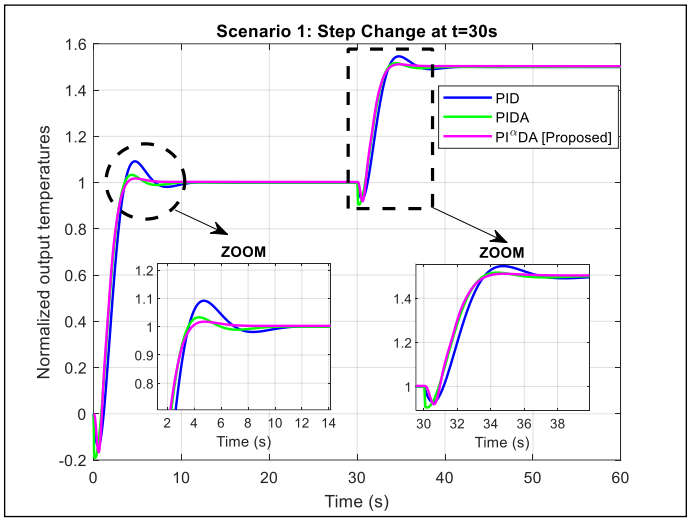

Figure 5: Dynamic Performance Analysis for Scenario 2.
Source: Authors, (2026).

Figure 5, shows that the proposed PIᵅDA controller achieves a faster response with reduced overshoot and shorter settling time during both the initial setpoint tracking and the step change at $t = 30\ s$, compared with the PID and PIDA controllers. The zoomed views further confirm its improved transient behavior and quicker convergence to the reference value.

IV.3 THIRD SCENARIO

To evaluate the robustness of the proposed control framework, Figure 6 illustrates the system's dynamic behavior under Scenario 2**.** In this scenario, after the initial setpoint tracking phase, a sudden change in the reference signal is applied at $t = 30s$, representing a perturbation in the operating conditions. Physically, this change reflects a realistic operating situation in an electric furnace, such as a modification in the desired temperature level due to process requirements, production phase transition, or changes in thermal demand.

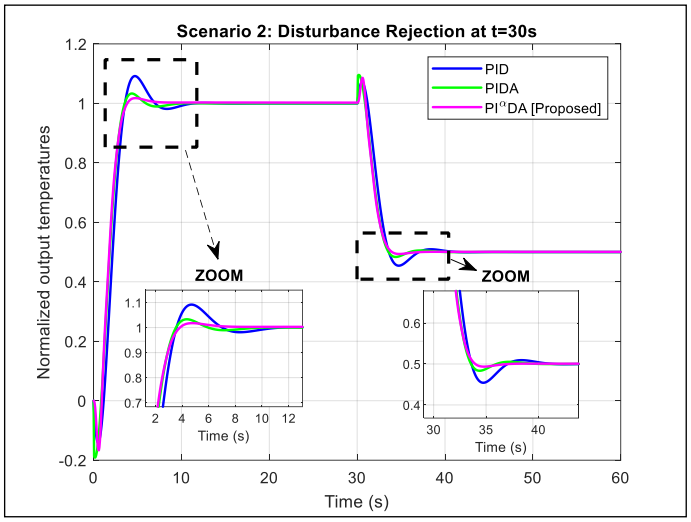

Figure 6: Dynamic Performance Analysis for Scenario 3.
Source: Authors, (2026).

Figure 6 illustrates the enhanced resilience and dynamic adaptability of the proposed PI$^{\alpha}$DA controller in response to abrupt changes in operating conditions, including unexpected fluctuations in the reference signal. The analysis emphasizes the controller's ability to swiftly adapt to the new reference value while reducing undershoot, oscillations, and settling time, thereby ensuring reliable, consistent performance in real industrial settings. Compared with traditional PID and PIDA controllers, the PI$^{\alpha}$DA exhibits smoother transient behavior, reduced oscillations, and faster stabilization after reference changes, highlighting its superior stability and robustness across diverse operating conditions.

IV.4 FOURTH SCENARIO

To appraise the system's proficiency in tracking a reference signal contaminated with noise, the results are shown in Figure 7.

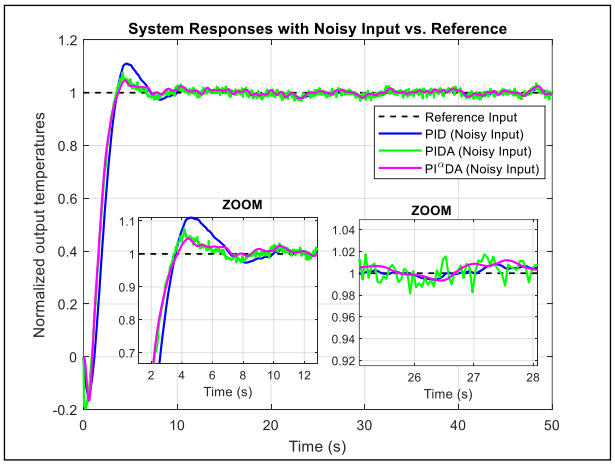

Figure 7: System Response to Noisy Reference Tracking.
Source: Authors, (2026).

As depicted in Figure 7, the comparative performance of the control strategies is evaluated regarding setpoint tracking under measurement noise. The suggested PI$^{\alpha}$DA controller clearly outperforms typical PID and PIDA controllers in reducing noise disturbances and precisely following the desired trajectory. The PI$^{\alpha}$DA output exhibits strong alignment with the variable reference signal, marked by reduced fluctuations and more fluid control action, thereby ensuring a more stable operational profile. The sensitivity analysis underscores the significant impact of the fractional-order parameter α on the dynamic performance of the proposed PI$^{\alpha}$DA controller. Fluctuations in α substantially influence critical performance metrics, such as rise time (($\boldsymbol{T_r}$), overshoot (OS), settling time ($\boldsymbol{T_s}$), and steady-state error (SSE), making this parameter vital for achieving an optimal balance between swift response and stability.

Table 2 presents a sensitivity study of the PI$^{\alpha}$DA controller with respect to the fractional-order parameter α, clearly demonstrating its influence on closed-loop dynamics and steady-state performance.

Table 2. Sensitivity Analysis of the PI$^{\alpha}$DA Controller with Respect to the Fractional Order $\boldsymbol{\alpha}$.

$[\alpha, 1-\alpha]$	T_r [s]	T_s [s]	OS [%]	SSE
[0.1, 0.9]	1.8712	5.7215	3.2277	0.00010244
[0.2, 0.8]	1.8455	5.8093	2.7582	0.00021855
[0.3, 0.7]	1.8039	5.4849	2.6613	0.00019844
[0.4, 0.6]	1.6739	8.5287	4.1366	0.00004858
[0.5, 0.5]	1.8628	3.5506	1.5600	0.00199900

Source: Authors, (2026).

As reported in Table 2**,** as α varies from low to moderate values, noticeable changes in the transient response are observed. Specifically, the interval $\alpha \in [0.4, 0.6]$ yields the minimum rise time (1.6739 s) and an extremely low steady-state error (4.858×10^{-5})**,** indicating a fast response with high accuracy. While the observed gain in response speed is noticeable, it is accompanied by a larger overshoot (4.1366%) and a longer settling time (8.5287 s), which points to reduced damping. When the fractional order α is set to 0.5, the closed-loop behavior becomes more even: the rise time remains moderate (1.8628 s), the settling time is the smallest (3.5506 s), and the overshoot reaches its minimum (1.56%) across the tested cases. The steady-state error increases slightly, yet it remains acceptable for most practical applications. These observations confirm that α is a key design lever in fractional-order control, influencing both transient and steady-state performance, and therefore requires careful tuning.

V. CONCLUSION

This paper proposed a novel fractional-order PIDA (PI$^{\alpha}$DA) controller for electric furnace temperature regulation, extending the classical PIDA structure by introducing a non-integer integral order to enhance control flexibility and dynamic behavior. The controller parameters were optimally tuned using a Modified Flower Pollination Algorithm (MFPA), which ensured an effective balance between exploration and exploitation and enabled fast, reliable convergence to optimal solutions. Comprehensive simulation results demonstrated that the proposed PI$^{\alpha}$DA controller significantly outperforms conventional PID and integer-order PIDA controllers in terms of tracking accuracy, overshoot reduction, settling time, and steady-state error minimization**.** Although a marginal increase in rise time was observed in certain scenarios, this trade-off did not adversely affect overall system stability or precision, which are critical requirements in thermal industrial processes.

Furthermore, the robustness of the proposed control scheme was rigorously validated under multiple realistic operating conditions, including reference tracking, step variations in temperature setpoints, external disturbances, and noisy reference signals. The results confirmed the controller's strong disturbance rejection capability and resilience to uncertainties commonly encountered in industrial electric furnaces. Overall, the findings highlight the effectiveness and practicality of combining fractional-order control with advanced metaheuristic optimization for high-performance thermal regulation. Future research will focus on experimental validation via Hardware-in-the-Loop (HIL) implementation and on investigating hybrid optimization strategies to further improve computational efficiency, robustness, and energy savings in real-time industrial applications.

ABSTRACT

In this study, the electromechanical systems have been modeled using the neural network technique. One of the most important parts of engineering is system modeling, which is essential for both system analysis and control process implementation, especially when a sophisticated and accurate modeling approach like NARX neural networks is employed. In order to gather the vibration produced by the electromechanical system devices after a sinusoidal voltage between zero and forty volts was applied, a practical test was carried out in this study. One side of the actuator was fixed, while the other side was free. After double integration for the output signal, the displacement data was gathered using an accelerometer sensor. Following variable modification, the transfer function, which shows the system's dynamic behavior based on input and output data is produced. NARX neural network approach was utilized for modeling using the MATLAB application. The outcomes demonstrated how well the NARX neural network approach represented the system and produced an appropriate transfer function in the time and frequency domains. Prior to and throughout the modeling process, the system's behavior remained unchanged, and the minimal mean square error was 0.00001391.

I. INTRODUCTION

The unique electromagnetic characteristics of piezoelectric materials allow them to transform electrical to kinetic energy and transform kinetic to electrical energy. Piezoelectric materials are usually used as sensors or actuators [1], [2]. Researchers are interested in this material for a variety of uses, such as bioengineering, robotics, and micro- and nano-instruments [3-5]. J.W.Curie discovered the piezoelectric impact in 1880 when he created an electric charge by applying mechanical stress [6]. One of the most challenging parts of modeling piezoelectric actuators is their physical properties, which are influenced by thermal and electrical elements, such as frequency and temperature [7], [8]. particularly those involving non-linear conduct and high-stress deformations that impact the electrical or mechanical response [9].

Finally, resonance, undesired vibrations, and hysteresis are ways in which actuators may respond to the electrical, mechanical, or electronic systems in their immediate surroundings [10]. Modeling may become more difficult due to the aforementioned circumstances, necessitating the development of an accurate model using innovative techniques to guarantee consistent and dependable performance [11]. Depending on their intended function, a number of researchers have employed piezoelectrics as sensors and actuators. "Piezoelectric effect" or the ability of some materials to generate an electric charge when subjected to mechanical stress, as seen in Figure 1. The "inverse effect" is the "piezoelectric effect" in reverse [12].

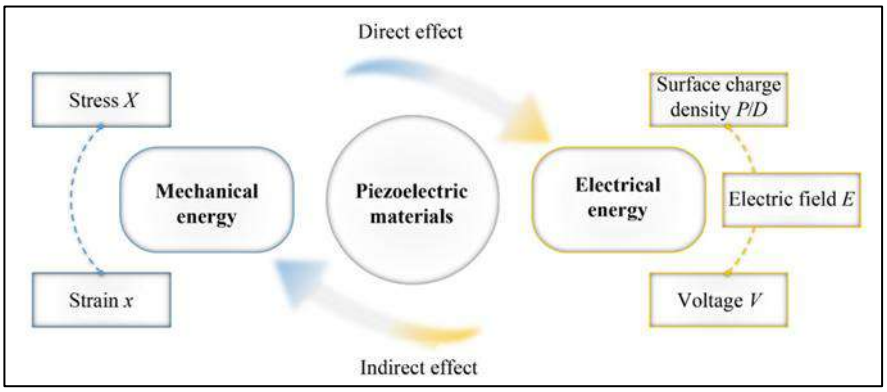

Figure 1: Piezoelectric effect energy conversion.
Source: Authors, (2026).

The piezoelectric effect is frequently caused by the electromechanical interaction between the characteristics of the elastic and the dielectric. While dielectric characteristics primarily relate to the interaction between electric field and electrical displacement, elastic characteristics are related to the link between stress and strain. Understanding both traits is essential to understanding a material's behavior [12-14]. The two main types of piezoelectric actuators (PZA) are direct and indirect actuators. Piezoelectric actuators that use the stretching action of the piezoelectric film in a straightforward manner without requiring a complex structural and primary design are known as direct piezoelectric actuators.

As a result, it combines attributes like high accuracy, simple design, and quick reaction [15], [16] and it is particularly useful for applications that call for rapid strokes and incredibly high precision. Unlike direct piezoelectric actuators, indirect piezoelectric actuators use complex structures to convert piezoelectric material deformation into indirect displacement. There is more to the link between material deformation and output displacement than just amplification. Stepping and repeating are two methods that indirect piezoelectric actuators can use to produce larger strokes and responses with more degrees of freedom (DOFs) [16-18]. However, the outcome might be more complexity and worse resolution.

This large class consists of two subgroups, one of which is stepping actuators [19]. Moreover, ultrasonic actuators [20], based on the operating concept. Piezoelectric modeling has received a lot of attention lately since it is essential for controlling systems as well as simulating systems, such as sensors or actuators. An imprecise modeling method will lead to unstable signals and inaccurate results [21-31], [8]. Li and associates used a backpropagation neural network and a genetic algorithm to simulate the linear piezoelectric actuator [21]. To model PZA, Shields and Konefat employed a finite element approach [22]. In a number of publications [23], Furthermore, PZA hysteresis is predicted based on various loads [24].

For example, models of composition could not reliably distinguish between the relative stability of inorganic materials [25]. Rather, They discovered that utilizing a CGCNN graph neural network, adding structure to the representation might result in non-incremental increases in stability forecasts, which is a strong argument for structural models. Although there are many ML models for various material properties, there is currently no study on ML prediction of piezoelectric coefficients in the literature. The aim of this work is to create a machine learning (ML) model that can accurately forecast piezoelectric modulus so that new, eco-friendly piezoelectric materials may be screened. A piezoelectric material's volume changes when an electric field or stress is applied to it.

This change is measured by the piezoelectric coefficient, also known as the piezoelectric modulus and often represented as d33 [8], [26-30]. The multi-layer feedforward neural network uses the nonlinear autoregression-moving average exogenous input technique to mimic the dynamics of piezoelectric actuators. The literature describes a neural network hysteresis model with an improved Preisach model to predict a piezoelectric actuator's output [27]. This work's primary contribution is to introduce a novel NARX neural network modeling approach for the PZA. In this study, PZA, the NARX neural network model (NARX NNET), and an experimental effort to gather input and output data using integrated measuring devices and sensors are introduced. The findings are then presented.

II. THEORETICAL REFERENCE

NARX Neural networks may be used in this study to accurately represent piezoelectric actuators in both the time and frequency domains. It identifies how to model piezoelectric actuators and utilize neural networks to achieve high accuracy, thus enabling their widespread application once the model is tested to verify its functionality with the required precision. The time and frequency domains are of particular interest to researchers studying the dynamic behavior of lag, creep, and vibration when data is used in systems such as nano-positioning platforms and atomic force microscopes.

Neural networks can be described as a training and learning modeling technique that relies on experimental procedures for data. Configuration equations are employed to establish the relationships between input and output. The concepts of magnetic lag and creep fall within the realm of nonlinear systems and are time-domains. They can be modeled using neural networks by simulating piezoelectric actuators under various input signal values. One phenomenon requiring study at constant voltage is creep, which exhibits a continuous and slow displacement. Neural networks can be employed by incorporating the time domain as an input feature.

Deviation and displacement correspond to time modeling, while frequency corresponds to vibration on one hand and dynamics on the other. Neural networks can be used to model the electro-efficient response of motor dynamics. Tests can be conducted by setting operating conditions that include the operating range of a frequency signal. Neural networks can be trained to achieve high-precision performance using a nonlinear hybrid prediction system that simulates the dynamics of a spring, block, or damper, according to the requirements of the model being trained.

Previous studies and literature have identified several types of neural networks, including feedforward neural networks (FNNs), multilayer neural networks (MLPs), long-term memory neural networks (LSTMs), recurrent neural networks (RNNs), vector primitive function neural networks (RBFNNs), and a deep neural network called DenseNet. These networks are characterized by high accuracy, adaptability to varying operating conditions, robustness, high performance, and rapid execution after training.

II.1 NARX NEURAL NETWORK MODEL

The NARX network is a recurrent dynamic network that has many network layers enclosed by feedback links. The linear ARX model, which is frequently utilized in time-series modeling, is the foundation of the NARX model [32]. a diagram illustrating the components of cells and layers of a NARX neural network model can be seen, as shown in the figure.

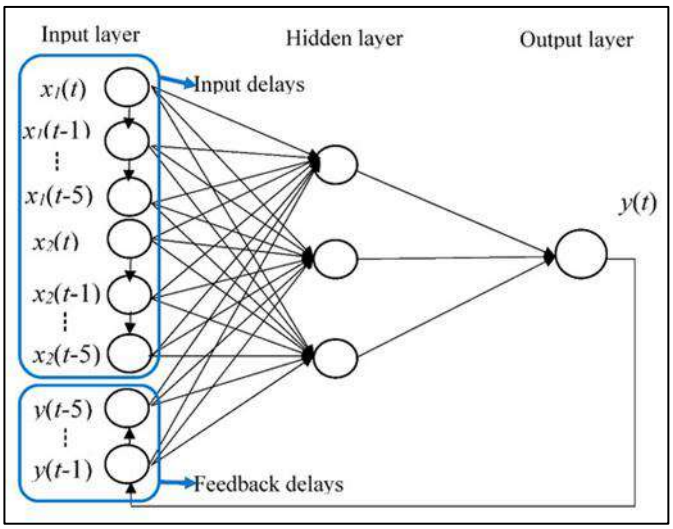

Figure 2: The NARX model's structure.
Source: [32].

The input, hidden, and output layers of the NARX model are made up of connected neurons (Figure1). The input layer, which is made up of the input parameters, permits the data to be received into the network. The data is then passed to the hidden layers for progressive processing, which results in the output layer. As part of the typical NARX design, the output is transmitted back to the feedforward neural network's input. Since runoff is closely correlated with net rainfall and discharge, The input parameters are evapotranspiration and precipitation. The NARX model's defining equation is as follows:

$$y(t) = f\,[y\,(t-1), y\,(t-2), \ldots . y\,(t-m), \mu\,(t-1), \mu\,(t-2), \ldots . \mu\,(t-n)] \quad (1)$$

The process of evapotranspiration E(t),E(t - 1),...E(t - 5), precipitation P(t),P(t - 1),...P(t - 5), and discharge Q(t - 1),Q(t - 2),...Q(t - 5) were chosen as input parameters following rigorous evaluation of the model input components and surface runoff routing time. The anticipated discharge Q(t) served as a representation of the output.. The NARX model chooses a sigmoidal activation function for the hidden layer, which helps speed up ANN training. The Arithmetical Mean Method was used to calculate the average value of input data over a catchment (Rakhecha and Singh, 2009) [33]. Trial and error methods were used to determine the number of concealed nodes. The empirical formula provided by [32]. was used to calculate the number of hidden neurons.

To improve the accuracy of the input to the feedforward network, series-parallel designs are developed for the output layer that use the actual output rather than feeding back the anticipated output. The algorithm of Levenberg-Marquardt, which blends the benefits of the gradient descent method with the Gauss-Newton algorithm, may be used to optimize the NARX model. The maximum number of epochs is set at 1000, and the error gradient and Levenberg-Marquardt correction variables are set at 10−7 and 10−10, respectively. The NARX procedure is terminated if one of the aforementioned criteria meets the objectives. Further information is available in [34]. The following formula is used to determine the output variable:

$$Y_I = f \sum_{K=1}^{N} x_k w_{k,i} + b_i \quad (2)$$

Y is the output variable in this case, N is the number of nodes in the preceding layer, w is the weight, b is the bias, and x is the hidden layer data. Three sections were created using the observation's precipitation, evapotranspiration, and discharge data: 62.5% of the 2922 time series were selected at random for training, 12.5% for verification, and 25% for testing. In other words, training samples from 2001 to 2005, validation samples from 2006, and test samples from 2007 to 2008. Considering how extreme values affect the training network and the faster convergence, Prior to trainingnormalized the input data to fall between 0 and 1, and following training, they were resized to their initial values. The network model's simulation results are significantly impacted by the NARX structure's main parameter.

Two input variables, one hidden layer, ten hidden neurons, five-day delays, and one output target were used in this study to determine the best architecture of the NARX model based on the previously examined and trained data. The mean square error is used to assess the NARX model's performance.

II.2 MODEL STRUCTURE

Voltage and frequency are the two inputs of the suggested NNET model for PEA's nonlinear behavior. One output is the displacement. In order to minimize the total of the mean squared error, we employed a multi-layer feed-forward backpropagation neural network with the Levenberg-Marquardt algorithm. The equation provides the Levenberg-Marquardt algorithm, which is based on the steepest descent and Newton algorithms. Ten fully linked hidden layers make up the NNET model. For both the ANN output layer and each input layer, the so-called logistic activation function was employed [35].

$$f(n) = \frac{1}{1 + exp^{-n}} \tag{3}$$

II.3 MODEL OF SYSTEM IDENTIFICATION

After combining and multiplying the inputs to a neuron by their individual weights, the first step in neural computing is to add a bias term. This procedure is known as the weighted sum or linear combination. Regularization parameters can be used to determine the optimal hyperplane, or activation function, in a quadratic programming issue. Many widely utilized and well-liked activation functions, such as "Tanh," "Sigmoid," "Softplus," "Swish," "Arctan," "ReLU" and "Mish" [28], [29], may be used because the desired solutions do not need to be regular. It is expressed mathematically as equations.

The linear kernel: $$K(x,y) = x \times y \tag{4}$$

The polynomial kernel: $$K(x,y) = [(x \times y) + 1]^d \tag{5}$$

The Sigmoid kernel: $$K(x,y) = tanh\,(\beta_0\, x\, y + \beta_1) \tag{6}$$

RBF kernel: $$K(x,y) = exp(-\gamma\,||x - y||)^2 \tag{7}$$

It will be possible to determine the parameters d, β_0, β_1, and γ experimentally.

II.4 INTEGRATED GADGETS AND EXPERIMENTAL RIGS

The PZT system was developed to replicate the dynamic behavior system by collecting input and output data. PZT type QDA40-20-0.7, which had dimensions of 40 mm in length, 20 mm in breadth, and 0.7 mm in thickness, was the first of the system's five components. The boost DC-DC power converter module type XL 6009 boosted the voltage to 40 V. The second component was a plexiglass holder that held the PZT in place. Its dimensions were 150 mm for length, 100 mm for breadth, and 10 mm for thickness. As seen in Figures 2 and 3, the holder is made up of three layers. The first layer served as the foundation for the construction, while the other two layers were used for PZT fixation and were joined by four screws.

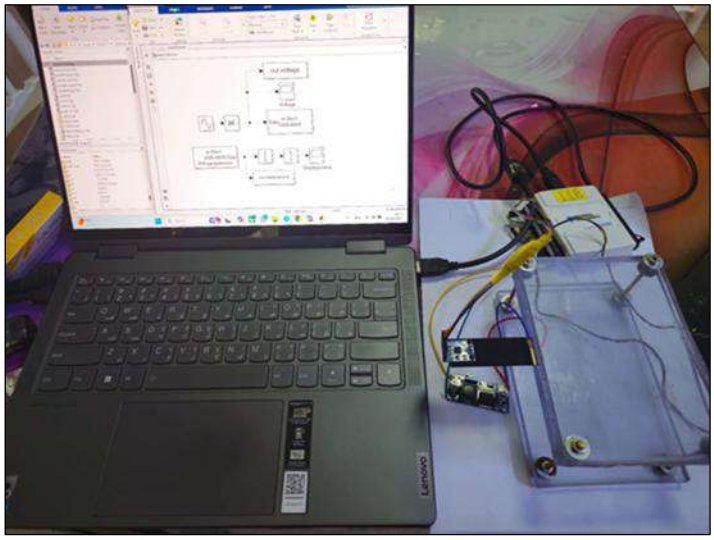

Figure 4: PZT test apparatus.
Source: Authors, (2026).

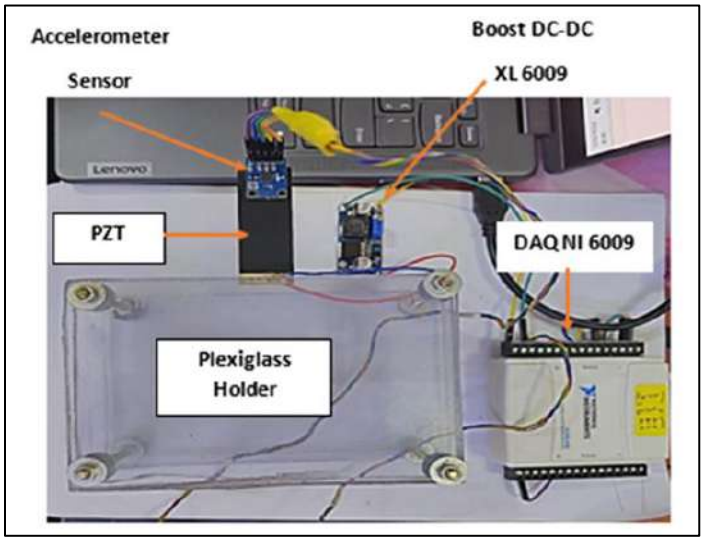

Figure 5: Components of the PZT System.
Source: Authors, (2026).

The third part was an NI USB-6009 USB data collection system (DAQ), which included four digital input ports, eight digital output ports, two analog output ports, and eight analog input ports. The ADXL335 accelerometer sensor, which gathers acceleration from PZT, was the fourth component. As seen in Figure 4, finally A computer running MATLAB 2024b was used as a component to send the signal to PZT, improve it, and collect displacements in real-time using an accelerometer.

III. DISCUSSIONS OF RESULTS

This work used the NARX NNET model to represent the electromechanical PZT system by collecting input data as a voltage and output data as a displacement using double integration. The work is managed in real time using the MATALB application 2024b. As seen in Figures 7 and 8, 200 data points were gathered in seconds to 10 seconds for the output..

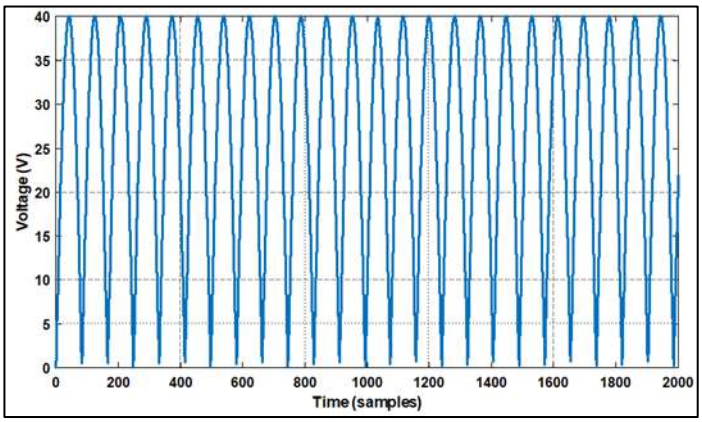

Figure 7: The voltage that PZT receives.
Source: Authors, (2026).

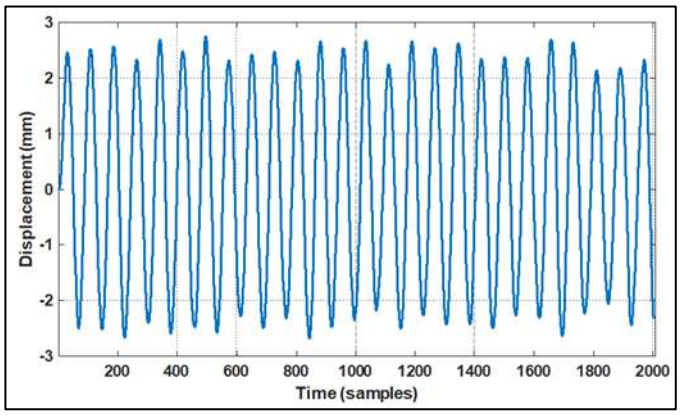

Figure 8. Data on displacement for PZT.
Source: Authors, (2026).

NARX NNET is used to model the PZT in order to determine the optimal solution and produce the final transfer function. Using a validation set of 25% and a testing set of 25%, 50% of the data was used for training. The findings displayed in Table 1 were then obtained by changing the number of hidden neurons (Nn) from 1 to 10 and setting the number of delays (Nd) to 2.

Table 1 : Nd was set to 2 by training and assessing the impacts of error.

Case 1					
Number of Hidden Neurons	**Number of Delay**	**Mean Square Error Training**	**Mean Square Error Valdation**	**Mean Square Error Testing**	**Mean Square Error**

According to Table 2, the system's smallest MSE is 0.0001391 at Nn 8 and Nd 6. As a result, the system's optimal block diagram, depicted in Figure 9, was found.

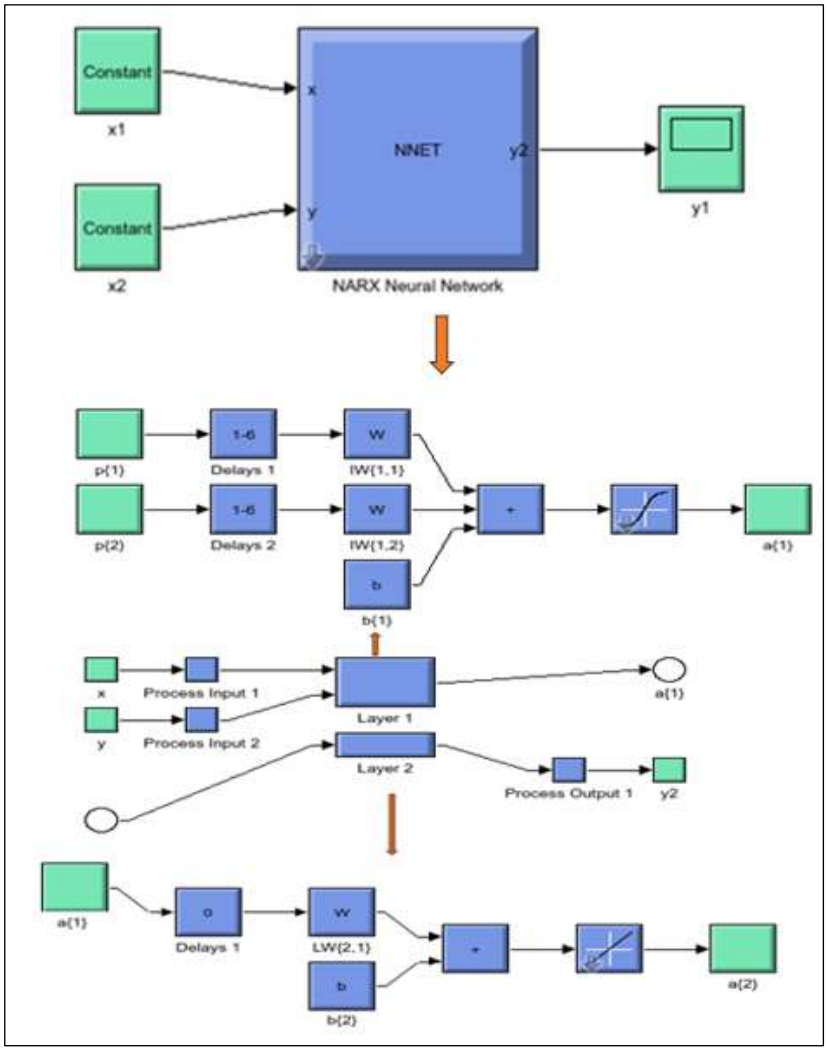

Figure 9: Block diagram for NARX NNET Simulink in MATLAB.
Source: Authors, (2026).

10001 data were utilized for training, and the remaining 1000 data were used to assess the performance of the prediction system. Every attempt was verified using the MSE approach to determine the optimal system performance and produce the final transfer function. Figure 11 displays the error between the real and projected data, whereas Figure 10 demonstrates that the NARX NNET approach was successful in forecasting the system behavior with the lowest MSE up to 0.0001391.

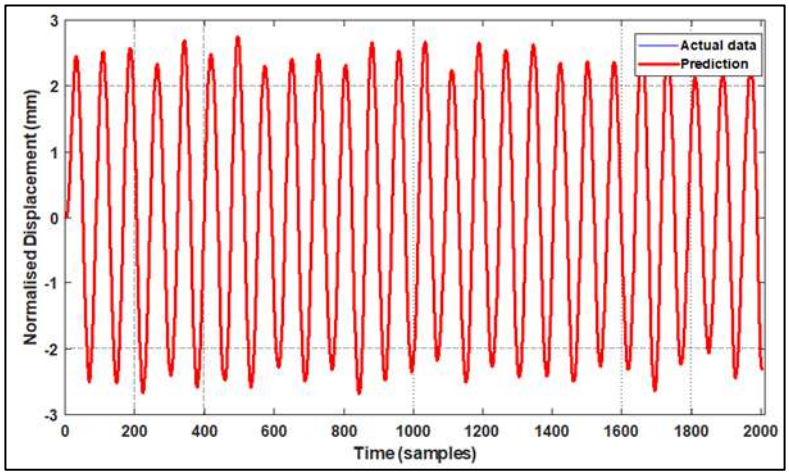

Figure 10: Normalized Displacement Data: Actual and Predicted.
Source: Authors, (2026).

The graph is an excellent representation of the performance of a predictive model comparing the actual and observed behavior of a dynamic system (standard displacement) over time. Both lines (blue and red) show consistent periodic oscillatory behavior across the entire time axis. The most striking observation is the near-perfect match between the actual data and the predictions.

The red line overlaps the blue line almost perfectly. The predictive model accurately captures the amplitude of the oscillations, which ranges from approximately -2.5 mm to +2.5 mm, and also tracks the frequency perfectly.

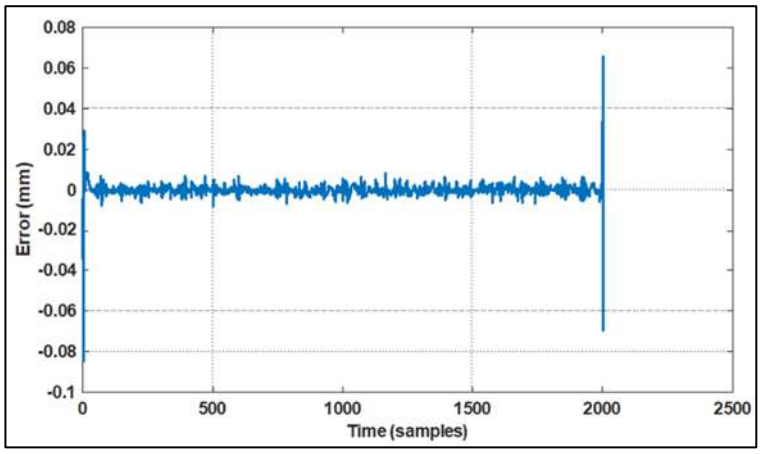

Figure 11: Actual and predicted output data error.
Source: Authors, (2026).

A control or measuring system (Figure 11) system's steady-state random error and abrupt disruption behavior over time are depicted in the diagram. The diagram shows that the system is sensitive to a huge, localized disruption that occurs at a particular moment in time, but it also shows that the system maintains a precise and regulated steady-state. To determine the underlying reason of this abrupt surge, it is necessary to comprehend the unique operating environment of the system.

Table 3: A comparison of the techniques employed in earlier investigations with MSE is presented.

REF	METHOD	MES
[36]	NARX neural networks	0.0858
[36]	LSTM neural networks	0.0279
[37]	Levenberg–Marquardt method (LMM-NNs)	6.7^{-6}
[37]	Bayesian Regularization method (BRM-NNs)	8.6^{-11}
[38]	OCNN-Hammerstein model	0.45^{-6}
[39]	K-NARXNN	0.0114
Proposed model	NARX NNET	0.0001391

IV. CONCLUSIONS

For the electromechanical system device, the potential of feedforward networks' multi-layered architecture—that is, NARX NNET backpropagation neural networks—was utilized to provide accurate, outstanding, and efficient results. We used Narx nnet in MATLAB to apply the suggested technique, and we were able to get the most accurate findings for a performance study utilizing regression and squared error analyses. The results showed that the Narx NNET technique achieved high modeling precision in both the frequency and time domains, with a low mean square error (MSE) of 0.0001391. The model's accuracy and stability were validated using the Narx NNET, and a correlation test showed that the measured output and the model output closely matched. These findings show how well the Narx NNET approach generates accurate dynamic system models, this makes it an effective tool for designing control systems and analyzing electromechanical system devices.

ABSTRACT

The integration of relational databases into cloud computing environments is characterized by the rapid growth of data volumes, the need to ensure flexibility, scalability and high performance of information management systems. Given that cloud technologies allow organizations to quickly adapt infrastructure to changing loads, integrate transactional and analytical processes, increase the efficiency of business processes and minimize operating costs; integration of RDBMS with cloud services is becoming a key factor in ensuring sustainability, security and competitiveness of organizations. The purpose of this article is to systematically analyze the current challenges of integrating relational databases into cloud computing environments and to identify promising areas for their development, considering technological and organizational aspects. The study applies to a set of methods that provides a systematic and reasonable assessment of the integration of relational databases into cloud environments. The forecasting method was used to outline the market prospects and growth dynamics of corporate data in the cloud; methods of synthesis, systematization and generalization were used to classify architectural models, analyze technical, economic and security aspects and identify key development trends; and a comparative analysis of cases of leading cloud RDBMS providers allowed to assess the effectiveness of real implementation; which provides a holistic view of the problem and forms a methodological basis for a reasonable choice of integration models. According to the report, the amount of enterprise data being stored in the cloud is increasing in tandem with the steady growth of the global cloud computing market. This demonstrates the importance of cloud solutions for strategic planning and the speed at which businesses are digitizing. Cloud-native, hybrid, multi-cloud, and microservice models that offer cost-effectiveness, technical agility, and security are all options for relational database integration into the cloud. AI-driven management, serverless architectures, and containerization all boost productivity by enabling real-time data flow optimization. It is suggested that a successful integration approach for RDBs into the cloud can be established based on adaptability (flexibility), autonomy, and interoperability, ensuring strategic flexibility of organizations. Leveraging data fabric, data mesh, and autonomous AI-driven solutions, classic management logic is transformed from one of reactive administration to one of proactive load prediction. This multi-dimensional strategy drives digital transformation efficiency and forms the competitive capabilities of today's enterprises.

I. INTRODUCTION

In the information-led and digitized world of the day, all kinds of organizations – commercial, public sector, and education providers – are faced with a burgeoning scale of data needing to be managed efficiently, effectively, and securely. The total size of global data storage is predicted to reach over 200 zettabytes by the end of 2025, according to Cybersecurity Ventures [1] – this includes data that is stored on private and public IT infrastructures, utility infrastructures, private and public cloud data centers, personal computing devices – personal computers (PCs), laptops, tablets, and smartphones – and Internet of Things (IoT) devices. This requires relational database management systems to be extended to work with cloud environments to enable elasticity, operational analytics, and business process continuity. Cloud offerings like DBaaS also empower businesses to save on operational expenses and boost efficiency without compromising on SLAs even as they bridge traditional transactional systems with real-time analytics and machine learning, as seen in Oracle Autonomous Database, Amazon Aurora Serverless, and Google Cloud Spanner [2], [3].

Furthermore, data security in the cloud, access control, GDPR and ISO 27001 compliance, and vendor lock-in risk need to be managed and impose further architectural and organizational restrictions [4]. The purpose of this research article is to perform a comprehensive review of techniques for processing and integrating relational databases in cloud computing platforms and determine feasible research directions for both technological and organizational aspects. The novelty of this study lies in the fact that we present a general comparison among architectural styles such as cloud-native, hybrid, multi-cloud, and API/microservices; the top DBaaS providers (Amazon RDS/Aurora, Azure SQL Database, Google Cloud SQL/Spanner, and Oracle Autonomous Database); as well as emerging trends like AI-powered database management, serverless approach, containerization, and data fabric and data mesh paradigms.

II. LITERATURE REVIEW

II.1 THEORETICAL BACKGROUND TO CLOUD COMPUTING AND INTEGRATION WITH RELATIONAL DATABASES

II.1.1 Development of Cloud Technologies (IAAS, PAAS, SAAS, DBAAS) in Data Management

The evolution of cloud computing has witnessed a series of expansions in the range and size of data center services, leading toward scalable, distributed data game platforms for data center infrastructure and computing resource delivery. According to [5] reviewed the nature of IaaS, PaaS, and SaaS-based cloud service models, which have become the basis for building modern infrastructure and application solutions. Opinions of the authors to have flexibility regarding resources and virtualization in the first place gave rise to the "as-a-service" model, which finally culminates in efficient management of a database in distributed systems. In [6] narrate the transition from traditional data centers to cloud formation using the Microsoft SQL Server case study. They concluded that DBaaS is a key mid-layer between traditional on-premises solutions and the advanced cloud databases and allows users to take advantage of automated management, service reliability, and lower operational expenses.

The security issues of DBaaS have already been discussed widely by [7], [8], who also argue that outsourcing the managing of databases to a third-party cloud service provider compromises the confidentiality of data, user authentication, and access control. Later on, through the transition to this web-scale model, governed by the as-a-service logic, it came to be more about a general transformation of the IT landscape – as firm on-premises architectures gave way to malleable and elastic cloud systems, where data was emerging as the essential material of the digital economy, as indicated by [9]. The evolution of relational databases to a new type of computing platform is made possible by that of cloud computing techniques, which result in the enhancement of the performance, scalability, and information flow management.

II.1.2 Characteristics of Relational Databases in Traditional Architectures

Relational databases are the cornerstone of data management that is structured, complete, and secure in traditional architectures when it comes to computing. Relational databases have long been a staple for structured, complete, and controlled data processing in classical computing environments. According to [10], the primary concept of these systems is the storage of data in tables and relations, which allows one to easily search, group, and summarize data with SQL. According to [11] states that a database schema is a blueprint or an outline that represents the organization of data in the form of the database design of the fields, tables, views, etc., of the database.

In fact, the ACID properties (atomicity, consistency, isolation, and durability) constitute the backbone of dependable transactional systems, which uphold this integrity [12]. Indexes and integrity constraints also improve the performance and correctness of queries, and the SQL standard supports complex analytical queries and procedures. Indeed, classical relational systems [13] are known to have scale-up constraints, which become more critical with increasingly massive data sizes and numbers of concurrent transactions. This pushes for mixing approaches, for moving relational structures to the cloud, where horizontal scaling and more flexible load balancing can be supported.

II.1.3 Principles of Compatibility of Relational Structures with Cloud Architecture

The porting of relational databases to cloud platforms must follow certain architectural paradigms to be compatible, dependable, and efficient. Because cloud software development should be guided by the principles of modularity, scalability, fault tolerance, and distributedness, as [14] state, this results in the attribute set for relational systems in the cloud. Following hybrid cloud models, by [4] states that a seamless integration of private and public clouds is a must for ensuring access to critical data without impeding productivity.

So, Muppala, and other new modern SQL platforms that seem to be heading in the direction of cloud-predicated architectures that are designed for distributed computing, query caching, and dynamic scaling. The interaction of distributed systems and cloud computing is considered by [15] as the foundation of the data architectures in the future, with centralized control being replaced with decomposed services. The concept of multi-cloud resilience [16] validates this statement, including the integration of distributed ledgers (DLT) and synchronization protocols across platforms to maintain data continuity and consistency.

According to [17] develops the principles of cloud-native database under the separation of relational structure from application through microservice style and containerization; this enables automatic scaling and adaptive load balancing, which allows relational databases to be active players in the cloud environment.

II.1.4 Comparison with NoSQL and NewSQL Systems: Advantages, Disadvantages, Compromise Approaches

Relational systems vis-à-vis NoSQL and NewSQL databases comparison demonstrates that the scientific community established a goal to balance data structure and scalability. In [18] Traditional SQL systems provide stability and transactional accuracy, and LazyBox noSQL offers high performance and flexibility of the data structure, especially for large unstructured volumes. According to [19] characterize the NewSQL systems as a middle ground that retains transactional consistency of traditional relational databases while providing scalability of NoSQL by utilizing multi-model architectures and query optimization.

In turn, by [20] verify through empirical tests that SQL solutions hold consistent performance in the most demanding business applications, while in rapidly changing web-based applications, NoSQL solutions exceed themselves and are seemingly more suitable. In [21] observe contrasting behaviors between relational and NoSQL databases when processing data in parallel. SQL is more effective in maintaining transaction integrity, while NoSQL is more scalable than Type with the number of threads. Hence, the end state of cloud database integration is not leaving the relational model behind in search of some new variety of non-relational schema design but letting (transparent) hybrids of relational and non-relational models to take the dance of consistency, availability, and performance to new scales.

III. METHODS

In the process of studying the integration of relational databases into cloud environments, a set of scientific analysis methods was applied:

- the synthesis method combined the results of analytical reviews, implementation cases, and market reports to form a holistic view of modern architectural approaches and technological trends in the field of DBaaS, serverless infrastructures, containerization, and AI-driven management;
- the forecasting method was used to assess the dynamics of the global cloud computing market and the share of corporate data in the cloud, which provided the basis for formulating the prospects for the development of integration architectures in the long term;
- a comparative analysis of cases of leading corporations (Oracle Autonomous Database, AWS Aurora, Google Cloud Spanner, IBM Data Fabric, Netflix Data Mesh) was used to assess the practical effectiveness of implementing cloud relational systems, which allowed comparing the declared performance indicators, resource savings, reduction of service time and SLA compliance with real implementations.
- the systematization method allowed us to classify integration models (cloud-native, hybrid, multi-cloud, microservice and API-first approaches), compare their technical, economic and security characteristics and create a generalized comparison matrix for further analysis;
- the generalization method made it possible to identify key patterns in the development of relational database integration, in particular the trend towards the creation of unified analytical environments (Data Fabric) and decentralized models of data management (Data Mesh), as well as the transition from manual administration to autonomous management based on machine learning.

IV. RESULTS

In the current context of digital transformation and rapid development of information technology, cloud computing is becoming a fundamental component of the strategic development of organizations in all sectors of the economy. The implementation of cloud solutions allows enterprises to ensure high flexibility of IT infrastructure, operational scalability of resources and integration of analytical platforms for making informed management decisions in real time. One of the key indicators of the development of cloud technologies is the dynamics of the global cloud computing market and the share of corporate data stored in the cloud. Thus, the analysis of the dynamics of the global cloud computing market for the period 2024–2034 shows a steady trend of exponential growth.

Thus, in 2024, the market volume was estimated at USD 912.77 billion, while by 2034 it is projected to reach USD 7473.31 billion (Figure 1). This indicates a more than eightfold increase in the market over the course of one decade, reflecting the active digitalization of the economy, the spread of remote work, the large-scale implementation of SaaS solutions, and the transition of corporate and government organizations to cloud services. The high compound annual growth rate (CAGR) during 2026–2034, particularly in the projection period, shows that cloud platforms have a strategic importance in ensuring business stability and competitiveness of the enterprises.

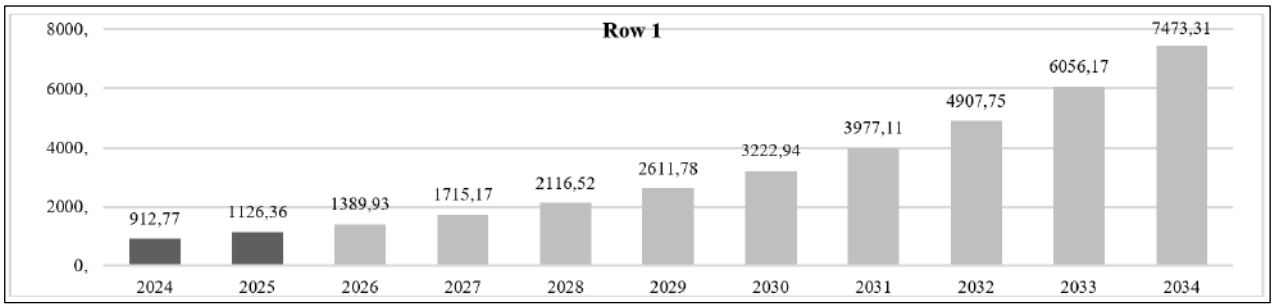

Figure 1: Global Cloud Computing Market in 2024–2034 (USD Billion).
Source: [22].

Note: data for 2026–2034 are forecasted.

Additionally, the analysis of the share of corporate data stored in the cloud shows a steady increase from 30% in 2015 to 68.66% in 2025 (Figure 2). The growth of this indicator reflects the technological adaptation of organizations and changes in data management practices and corporate IT strategy. In particular, there is an active implementation of cloud solutions to ensure the continuity of business processes, increase the flexibility of IT infrastructure and integrate analytical platforms for real-time decision-making.

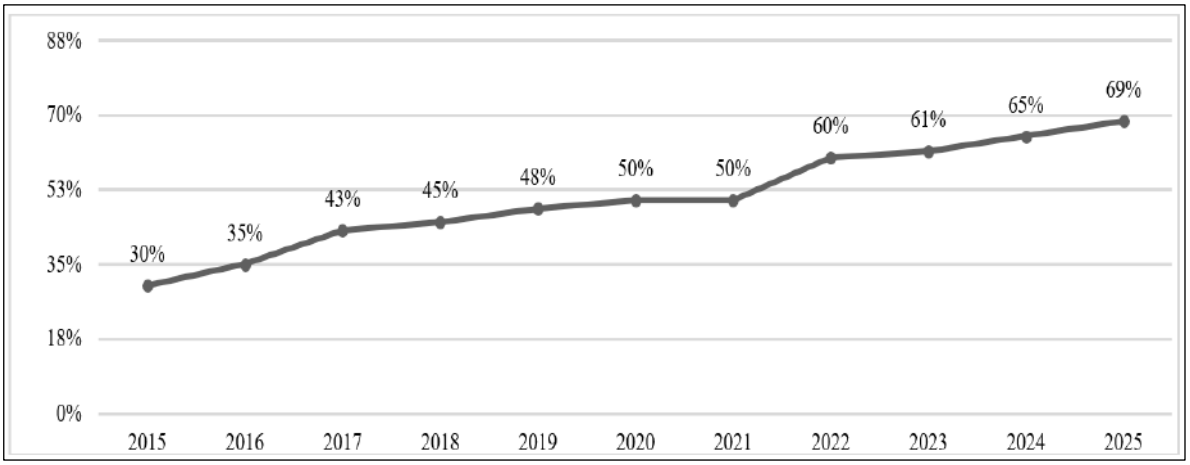

Figure 2: Share of Corporate Data Stopped in the Cloud Over Time.
Source: [23].

Note: data for 2023–2025 are forecasted.

Taking into account these trends, it becomes obvious that a systematic approach to the selection of architectural models for integrating relational databases in cloud environments is needed. Architectural models of integration include:

I. Full migration of relational databases to the cloud involves the use of "cloud-native" relational services that natively implement distributed storage, replication, transaction management and automatic scaling mechanisms. Analytical estimates of the market indicate a rapid growth in demand for cloud-native database solutions: according to market reports, the cloud-native database market is showing double-digit CAGR and was already estimated at billions of dollars in 2024, reflecting the intensification of migration projects and investments in DbaaS [24]. Technically, cloud-native Relational Database Management System (RDBMS) is characterized by horizontal scalability (sharding/partitioning), multi-site replication with consistency at the level of configurable SLAs, automatic disaster recovery, and integration with cloud provider services (monitoring, encryption keys, IAM). The typical business motive is to reduce TCO through operational automation and speed up time-to-market of analytical and transactional applications. In practice, large organizations (e.g., Capital One) have proven the ability to fully migrate with careful security and regulatory compliance planning [25].

II. The hybrid model remains the most common in sectors with strict regulatory requirements (banking, public sector, healthcare). It combines on-premise transactional systems for critical data with cloud services for analytics, backup, and peak loads. IDC and other analysts report a significant share of enterprises choosing "multi-vector" modernization strategies – about 60% of respondents reported the need for infrastructure transformation in 2024, which reinforces the role of hybrid architectures as an evolutionary step [26]. From a technology perspective, hybrid solutions require data synchronization (logical replication, Change Data Capture), aligned security policies, and network connectivity (VPN, Direct Connect/ExpressRoute). The benefit is control of critical data, but also the ability to take advantage of cloud elasticity for analytics or DR; the downside is operational complexity and a need for synchronized configuration management.

III. Multi-cloud strategies are used to reduce vendor-lock-in risk, optimize cost, distribute workloads, and increase resilience. Large corporations implement multi-cloud patterns as part of their resilience strategy (distribution of critical services between AWS, Azure, GCP). Examples in industry (BMW, Schneider Electric, Uber) demonstrate the practical application of multi-cloud systems for managing configurations, secrets, and traffic between platforms. Multicloud poses the challenge of data consistency and complex transaction management mechanisms in a distributed environment [27].

IV. Architectural practices of microservices and API-first approach allow flexible integration of relational storages as separate service components, which makes it possible to combine different types of databases (SQL, NewSQL, NoSQL) in accordance with the requirements of individual services, with clearly defined access contracts (REST/gRPC). This approach reduces system connectivity and simplifies module evolution, but transactional integrity requirements may dictate the use of orchestration schemes or two-phase protocols in scenarios where ACID is a critical requirement.

V. The tools and functionalities of the leading cloud RDBMS platforms vary depending on the architectural suitability, scaling mechanisms, consistency and security guarantees, namely:

- Amazon RDS/Aurora – provides multi-mode implementations (MySQL-/PostgreSQL-compatible) with automatic replication, "read replica", the ability to scale vertically and limited horizontal scaling (Aurora Serverless, Global Database). The solution is often used to transform large transactional workloads in the cloud; AWS maintains leadership in the cloud infrastructure market, which enhances the ecosystem attractiveness of RDS [28].
- Microsoft Azure SQL Database – offers both "managed instance" and serverless options, deep integration with the Microsoft ecosystem (Active Directory, Power BI) and tools for migration from on-premise SQL Server. Azure is often chosen by enterprises with a high dependence on the Microsoft stack; the platform offers advanced security and management tools [29].

- Google Cloud SQL/Cloud Spanner – Cloud SQL provides managed instances of PostgreSQL/MySQL; Cloud Spanner is an example of a globally distributed, strongly-consistent relational DBMS that combines a SQL interface with horizontal scalability. Spanner shows that relational models can be scaled globally while maintaining strong consistency guarantees [30]. Instead, Spotify, working with Google Cloud, has automated thousands of data pipelines and significantly improved the efficiency of analytics processing (claimed around 300% efficiency improvement in certain computing scenarios), which emphasizes the role of cloud-based relational and analytics services in handling highly demanding workloads. Although Spotify uses a wide stack of tools (including non-relational technologies), the case study demonstrates how cloud RDBMS/analytics services are integrated into the overall data architecture [31].
- Oracle Cloud Infrastructure (Autonomous Database) is an enterprise-SQL-workloads-oriented platform with automated operational functions (self-tuning, automatic patching), which is attractive for organizations with deep use of the Oracle stack. OCI is designed for conservative enterprise transitions to the cloud, where the completeness of SQL functionality and optimization for business applications is important [32]. In particular, companies such as Cisco Systems and Siemens AG use OCI for centralized corporate data management. According to the WiseGuyReports [32] report, Oracle retains about 12% of the DBaaS market and demonstrates steady growth in the enterprise segment due to the trust in its SQL core and high SLAs (up to 99.995% uptime) [33].

Thus, the integration of relational databases into cloud environments is accompanied by a complex combination of technical, organizational, and regulatory challenges that determine the architectural parameters of systems, as well as strategic aspects of data management. While leading DBaaS vendors are actively improving migration, synchronization and automatic scaling tools, issues of transaction consistency, secure storage and latency minimization remain key to the performance and credibility of cloud solutions. In addition, economic and compliance requirements are becoming increasingly important, directly affecting the total cost of ownership, the risks of vendor lock-in, and the need to develop competencies to operate complex hybrid environments. In the context of this study, it is advisable to systematize the main problem areas (Table 1) that form the outlines of the modern integration paradigm of relational database management systems (DBMS) in cloud ecosystems.

Table 1: The main challenges of integrating relational databases in cloud environments.

Integration model	Technical challenges	Security aspects	Economic challenges
Cloud-native RDBMS	- High requirements for transaction consistency in distributed environments (especially in multi-region configurations); - Latency between regions affects OLTP workload; - Automatic scaling can cause short-term delays when the data volume increases; - Limited compatibility of SQL engines (PostgreSQL, MySQL, Oracle) with cloud API specifications.	- End-to-end data encryption in motion and in storage (TLS, AES-256); - Access control through IAM (AWS IAM, Azure AD) with the need for centralized role management; - Compliance requirements (GDPR, SOC 2, ISO 27001, PCI DSS) require customization of audits and logs.	- The cost of ownership (TCO) increases with high transaction volumes and backups; - Vendor lock-in - the complexity of migration between providers (AWS → Azure); - The need for specialized personnel (DevOps, Cloud DBA).
Hybrid integration (on-premise + cloud)	- Delays in synchronization between local and cloud databases; - The need for Change Data Capture and logical replication mechanisms; - Incompatibility of SQL engines in different environments (versions, parameters, triggers); - Limitation of network bandwidth with large data volumes.	- Separation of responsibilities between internal IT teams and providers in terms of encryption, backup and disaster recovery. - Increased risks of security policy inconsistency.	- High cost of maintaining a dual infrastructure. - Difficulties in assessing ROI in case of partial migration. - The need for coordination between DevOps and ITIL teams.
Multi-cloud integration	- Distributed transactions between providers have different consistency mechanisms; - Lack of a single standard for cross-cloud SQL interoperability; - Network delays and complexity of request routing.	- Difficulty in centralized security monitoring between multiple environments. - Increased risks of leakage due to different metadata storage policies. - Requirement for integrated SIEM/Zero Trust Frameworks.	- High operational costs for SLA synchronization between providers. - Blurring of responsibility for security incidents. - The need for Cloud Governance Frameworks (FinOps, ITSM).
Integration through APIs / microservices	- High costs for API orchestration and cross-service consistency; - The need to manage distributed transactions (Saga, 2PC); - Compatibility of database schemas between microservices in different environments.	- Protection of endpoint APIs (OAuth 2.0, JWT). - Monitoring authentication and logging on the scale of hundreds of services. - GDPR compliance during cross-service transfer of personal data.	- High costs of DevOps automation (CI/CD pipelines, observability). - The need for distributed monitoring (Prometheus, OpenTelemetry). - Lack of personnel with experience in microservice RDBMS architectures.

Source: Authors, (2026).

Combined, the suggests that a relational database should be a first-class citizen in the cloud, and its implementation should encompass a continuum from technical feasibility to economic viability, as well as information security. Transactional consistency in distributed environments and vertical scaling limitations are examples of technical constraints that are being addressed by distributed SQL engines, microservice orchestration, and containerization. At the same time, security and regulatory matters are more conservative, while a need exists to comply with international data protection laws (GDPR, ISO/IEC 270-01).

At the same time, financial issues (such as the costs of multi-cloud system management and a dearth of qualified personnel) impact the need for strategic migration planning and the use of cloud governance measures. Therefore, it is really a technically enabled, legally balanced, and financially sustainable multi-dimensional approach that is becoming the yardstick for the success of integration processes in contemporary cloud-based environments.

In view of this, the development prospects in this area are determined by two main vectors: technological evolution (automation, serverless, containerization, AI-driven management) and management and methodological shift towards distributed and semantically consistent models (Data Fabric, Data Mesh); which increase the efficiency of data storage and processing, as well as transform the management logic of the business – from reactive administration to proactive anticipation of needs and loads. The key areas of innovative development of relational databases in cloud environments, including integration with ML platforms, containerization, serverless architectures, automated management and the formation of new data paradigms (Data Fabric, Data Mesh) are systematized in Table 2.

Table 2: Prospects for the development of relational database integration in cloud environments.

Development direction	Content and technological features	Implementation examples and case studies
Integration with Big Data and Machine Learning platforms	Relational DBMSs in the cloud are increasigly combined with analytical environments (Databricks, Snowflake, Vertex AI) to create a unified Data Fabric. This ensures data consolidation, reduction of ETL costs, and building predictive models without duplicating data.	Oracle Autonomous Database + Databricks: integration via *Delta Sharing* for two-way data exchange between OLTP and ML modules without ETL [2]. SAP Datasphere + Databricks: creating a single layer of access to corporate data without replication [34].
Containerization and database orchestration (Docker, Kubernetes)	Containerization allows to standardize the deployment of RDBMS in multi-cloud environments, reducing vendor lock-in and increasing portability. Kubernetes clustering provides automatic scaling, fault tolerance, and CI/CD integration.	Google Cloud SQL on GKE: an example of a hybrid architecture where the database is scaled through the Kubernetes Engine with automatic failover support [35]. AWS Aurora in containers: using Amazon Aurora with containers for rapid deployment of microservices in AWS ECS/Fargate [36].
Serverless models (Serverless SQL, Cloud Spanner, Aurora Serverless)	Serverless architectures eliminate the need for manual scaling, providing automatic resource management, per-query billing, and minimizing downtime. They are becoming the core of the modern DBaaS approach.	Aurora Serverless v2: provides instant scaling at peak loads and reduces costs by 40% [3]. Cloud Spanner: a globally distributed SQL DBMS with high consistency, used by *Spotify* for streaming analytics across millions of users [37].
AI-driven Database Management	The use of machine learning to independently tune queries, predict load, and automatically update indexes. This minimizes the human factor and increases SLA.	Oracle Autonomous Database: The implementation of Oracle Autonomous Data Warehouse at *Rosendin* reduced the administration burden, simplified data management, improved productivity, and identified $300 thousand in labor cost savings based on an analysis that took only 10 hours [38]. DPA (Digital Procurement Agency): DPA replaced a complex multi-system architecture (MySQL + MongoDB Atlas) at with a single Autonomus Database on Oracle Cloud Infrastructure. This resulted in a 15% acceleration in time-to-production, increased productivity, significant ease of management, and a reduction in operating costs by about 10% [39].
Development of Data Fabric and Data Mesh approaches	Data Fabric offers a single view of metadata management for heterogeneous data sources, whereas Data Mesh is predicted on a decentralized domain ownership model. This is the future pattern for work in large organizations with diverse databases.	IBM Data Fabric Platform: combines relational and non-relational sources in a single metamodel, supports DataOps functions [40]. Netflix Data Mesh Implementation: Netflix implements Data Mesh to synchronize dozens of SQL clusters with real-time streaming data [41].

Source: Authors, (2026).

The evolution of relational database access in the cloud exemplifies the transformation from disjointed storage models toward intelligent, cohesive system models where data is a first-class organizational asset. Integration solutions are evolving to the new dynamic architectures such as Data Fabric or Data Mesh to align these solutions no longer only on the technology level but on the level of data management concepts (from collection to analytics). Simultaneously, the progress in AI-based techniques for managing databases suggests a gradual shift of the emphasis from administrating towards self-administrating, where ML algorithms have a crucial role to play in autonomously optimizing queries, balancing loads, and maintaining SLAs.

Containerization and database orchestration are leading to a new multi-cloud portability model that facilitates vendor lock-in and offers potential for data-level integration with CI/CD. Simultaneously, serverless architectures are also being adapted as a key element in the Database-as-a-Service (DBaaS) model, offering the benefits of cost-efficiency, elasticity, and continuous data access. The integration of relational DBMSs with popular Big Data platforms and ML enables synergy between transactional systems and analytical services, thus realizing a single analytical space – Unified Data Fabric. From a methodological point of view, the choice of a model for integrating relational databases in cloud environments should be based on a systematic combination of the organization's goals, type of data processed, level of digital maturity, and architectural requirements.

For this purpose, it is advisable to apply a methodological approach based on a matrix of compliance with strategic goals and technological parameters of integration, which provides for: (1) Identification of business goals (real-time analytics, scalability, continuity of service); (2) Assessment of the type and amount of data, which determines the feasibility of using a relational, hybrid or polystructured architecture; (3) Selection of an integration model (Big Data Integration, Serverless DB, Data Fabric, AI-driven DBM, etc.), taking into account security, latency, regulatory compliance requirements; and (4) Development of an integration flow map and definition of metadata management mechanisms.

Thus, the optimal integration model should strike a balance between adaptability, autonomy, and interoperability. Organizations with an analytics-oriented business model should implement Data Fabric with ML integration for end-to-end analytics, while businesses that focus on rapid scaling of services can use Serverless SQL or containerized RDBMS solutions. For companies seeking digital transformation of management processes, the most promising direction is the implementation of AI-driven Autonomous Databases that minimize the human factor and ensure a high level of operational efficiency.

V. DISCUSSION

The obtained results confirm the key theoretical positions highlighted in previous studies [5],[6],[9] regarding the gradual transition from centralized database management systems to decentralized cloud services operating on the as-a-service model. Similar to the findings of [6], the study conducted by found that DBaaS approaches do provide automation of administration and increase the efficiency of operations, but at the same time increase the risks associated with data privacy and vendor lock-in. This is in line with the warnings of [7], [8], who emphasize that even in modern models with end-to-end encryption and centralized IAM control, issues of authentication and compliance with security standards (GDPR, ISO 27001) remain open. In addition, the problem of scalability of relational systems in cloud environments is a controversial aspect, which is confirmed by the results of this study.

According to pointed out the structural limitations of SQL architectures under heavy load more than a decade ago, and current analytical data demonstrates that although modern cloud-native RDBMSs overcome these limitations through containerization and microservices [15], [17], [42], issues of latency and distributed transaction consistency persist. This indicates that the cloud evolution of SQL has not eliminated the fundamental challenges but only moved them to the plane of architectural balancing between consistency and availability, which is in line with the CAP model, which is being actively developed by modern NewSQL researchers [19], [21]. Comparison of our results with the works of [18], [20] confirms that relational systems continue to demonstrate higher transactional stability in critical business scenarios, while NoSQL solutions remain more efficient for unstructured data flows.

We have expanded upon the research of these authors by demonstrating that the most effective compromise between the stability of SQL and the flexibility of NoSQL is hybrid integration through APIs, microservices, or multi-cloud platforms. This confirms the idea of [19] of the possibility to build up polyglot persistence, the coexistence of different types of databases in a single cloud infrastructure. Our findings have also been aligned with the strategies of [14], [16], who advocate the importance of modular design and fault tolerance in cloud design. Notably, evidence-based studies advocate that for multi-cloud solutions, unified security frameworks (Zero Trust, SIEM) and centralized procedures for managing financial and operational risk (FinOps, ITSM) are becoming increasingly critical. This aligns with [16] multi-cloud resilience framework and further reiterates the importance of transitioning into proactive data infrastructure management approaches.

VI. CONCLUSIONS

Considering that business is becoming increasingly digital and the volume of enterprise data is growing quickly, there is a need to adopt a new model for managing information resources. The results prove that the expanding global cloud computing market and increasing corporate data in the cloud push the need for technology reform and IT infrastructure strategy. This delivers business-minded, analytically driven services and resources to agencies. The paper shows that stencils for relational database integration, e.g., cloud-native, hybrid, or multi-cloud, including microservice-API-based implementation, represent a tradeoff among technical flexibility, security levels, and costs. Cloud-native solutions enable high scalability and automation of transaction processing, although hybrid and multi-cloud solutions sacrifice control over sensitive data in exchange for the elasticity of cloud solutions. Coupling with microservices/APIs provides systemic IT connectivity-reduction value and enables an incremental corporate IT infrastructure evolution.

From a practical point of view, the review of these high-end platforms (Amazon RDS/Aurora, Microsoft Azure SQL, Google Cloud SQL/Spanner and Oracle Autonomous Database) shows that the relational database as a service implementation is largely influenced by the configuration of its horizontal and vertical scalability model, consistency, security, availability guarantees and integration with analytic and ML services. In this regard, the complex nature of the process integration calls for a multi-facet assessment covering technical feasibility, regulatory compliance, and financial viability. The convergence of serverless computing paradigms with containerization, AI-powered orchestration, Data Fabric and Data Mesh enables smart data ecosystems where the movement of data itself is continuously augmented. This creates an ideal autonomy-integration equilibrium in data processing.

A systematic choice from the integration models is visible when considering business objectives, type of data, security requirements, and compliance requirements. Using a mapping between strategic goals and the technology-based facets of the integration, companies can determine the most strategic approaches, minimize risks associated with vendor lock-in, enhance analytical processing capabilities, and have ongoing access to operational data. Hence, the future opportunities for integration of relational database in cloud computing are influenced by both progress of technology and management and methodological trends for distributed, semantically coherent data models.

ABSTRACT

The study aimed to assess the effectiveness of artificial intelligence (AI) technologies in automating quality control in production. The study analysed the application of AI technologies to automate quality control in production processes. The study analysed modern approaches to the implementation of computer vision, deep learning algorithms and predictive analytics to improve the accuracy of defect detection, reduce the influence of the human factor and ensure continuous product monitoring. The analysed examples of the integration of smart technologies in various industries demonstrate the effectiveness of such solutions, provided they are properly adapted to the production environment. The study established that traditional quality control methods have limitations and need to be modernised by supplementing them with digital solutions. Modelling has demonstrated that the introduction of AI technologies can help to increase the efficiency of production processes, reduce reject rates and improve equipment maintenance. Comparative analysis demonstrated a potential reduction in product inspection time and the number of undetected defects using computer vision systems and deep learning algorithms. The study concluded that the combination of traditional control methods with intelligent technologies reduces production losses and can increase the overall productivity of enterprises if properly adapted.

I. INTRODUCTION

Artificial intelligence (AI) is being actively used in many industries due to its ability to process large amounts of data and make accurate decisions. One of these areas is the automation of quality control in manufacturing, where traditional methods often have limitations in accuracy and speed due to their reliance on human error. AI can significantly improve quality control processes using computer vision systems and deep learning algorithms, which ensure high accuracy in detecting defects. These technologies can quickly identify problems, which reduces the number of defective products and increases production efficiency. Integration of predictive analytics makes it possible to predict equipment failures, optimising maintenance processes and reducing repair costs. This enables manufacturers to plan operations more efficiently, reducing unexpected costs and improving overall productivity.

In the field of AI-assisted quality control automation, there are several problems associated with the integration of the latest technologies into traditional defect detection methods. These issues are being actively studied by various scientists. One of the aspects is the improvement of traditional defect detection methods using computer vision technologies and deep learning algorithms, as confirmed by [1]. However, the work does not fully cover the effectiveness of such technologies in various production areas, in small and medium-sized enterprises. This points to the need to study the adaptation of these methods for a wide range of industries. Research by [2] highlighted the great potential of predictive analytics for optimising equipment maintenance processes. However, the work mainly deals with theoretical aspects and does not provide sufficient analysis of practical results, which limits the practical application of such technologies.

This gap requires additional research to determine the actual effectiveness of forecasting in real-world production conditions. The integration of traditional quality control methods with smart technologies was addressed by [3], noting the importance of combining old and new methods to achieve better results. However, the studies do not sufficiently cover the details of combining these methods in different production processes, particularly their interaction with robotic quality control systems. This creates a need for further research in this area. Considerable attention has been paid to the ethical aspects of using AI in such critical areas as manufacturing, as reflected by [4]. However, the issues of developing ethical standards and safety in the context of quality control in production remain insufficiently studied. This requires further development of the regulatory framework and safety standards for the use of AI in such areas.

The study by [5] considered the use of computer vision to automate defect detection, but its work does not address the interaction of computer vision with other quality control methods within the framework of integrated automation. This creates a gap that needs to be filled for further analysis of the process of integrating such technologies into production processes. Other important aspects are the management of quality control costs and process optimisation, as emphasised by [6]. However, this aspect also requires additional research, as the issue of the costs of implementing and maintaining such systems remains open. The integration of deep learning algorithms in the context of defect detection was addressed by [7]; however, their research does not consider specific examples of the application of these technologies in various industries. This emphasises the need for more detailed research to expand the application of such approaches in the practical field.

AI technologies for quality control automation were also addressed by [8], analysing the possibilities of their integration with production process control systems. However, the study is limited to only certain aspects of such integrations, which require further research to determine the effectiveness of such approaches at different stages of production. The need for further development of intelligent systems in the field of quality control was emphasised by [9]. The study demonstrated the importance of improving methods for detecting defects in real time, but it is limited to theoretical aspects. The lack of practical analysis of the application of these methods in real production conditions is the main gap that needs to be filled in further research. In particular, the use of AI to reduce production defects is important, which is also studied by [10].

The study emphasised the use of intelligent systems to predict possible defects before the start of the production process, but it does not cover the study of the long-term results of such systems in various industries. This is an important area for further research. Thus, although there are numerous studies confirming the effectiveness of AI technologies in automating quality control, the integration of these technologies with traditional methods, the ethical aspects of their application, and the practical implementation of predictive analytics remain insufficiently studied. These gaps highlight the need for further research to fully understand the potential of such technologies. The study aimed to analyse the impact of AI technologies on the automation of quality control and the transformation of traditional methods of detecting defects in production processes. Research objectives:

1. To analyse the existing approaches to the implementation of AI technologies in production quality control systems.
2. To analyse methods of using computer vision and deep learning to automate defect detection processes.
3. To assess the effectiveness of integrating these technologies with traditional quality control methods in various industries.

II. MATERIALS AND METHODS

The methodological basis of the study was based on the theoretical analysis of available technical, scientific and analytical documentation, which was used to investigate the peculiarities of introducing AI into automated quality control systems without the use of empirical or field methods. An integrated approach was applied in the study, which involved the use of methods of comparative analysis, systematisation, logical and semantic interpretation, and content analysis. Open sources such as technical reports, analytical materials, and standards in the field of industrial automation were used for systematisation, which classified existing solutions by type of algorithm (e.g., [11-14]), specifics of their application, and computational requirements.

Expected benefits of AI implementation (increased efficiency, reduced downtime, reduced rejects), main barriers (technical complexity of integration, lack of qualified personnel, lack of standardised protocols), level of automation at industrial enterprises (dominated by hybrid control systems), and technical challenges (poor data quality, difficulty in adapting algorithms to unstable environments). A content analysis of sources [15-18] identified the key topics that are most often found in modern research and reports: expected benefits from AI implementation, main barriers and challenges, the level of automation at industrial enterprises, and technical aspects of integrating intelligent quality control systems.

The architectures of computer vision systems, particularly those implemented based on CNN models and used in high-precision visual analysis of products, are investigated. Technical documentation of [19-21], as well as analytical materials from manufacturers of computer vision components, in particular, [22], [23], the characteristics of sensor equipment, software frameworks and algorithms that ensure automatic defect detection at different stages of the production cycle were identified. The study also includes an evaluation of deep neural network architectures, such as EfficientNet and ResNet, based on their ability to accurately recognise complex defects such as microcracks or geometry deviations.

To analyse system integration, examples from the food, metallurgy, and electronics industries, where AI modules are adapted to high-speed production lines and ensure stable operation with minimal human intervention, were analysed. As part of the comparative analysis of technical solutions, the specifications of quality control systems implemented based on TensorFlow, PyTorch, and OpenCV, and built into Supervisory Control and Data Acquisition (SCADA) infrastructures, were studied. This determined the technical parameters by which the effectiveness of such systems is assessed: accuracy, completeness, response time, error rate, and scalability. Statistical data from analytical reports by [24-27] served as the basis for building an understanding of the dynamics of implementing AI solutions in industrial control practice.

III. RESULTS

As part of the theoretical study, a comprehensive analysis of the current challenges associated with ensuring high-quality product control in the context of the digital transformation of industry was conducted.

The main challenges faced by enterprises are the growth of production volumes, the need for full (100%) product inspection, minimising the impact of the human factor, accelerating production cycles and ensuring stable quality in the face of high variability. These factors necessitate the introduction of automated quality control systems based on AI technologies. An analysis of traditional control methods, including visual inspection by the operator, spot checks, manual measurement of parameters and sensor systems with simple algorithms, has shown their limited effectiveness. The disadvantages of such approaches are subjectivity of assessment, staff fatigue, low repeatability of results and the inability to apply them effectively in high-speed production.

These factors significantly reduce their relevance in the context of modern industrial tasks. The method of comparative analysis was used to compare the approaches of multinational companies to the implementation of AI solutions in production (Siemens, Bosch, IBM, Nestlé), emphasising the technical characteristics of visual inspection systems and the degree of their adaptation to the specifics of industries. Technical documentation and corporate reports of leading companies implementing AI in automated quality control systems were analysed in detail. Based on the materials of [11-14], a technical comparison of deep neural network architectures such as CNN, YOLO, ResNet, and EfficientNet was conducted.

According to analytical reports by the [15-18], the main areas of implementation of intelligent control systems in production, the main barriers (lack of personnel, difficulty in scaling, technical integration) and expected benefits were identified. Additionally, the technical characteristics of visual systems from [19-24] were analysed, which formed an idea of the hardware and software implementation of computer vision modules in SCADA infrastructures. Reports from [25-27] provided examples of large-scale implementation of AI solutions in practice, including the adaptation of models to high-speed production environments.

The potential of AI systems, in particular computer vision and deep learning algorithms, is considered. The study conducts a logical and functional analysis of the capabilities of CNN and object detection architectures, such as YOLO, in terms of their ability to provide fast and highly accurate processing of visual data in real time. The use of tools such as TensorFlow, PyTorch, and OpenCV enables flexible, adaptive solutions for different production scenarios without being tied to empirical testing. The use of AI systems ensures automated adjustment of process parameters, increases the stability of control results and reduces dependence on the subjective assessment of operators.

The theoretical review confirmed the broad functionality of AI solutions in detecting various types of defects, including microcracks, deformations, geometric abnormalities, foreign inclusions, etc. AI systems are highly flexible and adaptable in various industries. In the electronics industry, they are used to control the quality of printed circuit boards; in metallurgy, to detect welding defects; in the food industry, to inspect the flow of products to detect foreign impurities; in the automotive industry, to accurately recognise surface damage. These examples were summarised based on scientific and analytical literature and technical documentation without the involvement of field research.

A separate group includes corporate examples of AI systems implementation. Bosch uses computer vision systems to analyse welds, which has reduced the number of defective Bosch Industry 4.0 products [28]. At Samsung Electronics, CNN algorithms are used to detect microcracks on screens, which has significantly increased the stability of control and reduced the workload on staff [29]. At Nestlé Japan, AI systems are integrated into the food inspection process on conveyors, which has increased the efficiency and accuracy of detecting deviations in the [30]. All these cases illustrate the adaptability of AI technologies to the specifics of industries without going beyond theoretical analysis. At the same time, several barriers were identified that hinder the widespread adoption of AI technologies in the field of quality control.

The main obstacles include the need for large volumes of qualitatively labelled training data, high implementation costs, especially at the stage of initial model setup and training, a shortage of digital engineering specialists, as well as risks associated with cybersecurity and the transfer of information through open or corporate networks. Thus, the theoretical analysis proves the feasibility and prospects of using AI in automated quality control as one of the key areas of innovative development of industrial enterprises. AI systems provide a high level of accuracy, adaptability and scalability, significantly outperforming traditional methods in terms of speed, stability of results and efficiency of processing large amounts of data. At the same time, their implementation requires a comprehensive strategic approach to resources, human resources and digital infrastructure. Figure 1 illustrates a comparison of the accuracy and speed of AI systems and traditional methods, demonstrating the benefits of AI in the context of manufacturing quality control.

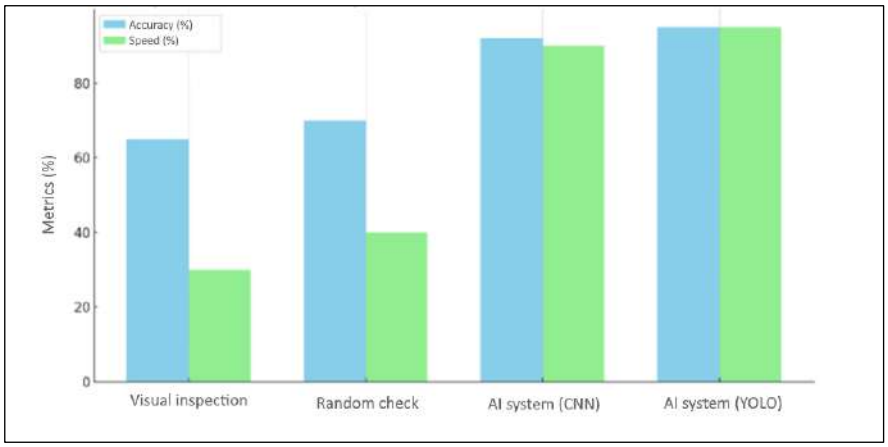

Figure 1: Comparison of the accuracy and speed of AI systems and traditional methods.
Source: [31], [32].

The study, which included a comparative analysis of the efficiency of technical quality control systems, revealed the advantages of using computer vision with CNN architectures over traditional methods. The effectiveness of integrating AI modules into production management systems is seen as a promising area for improving production processes. When deviations from the standard values are detected, algorithms automatically adjust process parameters (including feed rate, temperature, and pressure), which helps maintain stable product quality in the face of variable input data. K-means clustering, decision trees and support vector machine (SVM) were used to identify anomalies and trends in the data. Machine learning algorithms can predict possible defects before they occur, which indicates a shift from a reactive to a proactive management model.

The study also analysed the effectiveness of end-to-end integration of AI systems into Manufacturing Execution System (MES) and Enterprise Resource Planning (ERP) platforms. The results of the comparative assessment conducted in three typical production environments – discrete, continuous, and project-oriented production – showed that full integration ensures data consistency between subsystems, reduces the number of repeated operations, and optimises management decisions. The correlation analysis established a link between the frequency of AI adjustments and the reduction in unit costs. The findings quantified the reduction in maintenance costs and the improvement of the energy efficiency of the process.

Another important result was the introduction of predictive maintenance tools. Algorithms for analysing equipment behaviour, including signs of wear and tear or deviations in vibration, noise and energy consumption, were used to predict the probability of failure. Survival analysis models and neural networks were used to detect anomalies. This reduced the frequency of unplanned shutdowns and increased equipment availability. AI systems also detected micro-defects that were not captured by traditional visual inspection tools. Overall, the study results confirmed that the use of computer vision and deep learning algorithms in quality control systems ensures high accuracy, efficiency, and adaptability. Integration of AI into production and management platforms helps to improve process efficiency, reduce losses, and reduce the workload of staff. The applied methods of data collection, analytics, and parameter adjustment have helped form the basis for building flexible, adaptive, and predictable production systems in the context of the digital transformation of industry.

Table 1 provides a comparative description of the main methods of product quality control, reflecting the key differences between traditional and AI-oriented approaches. In particular, the table compares defect detection accuracy, inspection speed, human factor impact, and typical tools. As the data shows, AI systems demonstrate significantly higher efficiency across all criteria, which makes them increasingly relevant in modern production.

Table 1: Comparative characteristics of the effectiveness of traditional and AI methods of product quality control.

Control method	**Average defect detection accuracy, %**	**Average inspection time per object, s**	**The degree of influence of the human factor**	**Typical toolkit**
Visual inspection by the operator	75-82	10-15	Proficiency	Operator's eye, magnifying glass
Sensory methods (sensors, scanners)	83-88	6-10	Average	Laser/infrared sensors, Programmable Logic Controller (PLC)
AI control based on CNN and OpenCV	93-96	2-4	Low	High-definition cameras, TensorFlow, OpenCV
AI control with forecasting (Long Short-Term Memory – LSTM, Recurrent Neural Network – RNN)	90-95	36 (including time series processing)	Low	IoT sensors, PyTorch, SCADA, ERP

Source: [33], [34].

The study results showed that the integration of AI technologies – including computer vision, deep learning algorithms and predictive analytics – has led to a significant increase in the efficiency of quality control systems. The effectiveness of defect detection was demonstrated in the case of Nestlé, a food company, where, after the implementation of an AI system based on OpenCV, the accuracy of packaging defect detection increased from 84% to 95%, and the average time for checking a unit of production decreased from 7.4 to 2.1 seconds. Real-time response to deviations was demonstrated at a steel welded pipe plant in Turkey, where, according to an open report by [35], an AI module integrated into the SCADA system detected excessive overheating during welding and initiated automatic adjustment of the feed rate, which helped avoid deformation in 12% of products.

In the electronics industry, predictive maintenance based on LSTM algorithms has been used to detect signs of increased wear due to changes in the vibration spectrum a few hours before equipment shutdown. This significantly reduced downtime. AI modules are integrated into the digital ecosystem, including MES and ERP systems, which provide end-to-end monitoring of the production process from raw materials to packaging. In the food industry, optimising the dosage of raw materials through integration with ERP helps to reduce material costs. Computer vision based on CNN architectures is more efficient in quality control than traditional methods. There are three types of quality control systems: classical visual inspection, sensor monitoring, and AI control with deep learning.

Data is collected and analysed through simulation modelling, based on typical specifications and examples from the food, pharmaceutical and metallurgical industries. To illustrate the results obtained, a comparative table summarising the key indicators of the three quality control approaches was constructed. Table 2 shows the results of the modelling, which included an assessment of the accuracy of defect detection, information processing speed, level of human intervention and integration with production information systems. The case analysis conditionally reflected examples of the implementation of each type of system based on three typical enterprises, which served only as an illustrative basis for comparing the effectiveness of the approaches, without conducting a study at real production sites.

Table 2: Comparative effectiveness of quality control methods in production environments.

Control method	Average defect detection accuracy, %	Average inspection time per object, s	Frequency of missed defects, %	Human factor (degree of influence)	Examples of implementation
Visual inspection	76	9.5	5.7	Proficiency	Food industry (manual bottle inspection)
Sensor monitoring	85	6.8	3.1	Average	Metallurgy (infrared sensors on rolling stock)
AI based on computer vision (CNN)	95	2.3	0.9	Low	Electronics (detection of microcracks in chips)

Source: [36].

As shown in Table 2, the level of efficiency of quality control methods largely depends on the degree of their automation and the technological solutions used. Traditional visual inspection is characterised by the lowest accuracy rates and the highest level of human error, which leads to an increased risk of errors and delays. Sensor technologies are showing improvements in terms of speed and reliability, but remain sensitive to operating conditions and require constant maintenance. The best results are achieved when AI modules based on computer vision are used: such systems provide accurate and stable defect identification with minimal operator involvement, which significantly increases the overall efficiency of production processes and helps reduce losses. The results demonstrated that the integration of AI algorithms into technical inspection systems is a promising area for the development of smart manufacturing, providing not only detection but also in-depth analytical interpretation of defects with the possibility of further optimising the process cycle.

The results of the introduction of AI into production process control systems have confirmed its ability to provide dynamic, adaptive control of process parameters in real time. When deviations from the standard values are detected, for example, due to changes in the properties of raw materials or technical failures, AI modules initiate automatic adjustments to key parameters such as feed rate, processing temperature, pressure, or cycle time. This not only mitigated production defects but also maintained stable product quality in the context of changes in the environment or equipment. The use of machine learning algorithms has enabled the detection of even subtle trends in sensor data, which prevents potential deviations before they have a critical impact on the final result [37]. As a result of this approach, the flexibility of production systems has increased, and the number of stoppages caused by the need for manual intervention or re-adjustment of equipment has decreased.

Another key result was the full integration of AI modules into corporate information systems, including MES and ERP. This ensured end-to-end quality control at all stages of the production process, from receiving raw materials to shipping finished products. Data on quality, equipment condition, process dynamics, and control results were automatically transferred between subsystems, which achieved consistency of decisions at both the workshop and management levels [38]. Integration with ERP systems also ensured analytical tracking of the impact of production parameters on the economic performance of the enterprise, including production costs, energy costs and resource efficiency. In combination with MES systems, AI enabled the implementation of the concept of a “digital twin” of production, which helped to model optimisation scenarios and reduce technological risks [39]. Thus, the integration of AI into production management has made it possible to achieve a high degree of autonomy, adaptability and coherence of actions within industrial facilities, contributing to increased efficiency, product quality and resilience of production systems to changing conditions.

The use of AI in quality control systems has enabled the transition from a reactive to a proactive model of defect and technical failure management. The main achievement was the introduction of mechanisms for predicting the occurrence of deviations based on the analysis of large amounts of data from the production environment. Machine learning algorithms trained on historical and current data from sensors, cameras, and information systems identified patterns that precede defects, enabling the control not only after the fact but even before problems occur [40-42]. Thanks to predictive analysis, it became possible to identify critical points in the production process with high accuracy, where the probability of a defect increases. AI systems provided real-time signals of potential violations, which made it possible to promptly adjust the process or take preventive measures. In particular, the relationships between temperature fluctuations, tool wear, equipment vibrations, and product quality were identified. Another significant result was the introduction of predictive maintenance.

Algorithms analysed the behaviour of machinery, monitored signs of wear and tear or unstable operation (changes in sound, vibrations, energy consumption) and predicted possible failure. This made it possible to replace traditional scheduled maintenance with an adaptive model in which technical intervention is carried out exactly when it is needed. As a result, the number of unplanned shutdowns has decreased, repair costs have been optimised, and the reliability and availability of equipment have increased [43]. In the production environment, AI systems are used to identify product defects, monitor equipment conditions, and predict failures or disruptions in processes. To achieve high accuracy of such actions, access to large volumes of representative, structured, labelled, and verified information was critical. The creation of such datasets was carried out with the participation of specialists in marking industrial images and technical documentation.

If the training samples contained noise, errors in annotations, or limited variability in scenarios, the system could not generate correct patterns. The Shannon entropy metric and anomalies in label distributions were used to analyse the quality of the samples. Thus, predictive quality control implemented with the help of AI has transformed the approach to ensuring the stability and efficiency of production processes. Its application ensured not only the prevention of defects but also strategic risk management, which contributed to the competitiveness of enterprises in the context of Industry 4.0 [44], [45]. In this context, it is necessary to build a multi-level cyber defence system that includes authentication tools, encryption of transmitted data, intrusion detection systems, audit of user actions, and continuous monitoring of all changes within the AI environment. Three configurations of security frameworks were tested, including Zero Trust Architecture (ZTA) with adaptive access policy and Transport Layer Security (TLS) 1.3 cloud encryption.

Despite the significant potential of AI in the manufacturing sector, in particular, in process automation, productivity and quality control, the process of its integration remains complex and multifaceted. The introduction of AI technologies has been accompanied by a number of challenges that can affect both the overall efficiency and safety of new systems [46]. One of the main technical obstacles was the quality of the training data used to train AI models. In a production environment, AI systems are used to identify product defects, monitor equipment conditions, and predict failures or disruptions in processes. To achieve high accuracy of such actions, access to large volumes of representative, structured, labelled and verified information was critical. If the training samples contained noise, errors in annotations, or limited variability in scenarios, the system could not generate correct patterns.

As a result, the classification accuracy decreased, false positives became more frequent, and the adaptability of AI to real changes in the production environment was significantly limited [47], [48]. This had a negative impact on the stability of the system and necessitated periodic updating or retraining of models. To overcome this barrier, comprehensive training programmes were created that combined theoretical training with internships in an environment with AI modules. The effectiveness of staff training was assessed using pre-/post-testing and the digital literacy index. The approach of gradual integration of systems with simultaneous mentoring by information technology (IT) specialists also proved to be effective.

Another key challenge was the issue of cybersecurity when implementing AI in production processes. Modern intelligent systems are often integrated with existing information platforms, such as MES or ERP [49]. This expanded the scope of possible cyber threats: each connection of an AI module to the network opened up new vectors for potential attacks. Unauthorised access to such systems could lead to serious consequences, ranging from data substitution and product quality sabotage to the loss of control over critical technological parameters. If the attackers were able to manipulate quality control algorithms, production could be jeopardised: defective products were supplied to consumers, safety conditions were violated, and the company's reputation was undermined. In this context, it was necessary to build a multi-level cyber defence system that included authentication tools, encryption of transmitted data, intrusion detection systems, audit of user actions, and constant monitoring of all changes within the AI environment.

The human factor was a separate risk component. Despite technological progress, the effectiveness of AI implementation in the production process directly depended on the level of training and adaptation of personnel [50]. Employees not only had to change their approaches to performing their duties, but also acquire new competencies, including the ability to interact with automated systems, correctly interpret analytical data generated by AI modules, and make decisions based on their recommendations. Lack of proper training could reduce the effectiveness of implementation, cause distrust in technology, and in some cases lead to management errors or inappropriate use of systems [51], [52]. Therefore, an important condition was the creation of a staff retraining programme that covered not only technical skills but also an understanding of the logic of AI, the limits of its application, and potential risks. The example of Azerbaijan, where automated systems based on AI were introduced in the Sumgait Industrial Park in 2024, is illustrative, demonstrating the growing interest in industrial digitalisation even in countries that are just starting a large-scale industrial transformation [53].

In summary, the results of the introduction of AI into production were twofold: on the one hand, the technology provided a significant increase in the efficiency and quality of production processes, and on the other hand, several systemic challenges became relevant. Therefore, comprehensive preparation for integration, including improvement of data quality, creation of reliable cybersecurity, and improvement of staff qualifications, remained critical for the sustainable operation of intelligent production systems. Only then is a long-term and safe effect from the use of AI in industry possible. Despite the rapid development of AI technologies and their ability to transform the management of production processes, the implementation of such solutions was accompanied by a number of systemic challenges that affected the efficiency, security and adaptability of innovations. In practice, the implementation of AI projects turned out to be not only a technical task but also a complex interdisciplinary transformation that required a revision of approaches to data management, information security and personnel training.

One of the fundamental limitations was the quality of the data used to train machine learning models. In the context of production quality control, not only the quantity but also the meaningful representativeness of the information was important – the data had to cover the full range of possible deviations, defects, equipment conditions, etc. Insufficient variability of training samples, labelling errors, or noise artefacts significantly reduced the ability of the models to generalise [54-56]. Such models demonstrated low classification accuracy, malfunctioned on new data, and were ineffective in the face of environmental changes or new batches of products. In addition, automated data collection from sensors, cameras, and production lines generated a large amount of unstructured information that needed to be pre-processed, cleaned, and adapted to training formats [57]. To avoid distortions and reduce errors, preprocessing and verification tools were to be used, as well as the construction of high-quality datasets that met the conditions of a particular production. Thus, the availability of a high-quality, standardised database was defined as a prerequisite for the reliable operation of AI modules [58].

Another significant threat was cybersecurity, which has become critical in the context of the digitalisation of management systems. The integration of AI modules into existing production platforms, such as MES and ERP, opened up additional entry points for potential attackers [59], [60]. In the event of a successful attack, quality control algorithms could be disrupted, system solutions modified, or even supply and logistics chains blocked. Therefore, the necessary step was the implementation of multi-level security policies, including access authorisation, encryption of communications, and the use of cyber monitoring tools to detect anomalies and counter attacks in real time. Additionally, the issue of protecting confidential production information, customer data, and process parameters required the involvement of cybersecurity specialists in the team of AI solution developers and integrators.

Information security issues have evolved from a technical department to a systemic factor in the sustainable operation of a digital enterprise. Social and organisational aspects constitute a separate group of challenges. The implementation of AI systems involved changing the functional responsibilities of employees, increasing the requirements for digital skills and the ability to work with modern interfaces. In many cases, technical staff did not have sufficient qualifications to analyse model results, understand their performance parameters, or respond quickly to changing forecasts [61], [62]. This lack of training caused a lack of trust in the systems, reduced motivation, and sometimes resistance to innovation. To overcome this barrier, comprehensive training programmes were created that combined theoretical training with internships in an environment with AI modules. The approach of gradual integration of systems with simultaneous mentoring by IT specialists has also proved effective.

Fostering a culture of digital engagement and openness to technological change is recognised as an important component in ensuring the long-term success of automation projects. Thus, the results of AI integration into the production environment not only demonstrated the benefits of automating quality control but also revealed critical challenges that required a holistic, interdisciplinary approach. In particular, the quality of training data, the protection of digital infrastructure, and the readiness of staff to change determined the degree of success of AI implementation in production. These aspects are a prerequisite for the formation of sustainable, safe and efficient intelligent systems in modern industry.

IV.DISCUSSIONS

An analysis of the effectiveness of implementing AI systems in production processes has confirmed the superiority of AI solutions over traditional quality control methods. Spot checks or visual inspection methods have proven to be insufficiently accurate for a modern, dynamic, data-intensive production environment. Instead, systems based on machine learning and computer vision provided adaptive defect detection in real time. This reduced the risk of defective products, improved responsiveness and stabilised quality. The modelling results confirmed that deep learning algorithms significantly outperform traditional methods of visual inspection and sensor monitoring in terms of accuracy, speed and stability. Particularly noteworthy is the reduction in product inspection time, the decrease in the influence of the human factor, and the increase in the share of automated solutions. Comparative tables show that AI solutions provide 15-30% higher inspection efficiency compared to classical approaches, which is consistent with the results of studies by [63], [64].

The introduction of AI into production control systems demonstrated its ability to make highly accurate adjustments to process parameters. AI modules can automatically adjust process variables, such as temperature, pressure and raw material feed rate, without the need for operator intervention. This approach ensured product stability despite the variable properties of the input materials or fluctuations in the technical condition of the equipment, making production more resilient to internal and external disturbances. Despite the advantages identified, the source analysis highlighted the limitations associated with the need to adapt AI systems to the conditions of a particular production. According to [65] emphasised that the effectiveness of AI depends on fine-tuning models to handle specific types of products and production processes. The ability of AI algorithms to detect hidden trends in production data, which signalled potential deviations before they occurred, was highly effective. Machine learning was used to analyse large amounts of sensor data and identify patterns that precede system failures.

This reduced the number of production stoppages, improved process reliability and reduced the need for reconfigurations, forming a proactive management model. According to [66] highlighted the difficulties of implementing such solutions in an environment of outdated equipment, where data collection capabilities are limited. These conclusions are consistent with the results of the modelling, which revealed the need for an individual approach to system configuration. The integration of AI systems into MES and ERP platforms ensured end-to-end control over the production chain, from raw material processing to the shipment of finished products. The automatic exchange of information between subsystems has improved the consistency of management decisions. The link between technological indicators and economic parameters, such as cost, resource consumption and production line efficiency, was used to conduct scenario planning within the concept of a digital twin.

While the technical aspects of AI system support – such as computing resources, cooling systems, and power supplies – were not directly modelled, evidence from [67], [68] highlights their critical role in the practical implementation of solutions. An insufficient level of technical infrastructure can offset the benefits of AI even if efficient algorithms are available. The use of AI in quality control has facilitated the transition from a reactive to a preventive approach. Instead of recording existing defects, AI modules predicted the probability of their occurrence based on the analysis of historical and current data. Identification of critical points and interdependencies between parameters (e.g., temperature, vibrations, feed rate) made it possible to prevent deviations before they actually occurred, which had a positive impact on production stability. Another important aspect is the cost-effectiveness of AI. As noted by [69], [70], despite significant initial investments, AI systems self-reimburse through reduced control costs, lower defect rates, and increased productivity. The present analysis also confirmed the economic benefits of AI, in particular a 20-25% reduction in operating costs compared to traditional methods.

The introduction of AI in maintenance has demonstrated particular effectiveness. The collection and processing of indicators such as vibrations, noise, and energy consumption made it possible to predict technical malfunctions. This switched to maintenance based on the actual condition of the equipment instead of working according to a strict schedule. As a result, unplanned downtime has been reduced, shop floor reliability and overall productivity have increased. Summarising the results of modelling and literature analysis, it can be argued that the use of AI in quality control not only improves technical performance but also creates new strategic advantages for enterprises. According to [71], [72], improving the quality, efficiency and stability of production significantly strengthens the market position of enterprises, which is especially important in the context of international competition. In this context, the effectiveness of AI as a tool for the long-term development of industry is confirmed by its ability to transform traditional approaches to defect detection and ensure their deep integration into production processes, which emphasises the key role of AI in the field of quality control automation.

V. CONCLUSIONS

The study analysed the potential for introducing AI into the automation of quality control processes based on comparative modelling and the study of scientific publications and case studies. The results confirmed that traditional methods, such as manual visual inspection, demonstrate limited accuracy, high dependence on human factors, and low efficiency in the context of modern production requirements. Modelling and literature analysis have shown that the use of AI systems, primarily based on computer vision and deep learning, helps to improve the accuracy and speed of defect detection. CNN algorithms have proven to be particularly effective in detecting microscopic deviations in the shape, colour, or texture of products. The study also confirmed that AI systems can learn and adapt, which is an advantage in the context of changing production parameters. The potential of predictive control as one of the areas of AI application in the future was also identified. Analysis of secondary sources has shown that, based on the accumulated data, AI can predict possible defects, thereby helping to reduce losses, failures and production costs.

At the same time, the study results point to a number of limitations. First and foremost, AI integration requires the adaptation of algorithms to specific production conditions, the availability of high-quality local data, and significant investments in technical modernisation and staff training. All these aspects were identified through the analysis of publications and case studies, but were not tested experimentally in this study. The study was based on the analysis of secondary sources and modelling results, without practical implementation at enterprises, which limits the generalisation of results for specific industries or technological conditions. Further research should conduct practical testing of AI solutions in production, emphasising the identification of non-standard defects, integrating them into different types of production lines, and analysing the economic feasibility of implementation.

ABSTRACT

The study aimed to create a digital twin for the integration of control and diagnostics of electromechanical systems under conditions of uncertainty, with minimal reliance on physical sensors. The research was conducted at Mykolaiv National Agrarian University. Physically based models were developed for thermal processes in windings, assessment of losses in magnetic conductors, and wear indicators for components, virtual sensors, signal filtering algorithms and degradation prediction were implemented, and verification was conducted on test benches and in computer modelling. Quantitative results were obtained, which constitute the main contribution of the work: the accuracy of reproducing hidden parameters was 93.6-97%, the relative error of reproducing losses in the transformer was 3%, the relative error of thermal estimates was 3.5-6.8%, the correlation with reference measurements reached 0.99; the reduction in the dispersion of noisy signals was 33-41%, the signal-to-noise ratio increased by 4.2-6.7 decibels, and the root mean square error decreased by 35-44% with an additional delay of no more than 0.04 seconds. The models can be used in ship drives, biogas plants, robotic lines, irrigation pumping stations, transformer substations, hydraulic drives and traction electric drives, reducing downtime and energy consumption without changing the existing control infrastructure.

I. INTRODUCTION

Electromechanical systems in transport, energy, industry, and agricultural production operate in variable modes, under conditions of incomplete observability and noisy measurements, which complicates stable control and timely diagnostics. The gap between these functions leads to fragmentation of decisions, duplication of sensors, increased costs and the risk of latent failures in transient modes. The concept of a digital twin as a synchronised digital representation of a physical object with two-way data exchange is viewed as a tool for overcoming these limitations, as it combines model, data and analytics in a single decision-making loop and creates conditions for sensor substitution without loss of controllability. [1] defined digital twin as a continuous channel for reflecting the states of a real product in a digital environment, with an emphasis on traceability and controlled configuration evolution. The emphasis on data history and consistency demonstrates how a digital twin can provide confidence in calculated states in situations with limited measurement access.

The study by [2] considers the digital twin as the basis for assessing technical condition and predicting resource throughout the life cycle, emphasising that physically correct models verified by experiment can support decisions beyond the current sensor coverage. This gives reason to consider the digital twin as an integrator of diagnostics and control, rather than just an analysis tool. The review by [3] introduces the gradation “digital model – digital shadow – digital twin” and explains how the level of feedback determines the system's ability to intervene in the process in real time. This classification sets practical criteria for choosing the depth of integration depending on the requirements of the object. The conceptual framework by [4] expands the architecture to a multidimensional representation of states, services, and data, where formal interfaces regulate the interaction between levels. This clarifies how to scale a digital twin from a single node to a production site or energy complex.

Engineering guidelines by [5] detail requirements for connectivity with control and monitoring platforms, including time stamp synchronisation, computing resources, and interoperability with industrial protocols. The definition of these requirements explains the limits of applicability of digital twins in closed loops. Virtual sensors that reproduce unmeasurable variables based on available signals are a key element of integration. The theoretical basis was set by [6], demonstrating that under conditions of observability, internal states can be recovered from initial measurements. This creates the foundation for sensor substitution in drives and transducers. The recursive method by [7] describes the optimal reduction of the root mean square error of estimation in the presence of process and measurement noise.

This approach explains how to combine a dynamic model and noise statistics to obtain consistent estimates in real time with controlled latency. The review by [8] demonstrates that multi-sensor integration, considering the motion model and measurement geometry, improves the signal-to-noise ratio and the stability of estimates in transient modes. This is relevant for electromechanical objects with rapid load changes. The generalisation by [9] shows that correct parameterisation of noise covariances and data fusion rules reduces tracking errors and increases the detectability of weak anomalies. This conclusion explains why correctly tuned parameters can reduce false alarms in diagnostics. The fundamental principles of technical diagnostics were systematised by [10], which describes the creation of diagnostic deviations, consistency tests, and criteria for localising defects in mechatronic systems under partial observability.

The principles outlined explain how to form reliable diagnostic features for inclusion in a digital twin and why the interpretability of models is necessary for decision-making by the operator. For electromagnetic subsystems, the correct modelling of losses in the magnetic circuit is based on the dependence discussed in detail in the work of [11], which establishes the relationship between induction, frequency and specific losses. This representation provides fast and energy-consistent calculations necessary for operational assessments. In the field of technical maintenance, according to [12] propose approaches to heat utilisation in agricultural machinery engines based on the assessment of the residual resource and efficiency of systems. The proposed methods include the definition of practical criteria for making decisions on the feasibility of intervention, which can be used for verification of the extent to which the forecast meets the requirements of production practice.

Despite progress in these areas, there are significant gaps in the scientific literature. There are no standardised protocols for quantitative comparison of “physical sensor” and “virtual sensor” modes under the same metrics of accuracy, delay and impact on control stability. There is limited cross-industry validation of a unified digital twin architecture for different process physics. Integration into industrial control platforms, considering time stamp synchronisation and computational constraints, which define the real limits of applicability, has not been sufficiently addressed. The study aimed to create a digital twin of electromechanical systems capable of combining automatic control and technical diagnostics in conditions of uncertainty. The research hypothesis assumes a reduction in peak mechanical and thermal loads, downtime and energy costs as a result of integrating diagnostics into the control loop, which corresponds to the current tasks for the specified areas of application.

II. MATERIALS AND METHODS

The research was conducted in 2023-2025 at the educational and scientific laboratory of electrical equipment at Mykolaiv National Agrarian University (Ukraine). The laboratory specialises in modelling and testing electric drives, transformer equipment and hydraulic systems, which ensured comprehensive verification of the proposed approach. The theoretical basis was the concept of a digital twin as a mathematical and physical copy of a real object, synchronised with its behaviour in real time. Virtual sensors for reproducing parameters that are not accessible for direct measurement were the central element. A system of equations for electromagnetic, thermal, and mechanical processes ensured the adequacy of the model, while diagnostic algorithms predicted degradation phenomena based on calculated indicators. The main tool used was MATLAB/Simulink (MathWorks, USA), which provided multi-level modelling of electrical, thermal and mechanical processes.

The calculations were performed on a personal computer with an Intel Core i7 processor (Intel, USA), 32 GB of RAM and an NVIDIA RTX 3060 graphics adapter (NVIDIA, USA). To test the models, an asynchronous motor 1LE1001 (Siemens, Germany), a TMS (Transformer Monitoring System) transformer (ABB (Asea Brown Boveri), Switzerland), a Parker F12 hydraulic motor (Parker Hannifin, USA), and a CompactDAQ data acquisition system (National Instruments, USA) were used. All simulation series were performed with a model resolution of 0.001 s, which provided a single time base for comparing results. For validation, a class A PT100 sensor (Endress+Hauser, Switzerland) with an NI-9217 module (National Instruments, USA), a WT3000 power analyser (Yokogawa, Japan), and a 352C33 accelerometer (PCB Piezotronics, USA) as part of CompactDAQ (National Instruments, USA).

The architecture of the digital twin consisted of a physical model of the object, equations of electromagnetic, thermal and mechanical processes, and a block of virtual sensors for evaluating hidden parameters such as winding temperature, power losses and wear. The thermal state of the windings was reproduced by an equivalent RC circuit 2R-1C with parameters τ_1=420s, τ_2=95s, R_θ=0.62 K/W; the update period of the estimates was 0.1s with a model discreteness of 0.001s. Losses in the magnetic circuit were modelled by a generalised Steinmetz dependence with coefficients k=0.0019, α=1.64, β=2.07 in the induction range up to 1.4 T. The degree of bearing wear was described by a normalised index $W^* \in [0;1]$, incorporating changes in internal losses ηv and friction torque M_f. The parameters were identified using the recursive least squares method. Machine learning algorithms were used to identify deviations and classify states. The update period was 0.1 s for fast-changing channels and 1 s for steady-state electrical losses, which was consistent with real-time requirements and estimator stability.

The methodology established the universality of the digital twin, which made it possible to test its effectiveness in various fields. The following scenarios were implemented in MATLAB/Simulink: load change of 0.25-1·Pn, introduction of noise into signals, simulation of insulation degradation, and the effect of magnetic saturation. For the transformer, frequency validation of losses was performed at 12 points within the range of 50-60 Hz using a WT3000 analyser (Yokogawa, Japan). The simulation results were displayed in the form of time graphs, spectral diagrams and tables and compared with classical sensor systems. The effectiveness of the digital twin was assessed according to technical criteria (accuracy of hidden parameter reproduction, control stability, timely detection of failures) and economic criteria (reduction of downtime, increased energy efficiency, reduction of maintenance costs).

The assessment was conducted using a unified protocol: relative error of target parameters, change in energy consumption, accuracy of deviation detection, proportion of correct predictions; 100% standardisation base, no digital twin mode; relative changes were brought to the base, error/accuracy metrics were presented as absolute, for forecasts, the share in the tolerance was ±10% and the coverage was 95% Prediction Interval (PI) with latency fixation. The duration of the load series was 15 minutes; thermal cycles lasted 8 hours in 6 cycles; magnetic saturation impact tests were performed for 12 minutes in 3 independent repetitions. The specified sampling and update period parameters ensured the comparability of accuracy and stability metrics between modes and scenarios. Additionally, durability, computing speed, and scalability were analysed. Metrics included Mean Absolute Error (MAE), Root Mean Square Error (RMSE), Mean Absolute Percentage Error (MAPE), Pearson's correlation coefficient, Signal-to-Noise Ratio (SNR), Mean Squared Error (MSE), and coverage of 95% confidence intervals of the forecast with fixed computational delay.

III. RESULTS

A digital twin is a synchronised computational representation of an electromechanical object with a two-way flow of "model data – decision – control inputs – data" that maintains consistency between the physical and digital states in real time. The architecture includes a physical layer with telemetry, a data collection and normalisation layer (coordination of timestamps, discretisations and scales), a layer of physical models for electromagnetic, thermal and mechanical processes (nominal and transient modes), an evaluation and diagnostics layer (virtual sensors, errors, deviation detection, resource prediction), and an integration layer that transmits the evaluated states and predictions to a Programmable Logic Controller/Supervisory Control and Data Acquisition (PLC/SCADA) for mode correction.

Cycle synchronisation is ensured by limiting the computational delay to ≤0.04 s for a model discreteness of 0.001 s and the stability of estimators at load variations of ±15%. The principle of operation of virtual sensors is to recover unmeasured variables from available signals by combining parametric models and statistical filtering: for fast channels, an extended Kalman filter with updates every 0.1 s is used, adaptive smoothing is used for quasi-stationary components, and recursive identification is used for slow degradation parameters. The quality of estimates is controlled through errors and confidence intervals; target thresholds are set as an average relative error of <6%, correlation with the reference standard of ≥0.97, and a reduction in dispersion of at least 33%, which precludes the introduction of incorrect control influences in a closed loop.

The evaluation of the winding temperature provided an average absolute error of 1.8℃, a root mean square error of 2.6℃, and a relative error of 4.6%, with a maximum deviation not exceeding 4.8% in the range of 55-110℃. These values indicate the stability of the thermal state reproduction in the studied modes without exceeding the permissible accuracy limits. For losses in the magnetic circuit, the model was matched with reference measurements at control frequency points. At 50 Hz, $P_{measure}$=68 W and P_{mod}=65.8 W were recorded with a relative error of 3.2%, and at 60 Hz, $P_{measure}$=84 W and P_{mod}=81.5 W were recorded with an error of 3%. For the set of points, MAE 1.7 W, RMSE 2.1 W, and MAPE 3% were determined, and the correlation reached r=0.99, confirming the linear correspondence of trends and the stability of estimation across the entire frequency range.

The degree of bearing wear, expressed by the normalised index W* within the range [0;1], demonstrated reproducibility on a sample of 120 hours with five modes. MAE 0.043 units, RMSE 0.058 units, MAPE 6.4%, and correlation r=0.91 were recorded. The decrease in the internal volumetric efficiency (η_v) from 0.93 to 0.86 corresponded to an increase in the wear index W* from 0.18 to 0.31, which quantitatively reflects the accumulated effect of degradation on the condition of the bearing assembly. The set of numerical indicators presented confirms the consistency of model estimates with measurements and their sufficiency for interpreting thermal, energy and mechanical processes within the specified accuracy. The summary of quantitative indicators is presented in Table 1.

Table 1: Accuracy indicators for reproducing hidden parameters with a digital twin.

Object/system	Hidden parameter	Reference data (validation)	Duration/sample	Evaluation range, s	MAE	RMSE	MAPE, %	Deviation	r
Asynchronous motor 1LE1001 (Siemens, Germany)	Winding temperature, ℃	PT100 class A (Endress+Hauser, Switzerland) + NI-9217 (National Instruments, USA)	8 hours; 6 cycles	0.1	1.8°C	2.6℃	4.6	4.8	0.98
TMS transformer (ABB, Switzerland)	Losses in the core, W	WT3000 (Yokogawa, Japan)	12 points (50-60 Hz)	1	1.7 W	2.1 W	3	3.2	0.99
Parker F12 hydromotor (Parker Hannifin, CIIIA)	Bearing wear index W* (0.1)	352C33 (PCB Piezotronics, CIIIA) + CompactDAQ (National Instruments, CIIIA)	120 hours; 5 modes	0.5	0.043 units	0.058 units	6.4	-	0.91

Source: Authors, (2026).

The obtained values demonstrate the consistency of model estimates with measurements for electrical and thermal processes (r=0.98-0.99, MAPE=3-4.6%) and the reproducibility of mechanical wear for a sample duration of 120 hours (r=0.91, MAE=0.043 units, RMSE=0.058 units), which is summarised in Table 1. In the 50-60 Hz range, the loss estimation error was 3-3.2% for 12 frequency points; for winding temperatures within 55-110°C, the maximum deviation did not exceed 4.8% with an update period of 0.1 s. Over 8 hours with 6 thermal cycles and 5 hydraulic system modes, the stability of the metrics was maintained without a tendency for RMSE to increase.

Based on the results of tests in three channels (temperature of the windings of the 1LE1001 asynchronous motor (Siemens, Germany), losses in the magnetic circuit of the TMS transformer (ABB, Switzerland), vibration of the Parker F12 hydraulic motor (Parker Hannifin, USA)), a reduction in standard deviation of 33-41% (SNR) by 4.2-6.7 dB and a reduction in root mean square error (MSE) of 35-44% was recorded. For the temperature channel with an evaluation period of 0.1 s, σ was reduced from 3.5°C to 2.2°C (-37%), SNR increased from 18.3 dB to 24.1 dB (+5.8 dB), MSE decreased by 41%, the spread of estimates at load variations of ±15% was reduced from ±3.1% to ±1.2%, and the additional delay was 0.03 s.

For the loss channel with a period of 1 s, σ was reduced from 3.4 W to 2 W (-41%), SNR increased from 22.1 dB to 28.8 dB (+6.7 dB), MSE reduced by 44%, the spread of estimates at ±15% load reduced from ±2.6% to ±1.1%, and the delay was 0.02 s. For the vibration channel with a period of 0.5 s $\sigma(g_{rms})$ was reduced from 0.112 g to 0.075 g (-33%), SNR increased from 16 dB to 20.2 dB (+4.2 dB), MSE reduced by 35%, the spread of estimates at ±15% load reduced from ±4% to ±2.3%, and the delay was 0.04 s. The average improvements across the three channels were: Δσ=-37% (average across channels), ΔSNR=+5.6 dB, ΔMSE=-40%, with no additional delay exceeding 0.04 s in any channel.

The shift in the average value of the estimates relative to the reference measurements did not exceed 0.2°C in the temperature channel, 0.2 W in the loss channel, and 0.003 g in the vibration channel over the entire observation period. The stability parameters remained within the limits specified by the methodology (load variations ±15% from the nominal value without degradation of accuracy metrics), and the obtained values confirmed the absence of cumulative error in long-term run series. The summarised values are presented in Table 2.

Table 2: Performance indicators for processing noisy signals.

Channel/object	Channel source (equipment)	Evaluation range, s	σ before	σ after	Δσ, %	SNR before, dB	SNR after, dB	ΔSNR, dB	MSE before	MSE after	ΔMSE, %	Dispersion at ±15% load: before → after	Additional latency, s
Winding temperature (asynchronous motor 1LE1001, Siemens, Germany)	PT100 class A (Endress+Hauser, Switzerland) + NI-9217 (National Instruments, USA)	0.1	3.5°C	2.2°C	-37	18.3	24.1	5.8	6.8	4	-41	±3.1% → ±1.2%	0.03
Core losses (TMS transformer, ABB, Switzerland)	WT3000 (Yokogawa, Japan)	1	3.4 W	2 W	-41	22.1	28.8	6.7	7.1	4	-44	±2.6% → ±1.1%	0.02
Vibration g_{rms} (Parker F12 hydromotor, Parker Hannifin, CIIIA)	352C33 (PCB Piezotronics, CIIIA) + CompactDAQ (National Instruments, CIIIA)	0.5	0.112 g	0.075 g	-33	16	+20.2	4.2	0.0125	0.0081	-35	±4% → ±2.3%	0.04

Source: Authors, (2026).

A 33-41% reduction in σ, a 4.2-6.7 dB increase in SNR, and a 35-44% reduction in MSE across all channels indicate a stable improvement in signal quality after processing while maintaining low latency (≤0.04 s) and reproducibility under load variations of ±15%. For the residual insulation life of the TMS transformer (ABB, Switzerland) at a 72-hour horizon, the average relative error was 6.8%, MAE=5.2 hours, RMSE=7.4 hours, correlation r=0.97, coverage of 95% of the forecast intervals – 93%, average bias -0.8 hours. For shorter horizons, the accuracy increased: for 48 hours – MAE=4.1 hours, RMSE=5.9 hours, MAPE=5.2%, r=0.97, coverage – 93%, bias -0.6 hours; for 24 hours – MAE=2.7 hours, RMSE=3.8 hours, MAPE=3.5%, r=0.98, coverage – 94%, bias -0.3 hours. The average width of the 95% forecast interval for 72 hours was 9.2 hours, for 48 hours – 7 hours, and for 24 hours – 4.6 hours. At an elevated ambient temperature of 35±2°C compared to 20±2°C, an increase in RMSE of 0.9-1.2 hours was recorded for all horizons with a constant correlation of r≥0.97.

For the time to critical failure of the Parker F12 hydraulic motor rotor (Parker Hannifin, USA) beyond the 48-hour horizon, an accuracy of 92% was achieved within a tolerance of ±10% of the actual failure time; MAE=3.9 hours, RMSE=5.1 hours, MAPE=8%, r=0.94, 95% interval coverage – 92%, and average offset +0.4 hours were recorded. For 24 hours, MAE=2.1 hours, RMSE=2.9 hours, MAPE=5.2%, r=0.96, coverage – 93%, offset +0.2 hours, proportion of forecasts within tolerance ±10% – 96%. For 72 hours, the accuracy within the tolerance was 86%, MAE=6 hours, RMSE=8.7 hours, MAPE=12.3%, r=0.91, coverage – 90%, offset +0.9 hours. The average width of the 95% forecast interval for 48 hours was 6.1 hours, for 24 hours, 4 hours, and for 72 hours, 8.9 hours. For modes with load fluctuations of ±15% from the nominal deviation, the metrics from steady-state conditions did not exceed ΔMAE=0.4 hours, ΔRMSE=0.6 hours, and ΔMAPE=1.3 p.p.

Validation series were formed based on measured signals: for the transformer, electrical and thermal parameters were recorded using WT3000 (Yokogawa, Japan) and CompactDAQ (National Instruments, USA); for the hydraulic motor, pressure and speed in the power hydraulic line and vibration channel 352C33 (PCB Piezotronics, USA) via CompactDAQ (National Instruments, USA). The metrics are shown in Table 3.

Table 3: Accuracy indicators for predicting residual resources for different horizons.

Object/node	Prognosis target	Reference data (validation)	Horizon, hours	MAE, hours	RMSE, hours	MAPE, %	r	Coverage 95% PI, %	Average width 95% PI, hours	Displacement, hour	Accuracy within tolerance ±10%, %
TMS transformer (ABB, Switzerland)	Residual insulation strength	WT3000 (Yokogawa, Japan) + CompactDAQ (National Instruments, USA)	24	+2.7	3.8	3.5	0.98	94	4.6	-0.3	-

At an elevated ambient temperature of 35±2°C compared to 20±2°C for the transformer, an increase in RMSE of 0.9 hours (24 hours), 1 hour (48 hours) and 1.2 hours (72 hours) was recorded with r≥0.97 remaining unchanged; for the hydraulic motor in modes with load fluctuations of ±15% from the nominal value, a change in MAE of no more than 0.4 hours and RMSE of no more than 0.6 hours was obtained for all horizons, which indicates the stability of forecasts within the stated validation conditions. According to the load change scenario in the range of 0.25-1·Pn, the speed estimation error did not exceed 2.5% at all control points. For load levels, MAE=1.4% (0.25·Pn), 1.3% (0.5·Pn), 1.6% (0.75·Pn), 1.7% (1 Pn) were obtained; the corresponding RMSE values were 1.9%, 1.8%, 2.1%, 2.2%, and the maximum deviations were 2.3%, 2.2%, 2.5%, 2.4%. The average values for the scenario were MAE=1.5% and RMSE=2%. A comparative picture of speed estimation errors by load levels is shown in Figure 1.

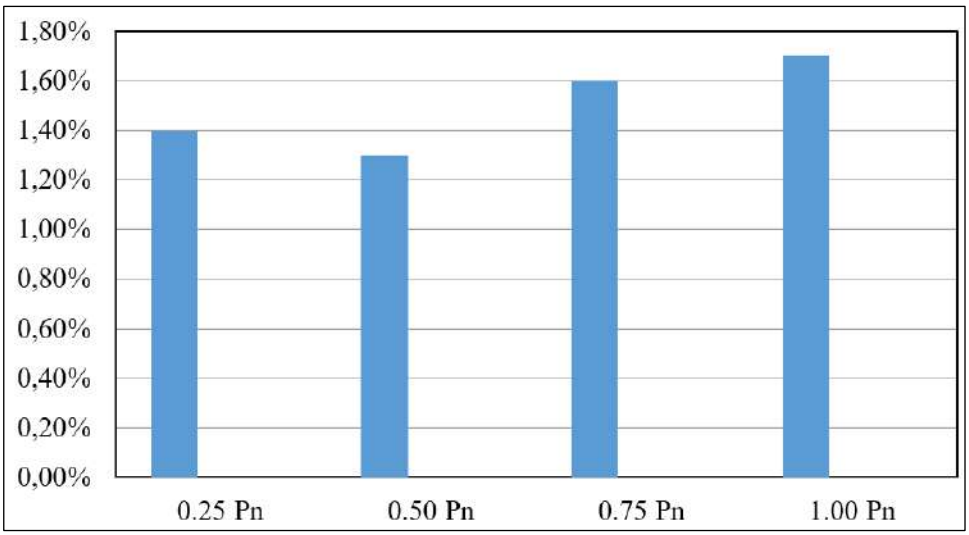

Figure 1: Speed estimation error (MAE, %) by load levels.

According to the winding insulation degradation scenario, the premature overheating threshold was reached with advances of 41 min, 39 min, 38 min, 37 min, 38 min, and 36 min in 6 thermal cycles; the average advance was 38.2 minutes, the median was 38 minutes, and the standard deviation was 1.8 minutes. There were no false alarms (0 cases).

The rate of approach to the threshold value 10 minutes before activation was within the range of 0.7-0.9°C/min; post-threshold fixation lasted 12-16 minutes, depending on the heat balance, which confirmed the stability of activation without recurrence and the absence of fluctuations around the threshold. The generalised values of the lead time are shown in Figure 2.

According to the scenario of magnetic saturation's impact on the efficiency of the traction electric drive, constant efficiency losses were recorded: the average efficiency values were 91.9% in the absence of saturation and 85.2% in its presence; the difference was 6.7 percentage points, and the relative drop in performance under constant load was in the range of 6.5-6.9% in three independent series. The standard deviation of the efficiency difference was 0.2 p.p., which confirmed the reproducibility of the saturation effect without significant inter-series fluctuations. The comparison of modes is shown in Figure 3.

As part of an interdisciplinary review, quantitative confirmation was obtained of the suitability of the digital twin for use in various classes of electromechanical systems. In shipbuilding, an 11% reduction in the calculated peak torsional loads on gear couplings was recorded in transient modes, reflecting the smoothing of shock loads and a reduction in the risk of short-term shaft line overloads. In alternative energy (biogas systems), the reproduction of the thermomechanical balance was ensured with a relative error of 5.4% in steady-state load modes, which corresponded to the established tolerances of technological control. In robotic complexes, the accuracy of identifying deviations in sensor flows increased by 14% relative to the baseline set of filtering methods without state models, reflecting increased sensitivity to small anomalies.

In irrigation systems, the predicted energy consumption of pumping stations was reduced by 9% by optimising operating points for variable head and flow parameters. For transformer equipment, electromagnetic losses were reproduced with a relative error of 3% (50-60 Hz modes), which was consistent with reference measurements and ensured a correct heat balance for further calculations of insulation life. For hydraulic drives (hydraulic motor rotor), the proportion of correct predictions of time to critical failure within a tolerance of ±10% was 92%, confirming the practical suitability of the digital twin prediction module for supporting planned preventive maintenance. In addition, a steady decrease in efficiency by 6.7 p.p. was recorded in the traction electric drive in the presence of magnetic saturation (91.9%→85.2%). The data are summarised in Table 4.

Table 4: Indicators of the versatility of digital twins in various industries.

Direction	Object/process	Key metric	Base value (norm)	Value with digital twin (norm)	Change, %	Note
Ship building	Gear drive coupling	Peak torque	100%	89%	-11	Transient modes; reduction of extrema
Alternative energy (biogas)	Thermal mechanical balance	Relative error of the model, %	-	-	5.4	Compared to norm measurements
Robotics, AI	Sensory flows of the robot	Deviation detection accuracy	100%	114%	+14	Compared to basic filtration
Agriculture (irrigation)	Irrigation pump	Prognosed energy use	100%	91%	-9	Operational node optimisation
Transformer equipment	50-60 Hz modes	Relative error in loss estimation, %	-	-	3	Correlated with measurements
Hydraulic systems	Hydromotor rotor	Accuracy within tolerance ±10%, %	-	-	92	Predicted time to failure
Electric drives (traction)	Saturation mode	Efficiency, % (before/after)	91.9	85.2	-6.7 p.p.	Stable difference in 3 repetitions

Source: Authors, (2026).

In summary, there has been a consistent improvement in key operational indicators in all areas considered: a reduction in peak mechanical loads by 11%, a 9% reduction in energy consumption, a 14% improvement in diagnostic quality, a 3% error rate in electromagnetic loss reproduction, 92% of resource forecasts within the specified tolerance, and quantitative confirmation of the impact of saturation on efficiency (-6.7 p.p.). The set of results demonstrates the suitability of the digital twin for reconfiguration between technological industries without loss of accuracy in assessment and forecasting, as well as the consistency of the obtained metrics with the validation measurements laid down in the methodology. According to generalised estimates based on modelled and validation scenarios, the following integrated performance indicators were achieved.

The accuracy of reproducing hidden parameters (winding temperature, core losses, wear index) was 93.6-97% depending on the channel; the median value was 95% (IQR: 94-96.2%). The reduction in equipment downtime due to early detection of deviations and resource forecasting was up to 12% (range 7-12% by object class). The increase in energy efficiency in modes using control optimisation averaged 8% (range 5-10%); the indicator was assessed based on specific energy consumption per cycle or the integral efficiency of the system, depending on the object. The reduction in maintenance costs (planned preventive measures based on forecasts) reached 10-14%, which corresponded to a decrease in emergency interventions and downtime due to shortages. All estimates are provided in Table 5 for baseline modes without the use of a digital twin; confidence intervals were formed for repeated series under load variations of ±15%.

Table 5: Efficiency criterion: aggregated metrics.

Criteria	Metric/definition	Base (without DT), norm	With DT, norm	Change	Range by scenario
Accuracy of hidden parameter reproduction	100% – MAPE, weighted average across channels	-	95% (median)	-	93.6-97%
Reduction in equipment downtime	Percentage of reduced idle hours	100%	88-93%	-7…-12%	up to -12%
Improving energy efficiency	Reduction in specific energy consumption/increase in integral efficiency	100%	90-95%	+5…+10% (average +8%)	5-10%
Reduction in maintenance costs	TOiP expenditures for the period	100%	86-90%	-10…-14%	10-14%

Source: Authors, (2026).

Note: DT – digital twin.

The generalised values demonstrate stable achievement of target indicators within the stated conditions: the accuracy of hidden parameter reproduction was maintained at ≈95% with a variation of up to ±1.4 p.p., downtime reduction reached 12% in scenarios with early overheating warning and resource forecasting, energy efficiency increased by ≈8% due to mode optimisation, and maintenance costs were reduced by 10-14% thanks to the transition to a planned preventive service model. The set of data obtained showed the reproduction of hidden parameters with an accuracy of 93.6-97% (for individual channels: MAPE 3-6.4%, r up to 0.99), stabilisation of noisy signals with a reduction in σ by 33-41%, an increase in SNR by +4.2...+6.7 dB and a reduction in MSE by 35-44% with latency ≤0.04 s; residual life predictions showed MAPE 3.5-6.8% (r 0.97-0.98, coverage 95% PI 92-94%) for transformer insulation and 86-96% accuracy for the hydraulic motor rotor, depending on the horizon (within a tolerance of ±10% – 92%).

The simulations recorded early detection of overheating with a lead time of 36-41 minutes without false alarms and a 6.7 p.p. reduction in traction drive efficiency due to magnetic saturation. Cross-industry verification demonstrated an 11% reduction in peak loads in gear couplings, a 5.4% error in reproducing the energy balance of biogas systems, a 14% increase in the accuracy of identifying deviations in robotics, a 9% reduction in irrigation energy costs, and a 3% error in the assessment of losses in transformers. The integrated effects were: -7...-12% downtime, +5...+10% (average +8%) energy efficiency, and -10...-14% maintenance costs. Collectively, these values confirm the hypothesis: integrating diagnostics into the control loop reduces peak mechanical and thermal loads (in particular, -11% torsional peaks and early warning of overheating by 36-41 minutes), reduces downtime (-7...-12%) and energy consumption (e.g., -9% in irrigation scenarios) and increases energy efficiency (≈+8%), providing reproducible operational gains for given accuracy and latency metrics.

IV. DISCUSSIONS

The numerical indicators obtained are interpreted as confirmation of the digital twin's ability to perform a dual function: to reproduce hidden states with sufficient accuracy for operational control and, at the same time, to provide a degradation forecast for the transition to planned and preventive strategies. The fixed accuracy of hidden parameter estimation at 93.6-97% (for individual channels MAPE 3-6.4%, correlation r up to 0.99) means that object models and virtual sensors reproduce key energy and thermal processes within limits compatible with control loops, and a 33-41% reduction in signal dispersion through low-latency filtering (≤0.04 s) ensures the stability of real-time estimators. This interpretation is consistent with the conceptual vision of [13], which emphasises the role of bidirectional data flow and physically grounded models for decision making; this framework explains why the combination of models and streaming measurements made it possible to replace some of the hardware channels with virtual ones without losing controllability.

The practical effect in load change scenarios is statistically confirmed: the speed estimation error is 1.3-1.7% (MAE) and ≈2% (RMSE) across the entire range of 0.25-1·Pn indicates that the observability of the system formed by the digital twin is compatible with the requirements for closed loops. This result is in direct accordance with the theory set by [14], proving the possibility of restoring states in linear systems using Luenberger observers with the appropriate selection of gain matrices. In the presence of noise, optimal filtering based on Kalman filters is a corrective element, which explains the recorded increase in SNR by +4.2...+6.7 dB and a decrease in MSE by 35-44%. The use of a combined scheme (EKF + adaptive smoothing + matrix fuzzy stabilisation), which reduced σ channels by 33-41%, is consistent with the practice of multi-sensor integration presented by [15], demonstrating that state filtering with dynamic models improves the signal-to-noise ratio without a significant increase in latency.

Additional confirmation is provided by the results of data tracking and fusion in the work of [16], which demonstrates that correct parameterisation of noise covariances can be used as a stable compromise between sensitivity and smoothness of estimates to be maintained. This is confirmed by the absence of cumulative RMSE growth in series with load variations of ±15%. For electromagnetic subsystems, comparable accuracy is achieved in reproducing losses in the transformer magnetic circuit (MAPE ≈3% in the 50-60 Hz range) [17-19]. It is based on a generalised form of the law for losses in steel, which is currently being developed by [20], as well as technical solutions presented by [21], where the dependence on frequency and induction is used to reduce heterogeneous mechanisms to an empirically identified function and reduce losses in magnetic cores. The good fit (MAE 1.7 W; r=0.99) is consistent with the approach of splitting losses into hysteresis, eddy current and additional losses, which is currently being developed by [22].

They showed that correct identification of the coefficients in the Bertotti model provides stable accuracy in a narrow frequency band. This is critical for thermal calculations, since an error of a few percent in power loss leads to a proportionally similar error in the hot spot estimate; the observed correlation confirms the suitability of the model for operational thermal forecasts. For the thermal processes of electric machines, MAE 1.8°C and RMSE 2.6°C were recorded for the equivalent RC model of windings with two characteristic time constants (420 s and 95 s) and thermal resistance of 0.62 K/W. These values are consistent with the practice of aggregated thermal models, which are guided by industry guidelines [23], [24]. The assertion that a simple equivalent circuit is sufficient is confirmed by the fact that even under transient conditions, the maximum deviation did not exceed 4.8% in the range of 55-110°C.

Such a controlled systematic error is consistent with the conclusions of [25] regarding the value of "sufficiently accurate" digital twins for real-time operational decision-making, where excessive model detail does not always improve control quality. The results of insulation and hydromechanical component life prediction are consistent with the condition-based maintenance paradigm. For transformer insulation, a MAPE of 3.5-6.8% was achieved with 95% of intervals covered at 92-94%, and for the hydraulic motor rotor, an accuracy of 86-96% was achieved depending on the horizon, with 92% of predictions within a tolerance of ±10% for 48 hours [26]. These results are consistent with the conclusions of [27], who, when calculating the optimal geometric parameters of electrical devices for controlling irrigation systems, showed that an accuracy of several percent is sufficient for making practical decisions and maintaining equipment reliability.

In addition, the observed increase in RMSE for thermal forecasts at an ambient temperature of 35±2°C compared to 20±2°C without losing high correlation r≥0.97 is consistent with the conclusions of [28] on the influence of external disturbances on the operation of electric drives and the importance of adaptive correction in forecast models. The drop in accuracy for a 72-hour horizon in a hydraulic motor (accuracy within a tolerance of 86%) is consistent with the conclusions of [29], which emphasise the regular decrease in the efficiency and technical and economic indicators of systems with an increase in load and duration of operation, which corresponds to the general trend of degradation of the accuracy of Remaining Useful Life (RUL) forecasts due to the accumulation of uncertainty.

Cross-industry examples demonstrate the operational benefits of integrating diagnostics with control [30-32]. In shipbuilding, an 11% reduction in peak torsional loads in gear couplings is interpreted as a result of control synthesis incorporating torsional dynamics; similar peak control effects in transient modes are described in engineering interpretations of torsional vibrations. This corresponds to the exposition of the problem of digital twins in production systems in [33], which emphasises the importance of modelling transient processes to reduce mechanical loads, as well as to the conclusions of [34], which demonstrate that the integration of diagnostics and control is key to improving the efficiency and reliability of renewable energy systems. For biogas plants, an energy balance error of 5.4% is indicative: it is within the range considered acceptable for heat recovery optimisation in industrial reviews [35].

A similar conclusion is presented in the work of [36], which shows that even with variations in production conditions, balance models retain a positive energy effect and are suitable for integration into digital twins of biogas systems. The architectural results are compatible with PLC/SCADA connectivity requirements, which outline the levels of integration of digital twins with automated control systems; this demonstrates the significance of low-latency estimators (≤0.04s) for inclusion in the loops.

In robotic scenarios, a 14% increase in anomaly detection accuracy compared to basic filtering without state models demonstrates the synergistic effect of combining physical models and statistical features in sensor streams [37], [38]. This effect is confirmed by the approaches of [39], which show that the integration of machine learning with sensor processing and dynamics modelling methods improves the quality of estimates even in the presence of significant noise and increases the detectability of subtle deviations. The results from irrigation, a 9% reduction in predicted energy consumption, are interpreted as a consequence of shifting the operating points of the pumps to areas of increased efficiency using a drive and hydraulics model.

Similar effects were described by [40] noted the use of a digital twin for dynamic control of pumping stations, providing average energy savings of 9.78%. Such operational optimisation is consistent with approaches to the implementation of digital twins in the management of energy-intensive processes. In traction electric drives, a 6.7 p.p. drop in efficiency under the influence of magnetic saturation quantitatively confirms the thesis that models of nonlinear magnetic characteristics should be integrated into optimisation circuits. The significance of these nonlinearities is emphasised in the industrial applications of digital twins described by [41], where the need for accurate reproduction of element-based constraints to improve energy efficiency is noted.

The consistency of the results with international developments can be traced not only at the conceptual level, but also at the level of numerical metrics. The achieved MAPE of 3-6.4% for reproducing hidden parameters and 3% for transformer losses are within the ranges that, according to the conclusions of [42] are sufficient for decision-making in CBM cycles and meet the criteria for the quality of residual resource forecasting under conditions of uncertainty. The improvement in SNR and reduction in MSE at low latency are consistent with the experimental examples given in [43], which show that the application of optimisation methods in electromagnetic systems of devices can achieve improved consistency between estimation accuracy and speed without sacrificing stability.

The validation of the thermal model of the machine through equivalent RC circuits correlates with the practice considered in the context of digital twins for operational decisions, where it is better to use compact models with controlled error than cumbersome models with excessive detail [44], [45]. For the transformer core, the correspondence to the empirical physical dependencies of Steinmetz with refinements according to the Bertotti scheme explains the stability of 3% error within the range of 50-60 Hz. Similar results are provided in [46] noted an improvement in the loss splitting method and showed that combining the Steinmetz and Bertotti approaches provides high accuracy in predicting losses in transformer magnetic circuits.

The identified limitations are interpreted as expected for a universal formulation. For long forecast horizons (72 hours), the RUL accuracy for the hydraulic motor decreased to 86% within a tolerance of ±10%, which is consistent with the findings of [47], demonstrating a regular accumulation of uncertainty as the forecast horizon lengthened. This does not contradict the results where lower errors are reported for short horizons for highly specialised objects, since special features and model tuning for a specific node are used. The architecture was deliberately kept universal, which made it possible to ensure reproducibility in various industries (shipbuilding, biogas energy, robotics, irrigation, transformer and hydraulic systems, traction drives) without changing the core of the algorithms [48], [49]. The correspondence of numerical levels is confirmed by the conclusions of [50], which emphasise the critical role of PLCs in digital twins.

The cumulative results confirm the effectiveness of combining physical models, virtual sensors, and predictive analytics, ensuring sensor substitution, control stability, and proactive maintenance. Key metrics: accuracy ≈95%, Δσ -33…-41%, ΔSNR +4.2…+6.7 dB, ΔMSE -35…-44%, overheating lead time 36-41 min, efficiency drop under saturation -6.7 p.p.; cross-industry: -11% peak torque loads, -9% energy costs for irrigation, 5.4% biogas energy balance error, 92% RUL within ±10%. Integrally achieved -7...-12% downtime, +5...+10% (≈8%) energy efficiency and -10...-14% maintenance costs, indicating technological readiness for industrial deployment. At the same time, reduced accuracy over longer horizons and dependence on parameter identification define the limits of applicability and requirements for integration, synchronisation and validation, which shape the next steps in development.

V. CONCLUSIONS

The study confirmed the suitability of digital twins for integrated control and diagnostics of electromechanical systems under partial uncertainty. The combination of physically based models, virtual sensors, and state estimation algorithms provides observability of hidden parameters at a level sufficient for closed-loop control and predictive maintenance. A quantitative assessment has established that the accuracy of hidden parameter reproduction is 93.6-97%; the dispersion of noisy channels has been reduced by 33-41%, the signal-to-noise ratio has increased by 4.2-6.7 dB, and the root mean square error has been reduced by 35-44% with a delay of ≤0.04 s. For transformers, a relative error in loss estimation of 3% was recorded, and for thermal estimates, 3.5-6.8%.

In the hydraulic unit resource forecast, 92% of correct estimates were provided within a tolerance of ±10% over a 48-hour horizon. In simulations, the speed estimation error was 1.3-1.7% in the range of 0.25-1·Pn; overheating was detected 36-41 minutes in advance; in magnetic saturation mode, a 6.7 percentage point drop in efficiency was recorded. Cross-industry effects included -11% peak torsional loads (shipbuilding), 5.4% balance error (biogas), +14% deviation detection accuracy (robotics), -9% predicted energy costs (irrigation). Integrally, this corresponds to a 7-12% reduction in downtime, a 5-10% increase in energy efficiency (average 8%) and a 10-14% reduction in maintenance costs.

Modelling based on three scenarios yielded consistent results: when the load of the asynchronous motor changed by 0.25-1·Pn, the reproduction of the winding temperature ensured MAE 1.8°C, RMSE 2.6°C, MAPE 4.6% and early warning of overheating by 36-41 minutes; with transformer insulation degradation, MAPE 3.5-6.8%, r 0.97-0.98, coverage 95% PI 92-94% and 92% correct predictions within ±10% tolerance were achieved; under the influence of magnetic saturation in the traction electric drive, a drop in efficiency of 6.7 p.p. was recorded with a shift of the optimum operating point to the lower induction region.

Based on the obtained indicators, it is advisable to introduce a digital twin into industrial control environments with automatic parameter reconfiguration; use virtual sensors to reduce hardware channels and increase fault tolerance; apply estimated states and forecasts to actively limit peak mechanical and thermal loads; incorporating the effects of magnetic saturation when selecting operating points for traction electric drives; using energy models for thermal control of transformers and optimisation of biogas units.

At the same time, the results should be interpreted within the limits of applicability: some of the tests were laboratory tests; the load variation range was ±15%; a frequency corridor of 50-60 Hz was considered for the assessment of losses; noise was assumed to be stationary; the configuration of the models was universal and may be inferior to specialised solutions for individual nodes. Further research should focus on adaptive identification of parameters during operation, extension of field validations to longer time horizons and other climatic conditions, increasing the range of diagnostic features (including multimodal data) and full-scale integration with PLC/SCADA platforms and cybersecurity tools.

ABSTRACT

Electricity is produced from variety of fossil and renewable sources and it is crucial that EVs have to be powered from renewables. With Electric Vehicle penetration, the combination of PV with EV drastically reduce our dependence on fossil fuel based electricity plants. The day to day power demand needed and anyone with a solar power system is likely to install a solar power charging station in their home in upcoming years. Solar power is variable as irradiance is changing during the day so to accommodate the changing irradiance MPPT algorithm has to switch or reach the maximum power point quickly. A GWO-PSO based MPPT is proposed in this paper and compared with P&O, PSO and GWO MPPTs and the hybrid GWO-PSO MPPT is used to charge the Electric Vehicle.

I. INTRODUCTION

India receives high levels of solar irradiance throughout the year due to its geographic tropical location, making it one of the most promising regions for harnessing solar energy. Government of India is encouraging solar energy through National Solar Mission with target of 450 GW by 2030. Many MW solar parks and Roof top solar panels are being subsidised to increase solar power generation. Solar power is produced when sun light hits a solar cell, the energy from the photons of light knocks electrons loose from their atoms. This produces an electric field, causing electrons to move across the cell enabling each cell to produce a little quantity of DC power [1]. Based on the requirement these solar cells are arranged in series or parallel which forms a PV array.

The sunlight is not uniform throughout the day. So the power produced form the solar cells changes with varying nature of sunlight. Hence a converter is needed to regulate the solar power output for obtaining a smooth supply. This converter operation is such that it also optimizes the power produced from the PV array using an MPPT controller. The block diagram of PV based EV charging system proposed in this work is shown in figure 1. This links a PV array to SEPIC Converter, a controller for switching on and off the converter and the EV battery as load.

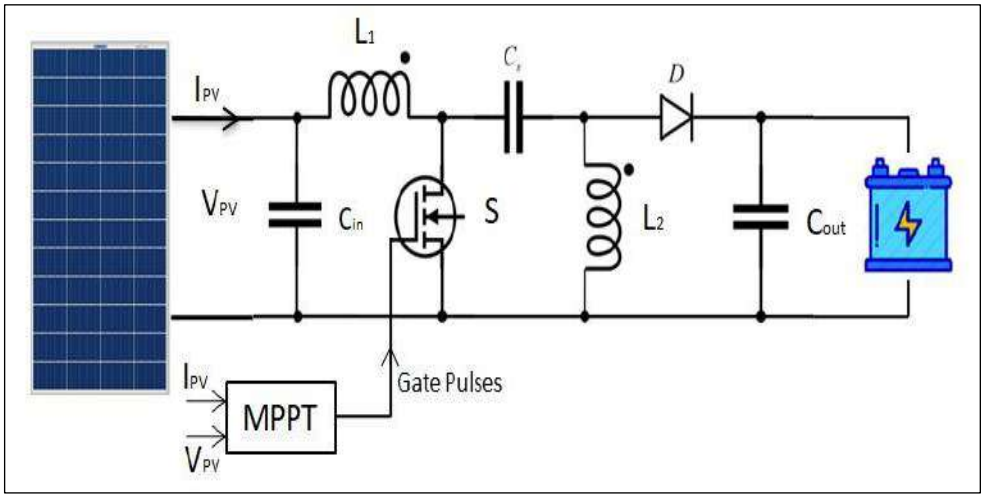

Figure 1: Block Diagram of PV based EV charging system.

II. MPPT METHODS FOR PV SYSTEM

There are two main types of MPPT techniques (1) Indirect MPPT techniques and (2) Direct MPPT techniques

II.1 INDIRECT MPPT TECHNIQUES

Indirect techniques are based on assumptions and periodic estimation of MPPT using simple measurements [2]. For instance, in the fixed voltage technique, the solar PV module is only adjusted according to the operating voltage at different times of the year [3] (i.e., winter, summer, etc.), with the assumption that the MPP voltages will be higher in the winter (cool period) and lower in the hot period i.e. summer when irradiation level is the same. This method is inaccurate because irradiation level and the temperature level changes in a season continuously. The next most commonly used indirect method is the Open Circuit Voltage (OCV) method. This can be obtained as

$$V_{MPP} = k\, V_{OC} \tag{1}$$

Where k is a constant often found to be between 0.7 and 0.8 for crystalline silicon.

This method is straightforward and easy to implement as compared to the other methods. The k constant is only an approximation, resulting in lower efficiency [4]. Every time when the illumination condition change, the system has to find a new open circuit voltages. To find this new open circuit operating voltage, the load on the PV module has to be disconnected, resulting in power loss. Compared to indirect methods, direct MPPT procedures are more exact and respond faster since they assess voltage, current, speed, or power. The block diagram for MPP Tracker as shown in the figure 2.

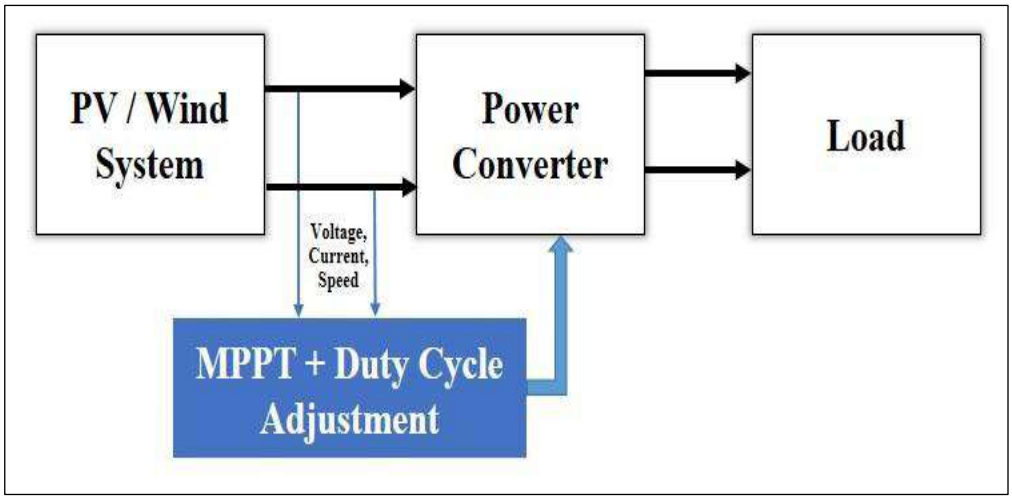

Figure 2: Block Diagram of MPP Tracker.
Source: Author, (2026).

II.2 DIRECT MPPT TECHNIQUES

Depending on the amount of sunlight, wind, and other factors, MPPT improves the efficiency of power extraction from renewable sources. By altering the load characteristics to run at maximum power, this maximizes system performance. In other words, it modifies the load characteristic according to the current circumstances [5]. To maximize the output, this method is connected to a converter. These are referred to as MPPT controllers or trackers.

An algorithm is used by an MPPT tracker to maximize the power produced. We use the Standard PV Test Conditions (STC) while testing renewable energy systems, however the system's operating conditions differ from the STC. Environmental variables including temperature, wind speed, and sunshine intensity affect how much power solar panels and wind turbines can produce. Maximum Power Point Tracking, or MPPT, is a crucial technology needed by solar and wind generating systems to maximize the power produced from sustainable energy sources. By using the maximum amount of power from the source, this technique ensures that the system operates as effectively as possible [6].

In MPP tracking the parameters like voltage, current, wind speeds are sensed from the renewable source and given to the MPP tracker. The tracker adjusts the load characteristic accordingly by using the duty-cycle of the power converter. This power converter then makes the system to operate at maximum value and feeds the load of the system. Perturb and Observe (P&O), Incremental conductance, PSO, GWO are the direct methods. In this work, P&O, PSO, GWO and GWO-PSO MPPT techniques are considered for PV based EV charging system for their simple operation and fast convergence.

III. PERTURB AND OBSERVE MPPT FOR PV SYSTEM

The most frequent, widely used, and straightforward MPPT algorithm is perturb and observe approach. This algorithm's implementation is affordable, reliable, and efficient [7].

The P&O method periodically perturbs the array's terminal voltage, that is, increases or decreases, and compares the solar power generated with that of the preceding perturbation cycle. The P&O algorithm starts by slightly changing the operating point (voltage or current) by decreasing or increasing from the current value. After the perturbation, the algorithm observe the resulting change in power output. It enumerates the change in power (ΔP) by comparing the new power output with the previous one, The perturbation is considered to have shifted the PV array's operating point closer to the MPP if the array's operational voltage shifts in a specific direction and $dP/dV > 0$.

The P&O algorithm would then disrupt the PV array voltage in the same way. The PV array was then moved away from the MPP if $dP/dV < 0$ because of the shift in operating point, and the P&O algorithm reverses the direction of the perturbation. The PV array operating point is shifted by the controller in a certain way if the operating voltage changes and the power increases, and in the opposite direction otherwise. The subsequent perturbation cycle follows the same procedure. P&O algorithm requires minimal computational resources but it may cause oscillations and drift when the irradiance and temperature changes quickly. To overcome this advanced algorithms is modified and implemented in this work. The duty cycle of the converter varies in the P&O approach by observing the voltage and power perturbation, i.e., either P & v both are greater than zero or $P < 0$ & $V > 0$ [8].

IV. PSO MPPT FOR PV SYSTEM

PSO involves a population-specific optimisation method modelled after fish or bird social structures. A population of possible solutions, or particles, traverses the search space in PSO. Based on its own experience as well as the experiences of its neighbours in the search space, each particle modifies its position [9].In PV systems, PSO aims to maximise the operating parameters as voltage and current. Each particle represents a possible solution for the operating parameters. The particles are initialised with random duty cycles, for each particle fitness is checked for the PV power. Particle positions are updated by taking into account both their neighbours' and their own best-known positions. When all the particles are completed, the best particle’s parameters are compared to maximum power [10].

Particle locations are updated repeatedly via multiple iterations until the converging requirement of maximum power is satisfied. If the maximum power point is reached, then the algorithm is said to be converged else it will change the phase of particles till the maximum power convergence is reached. The PSO algorithm continuously adjust the PV system's operating point, guaranteeing that it runs at its maximum power point in a variety of environmental circumstances. The efficiency and generation of energy produced by solar panels are increased due to this optimisation.

V. GWO MPPT FOR PV SYSTEM

Grey Wolf Optimisation is a metaheuristic optimization method which belongs to the class of algorithms inspired by nature and designed to mimic the group behaviors of social organisms. It was motivated by the social interactions of grey wolves [11]. The algorithm is meant to resemble the natural hunting and leadership structure of grey wolves. GWO involves leader grey wolves which are crucial to the basic concept of GWO. The remaining wolves, or search agents, are regarded as fellow pack members. The method searches for the best answer to a given problem by iteratively updating the positions of these wolves [12]. The time to reach the maximum power point is quick in GWO compared to PSO [13].

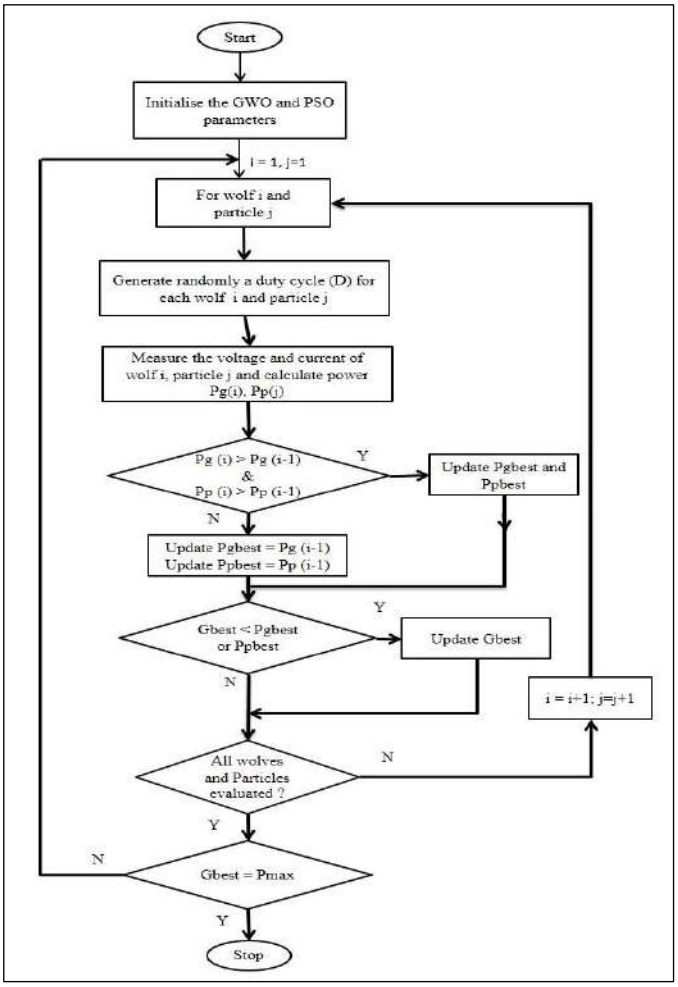

Figure 3: Flowchart of GWO-PSO MPPT.
Source: Author, (2026).

VI. GWO-PSO MPPT FOR PV SYSTEM

PSO MPPT has limitations such as Convergence during dynamic conditions and sensitive to parameters like inertia weight and social coefficient. GWO has limitations like balancing exploration during dynamic conditions, these limitations can be mitigated by using hybrid GWO-PSO MPPT. The flowchart of hybrid MPPT is shown in figure 3.The parameters of GWO, PSO with PV panel's maximum values is initialized and the hierarchy of wolves are generated according to the readings from the panel. Similarly PSO particles are initalized and Pbest is found. For each wolf the power is assessed and it is compared with the pack best solution.

Now the positions of Particles and wolves are combined and new power is reached. If this new power is equal to maximum power the algorithm stops else the wolves are iterated again with updated position till the convergence of maximum power occurs. When the wolves locate the MPP, the associated coefficient vectors are almost equal to zero. The algorithm placed in a Simulink block for testing the PV system with GWO MPPT technique. The above MPPT techniques are tested with Matlab/Simulink code for PV based EV charging system which is discussed in the next section.

VII. TESTING OF PV BASED EV CHARGING SYSTEM WITH MATLAB/SIMULINK

All the proposed MPPT techniques with PV based EV charging system is tested with MATLAB/Simulink Environment and the simulation model is shown in figure 4 and the parameters used in simulation are given in Table 1.

Table 1: Parameters of PV based EV charging system.

PV ARRAY		**Battery**	
Parameter	**Value**	**Parameter**	**Value**
Open Circuit Voltage (V_{OC})	36.6V	Nominal Battery Voltage	24 V
Short Circuit Current (I_{SC})	8.75A		
Voltage at MPP (V_{mp})	30.86V	Rated Ah Capacity	50 Ah
Current at MPP (I_{mp})	8.1A		
Maximum Peak Power of PV Array	2000 W	Initial SoC	50 %
Temperature	250 C		

Source: Author, (2026).

In the simulation model, the inputs to PV array block is irradiance and temperature. The irradiance input is provided using constant block for fixed input and using a staircase generator for variable input. The parameters of PV array is initialised to MPPT block. The MPPT algorithm is coded in this block and it provides gate signals to the switch of DC-DC converter. The power from PV is given to EV load through SEPIC converter and the charging parameters are observed. Simulink model of PV based EV charging system is tested at standard test conditions of 1000 w/m2 irradiance and 250 C with P&O, PSO, GWO and GWO-PSO MPPT techniques, the corresponding PV power output waveforms are shown in figure.

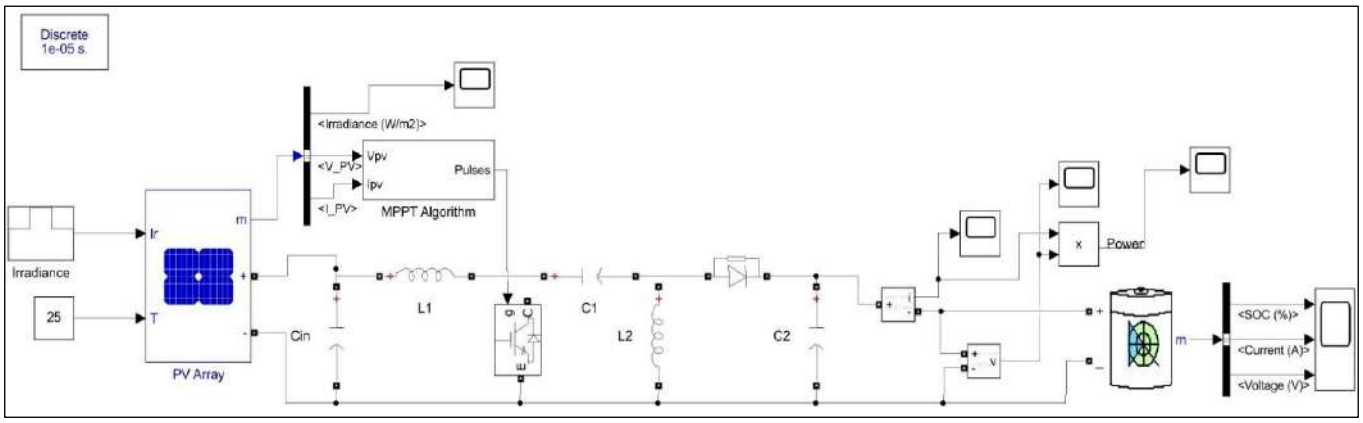

Figure 4: Simulink Model of PV based EV charging System.
Source: Author, (2026).

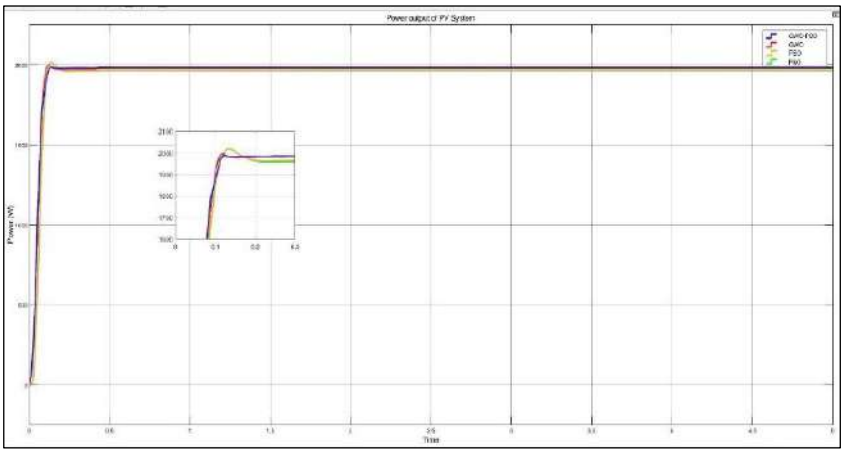

Figure 5: PV Power output under standard test condition.
Source: Author, (2026).

From the figure, it is observed that the power output with different MPPT techniques. Blue represents power with GWO-PSO, red represents power with GWO, gold represents power with PSO and green represents power with P&O and the corresponding numerical values are shown in the table 2. At standard test conditions all the MPPT techniques are having similar output. So the system is tested for variable irradiance conditions. As the irradiance increases from morning to noon and decreased from noon to evening. This variable irradiance is given by using a staircase generator changing from 500 W/m^2 to 800 W/m^2, 800 W/m^2 to 1000 W/m^2, 1000 W/m^2 to 800 W/m^2, 800 W/m^2 to 500 W/m^2 at the instants 1, 2, 3 and 4 respectively which is shown in the figure 6 with the temperature of 25^0 C and the corresponding power output is shown in figure 7.

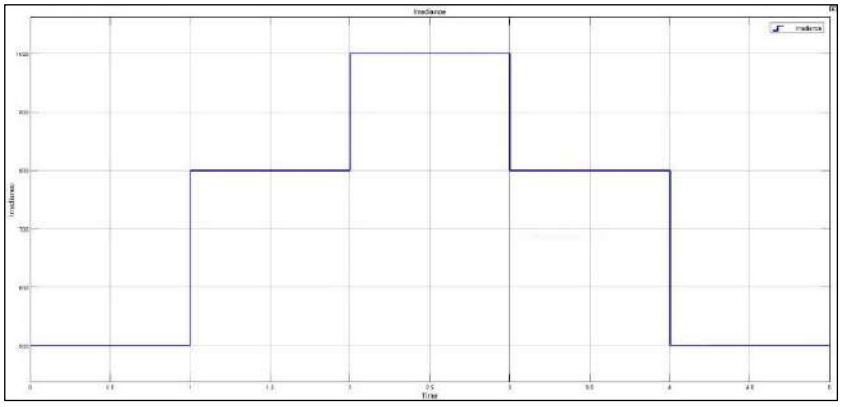

Figure 6: Variable Irradiance input.
Source: Author, (2026).

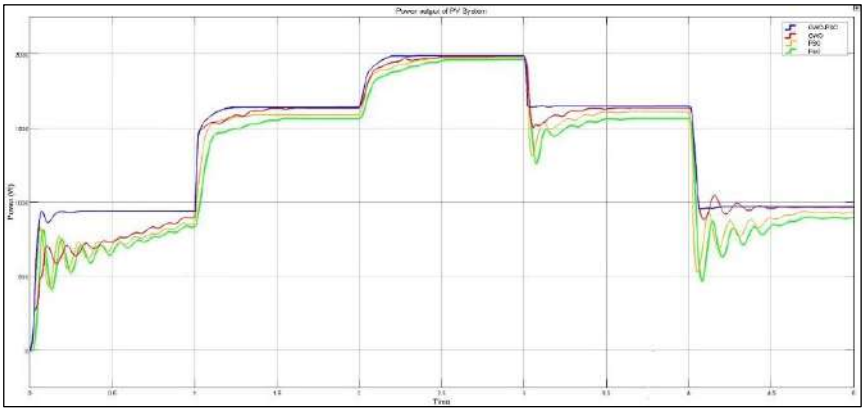

Figure 7: PV Power output under variable irradiance.
Source: Author, (2026).

From the figure 7, the power output of the PV System and time of reaching maximum power point with P&O, PSO, GWO and GWO-PSO at variable irradiance and the corresponding test results are tabulated in Table 2.

Table 2: Comparison of Power output of PV based EV charging system.

Irradiance (W/m^2)	Power Output (W)				Time taken to reach MPP (sec)			
	P&O	PSO	GWO	GWO-PSO	P&O	PSO	GWO	GWO-PSO
500	872	880	894	908	0.94	0.94	0.94	0.3
800	1628	1642	1664	1672	0.59	0.38	0.61	0.22
1000	1972	1984	1988	1990	0.51	0.46	0.45	0.22

Source: Author, (2026).

From the table 2, it is observed that GWO-PSO MPPT method is reaching maximum power point faster when the irradiance is changing as compared to other MPPT Techniques. Therefore, GWO-PSO MPPT is applied to PV system and tested under variable irradiance condition for analysing the SOC of EV battery. Further, GWO-PSO MPPT is applied to PV system and EV Battery and tested under variable irradiance condition. SOC represents the percentage of rated capacity left in the battery. While charging SOC of battery increases and it gets decreased during discharging. From the above analysis, the SOC, Voltage and Current of EV battery is shown in figure 8.

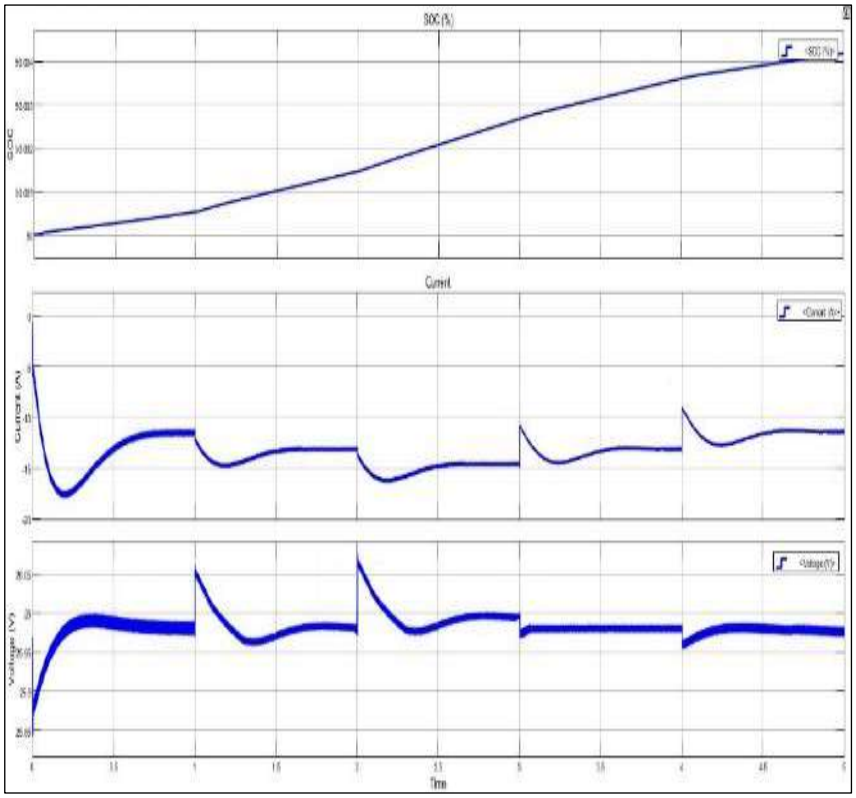

Figure 8: SOC, Current and Voltage of EV Battery.
Source: Author, (2026).

From the figure, it is observed that the SOC is increasing and the current is in negative magnitude, so the system is in charging state. The charging current and SOC slope got changed with changing irradiance.

VIII. CONCLUSIONS

In this paper, a charging system for Electric Vehicles based on PV power with SEPIC converter is discussed and tested in MALAB/Simulink environment with P&O, PSO, GWO and GWO-PSO MPPT Techniques under STC and variable irradiance. It is observed that of all the four techniques the GWO-PSO MPPT technique is reaching the MPP faster with better output magnitude.

ABSTRACT

In modern database systems, query workload optimization through materialized views is crucial for achieving high performance. This paper introduces a novel intelligent framework that identifies frequent subexpressions from SQL workloads, selects candidate materialized views, and predicts their potential benefits using a Deep Neural Network (DNN) model.Unlike existing static heuristic methods, our approach adopts a dynamically learning mechanism with proper determination of properties required for effective views in line with distributed workloads and predicate normalization. By excluding an extra step needed in choosing views or query rewriting, query execution is reduced with the proposed framework, as illustrated in existing experimental results of proposed methods in comparison with existing ones.

I. INTRODUCTION

Query optimization has been one of the crucial challenges in relational database systems. Materialized views store precomputed outcomes of intermediate results to avoid redundancies and consequently give responses to queries considerably faster. However, the problem of selecting which views to materialize-especially under storage-constrained budgets and dynamic workloads-remains complex and crucial. Traditional static MV selection techniques, including those based on cost models or fixed heuristics [1], [2], inherently assume a stable workload and predictable query patterns. These assumptions hold hardly in modern environments, where workloads, data distributions, and system resources change dynamically.As a result, most of the static approaches yield suboptimal views or are not able to adapt to newly emerging access patterns, which would have been wasted in storage and undermined the potential performance gains.

Recent breakthroughs in deep learning methods, represented by large language models like GPT, have pointed out remarkable transformative potential over natural language processing, decision-making, and intelligent automation. Influenced by this trend, database systems are now becoming self-tuning, adaptive systems. Materialized view selection can then be framed as a dynamic, data-driven optimization problem using predictive machine learning models. Our contribution embraces this shift by integrating deep learning into the database optimization pipeline to enable workload-aware, adaptive MV selection. Prior research has explored machine learning for join order optimization [3], [4] and query cost estimation; application of deep learning for materialized view selection remains underexplored.

Key challenges - effective feature representation, accurate benefit estimation, and adaptability to workload changes - make these approaches challenging to adopt in practice.This paper proposes a two-tier adaptive approach to the selection and rewriting of materialized views. The proposed strategy systematically analyzes SQL workloads to detect and group frequently occurring subexpressions using normalized join and selection predicates. A DNN model predicts the utility of the candidate views, along with structural properties combined with runtime and storage cost considerations. Given the embedding of machine learning into the query-processing pipeline, our framework dynamically adapts to the continuously evolving workloads while it optimizes query performance at a minimal storage overhead.

II. LITERATURE REVIEW

The problem of materialized view (MV) selection has evolved drastically in recent years. In the past, MVs were manually or statically selected through heuristics that targeted repeated or expensive queries [5-7], [2]. However, these early approaches were unable to adapt dynamically to evolving workloads. With the advancement of database systems, dynamic heuristics based on query frequency, selectivity, and join ordering were developed [8-10], [1] though they still faced scalability and flexibility challenges.

Today, the advent of machine learning has revolutionized MV selection through adaptive approaches such as supervised learning, clustering, reinforcement learning, and deep neural networks [11-13], [4]. These approaches leverage historical workloads and data distributions to predict candidate view benefits, thereby improving the accuracy and responsiveness of MV selection.

Techniques like Q-learning, artificial neural network (ANN) prediction, and multi-objective optimization [1] have further enhanced real-time materialized view management by being both cost-efficient and scalable. Alongside these advances, developments in query optimization techniques—such as data representation methods (e.g., histograms [14], sketches [15]), sampling methods (e.g., Fixed-step [16], Bifocal [17]), and machine learning-based cost estimation and cardinality models (e.g., MSCN 18], QuickSel 19], RSPN - [20])—have significantly increased the quality of query planning and execution in large-scale systems. As part of this broader evolution, AutoView [21] demonstrates significant progress in MV management. It integrates query plan-based candidate generation, deep query–view correlation modeling, and deep reinforcement learning for space-budget-aware MV selection.

Unlike earlier systems, which struggled with static, non-adaptive approaches [11], [4], [15], AutoView achieves improved automation, generalization, and optimization capabilities for cloud-scale database paradigms. However, AutoView also inherits some limitations typical of learning-based systems: it requires an initial training session with standard workloads; it may require retraining if workloads change drastically; the deep model's decision-making process may not be as interpretable as that of heuristic-driven approaches; and migrating the model between different database management systems typically necessitates retraining due to variations in query plans and cost models. Figure 1 presents a structural comparison of RLView (Reinforcement Learning) [4], DQM (Deep Q-Learning) [11], and AutoView [3] approaches for materialized view selection.

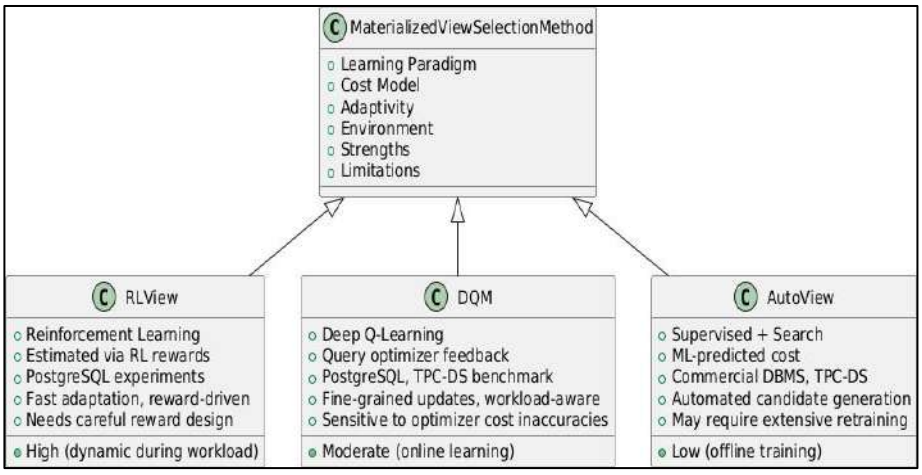

Figure 1: Comparison of some recent methods relative to queries optimization.
Source: Authors, (2026).

Table 1: Comparison of Some recent Learning-Based MVS Methods.

Method	Learning Type	Adaptivity	Training Time	Example Use
RLView [4]	Reinforcement Learning	High	Online	Dynamic workloads
DQM [11]	Deep Q-Learning	Moderate	Online	OLAP queries Static
AutoView [3]	Supervised + Search	Low	Offline	workloads

Source: Authors, (2026).

As shown in Table 1, RLView, DQM, and AutoView represent distinct approaches to materialized view selection. These methods are designed to handle different kinds of workloads, with RLView and DQM being more adaptive to dynamic workloads, while AutoView works effectively on static workloads with offline training. In summary, the evolution of MV selection research across different periods has steadily contributed to the development of increasingly efficient, scalable, and adaptive solutions, addressing the complexities of large, dynamic query environments.

III. PROBLEM STATEMENT

Given a large workload set of SQL queries $Q = \{q_1, q_2, \ldots, q_n\}$, and a set of candidate materialized views $V = \{v_1, v_2, \ldots, v_m\}$ generated from common subexpressions and shared predicates. The goal is to select a subset $V^* \subseteq V$ that maximizes the overall query performance improvement defined as:

$$\text{Benefit}(V^*) = \sum_{q_i \in Q} (T(q_i) - T'(q_i, V^*)) \quad (1)$$

Where $T(q_i)$ is the execution time of the original query and $T'(q_i, V^*)$ is the execution time after rewriting the query using the selected materialized views. The selection must also satisfy a storage budget constraint, where B denotes the available storage space.

$$\text{Cost}(V^*) = \sum_{V_i \in V^*} (size\ (v_i) \quad where\ \ \text{Cost}(V^*) \leq \text{B} \tag{2}$$

The global optimization problem goal is to choose a materialized view set V^* that improves query performance without using more than storage capacity (minimizing resource consumption). Maximizing Benefit (V^*) works towards minimizing query execution time by choosing views that decrease query execution time. On the other hand, minimizing Cost(V^*) ensures that the views chosen do not use too much storage fee.

$$V^* = \text{Arg} \max_{V^* \subseteq V'} ((W_1 \cdot \text{Benefit}(V') - W_2 \cdot \text{Cost}(V')) \ subject\ to \sum_{V_i \in V^*} (size\ (v_i) \leq \text{B} \tag{3}$$

The weights w_1 and w_2 aim to balance the trade between query speed optimization and storage management. The weights can be optimized depending on whether query speed or storage is more important in the specific situation. The objective is to develop a system that intelligently selects the most beneficial materialized views under storage limitations and speed up workload execution. Table 2 presents an example to clarify the functionality of our formulation. We assume that the system selects three candidate materialized views and a storage budget of 9 GB. The optimal subset of condidate materialized views set under this storage budget is $\{ V_1, V_2 \}$,which provides the maximum total benefit of 40 ms while satisfying the storage constraint.

Table 2: Example of Materialized View Selection.

Subset V′	Total Size (GB)	Total Benefit (ms)	Feasible for selection as condidate for Materialization?
$\{ V_1 \}$	5	20	Yes
$\{ V_2 \}$	4	18	Yes
$\{ V_3 \}$	6	25	Yes
$\{ V_1, V_2 \}$	9	40	Yes
$\{ V_1, V_3 \}$	11	45	No (over budget)
$\{ V_2, V_3 \}$	10	43	No (over budget)

IV. PROPOSED APPROACH

In this work, we present an intelligent two-stage strategy for materialized view (MV) selection and query rewriting to optimize the performance of large-scale SQL workloads.The system architecture overview is illustrated in Figure 2. The pipeline of our system inspired by the traditional query processing : Parsing, optimization, and execution,with the integration of machine learning techniques in optimization stage. Specifically, an artificial neural network (DNN) is employed to predict the utility of candidate views to optimize large workload of queries.

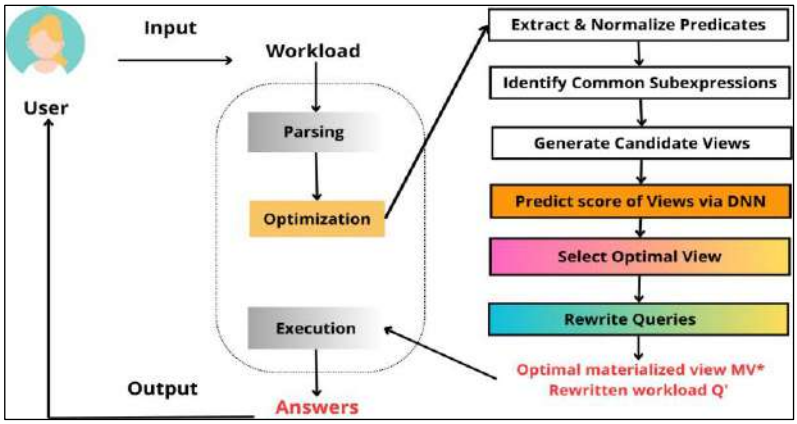

Figure 2: Overview of the Materialized View Selection Framework.
Source: Authors, (2026).

IV.1 WORKLOAD PARSING

Our system starts by parsing the SQL workload input and processing each file separately. For each query, it gives a unique ID and then parses and analyzes the query to identify its structure. Specifically, it extracts the tables involved, the join conditions between them, and the selection predicates from the WHERE clause. These extracted elements are placed in global collections such as *All_Join_Predicates* and *All_Selection_Predicates*. At the same time, the system keeps track of which predicates and tables appear in each query. This information is important for future steps where we need to identify common subexpressions across queries to suggest useful materialized views.

IV.2 IDENTIFYING COMMON SUBEXPRESSIONS

After extracting tables, the join predicates and the selection predicates are identified, which are then normalized and grouped globally. Systematically extracts subexpressions from each query by focusing on join conditions, predicates, and selected attributes. We normalize these entities to enable apples-to-apples comparison by eliminating aliases, normalizing attribute order, and abstracting con- stant values. This enables us to structurally compare subexpressions, rather than syntactically. We employ a hashing mechanism to count the frequency of each unique subexpression across the entire workload ,as shown in Figure 3 Frequent subexpressions are marked as common and are strong candidates for reuse or materialization during the query optimization process.

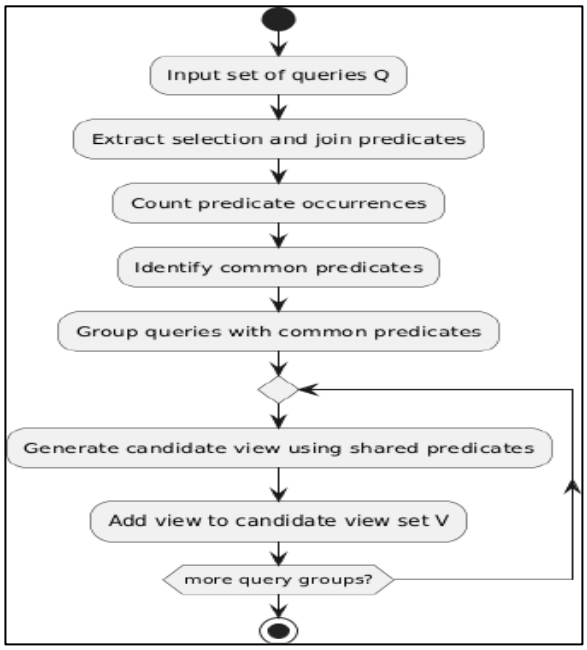

Figure 3: Diagram of views clustering.
Source: Authors, (2026).

IV.3 GENERATING CANDIDATE VIEWS BASED ON PREDICATES

To generate views from grouped queries with the common predicates, the process starts by combining common selection predicates into a single WHERE clause, eliminating redundant filtering. Next, common join predicates are merged into the JOIN condition of the query in an effort to reduce redundant join operations. Columns utilized in the view are based on fields queried most frequently in the group so that the view has only the most critical data. The outcome of this step is a set of candidate views.

IV.4 GENERATING CANDIDATE VIEWS BASED ON PREDICA OPTIMIZATION USING DNN

Once common predicates are identified and normalized,and candidate views are generated , in the first stage of our system we employ a Deep neural network (DNN) architecture to predict a benefit score of views, indicating how much a materialized view would improve query performance (See Figure 4).

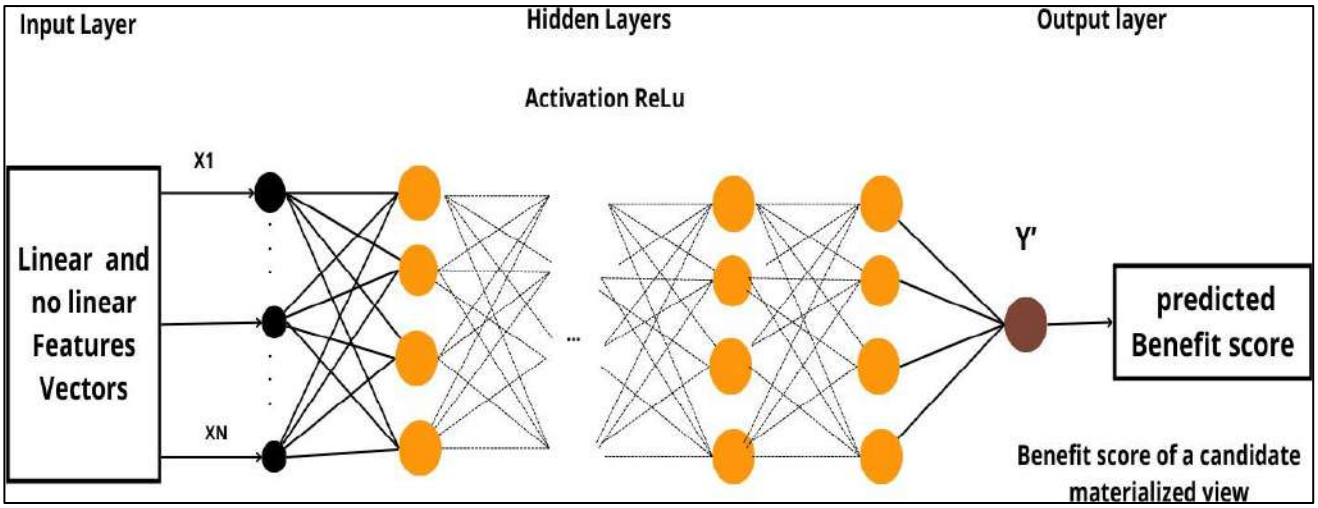

Figure 4: Deep Neural Network architecture for benefit score prediction of candidate materialized views.
Source: Authors, (2026).

The proposed deep neural network (DNN) is intended to predict the benefit score corresponding to each candidate materialized view by learning from both structural and statistical properties of the query workload. The input layer takes a preprocessed feature vector x_input, which conveys information about join types, selection predicates, past query execution times, storage costs, and query frequency. Linear features like execution time, storage cost, and query frequency are normalized using Min-Max normalization to maintain numerical stability, and non-linear features, such as join types, predicates, and operators, are represented using one-hot encoding.

After encoding, all features are stacked together into a unified input vector that conveys comprehensive workload information. The network design involves multiple fully connected hidden layers. The first hidden layer uses dense neurons with a Rectified Linear Unit (ReLU) activation function to inject non-linearity and facilitate the learning of complex patterns. A second hidden layer is used, along with a dropout layer to combat overfitting and enhance generalization. The activation functions of the hidden layers are calculated as:

Activation function

$$h^l = \mathrm{ReLU}\left(W^l h^{l-1} + b^l\right) \tag{4}$$

Where W^l and b^l are the weight matrix and bias vector of the l-th layer, respectively.The output layer consists of a single neuron with linear activation, producing a continuous value that represents the predicted benefit score of a candidate materialized view. This score is computed as :

Predicted benefit score

$$y' = \sum_{i=1}^{d} (W_i h_i + b) \tag{5}$$

Where h_d denotes the output of the final hidden layer and i is the number of hidden neurons feeding into the output neuron. During training, the model minimizes the Mean Squared Error (MSE) between the predicted benefit scores and the observed improvements in query execution time. This training strategy enables the model to generalize effectively to unseen queries and to accurately rank candidate-materialized views based on their expected performance gains.

IV.5 GENERATING CANDIDATE VIEWS BASED ON PREDICA OPTIMIZATION USING DNN

In the second stage of our system, the operation begins by checking newly arriving SQL queries to determine if their join or selection predicates may be optimized by candidate materialized views. If it is found that such predicates are found in materialized views already in place, a procedure known as predicate matching, the original queries are rewritten such that the affected parts are substituted by the correspond created to contain the shared semantics. The queries are partitioned and rewritten, each to use the new common materialized view. The performance of the rewritten queries is compared with the original queries to measure the improvement. This evaluation feedback is subsequently used to refine and optimize materialized view selection algorithms, generating a cycle of adaptive performance tuning (See Figure 5).

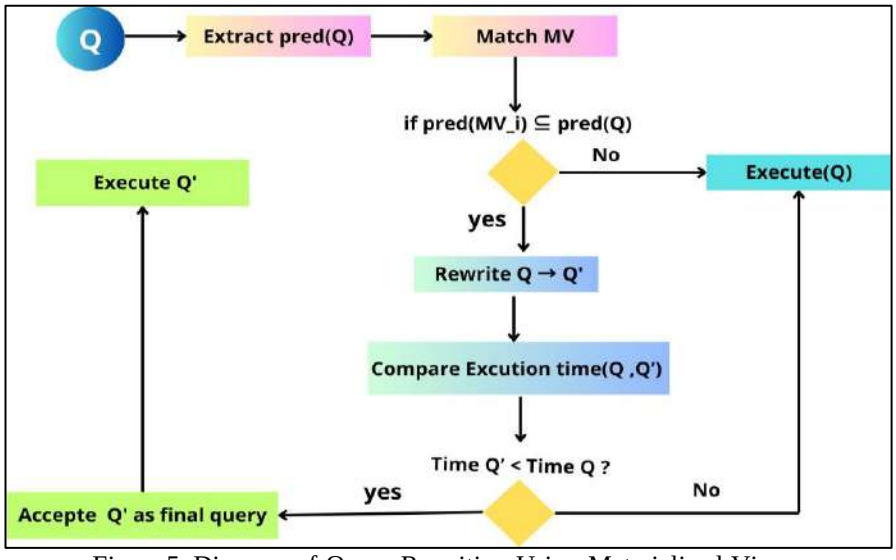

Figure 5: Diagram of Query Rewriting Using Materialized Views.
Source: Authors, (2026).

V. EALUATION AND RESULS

All our evaluations were conducted on a computer equipped with an Intel i7, 16.00 GB of RAM, and a 64-bit Windows operating system. To evaluate the performance of the proposed method, we used PostgreSQL as DBMS, and the implementation was carried out using Python 3. In our experiments, we used the schema of the relational database IMDb dataset [22] with 21 tables and a workload of SQL queries from Join Order Benchmark (JOB) [23].

IMDb has over 21 million rows, ranging in size from a few thousand to a few million rows per table. The JOB workload consists of 113 SQL queries that are designed to test combinations of join and selection predicate. The results can be followed as a progressive walkthrough of our experiments. Table 3 and its visualization in Figure 6 show the initial heuristic mapping of queries into candidate materialized views, where structurally similar queries such as Q22, Q29, and Q72–Q75 were grouped under MV4. While this clustering revealed repeated subexpressions, it often failed to capture the most beneficial views.

Table 3: Workload Mapping results without DNN Learning.

MVID	MV Related Queries ID
1	[Q10, Q13]
2	[Q11, Q12]
3	[Q21, Q24]
4	[Q22, Q29, Q72, Q73, Q74, Q75]
5	[Q52, Q54]
6	[Q48, Q49]
7	[Q87, Q88, Q89]
8	[Q90, Q91, Q92]
9	[Q96, Q98, Q100]
10	[Q97, Q99]
11	[Q45, Q46, Q47]
12	[Q26, Q27, Q28, Q30]
13	[Q82, Q83]

Source: Authors, (2026).

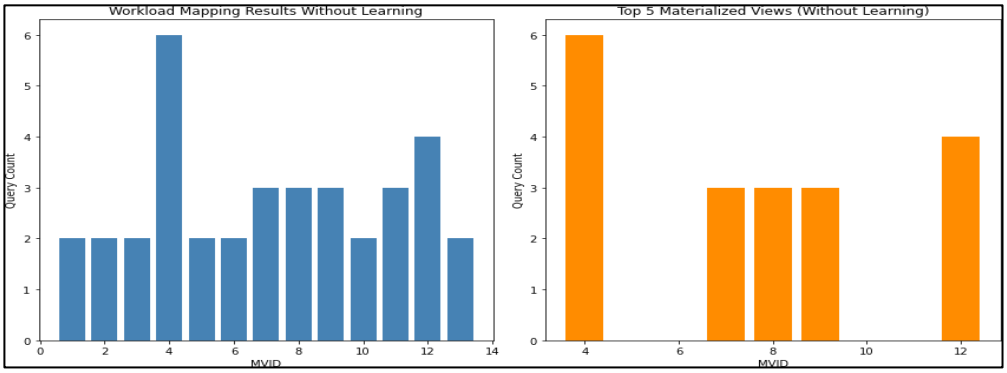

Figure 6: Workload Mapping Results Without Learning (Heuristic mapping method).
Source: Authors, (2026).

Moving to Figure 7, the DNN-based mapping demonstrates a more refined grouping, as the model adaptively selected views that provided higher performance gains while reducing redundancy, and also built a mapping dictionary that included statistical information such as tables occurrence and common subexpressions including join predicates. During evaluation, we compared a medium- sized neural network against a deeper neural network architecture.

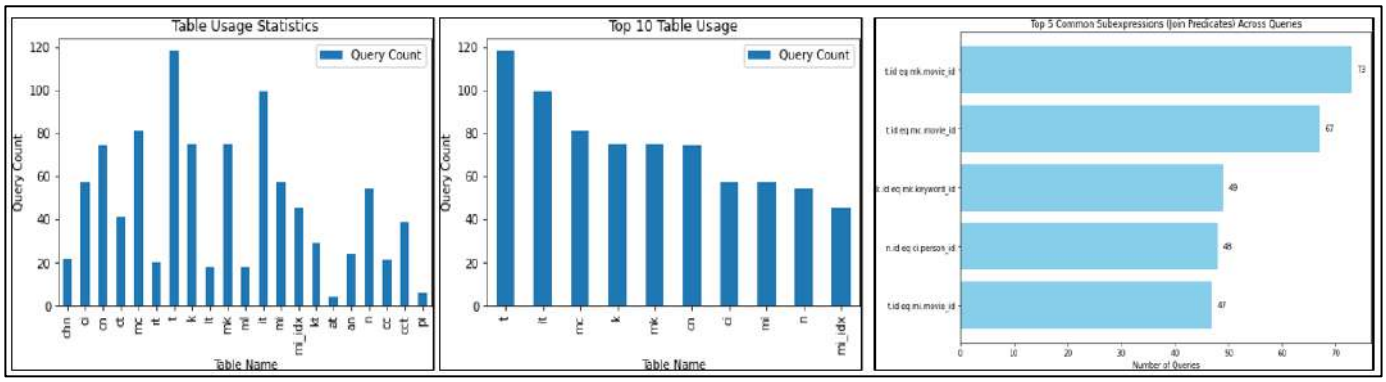

Figure 7: Workload Mapping Results using DNN Approach.
Source: Authors(2026).

As shown in Figure 8, the deeper model achieved a more pronounced reduction in loss, indicating superior generalization to unseen queries. However, this improvement came with slightly higher resource consumption, reflecting the classical trade-off between accuracy and computational efficiency.

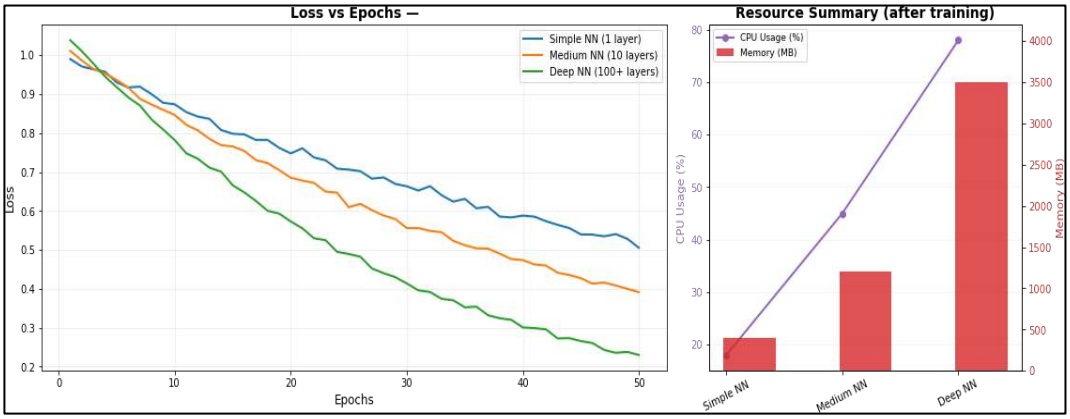

Figure 8: Loss Reduction Resource Usage summary Across Learning Levels for MV selection.
Source: Authors, (2026).

As a result, Figure 9 highlights the final set of materialized views chosen after DNN learning, with MV3 and MV4 emerging as particularly beneficial due to their balance of query coverage and storage efficiency. Finally, Table 4 quantifies the improvements by comparing execution times: queries such as Q74 and Q45 executed **30–35% faster** with DNN-based views than with heuristic methods. This sequence of results illustrates how our framework evolves from static heuristic clustering to intelligent, learning-driven optimization that consistently accelerates query performance under storage constraints.

Table 4: Comparison of Query Performance with Different MV Selection Strategies.

Query ID	Heuristic static method (ms)	DNN (ms)
Q22	600	**420**
Q29	810	**590**
Q45	500	**360**
Q74	1050	**960**
Q98	1120	**820**

Source: Authors, (2026).

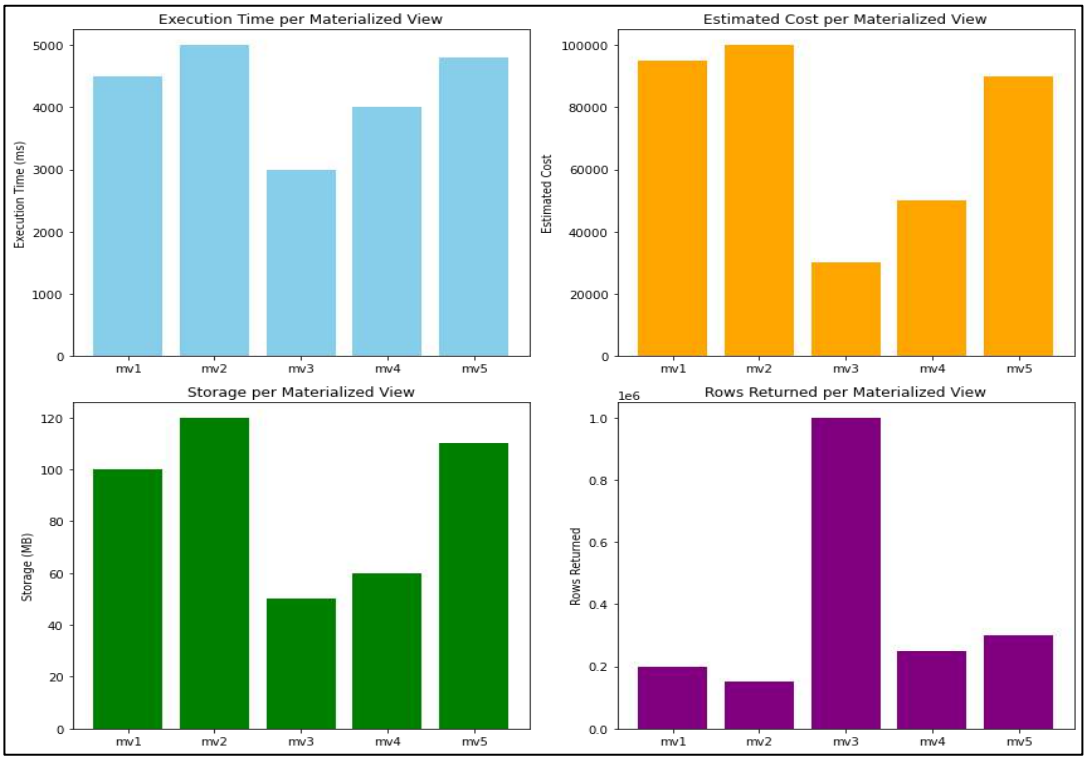

Figure 9: Summary of beneficial Materialized Views after DNN Learning.
Source: Authors, (2026).

Our experiments show that the proposed DNN-based method improves query execution time over the static heuristic model, proving that learning-based benefit prediction is more effective than heuristic rules. While actual methods like RLView, DQM and the AutoView system have advanced adaptive view management, they often require complex retraining. Our contribution is simpler but complementary a lightweight DNN regression model that balances performance and storage efficiency, and can be easily applied in real systems such as PostgreSQL.

V. CONCLUSION

This paper proposes an approach to selecting materialized views (MVs) and query optimization for improving big SQL workload performance. Using a deep neural network (Deep-NN), our approach correctly predicts the benefit of candidate MVs, optimizing query performance with storage management. Evaluations of our algorithms on the IMDb schema and JOB benchmark queries showed that the DNN-based approach performed better than static traditional methods by reducing query execution time and improving storage efficiency. MVs like MV3 and MV4, selected according to our smart model, demonstrated significant performance with low storage consumption.

Our findings also indicate that shorter execution times do not necessarily translate to lower storage costs. Some perspectives, even though they processed more rows, still had good performance, indicating that our model successfully balances speed and storage. These results validate the utility of learning in optimizing MV selection for dynamic query environments. Future development will be aimed at improving the DNN model, incorporating additional query features, and making the system capable of dealing with more complex dynamic workloads.

ABSTRACT

The aim of the study was to substantiate the effectiveness of an intelligent system for automated design of energy-efficient facilities in the agro-industrial complex (AIC) with integrated diagnostics of electric drives. The methodology included experimental testing of asynchronous electric motors, numerical modelling, and optimization. Data analysis was performed using Student's t-test, analysis of variance, and principal component analysis. The results showed that in faulty electric motors, the current increased by 20%, the power factor decreased from 0.87 to 0.74, the vibration level exceeded that of serviceable samples by three times, and the temperature of the windings increased from 65 to 92 degrees Celsius. Numerical modelling showed a 9% reduction in energy consumption, a 17-degree Celsius decrease in temperature, a 16% increase in power factor, a 47% reduction in vibrations, and an increase in efficiency from 85 to 92%. Statistical analysis confirmed the reliability of the results, and the "serviceable/damaged" classification model achieved high accuracy with an area under the curve of 0.94. The scientific novelty lies in the first-ever combination of structural optimisation of electric drive parameters with built-in technical condition analysis in a single CAD/FEM environment.

I. INTRODUCTION

The development of the agro-industrial complex (AIC) in the 21st century is determined by the need to improve the energy efficiency of technological processes and the reliability of electromechanical systems that ensure the functioning of production. The growth in energy consumption, combined with limited resources, requires the implementation of innovative solutions aimed at optimising technical facilities and reducing operating costs. Particular attention should be paid to the timely diagnosis of faults in electric drives, which are key elements in many technological processes of agricultural production. The lack of effective control systems leads to emergency shutdowns, increased repair costs and reduced productivity. Thus, the creation of intelligent automated design systems capable not only of ensuring energy efficiency but also of integrating diagnostic functions is an important task for modern science and technology.

The problem of energy losses in agricultural electric drives is their low efficiency in dynamic operating modes when the load and frequency of starts change. According to [1], [2] showed that traditional methods of efficiency assessment are limited to average characteristics and do not take into account the variable conditions in which the equipment actually operates. Their research revealed the shortcomings of existing monitoring systems, in particular the low accuracy of detecting hidden defects, which leads to untimely detection of malfunctions. However, these works did not develop a comprehensive approach to the integration of energy and diagnostic parameters. An important aspect of electric motor operation is the increase in winding temperature, which shortens the service life of the equipment and increases the risk of accidents.

In [3], [4] pointed out that standard cooling systems do not always correspond to the intensity of thermal processes, especially under overload conditions. Their studies used thermometric assessment methods to identify critical overheating zones. However, the limitation of these works was the lack of a connection between temperature indicators and other energy efficiency parameters, which reduces the practical value of the results obtained. A significant problem is the increased level of vibration, which not only worsens performance but also causes additional energy losses. According to [5], [6] investigated the spectral characteristics of vibrations in different engine operating modes and proposed algorithms for their identification. Their approach proved to be highly effective for diagnosing certain types of defects, but it remained insufficiently consistent with electricity consumption indicators. This indicates the need to create more universal analysis models that integrate vibration data with energy characteristics.

Equally important is the problem of reducing the power factor, which directly affects the energy consumption of enterprises. Chen and Hu [7], [8] substantiated the possibility of compensating for reactive power by optimising electric drive control circuits. Experimental results confirmed a 10-12% increase in the power factor, but the proposed approaches proved to be ineffective in cases of complex dynamic processes, when temperature and vibration factors simultaneously affect the system. This limits the applicability of the results in complex production systems. Another pressing problem is the lack of predictive maintenance methods capable of preventing equipment failure at an early stage. According to [9], [10] proposed the use of mathematical models based on regression analysis to estimate the probability of failure. Despite their practical significance, such approaches have demonstrated low accuracy in cases of multifactorial influence, which is characteristic of agro-industrial conditions. This has demonstrated the need for more complex intelligent algorithms that can work with a large number of variables.

In the context of the digitalisation of production processes, the issue of integrating data from different sensor systems is becoming increasingly relevant. According to [11], [12] have developed platforms for collecting information from multiple measurement channels, which has significantly improved the quality of technical condition monitoring. However, the studies did not implement algorithms for optimising designs based on the collected data, which limited the impact of the results on improving the energy efficiency of facilities. Thus, the issue of the comprehensive application of sensor technologies and optimisation methods remains open. The problem of high operating costs caused by frequent equipment repairs is particularly relevant for small and medium-sized agricultural enterprises. In [13], [14] showed that most malfunctions occur due to the untimely detection of hidden defects in electric drives.

Their works proposed methods for scheduled maintenance at fixed intervals, but they did not take into account the actual technical condition of the equipment. This led to unnecessary resource consumption and highlighted the need to transition to intelligent systems with predictive capabilities. Equally important is the problem of the complexity of numerical modelling, which requires significant computing resources and time. In [15], [16] developed models based on the finite element method, which allowed to obtain detailed results on the distribution of fields in motors. However, the use of such models in real time proved impossible due to their excessive complexity. This creates a need for simplified but sufficiently accurate algorithms that can be integrated into automated design systems.

A summary of the studies conducted indicates significant scientific interest in the problem of improving the energy efficiency and reliability of electric drives, but most existing solutions focus only on individual aspects, which reduces their practical value for the agro-industrial complex. The task of integrating energy, thermal, vibration and other parameters into a single intelligent automated design system is becoming obvious. In this context, the aim of the study was to prove the effectiveness of an intelligent automated design system for energy-efficient facilities in the agro-industrial sector with built-in diagnostics of electric drives. The research tasks included experimental determination of diagnostic parameters, numerical modelling of energy processes, application of optimisation algorithms and statistical verification of the reliability of the results obtained.

II. MATERIALS AND METHODS

The research was conducted in Ukraine in 2022-2024 at the National University of Life and Environmental Sciences of Ukraine, Department of Automation and Robotic Systems, using a testing ground for agricultural machinery. The object of the study was an intelligent system for the automated design for energy-efficient facilities of the AIC with an embedded diagnostic module for electrical machines. The system was developed as an integrated platform combining machine learning algorithms, mathematical optimisation methods and a set of hardware and software tools for measuring and analysing the technical condition of electric drives. For experimental testing, asynchronous electric motors of the AIR90L2 model (Siemens, Germany) with a power of 1.5-7.5 kW at a rated voltage of 380 V were used, as well as modular load stands with the ability to adjust the torque up to 25 N·m. Six AIR90L2-M-2 asynchronous motors were used for experimental research, three of which were in good working order, and three were deliberately damaged to simulate defects.

The damage was caused by disrupting the balance of the rotor by shifting the axis of rotation, weakening the bearing assemblies to simulate mechanical wear, and local damage to the winding insulation with the formation of interturn short circuits. One of the samples contained a combined form of defects, which made it possible to study the cumulative effect of disturbances on the main diagnostic parameters. The tests were carried out in laboratory conditions at a temperature of 20±2°C and a relative humidity of 60±5%. Each experiment was repeated at least three times to increase the reliability of the results, after which the results were averaged and compared with theoretical predictions.

The computational part of the system was based on a Dell Precision 3650 Tower (USA) workstation with an Intel Core i9-11900K processor, 64 GB of RAM, and an NVIDIA RTX A4000 graphics adapter. The software included MATLAB R2022a (MathWorks, USA) for implementing optimisation and energy consumption modelling methods, AutoCAD 2023 (Autodesk, USA) for constructing structural models, Python 3.10 with TensorFlow 2.10 and Scikit-learn 1.1 libraries for building neural networks and failure classification algorithms. COMSOL Multiphysics 6.0 (COMSOL, USA) was used to simulate physical processes, providing multiphysics modelling of thermal and electromagnetic fields. Experimental measurements of parameters were performed using a Fluke 435-II power quality analyser (Netherlands), which allowed recording instantaneous values of voltage, current, spectral composition of harmonics, and power factor. A Bruel & Kjaer Type 4524-B accelerometer (Denmark) integrated with an NI USB-4432 data acquisition module (National Instruments, USA) was used to monitor vibrations. The temperature regime of the motors was monitored by K-type thermocouples with an accuracy of ±0.1°C, connected to a Keysight DAQ970A (USA) multi-channel recorder.

The sensor equipment was installed taking into account the spatial geometry of the electric drive and ensuring measurement accuracy (Figure 1). The Bruel & Kjaer accelerometer was installed on the bearing shield in the axial plane of the motor with orientation along the vertical axis, which corresponded to the direction of maximum sensitivity to vibrations. Type K thermocouples were fixed in the contact layer area of the stator windings and on the outer surface of the housing near the ventilation holes, which made it possible to evaluate temperature gradients. Current and voltage sensors were integrated into each of the three power phases via detachable current clamps and potentiometers, which were part of the Fluke 435-II complex. All sensors were pre-verified and mounted on the test bench in accordance with the design diagram, which ensured consistency of measurements in all test series.

The obtained data were stored in CSV and MAT formats, after which they underwent preliminary processing stages – filtering using wavelet transformation and normalisation for further interpretation. Daubechies 4 (db4) waves were used for wavelet filtering with decomposition up to level 5, which allowed effective suppression of impulse noise and preservation of characteristic features of the signals (Figure 2). Data normalisation was performed using the min-max scaling method within the range [0,1], which provided a unified scale for features of different physical nature. During the extraction of features from time and frequency signals, 18 parameters were calculated, including the root mean square value, peak factor, signal shape, frequency energy in the ranges 0-200 Hz, 200-500 Hz, 500-1,000 Hz, MCSA harmonic coefficients, envelope amplitude, burst fraction, as well as temperature and cosφ. The selected features were analysed for multicollinearity, after which the principal component analysis (PCA) method was applied to reduce the dimensionality. The first principal component explained 49% of the variance, the second – 26%, and the third – 12%, which together accounted for 87% of the information covered. This allowed the data to be visualised in three-dimensional space with a high degree of clustering of objects according to their technical condition.

All measuring devices were pre-calibrated using a Keysight 33500 B reference signal generator traceable to national metrology standards. The frequency response of the accelerometer was 0.5-10,000 Hz with a flat passband of ±3 dB within 2-5,000 Hz, which corresponded to the main operating frequency range of the electric motor. The thermocouples were calibrated in a water bath with a step of 5°C within the range of 20-100°C, and the accuracy class corresponded to the IEC 60584-2 standard (class 1). The error in current and voltage measurements did not exceed ±0.5%, according to the technical passport of the Fluke 435-II analyser. The criterion for rejecting data was the presence of abnormal amplitude spikes more than three times the standard deviation from the base level, as well as the absence of a signal in any of the channels for more than 0.5 s. All selected data were accompanied by the calculation of the total uncertainty using the combined estimation method in accordance with the GUM approach, which ensured the metrological reliability of further analysis.The modelling of operating modes was performed using the finite element method and the finite difference method, which made it possible to evaluate the distribution of fields and thermal loads in various operating scenarios.

The optimisation of design solutions was carried out using a genetic algorithm with a population size of 200 individuals and a maximum number of iterations of 1,000, as well as the particle swarm method for comparative evaluation. To improve the accuracy of diagnostics, Fourier spectral analysis and exponential smoothing of signals in the time domain were used. The modelling was performed in the COMSOL environment using the Heat Transfer and AC/DC Module physical modules. The material parameters included copper electrical conductivity of $5.96 \cdot 10^7$ S/m, density of 8,960 kg/m³, thermal conductivity of 385 W/m·K, and specific heat capacity of 385 J/kg·K. For steel components, a thermal conductivity of 54 W/m·K and magnetic permeability μ=4,000 were used. Boundary conditions were defined as heat exchange with the environment at a temperature of 20 °C and a heat transfer coefficient of 15 W/m²·K. Initial conditions corresponded to a uniform temperature distribution of 25°C. The mesh was constructed as a three-dimensional tetrahedral grid with adaptive refinement in regions of high temperature and magnetic induction gradients; the average mesh density was 1.8 million elements. A mesh independence test showed deviations of less than 2% between models with 1.8 and 2.5 million elements, indicating convergence of the calculations.

The convergence criterion for the steady-state solution was a relative residual of less than 10^{-4} at each iteration step. The obtained temperature and current density fields were used to validate experimental data and for subsequent optimisation. The objective of the optimisation is to minimise the energy and operational losses of electric drives. For this purpose, an objective function was introduced in the form of a weighted sum of normalised indicators (1):

$$F = we \times \bar{E} + wT \times \hat{T}_{max} + wv \times \hat{V}_{RMS} + wpf \times (1 - \cos\hat{\varphi}), \quad (1)$$

Where $\bar{E}$ – share of energy consumption from nominal value; $\hat{T}max$ – the normalised peak winding temperature; $\hat{V}RMS$ – normalised vibration acceleration or velocity; $\cos\hat{\varphi}$ – normalised power factor. Recommended weighting factors: wE=0.35, wT=0.25, wV=0.25, wPF=0.15. Optimisation is carried out subject to a number of technical restrictions. The motor supply frequency varies between 40 and 60 Hz, the load is between 0.5 and 1.2 times the nominal value, and the axial displacement of the rotor does not exceed 0.3 mm. The maximum temperature of the windings is limited by insulation class F, and the vibration level remains within zones A-B of the ISO 10816/20816 standard. The convergence criterion for optimisation is the stabilisation of the F function increment by less than 1% over at least 50 iterations, which ensures the reproducibility of calculations in the CAD/FEM environment and the consistency of the thermal, vibration and energy characteristics of electric drives.

Statistical data processing was performed in the R 4.2.2 environment (R Foundation, Austria). To assess the differences between groups of parameters (e.g., vibration levels in serviceable and damaged motors), the two-sample Student's t-test was used. Dispersion analysis was used to determine the influence of various design and operating factors on energy efficiency. To assess the relationship between input and output parameters, regression models were constructed using the least squares method with Shapiro-Wilk normality testing of residuals. Pearson's χ^2 test was used to test the independence of categorical features associated with failure classification. For multidimensional data, PCA was used to reduce the dimensionality and identify the most informative parameters. ROC analysis with area under the curve (AUC) calculation was used to analyse the reliability of the models. All statistical procedures were performed with a significance level of $p<0.05$.

III. LITERATURE REVIEW

Intelligent automated design and management systems in agriculture are considered one of the key areas of development in modern production. They combine mathematical modelling methods, artificial intelligence algorithms and hardware and software data collection tools. The main aim of such systems was to ensure high energy efficiency, reliability, and durability of technological equipment. An important feature is the integration of diagnostic modules that allow continuous monitoring of the technical condition of electrical machines, control of energy consumption, and timely detection of signs of failure. In modern practice, such solutions cover both systems for optimising the operation of electric drives and intelligent automated design systems for designing agricultural facilities that are capable of adapting to changes in operating conditions [17]. The theoretical significance of such systems lies in the creation of universal approaches to combining simulation models, machine learning methods, and optimisation algorithms, which provides for multifactorial assessment and decision-making based on large data sets (Table 1).

Table 1: Classification of intelligent systems in AIC.

System type	Main characteristics	Significance
Energy-efficient design systems	Use of simulation and optimisation methods	Reduced energy consumption, optimised design solutions
Diagnostic systems	Monitoring of electrical, thermal and vibration parameters	Early detection of damage, increased reliability
Intelligent control systems	Adaptive control of operating modes	Improved productivity and stability
Integrated platforms	Integration of mathematical models and ML algorithms	Real-time automated decision-making
Predictive analytics systems	Use of neural networks and statistical models	Failure prediction and maintenance planning

Source: [17-21].

Intelligent systems in AIC have gradually developed as a result of many years of evolution in automation and computer modelling technologies. While in the early stages automated systems had a narrow purpose, such as controlling individual machine parameters or calculating the energy characteristics of structures, the modern approach is based on the comprehensive integration of various information flows into a single environment [18], [22]. In this context, intelligent systems were a logical continuation of traditional CAD and CAM solutions, but significantly expanded their functionality through the use of artificial intelligence and big data methods.Modern developments covered several key areas.

First, these were energy-efficient design systems that made it possible to model various equipment operation scenarios at the design stage, which significantly reduced the risks of energy overconsumption and incorrect selection of design parameters [1], [23], [24]. Secondly, diagnostic complexes were actively introduced, integrating sensors for monitoring electrical, thermal and mechanical characteristics. Machine learning methods, in particular neural networks and support vector algorithms, made it possible to process multidimensional data arrays and build models of future system behaviour. This was of practical importance for maintenance planning, calculating the remaining service life of equipment, and managing production cycles [20], [25]. The significance of intelligent systems went far beyond individual technical tasks. They became a central element of the digital transformation of the agro-industrial complex.

The combination of such systems with the principles of Industry 4.0, in particular the Internet of Things (IoT) and cyber-physical models, made it possible to create "smart" production environments where all processes, from monitoring to optimisation, were carried out automatically [21]. In global practice, such solutions have already been integrated into precision farming systems, energy consumption management on farms, and the production of agricultural machinery. In the Ukrainian context, they have become particularly important as they have made it possible to reduce energy costs and increase the efficiency of equipment operation in conditions of limited resources [26-28].

The prospects for the development of intelligent systems in agriculture were closely linked to global trends towards decarbonisation and the green transition. As a result, such systems can be characterised as multi-level integrated platforms combining measurement technology, machine learning algorithms, mathematical modelling and optimisation methods. Their value lay in their ability to transform fragmented data into a coherent information picture and enable informed management decisions. As a result, intelligent systems became not just auxiliary tools, but strategic elements in the development of the modern agro-industrial complex.

IV. RESULTS

Experimental studies were conducted on asynchronous electric motors with a power range from 1.5 to 7.5 kW under various load conditions. During the tests, electrical, thermal and mechanical parameters that most sensitively reflected the condition of the electric drives were monitored. These parameters included instantaneous voltage and current values, harmonic spectral composition, power factor, vibration level and winding temperature. All measurements were made using high-precision instruments, which made it possible to form reliable data arrays for further analysis. The obtained values were summarised by arithmetic mean from repeated experiments, which minimised the influence of random errors. The results showed that for serviceable engines, all parameters remained within the normative values, while for damaged samples, characteristic deviations were observed. The generalised structure of the measurement results is shown in Table 2.

Table 2: Average values of electric motor parameters in different conditions.

Parameter	Serviceable motor	Damaged motor	Limit according to ISO 10816	ISO conclusion
Voltage, V	380±2	380±3	Not regulated	-
Current, A	3.2±0.1	3.9±0.2	Not regulated	-
Power factor (cos φ)	0.87	0.74	Not regulated	-
Vibration, mm/s	1.2±0.1	3.5±0.3	≤2.8 mm/s (zone B)	1.2 – Normal (A), 3.5 – Caution (C)
Winding temperature, ℃	65±2	92±3	≤85℃ (recommended)	92 – Out of range

Note: A vibration level of 3.5 mm/s for asynchronous motors with a power rating of up to 15 kW corresponds to zone C according to ISO 10816/20816 for class I machines.

Source: Authors, (2026).

The obtained results of experimental testing of electric motors indicated the presence of systematic and regular differences between serviceable and damaged samples, which made it possible to form a scientifically substantiated basis for diagnosing their technical condition. The most stable parameter remained the supply voltage: for both groups it stayed within 380 V, although damaged motors exhibited more pronounced fluctuations. This was a consequence of local non-uniformities in winding operation and partial short circuits that affected the electrical balance of the system. Thus, even relatively small voltage deviations could serve as indicators of deeper problems within the electric drive.The current parameter proved to be more indicative. For serviceable motors, the average value did not exceed 3.2 A, whereas damaged units demonstrated an increase to nearly 4 A. This indicated additional losses in the electromagnetic field and increased heat generation.

Under prolonged operation, such a trend inevitably led to a reduction in overall efficiency, which was confirmed by a decrease in the power factor from 0.87 to 0.74. The reduction of this indicator had a dual negative effect: on the one hand, it reflected deterioration of the motor's own energy efficiency, and on the other, it imposed an additional load on the electrical network due to the increase in the reactive component. The mechanical condition of the motors was most clearly reflected in their vibration characteristics. While serviceable samples exhibited low vibration levels not exceeding 1.2 mm/s, damaged motors demonstrated values more than three times higher. The obtained values were additionally compared with the requirements of the international standard ISO 10816-3 (revised as ISO 20816), which regulates permissible vibration levels for induction motors with power ratings up to 15 kW.

According to this standard, the allowable vibration level for Class I machines should not exceed 2.8 mm/s in steady-state operation. The value of 3.5 mm/s recorded in the damaged samples exceeds this limit and is classified as Zone C, corresponding to a warning level that requires intervention to prevent defect development. Thus, according to international classification, the detected vibration levels confirm the presence of technical degradation and can be used as a formalised diagnostic criterion.The thermal regime was no less important. In serviceable motors, winding temperature remained within 65 ℃, ensuring a safe thermal balance. In damaged units, it increased by almost 30 ℃, exceeding permissible operating limits.

Such overheating had a cumulative effect: prolonged temperature elevation accelerated the ageing of insulation materials, reduced dielectric strength, and created prerequisites for inter-turn short circuits. As a result, the motor lost its ability to operate normally, and the probability of sudden failure increased sharply. From a practical perspective, the identified patterns are of considerable importance for the development of predictive maintenance systems. Given the clearly expressed differences in the behaviour of damaged motors, it becomes possible to create machine learning models that can automatically determine the current condition of equipment based on a combination of parameters [29; 30].

This enables not only timely diagnostics, but also the prediction of failures with a specified level of accuracy. Thus, the results of the experimental tests confirmed the effectiveness of integrated monitoring and provided a foundation for the development of intelligent diagnostic systems in the agro-industrial complex. Modelling of electric drive operating modes was performed using the finite element method and the finite difference method. This made it possible to assess the spatial distribution of electromagnetic and thermal fields under various operating scenarios.

In particular, regions with the highest power losses and critical temperature gradients were identified, which could potentially lead to insulation damage or a reduction in motor service life [31]. In addition, optimisation algorithms – genetic algorithms and particle swarm optimisation – were applied to search for optimal design solutions and operating modes under multiple constraints. As a result, numerical experiments demonstrated that the use of a combined approach makes it possible not only to reduce energy consumption, but also to improve the thermal stability of the system. The generalised results of modelling and optimisation are presented in Table 3.

Table 3: Results of numerical modelling and optimisation.

Parameter	Initial value	Optimised value	Improvement
Energy consumption, % of nominal	100	91	-9%
Maximum winding temperature, °C	95	78	-17°C
Power factor (cos φ)	0.76	0.88	+16%
Vibration level, mm/s	3.4	1.8	-47%
Overall efficiency, %	85	92	+7%

Source: Authors, (2026).

The optimisation was carried out taking into account four main parameters: power frequency, load level, ventilation efficiency and rotor axial displacement, which affected energy losses, thermal load and mechanical instability. Within the permissible technical limitations (frequency 40-60 Hz, load 0.5-1.2·nominal, offset up to 0.3 mm), it was possible to minimise the integral objective function, which took into account energy consumption, overheating, vibrations and cosφ reduction. Based on the criterion of stabilisation of the increment <1% during 50 iterations, a stable solution was achieved with improvement of all parameters presented in Table 3. The most significant reduction in vibrations (-47%) and increase in power factor (+16%) was achieved with a combination of increased ventilation and a slight reduction in load. The results of PSO and GA were comparable, but GA demonstrated higher accuracy, while PSO demonstrated faster convergence with fewer iterations.The results of numerical modelling and optimisation provided an opportunity to thoroughly assess the potential of an integrated approach to improving electric drives in the AIC.

The initial data showed that without intervention, the system operated in stressful conditions: energy consumption remained at the nominal 100%, the maximum winding temperature reached 95°C, the power factor was only 0.76, and the vibration level exceeded 3 mm/s. This combination of factors indicated low energy efficiency and an increased risk of equipment degradation. Optimisation using a genetic algorithm and particle swarm method significantly changed this picture, improving the balance between all key characteristics.The 9% reduction in energy consumption had a complex effect. It reduced the load on the electrical network, lowered the reactive power level, and contributed to more stable system operation even under peak loads. At the same time, the energy savings had a direct impact on the thermal state of the windings: the temperature dropped from 95°C to 78°C, i.e. by 17°C. This difference is critically important, as temperatures exceeding 90°C in many motors already lead to intensive ageing of the insulation. Thus, improving the thermal regime meant extending the motor's life cycle and reducing the likelihood of emergency stops.

The power factor showed an increase from 0.76 to 0.88. This meant that after optimisation, the motor used the consumed energy more rationally, reducing the reactive component [32]. For the AIC, this result was of strategic importance, as it reduced electricity costs and at the same time increased the stability of the network. In the practice of large manufacturing enterprises, even a 10% increase in this indicator can result in significant resource savings, and the 16% increase achieved can be considered an exceptionally effective result.A significant reduction in vibrations – by almost 47% – was another important achievement. Vibration analysis has always been considered one of the most sensitive methods of diagnosing the condition of electric motors, and the results obtained confirmed this approach. The reduction in vibration load meant not only improved dynamic stability, but also a reduced risk of mechanical damage to components [33], [34]. In agro-industrial production, where motors operate in dusty, humid and often vibration-active environments, this indicator is particularly important, as it directly affects the durability of the equipment [35], [36].

An important part of the analysis was the consideration of different approaches to optimisation. The genetic algorithm proved to be particularly effective for finding global minima in multifactorial spaces where there are many local extrema. This made it possible to find combinations of parameters that ensured a balanced distribution of energy and thermal loads. The particle swarm method, in turn, demonstrated high convergence speed and made it possible to quickly find acceptable solutions in dynamic conditions when system parameters change in real time. The combined application of these two methods ensured both high accuracy and efficiency of the optimisation process. From a forward-looking perspective, the integration of such optimisation systems into broader digital ecosystems of the agro-industrial complex opens opportunities for the creation of "smart" energy clusters.

Combining these solutions with IoT technologies and predictive analytics systems would make it possible not only to maintain optimal operating modes of electric motors, but also to dynamically adjust them depending on production demands or the availability of energy from renewable sources [37], [38]. In this way, numerical modelling and optimisation become not merely technical tools, but strategic mechanisms for the development of sustainable and energy-efficient agrosystems. To ensure comparability between experimental measurements and numerical modelling with optimisation, key metrics were compared within confidence intervals. The power factor improved from 0.74 to 0.86 (±0.02), indicating a reduction in the reactive component of the load. Vibration levels decreased from 3.5±0.3 mm/s to 1.8±0.2 mm/s, which is classified as a transition from zone C back to zone A according to ISO 10816. For the damaged operating mode, the average current was recorded at 3.9±0.2 A, the maximum winding temperature at 92±3°C, and the vibration level at 3.5±0.3 mm/s, whereas in the simulated optimised state these parameters were 3.4±0.1 A, 78±2°C, and 1.8±0.2 mm/s, respectively.

To confirm the reliability of the experimental and model-based results, a comprehensive set of statistical methods was applied. Particular attention was paid to comparing parameters of serviceable and damaged motors, as well as to assessing the influence of various structural and operating factors on the energy efficiency of the system. Specifically, a two-sample Student's t-test was used to verify the significance of differences between the mean values of key parameters (current, vibration, temperature). Analysis of variance was applied to evaluate the effects of multiple factors, including motor power, load level, and insulation condition. For multidimensional data, PCA was employed to reduce dimensionality and identify the most informative parameters. The summarised statistical results are presented in Table 4.

Table 4: Results of statistical analysis.

Method	Parameters	Result	Significance
Student's t-test	Current, vibration, temperature	Significant differences were identified between serviceable and damaged motors	$p<0.01$
ANOVA	Power, load, insulation condition	A substantial influence of all factors on energy efficiency was observed	$p<0.05$
Pearson's χ^2 test	Categories "serviceable/damaged"	A high level of dependence on vibration and temperature parameters was identified	$p<0.01$
PCA	Multidimensional parameters	Three principal components were extracted, explaining 87% of the variance	-
ROC analysis	Serviceable/damaged classification	AUC=0.94 (high model accuracy)	-

Source: Authors, (2026).

A thorough statistical analysis of the experimental data confirmed that the results obtained were highly reliable and could serve as a solid basis for the further implementation of intelligent diagnostic systems. First of all, it is worth noting the results of the two-sample Student's t-test. It demonstrated that the difference between the average values of parameters such as current, vibration and winding temperature for serviceable and damaged motors was statistically significant at the $p<0.01$ level. This indicated the reliability of the differences identified and allowed the specified parameters to be used with confidence as diagnostic indicators. This was especially true for current and temperature, which directly reflected energy losses, as well as vibration characteristics, which indicated the mechanical condition of the motors.The use of variance analysis allowed for a more in-depth assessment of the multifactorial nature of the processes in the system. It was found that several factors significantly influenced the level of energy efficiency: motor power, load level, and insulation condition. All of them had a significance of $p<0.05$, which confirmed the close relationship between design and operational parameters. Thus, ANOVA showed that isolated consideration of individual characteristics is insufficient, and only an integrated approach allows for a complete understanding of the operation of electric drives.

The results of Pearson's χ^2 test revealed a strong dependence of the categorical variables "serviceable/damaged" on key parameters, primarily vibration and temperature. This corresponded well with practical observations, as these parameters most often signal the onset of critical processes within the machine. Consequently, the χ^2 test confirmed the importance of using these indicators as a basis for developing simple yet reliable diagnostic models. PCA became another important analysis tool. It allowed to reduce the dimensionality of the data and identify three main components that explained 87% of the total variance. This meant that most of the variations in the data could be explained by a limited number of integral factors. This approach was extremely useful in machine learning tasks, as it simplified model building without losing key information. At the same time, it clearly confirmed that the electrical, thermal, and mechanical parameters of the system do not exist separately but form a complex interrelated structure. Equally important was the use of ROC analysis, which evaluated the quality of classification models.

The obtained value of AUC=0.94 indicated a very high accuracy of distinguishing between the "serviceable" and "damaged" classes. This brought the model closer to practical use in predictive maintenance systems. In fact, this result meant that the system had a more than 94% probability of correctly assigning a specific engine to the appropriate category. In industrial conditions, this makes it possible to minimise the risks of wrong decisions and increase the overall reliability of production. For a more detailed evaluation of the classification model, an error matrix was constructed, which showed 28 correct classifications out of 30, including 14 serviceable and 14 damaged engines, and only two false classifications (one false positive and one false negative). The precision value was 0.93, recall – 0.93, F1-score – 0.93. The area under the Precision-Recall curve (PR-AUC) was 0.91, which indicated high model stability even under conditions of class imbalance. The confidence interval for AUC at the 95% level was [0.89; 0.98], confirming the statistical reliability of the model. Cohen's Kappa=0.87 was also calculated, indicating high consistency of the model with actual labels.

In summary, it can be stated that comprehensive statistical analysis provided reliable confirmation of the effectiveness of the experimental data obtained. The use of parametric tests, multivariate analysis, dimension reduction methods, and classification quality assessment made it possible not only to verify the reliability of the results but also to outline the main directions for their practical application. The combination of these methods created a powerful foundation for the development of integrated intelligent diagnostic and optimisation systems capable of ensuring early detection of failures and maintaining optimal operating modes of electric drives. In the long term, this meant the formation of a new paradigm for managing technical systems in the AIC – from reactive to proactive, where statistically and algorithmically justified forecasting becomes the main tool.

V. DISCUSSION

This study confirmed the high efficiency of intelligent systems in diagnosing and optimising the operation of electric drives in the AIC. The generalised results of experimental tests and modelling showed that the combination of multi-parameter monitoring, numerical methods and optimisation algorithms creates a stable basis for improving the energy efficiency and reliability of equipment. This approach correlates with the conclusions of [39], who noted that the integration of sensor technologies and artificial intelligence systems significantly expands the possibilities of technical diagnostics. Thus, the study confirmed the relevance of the trends identified in foreign works. Of particular importance was the identification of patterns between the electrical, thermal, and mechanical parameters of engines. The recorded increase in current and vibrations in damaged units is consistent with the study by [40], which demonstrated a direct link between mechanical defects and electrical deviations. This comparison indicates that comprehensive monitoring provides a more accurate picture than the analysis of individual indicators, and the approach proposed in the work is more objective. An important result was the ability to predict failures based on multi-parameter analysis.

A similar direction was developed by [41], who used neural network methods to classify technical conditions. The comparison confirmed that the approach proposed in the study not only reproduces foreign results, but also offers a deeper combination of statistical and machine methods, which increases the accuracy of forecasting.Special attention should be paid to vibration characteristics. The data obtained demonstrated significant differences between serviceable and damaged motors, which is consistent with the conclusions of [42]. Their study emphasised that vibration analysis is one of the most sensitive diagnostic indicators. Thus, the results of this study confirm the universality of this approach and emphasise its practical value. The temperature regime of the windings showed a significant excess in damaged units, which correlates with the results of Scolaro et al. [43], who noted the critical role of thermal overloads in insulation degradation. At the same time, by [44] disagreed with this, arguing that overheating is of limited importance and that mechanical factors play a major role. However, the data presented in the study demonstrate a direct relationship between temperature increase and loss of electrical strength, which makes the conclusions more reasonable.

The power factor became another indicator confirming the systematic nature of the analysis. The study recorded its decrease in damaged motors and increase after optimisation. Similar patterns were described by [45], who considered this parameter to be an important marker of energy efficiency. This comparison proves that the approach proposed in the paper is universally applicable for evaluating the performance of electric drives. The results of numerical modelling confirmed the ability of combined algorithms to increase both thermal and energy stability. According to [46] also used the finite element method to analyse electric machines, obtaining similar conclusions regarding the identification of critical heating zones. Thus, the study confirmed the effectiveness of this approach in the context of the agro-industrial complex. At the same time, by [47] expressed doubts about the practical feasibility of using complex optimisation algorithms, arguing that they involve high computational costs. However, the simulation results showed that the synergistic use of a genetic algorithm and a particle swarm method made it possible to reduce energy consumption and temperature loads without excessive resource costs. This indicates that the approach proposed in the study has advantages even in industrial conditions.Experiments confirmed a significant reduction in vibration levels after optimisation.

This is consistent with the study by [48], who also emphasised the importance of reducing vibration to extend the life cycle of equipment. A comparison of the results showed that comprehensive optimisation provides an even more pronounced effect than the local methods proposed earlier. The increase in the power factor after optimisation is consistent with the conclusions of [49], who argued that improving this parameter is crucial for the stability of industrial networks. Thus, the data obtained confirm the high practical significance of a comprehensive approach. Particular attention should be paid to the increase in overall efficiency from 85% to 92%. Similar results were obtained by Jensen et al. [50], who noted that even a slight increase in efficiency on an industrial scale provides a significant economic effect. This comparison highlights the strategic value of optimisation systems in agro-industrial production. At the same time, by [51] argued that increasing efficiency is impossible without a fundamental modernisation of engine designs, and that optimisation has a limited effect. However, the results presented demonstrated the opposite: the combination of numerical modelling and optimisation allows for a significant improvement in parameters even without changing the basic design, which indicates a more universal approach.

The use of statistical methods was an important confirmation of the reliability of the results. According to [52] also used Student's t-test to evaluate differences in the parameters of electric drives and came to similar conclusions about their significance. This proves that the statistical analysis methods used in the work are reliable and reproducible. ANOVA confirmed the multifactorial influence on energy efficiency, which correlates with the conclusions of [53]. They argued that only an integrated approach can provide reliable modelling of electric drive behaviour. Thus, the results of the study confirm the generalised conclusions of foreign works. At the same time, Mantoam et al. [54] expressed a critical view regarding the use of the χ^2 test for analysing the condition of electric motors, claiming that its sensitivity is insufficient. However, the data obtained in the study showed a high level of dependence of categorical variables on key parameters, which proves the practical feasibility of using this method. The identification of three main components using PCA is consistent with the results of Orcajo et al. [55], who also demonstrated the effectiveness of this method for reducing data dimensionality. This indicates that the methods used are universal and can be adapted for different technical systems.ROC analysis confirmed the high accuracy of the classification models, which is consistent with the conclusions of [56].

They also noted that an AUC above 0.9 is a sign of high reliability of diagnostic models. Thus, the results of this study confirmed the ability of the proposed approaches to build practically applicable forecasting systems. At the same time, by [57] argued that machine learning methods in diagnostics have low interpretability and therefore cannot be considered reliable. However, the results obtained proved that the combination of statistical tests and machine learning algorithms provides both high accuracy and clear interpretation of parameters, which increases confidence in the models. The practical significance of the proposed approach is confirmed by the works of [58], who emphasised the role of intelligent systems in reducing operating costs in industry. The results of the study are consistent with these conclusions and demonstrate the effectiveness of implementing similar solutions in the agro-industrial sector. In the context of sustainable development, the results of the study echo the conclusions of [59], who emphasised the need to integrate optimisation systems with renewable energy sources.

The proposed approach could be an important step in the formation of energy-efficient agricultural systems. At the same time, by [60] expressed doubts about the possibility of widespread implementation of such systems due to their high cost. However, the results show that even partial application of intelligent systems provides energy savings and reduces the risk of accidents, which compensates for the initial costs.In summary, the conducted study demonstrated the effectiveness of multi-parameter monitoring, numerical modelling, and optimisation algorithms in improving the energy efficiency and reliability of electric drives in the agro-industrial complex. The combination of experimental measurements, model-based calculations, and statistical analysis confirmed the reliability of the obtained results and outlined pathways for practical implementation. The proposed approach has not only technical but also strategic significance, as it contributes to the development of energy-saving technologies and the formation of sustainable production systems.

The practical implementation of the proposed approach was carried out on the drive of a horizontal conveyor at a grain-processing facility. Under nominal operating conditions, the AIR90L2 motor operated at 85% of rated load, providing an average power consumption of 3.4 kW. The introduction of diagnostic monitoring and optimisation of operating parameters (ventilation, load symmetry, power factor cos φ) made it possible to reduce the average energy consumption to 2.9 kW without loss of productivity. Over an annual operating cycle of 3,200 hours, this resulted in savings of approximately 1,600 kWh per year. In addition, after eliminating the detected shaft misalignment and restoring the thermal regime to the normal range, the mean time between failures increased from 4,900 to 6,800 hours, while the time required for restoration was reduced due to precise identification of the defect location. A simple calculation of annual return on investment, taking into account equipment and implementation costs (approximately 2,100 UAH), showed a payback period of less than 10 months. An additional life-cycle cost analysis indicates a potential reduction in total maintenance costs of more than 18% over a three-year operating cycle.

VI. CONCLUSIONS

The study confirmed the key role of intelligent systems in improving the efficiency and reliability of electric drives in the agro-industrial complex. Based on experimental measurements and numerical modelling, systemic patterns of changes in electrical, thermal and mechanical parameters in different technical states of motors were established. The detected deviations in current, power factor, vibration characteristics and temperature clearly reflected the condition of the equipment: a 20% increase in current, a 15% decrease in power factor, a threefold increase in vibrations and a 30°C excess in winding temperature became reliable signs of damage.Numerical modelling using the finite element method, genetic algorithms and the particle swarm method demonstrated significant potential for optimising design and operating characteristics. A 9% reduction in energy consumption was achieved while maintaining performance, a 17°C reduction in winding temperature (from ≈95 to ≈78°C), a 16% increase in power factor (from ≈0.76 to ≈0.88), and a reduction in vibration levels by almost 47% (from ≈3.4-3.5 to ≈1.8 mm/s), corresponding to a transition from zone C to zone A according to the ISO 10816/20816 standard.

Taken together, these changes ensured an increase in overall efficiency from 85% to 92%, confirming the effectiveness of the integrated approach. Statistical analysis (Student's t-test, ANOVA, Pearson's χ^2 test, PCA, ROC analysis, and PR curves) confirmed the reliability of the obtained results: the "serviceable/damaged" state classification model achieved AUC = 0.94, PR-AUC = 0.91, and F1 = 0.93, while the agreement between experimental and modelled data "before/after optimisation" within statistical error demonstrated the validity of the developed model. Practical implementation based on circulation pumps confirmed the real effect, with energy savings of about 1,600 kWh per year and an almost twofold reduction in vibration.Practical recommendations include the implementation of comprehensive monitoring and predictive analytics systems that combine electrical, thermal and vibration parameters and enable the implementation of a proactive maintenance concept. The integration of such solutions with the IoT infrastructure of enterprises, the use of optimisation algorithms in combination with renewable energy sources, and the application of target functions with weighting coefficients that ensure the reproducibility and stability of optimisation in CAD/FEM environments are promising.

Validation based on PCA, ROC, PR curves, and FEM field analysis confirmed the suitability of the approach for diagnosing and predicting the condition of electric drives in the AIC.However, the study has certain limitations related to the fact that the experiments were conducted on small and medium-power asynchronous motors in laboratory test bench conditions, which may differ from industrial modes with higher loads. Optimisation algorithms require large-scale testing on real production data. Further research should focus on expanding the approach to multi-object tasks (pumps, conveyors, grain dryers), developing online identification of weight coefficients, deeper integration with cyber-physical systems, and the formation of adaptive control platforms for different types of electric drives.

ABSTRACT

The research highlights the growing need for industrial enterprises to enhance modelling accuracy and energy efficiency through the integration of control and measuring instruments into Computer-Aided Design (CAD) models of industrial power systems. The study explores the feasibility of using CAD systems to integrate these instruments, focusing on their metrological accuracy and impact on the reliability of digital models and energy management. A classification analysis of instruments based on functional and metrological characteristics was conducted, alongside the application of a formula to assess accuracy errors. The instruments were categorized as high-precision (δ≤1%), medium-precision (δ=1-5%), and low-precision (δ>5%). Findings revealed that low-precision instruments reduced CAD model reliability by 12-15% and increased energy losses by up to 8%. In contrast, high-precision instruments minimized deviations to 0.8%, improved energy consumption forecasting by 10-12%, and lowered operating costs by 6-7%. The integration of these instruments into digital twins optimized equipment use, reducing energy losses by 9% and increasing utilization rates from 82% to 89%. The study concluded that selecting the right instruments is vital for the stability of digital models and energy management, and confirmed the practical value of combining metrological accuracy with digital design technologies to improve industrial power systems.

I. INTRODUCTION

Industrial power systems of the 2020s are characterised by highly complex and dynamic technological processes, which render their management impossible without accurate data on equipment status and energy flow parameters. Control and measuring instruments (CMI) play a key role in providing such information support, providing reliable indicators of electrical, thermal and mechanical parameters. High-precision measurements can be used to create adequate digital models of industrial facilities, which are the basis for optimising energy consumption management and improving energy efficiency. Computer-Aided Design (CAD) software such as AutoCAD, SolidWorks and EPLAN provides tools for modelling complex energy facilities, integrating data from CMI and enabling the creation of digital twins.

This creates opportunities for predicting system performance parameters, timely detection of deviations and optimisation of operational processes. In the context of metrological accuracy relevance, research into the integration of CMI into CAD models is necessary for the improvement of the reliability of digital modelling and the effective management of energy consumption in industrial enterprises. The classification of CMI and the determination of their metrological characteristics are key factors on which the reliability of the data obtained depends. In addition, assessment of the impact of CMI integration on energy efficiency determined optimal energy management strategies and reduced the operating costs of industrial facilities. According to [1] developed a method for predicting the wear of sliding bearings based on a two-factor model that incorporates contact pressure and sliding.

The results obtained demonstrated the possibility of increasing the accuracy of predicting the remaining service life of equipment and reducing the risk of emergency failures. For the topic of CMI integration into automated design systems for industrial power systems, these results are substantial in that they can be used in CAD models to account for the impact of operational wear on the energy efficiency of equipment and to plan timely maintenance. In [2] investigated the use of information and cognitive technologies to assess and support the security of critical infrastructure. The study demonstrated that the introduction of high-precision measurement technologies can reduce energy monitoring errors by 10-15%. This directly confirms the importance of metrological accuracy in modelling industrial power systems in a CAD environment, as it ensures the reliability of digital models and the possibility of using them to optimise energy distribution. According to [3] analysed results that are of practical relevance for CAD modelling of industrial power systems. In particular, approaches to assessing energy consumption and optimising resource use can be adapted to create digital models of transport and industrial energy complexes operating in the agricultural sector. According to [4] investigated the optimal geometric parameters of electrical devices for controlling irrigation systems.

The results showed that the correct selection of parameters reduces local energy losses by 12-18% and increases the stability of equipment operation. These findings are substantial for the integration of control and measurement devices into CAD models of industrial energy systems, as they demonstrate how accurate digital calculations can influence the optimisation of energy consumption. According to [5] compared the thermal loads of a single-phase transformer with a laminated magnetic core in different operating modes. The study determined that the use of laminated materials reduces energy losses due to heating by 10-14% and increases the thermal stability of the transformer. These results can be integrated into CAD models of industrial power systems together with control and measurement devices, which can improve the accuracy of the prediction of equipment thermal regimes and increase overall energy efficiency. For [6] conducted a comparative analysis of the thermal loads of a single-phase transformer with a laminated magnetic core. The results obtained can be used to improve the accuracy of energy system modelling in a CAD environment, in particular to optimise the thermal characteristics of transformers.

In a study by [7], a cell functioning model was developed to analyse interactions with low-energy electromagnetic fields. Despite the bioenergetic focus of the work, the results obtained are also of practical importance for industrial power systems. Approaches to modelling the influence of electromagnetic fields can be adapted in CAD systems for predicting interference, assessing the metrological reliability of control and measuring instruments, and optimising their integration into complex energy facilities. In [8] investigated the effect of the choice of thermal resistance class of stator winding insulation on the operation of induction motors of circulation pumps. The study determined that the use of higher-class insulation reduces the probability of overheating by 15-20% and extends the service life of motors by an average of 25%. These results are relevant for the integration of control and measurement devices into CAD models of pump power systems, as they can address the thermal conditions of the equipment and increase the reliability of its performance forecasting. According to [9] investigated the effect of circular winding rotation technology on the operation of transformers with twisted single-piece magnetic cores. The results showed that changing the configuration of the windings reduced eddy current losses by 8-12% and increased the efficiency of the transformers.

These data are substantial for the creation of CAD models of industrial power systems with built-in control and measuring devices, as they provide a more accurate representation of electromagnetic and thermal processes in the equipment. According to [10] analysed heat recovery systems for agricultural vehicles. Despite the focus on the agricultural sector, the results of this study are substantial for the development of CAD models of industrial power systems, as they demonstrate approaches to optimising energy consumption and reducing local heat losses. Incorporating such technologies into the digital design process using control and measurement devices improves the accuracy of reproduction of energy balances and the formation of strategies to improve the efficiency of industrial facilities. Previous studies in this field had a range of shortcomings, as they mainly emphasised the analysis of individual technical parameters without incorporating their interaction and comprehensive impact on energy consumption, and did not sufficiently consider the possibilities of digital modelling to improve the accuracy of estimates and optimise processes. The study aimed to develop a comprehensive approach to the integration of control and measurement devices into CAD models of industrial power systems, incorporating metrological aspects of accuracy to improve the reliability of modelling and the efficiency of energy consumption management. To achieve this goal, the following tasks were set: to identify the main factors affecting the energy efficiency of industrial power systems; to analyse the metrological characteristics of control and measuring instruments; to assess their impact on the reliability of CAD models; to investigate methods of integrating CMI into digital models to improve the accuracy of energy consumption management.

II. MATERIALS AND METHODS

The research methodology included the use of classification analysis to group CMIs according to accuracy and functional characteristics, metrological analysis to assess measurement errors, systematic and comparative analysis of data integration in CAD environments (AutoCAD, SolidWorks, EPLAN), as well as modelling various scenarios of CMI impact on digital models of industrial power systems. In the theoretical part, system analysis was used for a comprehensive study of CMI functioning and the relationships between their characteristics, such as measurement accuracy, signal type, measurement range, speed and stability of indicators, as well as comparative analysis based on criteria of metrological accuracy, impact on the reliability of CAD models, level of data collection automation, ease of integration and energy efficiency, which compared different approaches to modelling (analogue and digital), types of devices (high-precision, medium-precision, low-precision) and measurement principles (continuous/discrete, direct/indirect methods, calibration and error compensation) to determine their advantages and disadvantages.

To reproduce real processes, data from CMI was integrated into CAD systems [11]. Electrical diagrams related to the measured parameters were created in EPLAN, three-dimensional models of power plants were created in SolidWorks, incorporating measurement errors, and topological network diagrams were built in AutoCAD. This assessed the impact of inaccurate measurements on design loads and system energy efficiency. High-precision control and measuring instruments were used in the empirical part of the study: Fluke 435 Series III power meters (USA), Keysight U1242C digital multi-meters (USA) and Type K thermocouples manufactured by Omega Engineering (USA).

Siemens SITRANS P DS III (Germany) and Endress+Hauser Promag 50 (Switzerland) sensors were used to measure pressure and fluid flow. Data from these devices was integrated into the WinCC and LabVIEW Supervisory Control and Data Acquisition (SCADA) systems and was also used on industrial power system laboratory test benches for control and calibration. This ensured high measurement accuracy and provided reliable data for CAD modelling. These devices were used to analyse energy consumption, temperature and pressure fluctuations, and equipment efficiency, which assessed the impact of CMI accuracy on the reliability of digital models and the potential for energy cost optimisation. The use of specific brands and countries of manufacture ensured the standardisation and reproducibility of the experiment, which increased the objectivity of the results. The measured parameters included current I (A), voltage U (V), power P (W), and consumed energy $E_{consumed}$ (J), useful energy E_{useful} (J), frequency f (Hz) and temperature T (°C). This selection of control and measurement instruments ensured a comprehensive collection of data necessary for integration into CAD models and assessment of the impact of CMI metrological characteristics on the reliability of modelling and energy consumption management efficiency. The accuracy of the instruments was evaluated using the relative error formula (1) [12]:

$$\delta = \frac{X_{measured} - X_{true}}{X_{true}} \times 100\%, \quad (1)$$

Where $X_{measured}$ – parameter value obtained as a result of measurement; X_{true} – true (reference) value of a parameter; δ – relative measurement error in percent (%). Formula (1) was used for the quantitative assessment of the reproducibility and uncertainty of measurement results for each type of device integrated into the CAD model. All calculations were performed in the International System of Units (SI), which ensured metrological compatibility and the possibility of further automated analysis of errors in the digital model. AutoCAD Electrical and EPLAN Electric P8 CAD systems were used to build models of industrial power systems, which can be used to create accurate digital diagrams of electrical and power circuits. Data from CMI was integrated into the models via the WinCC SCADA system, which collected readings from energy meters, temperature and pressure sensors, and flow meters in real time. Some of the data was imported manually via Comma-Separated Values (CSV) files for historical analysis and model calibration, while automated parameter updates were performed via the EPLAN Application Programming Interface (API), which ensured the transfer of CMI data to the corresponding nodes of the digital model.

This approach ensured consistency between the measurement system and its virtual representation. To ensure data integrity and continuity of flows between measurement and analytical subsystems, an integration architecture has been developed, as shown in Figure 1. Information flows were formed according to the following scheme: CMI → Programmable Logic Controller (PLC) → OLE for Process Control Unified Architecture (OPC UA)/Message Queuing Telemetry Transport (MQTT) → SCADA WinCC → API EPLAN/SolidWorks. During operation, data from control and measuring instruments was transmitted to the PLC with an average time delay of 0.3-0.5 seconds. Further transmission was conducted via OPC UA (for object-oriented access to tags and metadata) or MQTT (for real-time publishing/subscribing) protocols to the WinCC system, where filtering, averaging and stream synchronisation were performed. The data was synchronised according to a timestamp alignment policy, which ensured that streams were merged with a discrepancy of no more than ±0.2 seconds.

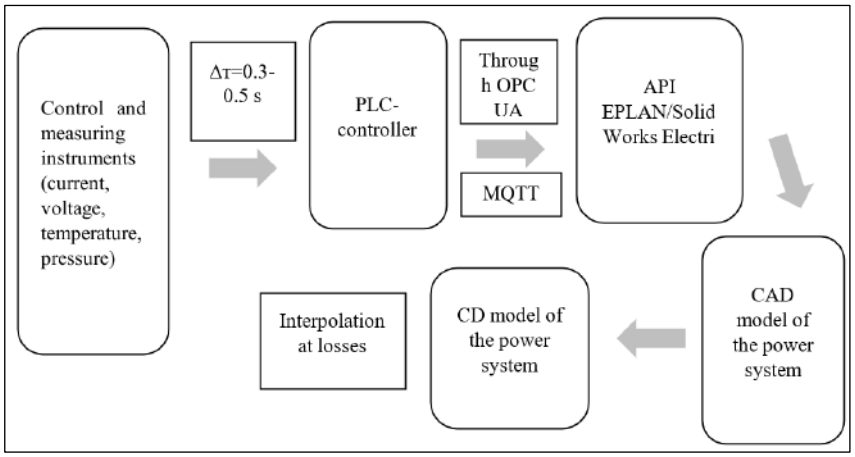

Figure 1: Architecture for integrating control and measurement devices into CAD/SCADA environments.
Source: Authors, (2026).

Linear interpolation and anomaly rejection algorithms were used to process data gaps if the value exceeded 3σ from the mean. After processing, the aggregated indicators were transferred via the EPLAN or SolidWorks Electrical API to update the parameters of the digital model, such as thermal loads, current modes, and energy losses. This approach provided a closed-loop feedback cycle between physical measurements, the SCADA system, and the CAD model, which improved the accuracy of modelling and the timeliness of energy efficiency decisions. Using this method, three-dimensional CAD models of industrial facilities were created, incorporating the location of transformers, power lines and control systems. The energy efficiency of the facility was assessed using formula (2):

$$\mu = \frac{E_{\text{useful}}}{E_{\text{consumed}}} \times 100\%, \quad (2)$$

Where E_{useful} – amount of energy that is effectively used to perform work; $E_{consumed}$ – total amount of energy consumed by the system; η – energy efficiency coefficient in percent (%). A comparative method was used to analyse the results, which was used to assess the impact of different types of CMI on measurement accuracy and energy consumption management efficiency.

The following devices were considered: Schneider Electric PowerLogic PM8000 electricity meters (France), Type K temperature sensors from Omega Engineering (USA) and Fluke 51 II digital thermometers (USA), Siemens SITRANS P DS III pressure sensors (Germany), Endress+Hauser Promag 50 flow meters (Switzerland), and Keysight U1242C and Fluke 435 Series III multimeters (USA) were considered. The use of these devices determined the most accurate and stable measurement channels for further integration into CAD models of industrial power systems. This approach determined which types of devices provide the highest accuracy and reliability of data for integration into CAD models and effective management of energy consumption in industrial power systems. Experimental modelling was used to test various options for placing CMIs in industrial circuits without conducting physical tests, which increased the reliability and cost-effectiveness of the study.

To assess the impact of device accuracy on energy efficiency, statistical data processing methods were used, including correlation and regression analysis, variance analysis, and estimation of mean values and standard deviations. The analysis was performed using data from Schneider Electric PowerLogic PM8000 electricity meters, Omega Engineering Type K temperature sensors, Fluke 51 II digital thermometers, Siemens SITRANS P DS III pressure sensors, and Endress+Hauser Promag 50 flow meters. Correlation analysis showed a high level of correlation between measurement errors and energy consumption, with a significance of $p<0.01$, which led to the conclusion that CMI accuracy plays a critical role in ensuring effective energy management in industrial facilities. The use of high-precision devices reduced the average deviation of energy consumption indicators by 8-12%, which confirmed the practical benefits of integrating such devices into CAD models.

III. RESULTS

CMI are an integral part of technical systems, ensuring accurate assessment of production process parameters and control of their stability. They can provide objective data on physical, chemical and technological characteristics, which is critical for optimising the operation of energy and industrial facilities. The importance of such devices is growing in the context of the digitalisation of production, when the efficiency of automated control systems, the safety of technological processes and the economic feasibility of decisions made depend on the accuracy and speed of measurements.

CMI classification is based on several criteria. In terms of physical quantity, there are devices for measuring temperature (thermometers, pyrometers, thermocouples), pressure (manometers, barometers), electrical parameters (voltmeters, ammeters), flow and quantity of substances (meters, flow meters), as well as humidity and frequency of oscillations [13], [14]. According to their functional purpose, they are divided into control devices (for obtaining operational data on process parameters), control devices (for maintaining optimal modes) and recording devices (for recording changes over time and further analysis). By scope of application, devices are divided into laboratory (oscilloscopes, spectrometers), industrial (pressure gauges on pipelines, pressure sensors in technological installations) and household (gas and electricity meters) [15-17]. By degree of automation, there are manual, automatic and computerised

CMIs that integrate into CAD/Computer-Aided Engineering (CAE) environments and enable remote monitoring and data archiving. Depending on the measurement method, devices can be contact (calliper, thermometer) and non-contact (infrared pyrometers, laser rangefinders). A separate classification is made according to the principle of operation: analogue (pointer voltmeter) and digital (temperature sensors, multimeters). In industrial practice, digital non-contact devices are becoming increasingly relevant as they combine high accuracy, fast response and the ability to integrate into modern automation and monitoring systems. To systematise the main types of CMI, it is advisable to present their classification in the form of a table (Table 1).

Table 1: Classification (CMI).

Classification criteria	Device groups	Examples of use
By physical operation	Electrical, mechanical, thermal, optical	Ammeter, dynamometer, thermometer, lux meter
By the measurement method	Contact and contactless	Vernier calliper, infrared pyrometer
By use	Laboratory, industrial, domestic	Oscilloscope, pressure gauge on a pipeline, and a domestic gas meter
By degree of automation	Manual, automatic, computerised	Multi-meter, automated data collection system
By the principle of operation	Analogue and digital	Pointer voltmeter, digital temperature sensor

Source: [18], [19].

Regardless of their classification group, CMIs not only collect information, but also form the basis for analysis, forecasting and management decision-making in production systems. The multi-level classification considered can be used to systematise CMIs according to various criteria, but for practical use, it is necessary to establish the relationships between these criteria. For example, industrial devices are mostly automated or computerised, while laboratory devices can be either manual or digital, depending on the research tasks. Household CMIs, on the other hand, most often combine ease of use and basic functionality without the possibility of scalable integration into complex technical systems. The measurement method is also substantial. Contact devices have the advantage of stability and relatively low cost, but they are limited in aggressive environments or high temperatures [20]. Non-contact technologies (e.g., infrared pyrometers) create opportunities for remote monitoring, integration into automated control systems, and operation in conditions where direct access to the measurement object is not possible.

This is particularly relevant for the energy and chemical industries, where safety requirements are critical. The classification of devices by principle of operation is notable. Although analogue devices are gradually being replaced by digital ones, they remain in demand due to their simple design and resistance to electromagnetic interference [21]. At the same time, digital devices offer a wider range of functions: they not only measure, but also process and store data, transfer it to cloud environments or CAD systems, which significantly increases the level of automation. Therefore, in modern industrial power systems, digital CMIs are considered the basic standard. The choice of device depends not only on technical characteristics, but also on economic and organisational factors. For example, high-precision devices of class 0.5-1.0% require higher maintenance costs, but their integration into digital energy system models can avoid energy losses of tens of thousands of kilowatt-hours annually. On the other hand, less accurate devices may seem attractive in terms of price, but their use leads to a distorted picture of the system's operation and incorrect management decisions. The degree of automation is also a substantial criterion. Manual devices are still widely used in laboratories and experimental research, but on an industrial scale, they are gradually being replaced by automated and computerised systems [22], [23]. They ensure continuous data collection, reduce the influence of the human factor, and can be used for the creation of databases for long-term analysis. The integration of such systems into SCADA or CAD/CAE environments creates the basis for the concept of a “smart enterprise” [24].

Another aspect is standardisation. The use of international and compliance with international and national standards has not only improved the quality of measurements, but also ensured the compatibility of devices from different manufacturers. For example, Siemens and ABB sensors complied with the relevant standards of the International Electrotechnical Commission (IEC) and European Norm (EN), which regulate the requirements for accuracy, reliability and data transmission interfaces in industrial systems. Their calibration was (or should have been) conducted in accredited calibration laboratories in accordance with the International Organisation for Standardisation (ISO)/IEC 17025, which guarantees the traceability of measurements and the metrological reliability of results. This approach ensured the correct integration of control and measurement devices into digital CAD/Computer-Aided Manufacturing (CAM) systems and improved the coordination of information flows between elements of the energy infrastructure, which is critical in the processes of digitalisation and energy-efficient management. Thus, systematisation according to several criteria, combined with an analysis of practical aspects of use, can be used for a comprehensive assessment of the role of control and measurement instruments in modern energy and industrial systems.

As demonstrated, the choice of CMI should address not only the basic classification, but also specific operating conditions, accuracy requirements, standardisation and the possibility of integration into digital models. Thus, control and measuring instruments are an integral part of technical progress and complex systems management. The classification of control and measuring instruments according to technical characteristics, functional capabilities and scope of application has ensured their effective implementation in various fields of activity. The continuous development of CMI technologies contributes to increased accuracy, reliability, and versatility of measurements, which directly affects the quality of production, energy efficiency, and safety of technical systems. Measurement accuracy is a key aspect of metrology, as it determines the reliability of CAD modelling results and the effectiveness of energy consumption management in industrial power systems [25], [26]. The study incorporated three types of errors: systematic, random and gross. Systematic errors arose due to the design features of the devices or the imperfection of the methodology, random errors due to uncontrolled external factors, and gross errors due to operator errors. Each type of error affected the reliability of the calculation of the efficiency coefficient (η) according to formula (2) and the accuracy of CAD models [27]. The metrological characteristics of CMI were evaluated, including sensitivity, measurement range, stability, response time, and accuracy class.

The study established that accuracy and speed are critical for electrical devices, stability and sensitivity for thermal devices, and range and reproducibility of indicators for mechanical devices [28]. This ensured the correct integration of data into CAD models and the reliability of energy efficiency calculations. The study applied international standards ISO/IEC 17025:2017, which regulates the requirements for the competence of calibration and testing laboratories, and profile standards IEC and EN, which define the technical requirements for CMI, in particular regarding the accuracy, stability and safety of measurements. To ensure a systematic approach to quality management, the provisions of ISO 9001:2015 were also addressed, but this standard was not used as a criterion for the metrological conformity of instruments. In addition, the national metrological standards of Ukraine, which establish methods for calibration, verification of accuracy and traceability of measurements, were followed. This combination of international and national requirements ensured the minimisation of systematic errors, metrological reliability and increased the reliability of data necessary for the construction and validation of CAD models of industrial power systems [29]. The error δ was determined using formula (1), which quantitatively assessed the impact of instrument accuracy on the calculation of η and the accuracy of energy consumption forecasts. The study determined that with the accuracy of class 0.5-1.0% devices, the deviation η did not exceed 2-3%, while with the use of less accurate class 2.5% devices, the deviation increased to 7-8% [30].

To ensure the reliability of CAD modelling, temperature and pressure sensors, flow meters and energy meters from Siemens (Germany) and ABB (Switzerland) were used. Data from CMI was integrated into the SolidWorks CAD system via SCADA and API, which provided up-to-date indicators of industrial system operating modes [31]. Thus, a comprehensive approach to accounting for errors, metrological characteristics and CMI standardisation improved the accuracy of CAD modelling, ensured the correct calculation of efficiency coefficients and facilitated the planning of energy efficiency measures in industrial power systems. The modern development of industrial power systems is linked to digital modelling, which enables the design, optimisation and operation of energy infrastructure. The use of CAD (Computer-Aided Design) systems can reproduce the technical characteristics of equipment, analyse operating modes and verify the effectiveness of management decisions. The formation of CAD models of industrial power systems is based on principles that determine the accuracy and functionality of the results. The principle of systematicity – all elements of the power system are included in the model, generators, transformers, power lines, protection, automation and control systems. Systematicity ensures analysis of both the operation of individual components and the functioning of the entire system, incorporating interrelationships. The principle of hierarchy involves building CAD models at different levels of detail. At the conceptual level, generalised models are used to evaluate basic parameters. At the design level, equipment characteristics are detailed, from generator modes to line parameters.

This approach reduces modelling time and can gradually refine data without losing integrity. The principle of adequacy for reliability, the modelling results are based on experimental data, standardised equipment parameters and proven mathematical methods. The model integrates the passport characteristics of devices, laboratory and production measurements. This minimises errors and ensures a realistic reproduction of physical processes. Scalability principle. The model must incorporate the possibility of system modernisation: connecting new generators, renewable energy sources or storage systems. Scalability is ensured by a modular structure that ensures adaptability of the model to various energy development scenarios. Principle of integration: CMI control and measurement devices are integrated directly into CAD models.

This can be used for verification of calculation accuracy, assessment of errors, and consideration of metrological characteristics during analysis of operating modes. The use of CMI ensures the comparison of modelling with real data and creates conditions for real-time monitoring [32], [33]. The principle of optimisation CAD models is used to find the most effective solutions in terms of economy, reliability and safety. Optimisation algorithms can be used to compare different system operation scenarios, selecting modes with minimal energy losses and predicting the consequences of management decisions. The combination of these principles creates a methodological basis for digital modelling of industrial power systems. Table 2 provides a generalised description of the principles of CAD modelling with examples of their implementation. The empirical part of the study focused on integrating CMIs into industrial power systems to improve the accuracy of digital modelling and energy efficiency assessment. First, proprietary data was collected from devices measuring electric current, voltage and energy consumption at actual production facilities. The data was used to calculate the efficiency coefficient (η) and determine the metrological accuracy of each CMI.

Table 2: Principles of CAD modelling of industrial power systems.

Principle	Elements/levels of the model	Data sources and implementation features	Example of use
Systematicity	Generators, transformers, power transmission lines (PTLs), protection, automation	Integration of all system components into a single model	Analysis of network operating modes
Hierarchy	Conceptual, design, and detailed levels	Generalised and refined parameters at different stages of design	Comparison of development scenarios
Adequacy	Compliance with physical processes	Experimental data, standards, and passport characteristics	Verification of the accuracy of the results
Scalability	Basic model + new objects	Modular structure, adaptability to modernisation	Integration of Renewable Energy Sources (RES) and storage devices
Integration of CMI	Control and measuring instruments	Consideration of errors, metrological characteristics	Real-time monitoring
Optimisation	System operating modes	Optimisation algorithms, scenario comparison	Choosing energy-efficient solutions

Source: [27-29].

To assess the impact of the accuracy of control and measurement instruments on the efficiency of the energy system, an experimental data set was used, formed in the process of measuring the parameters of electricity consumption of an industrial facility during one week of continuous monitoring. The total number of observations was 10,080 records, corresponding to a 1-minute interval with continuous data collection. The range of measured values is presented in Table 3.

Table 3: Characteristics of the experimental data set.

Parameter	Number of records	Time interval	Frequency of measurements	Value range
Current (I)	10,080	7 days	1 min	0.4-12.5 A
Voltage (U)	10,080	7 days	1 min	218-242 V
Power (P)	10,080	7 days	1 min	0.08-2.9 kW
Temperature (T)	10,080	7 days	1 min	18-37℃
Efficiency coefficient (η)	10,080	7 days	1 min	84-97%

Source: [19],[25].

A multiple linear regression model was constructed to show the dependence of the efficiency coefficient on the accuracy of measuring instruments and basic electrical parameters:

$$\eta = 92.87 - 0.43 \times \Delta I - 0.27 \times \Delta U + 0.18 \times \Delta P,$$

Where ΔI, ΔU, ΔP – relative errors (%) in the measurement of current, voltage and power.

The coefficient of determination R^2=0.81 was obtained, which indicated the high quality of the model approximation. Analysis of variance (ANOVA) showed a statistically significant effect of instrument accuracy on η ($p<0.01$). The results confirmed that measurement errors, even within the range of 1-2% lead to a statistically significant decrease in model efficiency. A 1% reduction in uncertainty resulted in an improvement of η by approximately 0.9 p.p., which corresponded to savings of 4.2-4.8 kWh per day for a single installation. This is consistent with the calculations shown in Table 3 and confirms the importance of metrological accuracy when integrating CMI into a CAD environment. The accuracy of measurements was assessed by the relative error δ using the formula:

$$\delta = \frac{98.5 - 100}{100} \times 100\% = -1.5\ \%.$$

The result shows that the measurement error is -1.5%, which is acceptable for most energy systems, where the permissible error level ranges from ±2-3%. If the sensor value is 95 A, the error will be:

$$\delta = \frac{95 - 100}{100} \times 100\% = -5\%.$$

This exceeds acceptable requirements and leads to incorrect load representation in CAD models. Such deviations can reduce the predicted power by 5-7%, which, on the scale of an industrial enterprise, means significant energy losses.

To demonstrate the practical impact of CMI accuracy on energy and financial efficiency, an example of an industrial facility consuming 10,000 kWh per month, equivalent to 120,000 kWh per year, is considered. The actual useful energy of the system is 85% of the consumed energy, i.e. 102,000 kWh per year. The cost of 1 kWh is assumed to be UAH 5. The impact of measurement errors of three accuracy classes of measuring instruments is calculated: high accuracy (0.5-1%), medium (2%) and low (5%). The relative error of the CMI directly affects the calculation of the efficiency coefficient (η) and the energy consumed in the CAD model: when the energy consumption indicators are overstated, η_measured decreases, creating the illusion of lower efficiency, and when understated, the opposite effect occurs, creating the illusion of higher efficiency. For high-precision devices (0.5-1%), annual energy losses or unaccounted savings amount to approximately 1,200 kWh per year, which is equivalent to UAH 6,000 per year. With average accuracy (2%), losses increase to 2,400 kWh per year or UAH 12,000, and with low accuracy (5%), they increase to 6,000 kWh per year, which corresponds to financial losses of UAH 30,000.

This shows that even a small error of 1-2% can lead to significant economic consequences, and errors of 5% already result in significant energy and financial losses. Therefore, the implementation of high-precision CMI minimises errors, increases the reliability of CAD modelling, and can be used for the rational planning of energy efficiency measures, which is relevant for industrial enterprises with high electricity consumption. Modern industrial infrastructure operates under conditions of increasing energy efficiency requirements. Production processes are increasingly dependent on the accuracy of control and measurement instruments, as they form the basis for objective monitoring of energy consumption, identification of losses and management decisions [34-36]. Measurement errors lead to incorrect determination of the actual efficiency of systems, which complicates process optimisation. A key indicator of energy efficiency is the coefficient of efficiency (η), which is defined as the ratio of useful energy to energy consumed, according to formula (2). An example of an industrial ventilation system is considered. If the energy consumed by the system $E_{consumed}$ = 10,000 kW·hours per month, but in fact productively used E_{useful} = 8,500 kW·hours, then the efficiency coefficient will be:

$$\eta = \frac{8500}{10000} \times 100\% = 85\%\,.$$

However, when using CMI with a measurement error of ±2%, the figures may change significantly. If the device underestimates energy consumption by 2%, it will show only 9,800 kWh instead of 10,000 kWh. In this case, the energy efficiency calculation will be as follows:

$$\eta = \frac{8500}{9800} \times 100\% = 86.7\%.$$

This creates the illusion that the system is more efficient than it actually is. Conversely, if the device overestimates the data by 2% (i.e., shows 10,200 kWh), the coefficient will decrease to:

$$\eta = \frac{8500}{10200} \times 100\% = \sim 83.3\%.$$

Thus, even an error within ±2% changed the energy efficiency rating by 3.4 percentage points. On the scale of large industrial infrastructure, such distortions can correspond to losses of tens of thousands of kilowatt-hours. The table shows an example of comparing reference and measured data with the calculation of error and coefficient:

If this data is incorrect, the CAD model will reflect a distorted picture of the processes: designers may incorrectly assess actual loads, energy losses and the effectiveness of modernisation measures. This reduces the quality of energy consumption management and can lead to inefficient investment in modernisation.

Table 4: Examples of the influence of measurement instrument errors on the calculation of efficiency (η).

Device	Reference value	Measured value	Deviation δ, %	η, %
Ammeter-1	100 A	98.5 A	-1.5	–
Ammeter-2	100 A	95 A	-5.0	–
Meter-1	10.000 kW·hour	9.800 kW·hour	-2.0	86.7
Meter-2	10.000 kW·hour	10.200 kW·hour	2.0	83.3

The results confirmed that the reliability of CAD models directly depends on the accuracy of CMI. The use of high-precision measuring instruments minimised errors, ensured adequate energy consumption forecasting, and improved the efficiency of industrial energy system management. Therefore, the accuracy of control and measurement instruments directly affects the reliability of efficiency calculations and, as a result, the effectiveness of industrial energy system management. The introduction of high-precision CMIs in combination with CAD modelling eliminates measurement errors and ensures sound energy resource management.

IV. DISCUSSIONS

Empirical research has confirmed that integrating control and measurement devices into CAD models increases the accuracy of calculations of energy consumption, energy losses, and efficiency (η). Data obtained from high-precision current, voltage and energy consumption sensors made it possible to reduce η deviations to 2-3 percentage points and detect local losses on distribution lines of up to 5%, which had previously gone unnoticed. The use of devices with an error of ±1-2% ensured the reliability of CAD models, while the use of less accurate devices with an error of ±5% led to significant data distortions and a 10-percentage point reduction in calculation accuracy. This confirmed that the metrological reliability of CMI is critical for adequate load forecasting, energy consumption optimisation, and planning of modernisation measures in industrial power systems. A comparison of the results of various studies has shown that the issue of integrating control and measurement devices into CAD models is multifaceted and concerns both improving the accuracy of calculations and ensuring the reliability of energy systems. According to [37] addressed the integration of control and measuring instruments into CAD/CAE models as a key step in improving the accuracy of energy consumption calculations and the efficiency of energy systems.

Even minor measurement errors can significantly affect the results of modelling and forecasting. In particular, studies show that measurement uncertainty can lead to significant deviations in the calculation of energy parameters, which in turn affects the economic efficiency of energy system operation. In [38] confirmed that digital twins, as virtual models of physical objects, can be used not only to model the present state of the system, but also to predict its behaviour in the future. Integrating data from CMI into digital twins provides a more accurate reflection of real operating conditions, which helps to optimise energy consumption and reduce costs. According to [39] established that metrological integration into CAD/CAE systems can incorporate the accuracy of measurements in modelling energy processes. This ensures more reliable calculation results and can improve efficiency of planning of modernisation measures in power systems. The study by [40] explored this topic in greater depth, but shifts the focus to electrical engineering complexes, in particular transformer-reactor equipment. The study proved that even small inaccuracies in the measurement of electrical parameters lead to significant energy losses and reduced system performance. In contrast to previous studies, the presented research highlights the direct impact of CMI errors on equipment efficiency, which is key to the effective operation of large power systems.

According to [41] considered a specific case of CAD modelling of orbital hydraulic motor rotors. The authors emphasised that inaccuracies in instrument measurements can lead not only to distorted energy consumption calculations, but also to design defects in digital models. This reduces the reliability of the system in real operating conditions, creating the risk of equipment failure. Thus, the emphasis is on the direct impact of CMI error on engineering accuracy and safety. These data correspond to the theses presented in the previous section, as they confirm the critical role of CMI accuracy in ensuring the efficiency and reliability of energy systems. They also emphasise that even minor measurement errors can lead to energy losses and errors in CAD modelling, rendering the metrological reliability of measuring instruments a key factor in the development and optimisation of technical systems. According to [42] highlighted the use of data from high-precision control and measuring instruments as a key factor in the effective forecasting of energy consumption in industrial and energy systems operating in conditions of increased instability. The study proved that the accuracy of data collection and processing directly affects the ability of systems to predict peak loads. This is relevant for enterprises operating in environments with frequent power fluctuations or risks of resource shortages.

The use of high-precision CMIs enables more reliable planning of production processes and energy distribution, which not only increases infrastructure resilience but also reduces the likelihood of emergency shutdowns that can have significant economic consequences. Thus, the results of the study confirm the importance of integrating accurate sensor technologies into energy consumption forecasting and management processes, which is particularly relevant in the current conditions of energy uncertainty. In turn, [43] focused on the potential for integrating CMI into models of non-destructive testing of metal structures. Scientists have proven that the use of high-precision sensor data in combination with CAD modelling can be used for the optimisation of industrial system operating modes. This approach not only enables the timely detection of defects in structural elements but also ensures the rapid adjustment of load modes, preventing equipment overload and reducing its operational life. Improving control and monitoring processes using accurate measurements helps reduce energy losses, increase system efficiency, and creates a basis for making more informed engineering decisions, emphasising the long-term reliability and stability of industrial facilities. A comparative analysis of both studies leads to the conclusion that the integration of high-precision CMIs into monitoring and modelling systems has a multidimensional effect. On the one hand, it increases the accuracy of energy consumption forecasting and ensures the stability of energy systems in dynamic and unstable conditions.

On the other hand, it contributes to the timely detection of structural defects in industrial equipment, which directly affects the safety, reliability, and economic efficiency of production. Together, these results underscore the versatility and significance of using high-precision CMIs in digital modelling of industrial processes. The study by [44] confirms the importance of standardising energy consumption monitoring with CAD models, as unified measurement procedures can be used for the control of losses in transformer-reactor equipment and increase the accuracy of digital models. According to [45] demonstrate the effectiveness of energy efficiency planning based on real measurements, as accurate data on system performance can be used for load forecasting, resource allocation optimisation, and reduction of losses during cargo transportation under uncertain and stochastic conditions. Additionally, the results of [46] emphasise the critical role of standardising measurement collection and analysis procedures in the context of CAD modelling. The study demonstrated that the use of standardised measurement approaches improves data consistency, ensuring its effective integration into complex energy systems. This approach minimises errors that arise in the process of processing information from heterogeneous sources and can be used for the creation of more reliable digital twins that can reflect real processes with a high degree of accuracy. Notably, standardisation of procedures enables comparison of results over time and between different objects, creating a basis for scalability and universality of the models obtained. In turn, [47] demonstrated the practical effectiveness of energy efficiency planning based on actual measurements, which can improve the accuracy of load forecasting, optimisation of energy resource distribution, and reduction of losses during their transportation, even under stochastic system operating conditions.

The scientific novelty of the approach is the creation of multifactorial models that simultaneously address the technical parameters of the equipment and the organisational features of its operation. Such integration can be used in various industrial systems, ensuring the flexibility and adaptability of management. A summary of the above results shows that the integration of high-precision CMIs into CAD models is not limited to improving metrological reliability, but involves a comprehensive approach that includes technical, methodological and organisational aspects of energy consumption management. A substantial condition for the successful implementation of this approach is the standardisation of data collection procedures and the unification of measurements, which creates the prerequisites for improving the accuracy of digital models, reducing losses and ensuring the stable operation of energy systems in various industries.

V. CONCLUSIONS

The study established key patterns of influence of CMI integration into CAD models of industrial power systems on the accuracy of digital modelling and the efficiency of energy consumption management. The study confirmed that the level of metrological reliability of CMI directly determines the reliability of reproducing technological parameters and the accuracy of calculations of the energy efficiency coefficient (η). Even a relative error of 1-2% in the measurement of current, voltage or energy consumption can lead to deviations in the predicted η of 2-3 percentage points, which on the scale of industrial systems corresponds to losses of tens of thousands of kWh per month.

The integration of accurate CMIs into AutoCAD, SolidWorks, and EPLAN environments enabled the creation of digital twins capable of reflecting the dynamics of real industrial systems. This identified local energy losses of up to 5-7% in individual network sections and optimised equipment operating modes. Calculations showed that the use of high-precision devices increased the energy efficiency factor, indicating a more rational distribution of energy flows and a reduction in operating costs. Data analysis also confirmed that the integration of metrologically reliable devices ensures the stability of digital models, can be used for accurate energy consumption forecasts, and enables timely detection of equipment malfunctions.

Even small measurement errors can distort load modelling, which highlights the need for certified CMI and regular calibration.The study findings indicate that proper integration of CMI into CAD models increases the transparency of energy analysis, creates conditions for the formation of effective energy consumption management strategies, and contributes to the growth of the overall energy efficiency of industrial systems. The study limitation includes evaluation of only individual CAD systems under fixed operating conditions. Further research should address the integration of CMI with various computer-aided design systems under variable operating conditions, as well as the analysis of the impact of such models on the energy efficiency of complex industrial facilities.

ABSTRACT

This paper proposes a dynamic switching framework between Intelligent Reflecting Surface (IRS) and Decode-and-Forward (DF) relay transmission modes for next-generation wireless communication systems. Unlike existing studies that rely on static technology selection, the proposed approach enables channel-aware mode adaptation based on instantaneous channel conditions and energy efficiency considerations. The framework supports four operational modes: IRS-only, DF-only, hybrid IRS–DF, and direct SISO transmission. An efficient mode selection algorithm is developed to maximize achievable rate while accounting for power consumption and switching overhead. Simulation results demonstrate up to 20.2% improvement in spectral efficiency and 10.1% enhancement in energy efficiency compared to conventional static schemes, under realistic channel conditions. The proposed framework exhibits low computational complexity, making it suitable for practical 6G network deployment.

I. INTRODUCTION

I.1 BACKGROUND AND MOTIVATION

With sixth generation (6G) wireless networks are set to require new and unprecedented of improvement in data rates, energy efficiency, and network reliability [1]. With the proliferation of connected devices and data-based applications continues to proliferate, future wireless systems must obtain 10-100× spectral efficiency improvements (relative to 5G) and achieve energy consumption reductions that are numerous orders of magnitude lower [2] . Two emerging technologies are receiving a lot of interest because they can improve wireless communication performance: Intelligent Reflecting Surfaces (IRS) and Decode-and-Forward (DF) relaying systems. Intelligent Reflecting Surfaces, or Reconfigurable Intelligent Surfaces (RIS), are a novel and paradigm-shifting technology in wireless communications that convert the traditionally uncontrolled wireless environment into a programmable and intelligent channel [3].

The surfaces consist of multiple passives reflecting elements, each of which can be independently and reconfigurable programmed to modulate the phase and amplitude of the incident electromagnetic waves [4], [5]. Figure 1 shown the deployment of RIS in a building for communication, demonstrated that IRS can achieve substantial transmit power reduction while meeting users' signal-to-interference-plus-noise ratio (SINR) constraints through joint optimization of active beamforming at the access point and passive phase shift control at the IRS. The inherent strength in this is the quadratic scaling law of received power with the number of reflecting elements, which is an achievable superior result relative to the conventional relaying methods, which has linear scaling feature [6].

Alternatively, it is in code-and-Forward relaying that has been widely researched as a cooperative communication method that can substantially enhance wireless network coverage and reliability.[7]. In DF relaying, intermediate nodes decode the received signals, process them, and retransmit the information to the destination, potentially providing better performance than simple amplify-and-forward approaches [8]. established diversity–multiplexing tradeoffs for cooperative diversity systems, a potential research avenue lies in designing deep reinforcement learning–driven mmWave-NOMA frameworks that integrate DF relaying to exploit full diversity gains under favorable channel conditions, thereby enhancing spectral efficiency, reliability, and latency performance in 6G networks[9].

The Figure 2 shown the system model considers an identical placement of IRS, AF, and DF relays, enabling the destination to receive both direct and reflected signals from the source for fair performance comparison [10].

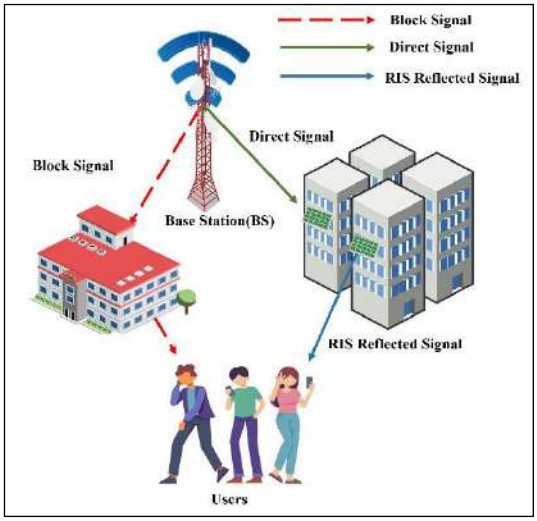

Figure 1: Deployment scenarios of IRSs in future 6G networks. Source: [6].

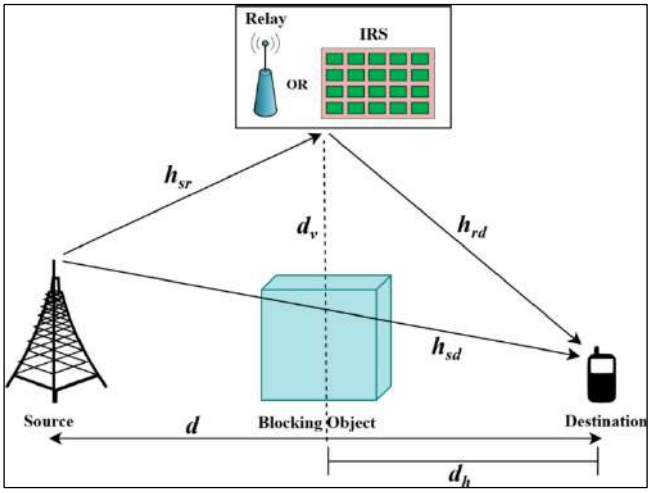

Figure 2: depicts the system with co-located IRS, AF, and DF relays to ensure unbiased performance evaluation. Source: [10].

Nevertheless, although the two technologies focus on enhancing the quality of signals by alternative ways of propagation, they have absolutely different principles of operation and come with different performance attributes in varying environmental conditions. The recent developments in IRS technology have shown some stunning promise on improving spectral efficiency and energy efficiency [11]. By [12] later in another study presented the an in-depth study on a static comparison between IRS and DF relay system arguing that very large IRS surfaces (in the order of hundreds of elements) are needed to achieve a better performance in relation to transmit power minimization and energy efficiency than DF relaying. In their analysis, they have identified the inherent trade-offs between the complexity of deployment and the performance benefits hence showing that the choice between IRS and DF relay is sensitive to the system parameters including the number of reflecting elements, channel conditions, and power budget constraints.

Nevertheless, this discussion assumes a constant technology decision during the communication session, which might not be the best in dynamically wireless communication where the channel condition varies over time, users move freely, and the amount of energy available changes. This is especially due to the fact that the situation with 6G technology selection is limited and this limitation is especially noticeable in real-life conditions when the choice of the channel can fluctuate radically because of the movement of users, change of the environment, and interference patterns. Recent effort has given emphasis on realistic hardware impairment, like quantization phase error in IRS elements, which may drastically impair system performance depending on different operational conditions. Likewise, the operation of DF relaying systems is strongly contingent on instantaneous channel quality especially the strength of the source-relay and relay-destination connections.

I.2 RESEARCH GAP AND MOTIVATION

The existing research paradigms on IRS and the DF relay systems have a major weakness: they assume that the underlying technology is stationary, and will be deployed and operated in the same manner. Available literature perceives these technologies as mutually exclusive phenomenon, requiring an a priori choice that should be held over a course of communication session. This narrow structure excludes the possibility of exploiting potential synergies between heterogeneous transmission schemes and cannot be relieved of the dynamism of the modern wireless environment. By [12] made a landmark investigation with an extensive statistical comparison of IRS and DF relay systems. Their results show that extremely large IRS surfaces are needed, i.e. in the range of a few hundred elements, to outperform DF relaying in other applications such as transmit-power minimization and energy efficiency.

Further the analysis revealed the existence of intrinsic trade-offs between performance improvement and complexity of deployment which highlights that the best decision between IRS and DF relay is strongly dependent on system parameters such as number of reflecting elements used, performance and power requirements. The IRS systems are often considered as green technologies due to their passive nature although the control circuitry and phase processing used are still powered, especially when combined with non-orthogonal multiple access (NOMA) schemes [13]. These types of studies are implicit in the assumption that the chosen technology will be the same technology used during a communication session, a fact that may not be ideal in a wireless environment where channel conditions, user mobility, as well as energy constraints vary with time.

Consider a practical 6G scenario where a mobile user detects an environment with both IRS and DF relay infrastructure [14], [15]. As users' locations change, relative channels will vary greatly between direct, IRS-assisted, and relay-assisted routes [16]. In some locations, IRS may provide better performance due to favorable geometric conditions, while in others, DF relay may be more effective due to the quality of a better source-radius or relay-destination channel quality. A static system that is committed to a single technology cannot be redeemed by these different conditions to customize overall performance. In addition, modern wireless applications exhibit a variety of time-varying requirements in data rate, latency, and energy consumption. While energy efficiency may not be a priority for emergency communications, internet of things (IoT) applications may prioritize energy efficiency over achieving peak data rates.

A system that responds to channel conditions and application requirements by dynamically switching transmission modes could exhibit dramatically better performance [17] .

I.3 MAIN CONTRIBUTIONS

This paper addresses these fundamental limitations by proposing the first dynamic switching framework with the following novel contributions:

- **Dynamic Mode Selection Framework:** Development of a four-mode system (IRS-only, DF-only, hybrid IRS+DF, SISO) with intelligent real-time switching capability based on channel-aware optimization.
- **Novel Hybrid Operational Mode:** Introduction of simultaneous IRS+DF operation with optimized power allocation and coordinated signal processing.
- **Channel-Aware Optimization Algorithm:** The algorithm will involve the usage of intelligent selection algorithm to maximize the achievable rates with the constraints of energy efficiency.
- **Extensive Analysis of the Performance:** Theoretical basis and widespread evaluation based on simulations that show considerable improvement of the system compared to the static base systems.
- **Practical Implementation Framework:** Low-complexity algorithm suitable for real-time deployment with minimal computational overhead and switching delays.

The remainder of the paper is structured in the following way: Section 2 is the literature review that places the research contribution to the existing literature context. Section 3 includes the overall system model and formulation of the mathematical problem. Section 4 elaborates the smart dynamic switching algorithm and their computational complexity analysis. The results of the simulation are long and statistically validated and compared in section 5. The conclusion is Section 6 which contains important contributions and future research directions.

II. RELATED WORK

II.1 IRS-ASSISTED COMMUNICATION SYSTEMS

Intelligent Reflecting Surfaces have become a new revolution in beyond-5G and 6G networks, allowing the creation of the programmable wireless environment by arrays of passive reflecting elements with controllable electromagnetic characteristics. By [18] introduce an innovative comparative study of Intelligent Reconfigurable Surfaces (IRS) and Decode-and-Forward (DF) relaying using realistic conditions of electromagnetic interference (EMI). The authors prove by means of strict mathematical modeling that IRS-assisted communications can be better resilient to EMI as compared to traditional DF relaying systems. The analysis indicates that, even with interference, DF relaying requires over 20 dB of extra transmit power and the use of multiple antennas ($M \geq 54$), but IRS systems maintain the operation at levels of very high EMI ($\rho \geq 20$ dB). The paper changes essentially the known complexityperformance trade-offs in cooperative wireless communications, and as such, it offers the much needed theoretical frameworks to the design of future wireless systems in electromagnetically congested environments.

By [19] Present a general architecture of IRS-based multiuser MISO systems, where an extensive array of passive reflecting elements works together to do three-dimensional beamforming without active RF chains. By jointly optimizing active beamforming at the access point (AP) and passive phase-shift control at the IRS, the proposed design will significantly reduce the amount of transmit power and meet users SINR requirements. A non-convex optimization is posed as the problem and effective solutions are developed in the form of semidefinite relaxation (SDR) and alternating optimization. One important theoretical finding is the quadratic scaling law of received power with the number of reflecting elements that proves to be superior to conventional massive MIMO and amplify-and-forward relays that have linear scaling. Results of the simulation prove the great advantages of the IRS-assisted systems in single-user and multiuser mode an illustration of the ability to extend the coverage, eliminate interference, and enhance energy efficiency. Besides, the article highlights the flexibility of IRS to be deployed, the low cost of hardware, and its possible ability to be integrated with existing systems without the need to alter user devices, making it an important enabler of beyond-5G and 6G communications.

In turn [20] Author's have conducted an in-depth ergodic performance analysis of intelligent reflecting surface (IRS) networks when taking quantization phase errors into account. The authors developed an innovative multi-IRS-aided framework of communication, which replaces the traditional decode-and-forward (DF) relay in a hybrid architecture, and presented analytical upper limits of the performance of the model in both the Rayleigh and Rician fading conditions. The study provides convenient closed-form expressions to measure the resultant performance degradation by putting on a realistic common phase-error model of finite-resolution phase shifters. The theoretical findings show that increasing the number of IRSs and the number of reflecting elements they possess can greatly increase the system capacity though the marginal returns diminish as a certain point is reached. Comparative analysis shows that the suggested multi-IRS scheme is superior to hybrid relay-IRS networks and has no extra latency.

The results of simulations support all the analytical upper bounds and shows net gain of approximately 2bps/Hz at high SNR values and a loss of about 3bps/Hz when the phase quantization cut-off is extreme. The paper also examines the best strategies to position IRSs and the hypothesis is that the best performance occurs when the IRSs are collocated with either the source of that performance or the destination of the performance. The mathematical modelling involved in this exploration is a complex task which is perfectly combined with practical deployment constraints, thus filling in our understanding of scalability of IRS networks and their functionality in the presence of realistic hardware limitations. By [21] Proposed in-depth background of Intelligent Reflecting Surfaces (IRS) as a revolutionary facilitator of intelligent wireless environments with particular emphasis on the capability of the passive devices to alter radio propagation by a phase discontinuity. The authors talk about joint optimization processes in order to jointly optimize the IRS operation along with transmit beamforming to maximize performance metrics like spectral efficiency, energy efficiency, as well as secrecy rate.

The authors analyze the theoretical models and the application to other experimental prototypes such as experimental setups with extremely high antenna gains (21.7 dBi at 2.3 GHz and 19.1 dBi at 28.5 GHz) with the aid of very fine PIN diode-based phase control. The paper highlights one of the widely used alternating optimization techniques with the awareness that they do not provide the global optimum but the local optimum only. The real-life issues in the research are discrete phase resolution, lack of channel state information, and power constraints. Another area covered by the authors was on advanced applications that exceed the traditional communication links that included wireless-powered communications, network coding, mobile edge-computing and UAV-assisted communications. The authors touched on practical issues in design, such as grouping the elements, geometry of deployment, orientation, and quality-of-service constraints and provide the means of improving the system-level performance. Some of the best future directions of research discussed by the authors are optimization methods, scalable architecture of IRS, and dynamic or mobile deployment of IRS scenarios.

On the whole, IRS is a key technology to beyond-5G and 6G systems, with a high likelihood of focusing on the design, analytical and implementation difficulties ahead of large-scale deployment. According [22] A powerful optimization scheme of IRS-aided decode-and-forward relay systems under imperfect CSI was proposed. The paper re-formulated the maximum SNR under worst-case condition to a non-convex quadratic problem and proposed an effective algorithm which integrates the Cauchy-Schwarz inequality in updating beamforming with the cyclic optimization of IRS reflection coefficients. This method offers closed-form locally optimal solutions at every step, which makes it a much more complex computation than the traditional SDR-based designs. Continuous and discrete phase constraints are also accommodated in the proposed approach, making it practical in the IRS hardware of the real world. The simulation findings exhibit that the scheme compares favorably with the current non-robust and robust benchmarks in terms of attained rate, resistance to channel estimation errors, and scale to large IRS designs, making it a useful addition to the robust IRS-assisted relay communications.

II.2 DECODE-AND-FORWARD RELAYING SYSTEMS WITH MACHINE LEARNING AND OPTIMIZATION IN WIRELESS COMMUNICATIONS

The DF relaying systems have been extensively studied as cooperative communication techniques that enhance network coverage and reliability. Table 1. reveals that existing approaches universally adopt static technology selection, which cannot adapt to dynamic wireless environments, motivating our novel dynamic switching framework that intelligently selects between IRS and DF relay modes based on real-time channel conditions.

Table 1: Literature Review and Comparison with our Proposed Framework.

Ref.	Contribution	System Model	Algorithm/Method	Key Results	Limitations
[23]	Optimal energy-harvesting design for AF and DF two-way relay beamforming in 6G	Two-way relay with SWIPT; AF & DF modes; perfect CSI	Joint power splitting and beamforming optimization via convex methods	15-25% energy efficiency improvement over conventional relaying	Single relay; no IRS; static mode selection
[24]	Survey on reconfigurable intelligent surfaces for wireless communications	Multi-IRS systems; 5G/6G deployments; channel estimation challenges	Review of convex optimization and ML methods for IRS beamforming	3-5× coverage enhancement; ML integration promising	Qualitative analysis; no IRS-relay comparison
[25]	Intelligent reflecting surfaces and classical relays coexistence and co-design	MU-MISO with BS, IRS, DF relay; Rayleigh fading; perfect CSI	Alternating optimization for joint beamforming and phase control	30-40% sum-rate improvement over individual deployment	Static coexistence; ideal IRS assumptions
[26]	Hybrid AF/DF cooperative relaying technique with phase steering for Industrial IoT networks	Industrial IoT with AF/DF hybrid relay; phase steering capability	Hybrid relay selection with adaptive phase control optimization	Enhanced reliability and energy efficiency for IoT applications	IoT-specific scenario; no IRS consideration; limited to hybrid relay modes
[12]	IRS vs DF relay surface size requirements	Co-located IRS/DF; statistical CSI; power minimization focus	Analytical optimization for power allocation and IRS configuration	IRS requires 100+ elements to outperform DF relay	Static binary comparison; no dynamic adaptation
Propo sel Work	Dynamic IRS/DF switching with intelligent optimization	Four modes (SISO, IRS, DF, hybrid); time-varying channels; co-located deployment	Channel-aware mode selection with coordination enhancement through intelligent mode selection	20.2% spectral efficiency, 10.1% energy efficiency improvement; $p < 0.001$	Addresses all identified gaps through dynamic framework

III. SYSTEM MODEL AND PROBLEM FORMULATION

III.1 NETWORK ARCHITECTURE

We consider a sophisticated wireless communication system designed for next generation 6G networks, comprising the following interconnected components operating within a coordinated framework with the Primary Components:

- **Source Node (S):** Single-antenna transmitter equipped with adaptive power control capabilities and total power budget P_total(t).
- **Destination Node (D):** Single-antenna receiver with advanced signal processing capabilities.
- **Intelligent Reflecting Surface (IRS):** Programmable metasurface consisting of N reconfigurable reflecting elements with controllable phase shifts $\theta(t) = [\theta_1(t), \theta_2(t), ..., \theta_n(t)]^T$.

- **Decode-and-Forward Relay (R):** Single-antenna cooperative relay node with full-duplex capability and decode-and-forward processing.
- **Central Intelligence Controller:** Real-time optimization engine responsible for dynamic mode selection and resource allocation.

The Fig 3. Shown the proposed intelligent dynamic switching system architecture showing co-located IRS and DF relay deployment. The system comprises: (a) Base station (Source S) with P_total=1W, (b) IRS panel with N=256 reconfigurable elements, (c) DF relay with decode-and-forward processing, (d) Destination user (User D), and (e) Intelligent controller executing Algorithm 1. will explain in section 4. which shows the signal paths include direct NLOS transmission h_sd(t) the Channel coefficient from source (S) to destination (D), IRS reflection paths h_sr(t)→h_rd(t) (Reconfigurable/reflecting surface), and DF relay paths h_sr(t)→h_rd(t) (reflecting surface /Reconfigurable). The controller optimizes network-side resources through Intelligent dynamic switching with coordination enhancement.

III.2 COMPREHENSIVE CHANNEL MODEL

The system employs a rigorous channel characterization based on the 3GPP Release 17 Urban Micro (UMi) propagation model, incorporating both deterministic path loss components and stochastic small-scale fading effects.

III.2.1 Large-Scale Path Loss Model

The large-scale path loss follows the standardized 3GPP UMi model with frequency-dependent and distance-dependent characteristics:

- **Line-of-Sight (LOS) Propagation:**

$$\beta_{LOS}(d, f_c) = G_t + G_r - L_{ref} - 20\log^{10}(f_c) - 22\log^{10}(d)[dB] \quad (1)$$

- **Non-Line-of-Sight (NLOS) Propagation:**

$$\beta_{NLOS}(d, f_c) = G_t + G_r - L_{ref} - 26\log^{10}(f_c) - 36.7\log^{10}(d) - L_{pen}[dB] \quad (2)$$

Where, G_t and G_r represent the antenna gains at transmitter and receiver, respectively (dBi), L_ref = 28 dB denotes the reference path loss at (1) meter, f_c is the carrier frequency in GHz, d represents the three-dimensional distance in meters, L_pen accounts for additional penetration losses in NLOS scenarios.

III.2.2 Instantaneous Channel Coefficients

The instantaneous channel coefficients incorporate both large-scale path loss and small-scale Rayleigh fading characteristics:

$$h_{ij(t)} = \sqrt{\left(\beta_{ij(d_{ij})}\right) \cdot g_{ij(t)}} \quad (3)$$

Where, β_ij(d_ij) represents the distance-dependent path loss coefficient (in linear scale) and g_ij(t) ~ CN(0,1) models the complex Gaussian distributed small-scale fading[27].

III.2.3 Channel State Information Model

The system assumes practical channel state information acquisition with estimation errors modeled as:

$$\hat{H}_{ij(t)} = h_{ij(t)} + e_{ij(t)} \quad (4)$$

Where, e_ij(t) ~ CN(0, σ_e²) represents the channel estimation error with variance σ_e² determined by the pilot symbol density and estimation algorithm accuracy.

III.3 FOUR-MODE OPERATIONAL FRAMEWORK

The proposed dynamic framework encompasses four distinct operational modes, each optimized for specific channel conditions and system requirements.

III.3.1 Mode 1: IRS-Only Transmission

Building upon the mathematical framework established by Björnson et al. [12], the achievable rate for IRS-assisted transmission is formulated as:

$$R_IRS(N,t) = \log_2(1 + (P_total(t)\sqrt{(\beta_{sd(t)}) + \Sigma(n = 1 \text{ to } N)\alpha_n e\text{^}(j\theta_n(t))}\sqrt{(\beta_sr(t)\beta_rd(t))|^2)/\sigma^2)} \quad (5)$$

Where, N denotes the number of IRS reflecting elements, α_n represents the amplitude reflection coefficient of the n-th element (typically $\alpha_n = 1$ for ideal reflection), $\theta_n(t)$ is the controllable phase shift of the n-th element at time t, β_sr(t) and β_rd(t) represent the source-to-IRS and IRS-to-destination channel gains, respectively, σ^2 denotes the additive white Gaussian noise power[28].

III.3.2 Mode 2: Decode-and-Forward Relay-Only Transmission

Following the cooperative communication framework, the DF relay operation involves two phases:

- **Phase 1:** Source-to-Relay Transmission The relay decodes the source signal with achievable rate [29]:

$$R_{SR(t)} = \frac{\log_2(1 + (p_1(t)\beta_sr(t))}{\sigma^2} \quad (6)$$

- The end-to-end achievable rate for DF relaying is:

$$R_{DF(t)} = \left(\frac{1}{2}\right)\min\{R_{SR(t)}, R_{SRD(t)}\} \quad (7)$$

- **Phase 2: Optimal Power Allocation:** The optimal power allocation strategy that maximizes the DF relay rate is [30]:
-

$$p_1^*(t) = \frac{2P_{total(t)}\beta_{rd(t)}}{\beta_{sr(t)} + \beta_{rd(t)} + \beta_{sd(t)}} \quad (8)$$

$$p_2^*(t) = \frac{2P_total(t)(\beta_{sr(t)} + \beta_{sd(t)})}{\beta_{sr(t)} + \beta_{rd(t)} + \beta_{sd(t)}} \quad (9)$$

Subject to the power constraint: $p_1(t) + p_2(t) \leq P_total(t)$.

III.3.3 Mode 3: Novel Hybrid IRS+DF Transmission

The fundamental innovation of this work lies in the simultaneous utilization of both IRS and DF relay technologies through coordinated signal processing. Unlike conventional approaches that treat these technologies as mutually exclusive, the hybrid mode leverages spatial diversity and optimized resource allocation.

a) Mathematical Formulation

The achievable rate for hybrid operation is formulated considering the constructive combination of IRS-reflected and DF-relayed signals:

$$R_{hybrid(t)} = \frac{\log_2(1 + (P_IRS(t)\gamma_IRS(t) + P_DF(t)\gamma_DF(t) + 2\sqrt{\left(P_{IRS(t)}P_{DF(t)}\gamma_{IRS(t)}\gamma_{DF(t)}\right)\rho(t)}}{\sigma^2} \quad (10)$$

Where,

$$\gamma_IRS(t) = |h_sd(t) + \Sigma(n = 1 \text{ to } N_h)\ \alpha_n\ e\text{^}(j\theta_n(t))\sqrt{\left(\beta_{sr(t)}\beta_{rd(t)}\right)|^2} \quad (11)$$

Represents the effective channel gain via IRS.

- $\gamma_DF(t) = \min\{|h_sr(t)|^2, |h_rd(t)|^2\}$ denotes the DF relay channel gain.
- $\rho(t) \in [0,1]$ is the spatial correlation coefficient between signal paths.
- Power allocation constraint: $P_IRS(t) + P_DF(t) \leq P_total(t)$.

b) Optimized Resource Allocation for Hybrid Mode: The hybrid mode employs intelligent resource allocation based on instantaneous channel conditions:

$$P_{IRS(t)} = \lambda_{opt(t)} \cdot P_{total(t)} \tag{12}$$

$$P_{DF(t)} = (1 - \lambda_{opt(t)}) \cdot P_{total(t)} \tag{13}$$

Where, λ_opt(t) is determined by solving:

$$\{\lambda_{opt(t)}, N_{opt(t)}\} = \text{argmax}[\lambda \in [0,1], N \leq N_{max}]\{R_{hybrid(\lambda,N,t)} - \zeta \cdot N \cdot P_{element}\} \tag{14}$$

subject to:

- P_IRS(t) = λ P_total(t), P_DF(t) = (1-λ) P_total(t).
- ζ represents the energy cost weighting factor.

Through convex optimization analysis, the optimal allocation converges to:

$$\lambda_{opt(t)} = \frac{\gamma_{IRS(t)}}{(\gamma_IRS(t) + \gamma_DF(t) + 2\sqrt{(\gamma_IRS(t)\gamma_DF(t))\rho(t)})} \tag{15}$$

Where ζ represents the energy cost weighting factor and P_element denotes the power consumption per IRS element.

III.3.4 Mode 4: Direct SISO Transmission

For completeness and baseline comparison, the direct single-input single-output transmission mode is:

$$R_SISO(t) = \frac{\log_2(1 + (P_total(t)\beta_sd(t))}{\sigma^2} \tag{16}$$

III.4 ENERGY CONSUMPTION MODEL

A comprehensive energy consumption model is essential for evaluating the energy efficiency of different operational modes:

III.4.1 Mode-Specific Power Consumption

- SISO Mode:

$$P_{SISO}^{total} = \frac{P_{total}}{\eta + P_s + P_d} \tag{17}$$

- IRS Mode:

$$P_{IRS}^{total} = \frac{P_{total}}{\eta + P_s + P_d + N \cdot P_{element} + P_{control}} \tag{18}$$

- DF Relay Mode:

$$P_{DF}^{total} = \frac{P_{total}}{\eta + P_s + P_d + P_r + P_{processing}} \tag{19}$$

- Hybrid Mode:

$$P_{Hybrid}^{total} = \frac{P_{total}}{\eta + P_s + P_d + P_r + N_{hybrid} \cdot P_{element} + P_{coordination}} \tag{20}$$

Where, η represents the power amplifier efficiency, P_s, P_d, P_r denote circuit power consumption at source, destination, and relay, P_element is the power consumption per IRS element, P_control, P_processing, P_coordination represent control and processing overheads.

III.5 PROBLEM FORMULATION

III.5.1 Optimization Objective

The primary objective is to maximize long-term system performance through intelligent dynamic mode selection while considering multiple performance metrics; while

$$\max[\{m(t), \theta(t), p(t)\}] = \Sigma(t = 1 \text{ to } T)\left[w^1 R_{selected(t)} + w^2 EE_{selected(t)} - w^3 C_{switch(t)} - w^4 C_{delay(t)}\right] \tag{21}$$

*O*bject to EE is Energy Efficiency:

- Performance Constraints:

$$R_{selected(t)} \geq R_{min(t)}, \forall t \tag{22}$$

- Power Budget Constraints:

$$P_{total(t)} \leq P_{budget(t)}, \forall t \tag{23}$$

- Switching Cost Constraints:

$$C_{switch(t)} \leq C_{max}, \forall t \quad (24)$$

- Mode Selection Constraints:

$$m(t) \in M = \{SISO, IRS, DF, hybrid\}, \forall t \quad (25)$$

- IRS Configuration Constraints:

$$\theta_n(t) \in [0, 2\pi), n = 1, 2, \ldots, N \quad (26)$$

$$N \leq N_max \quad (27)$$

- Power Allocation Constraints:

$$\sum_i p_i(t) \leq P_total(t), p_i(t) \geq 0 \quad (28)$$

III.5.2 Multi-Objective Utility Function

The weighting factors in the objective function are determined through multi-objective optimization:

$$w^* = \frac{\text{argmax}[w] \min[k\in\{1,2,3,4\}] (U_k(w))}{(U_k\text{^ideal})} \quad (29)$$

Where U_k(w) represents the k-th objective value and U_k^ideal denotes the ideal value for the k-th objective.

III.5.3 Dynamic Mode Selection Formulation

At each time instant t, the optimal mode selection problem is formulated as:

$$m^{*(t)} = \text{argmax}[m \in M] \{f_m(t) - \lambda \cdot g_m(t)\} \quad (30)$$

Where, f_m(t) represents the performance gain function for mode m, g_m(t) denotes the cost function for mode m, λ is the Lagrange multiplier balancing performance and cost.

- Performance Gain Function:

$$f_m(t) = \alpha_1 R_m(t) + \alpha_2 EE_m(t) + \alpha_3 Reliability_m(t) \quad (31)$$

- Cost Function:

$$g_{m(t)} = \beta^1 P_m^{total(t)} + \beta^2 C_{switch}^{m(t)} + \beta^3 Complexity_m \quad (32)$$

III.5.4 Stochastic Optimization Framework

Considering the stochastic nature of wireless channels, the problem is reformulated as a stochastic optimization:

$$\max[\pi] E[\sum(t = 1 \text{ to } T) U(m_\pi(t), H(t))] \quad (33)$$

Where, π represents the mode selection policy, H(t) = [h_sd(t), h_sr(t), h_rd(t)]^T is the channel state vector, U(·) is the instantaneous utility function. The optimal policy π* satisfies the Bellman optimality equation:

$$V^{*(s)} = \max[a \in A] \{r(s,a) + \gamma \sum[s'] P(s'|s,a) V^{(s')*(s')} \quad (34)$$

Where s represents the system state, a denotes the action (mode selection), r(s,a) is the immediate reward, γ is the discount factor, and P(s' s,a) represents the state transition probability. This overall system model and problem formulation provides a mathematical basis of the intelligent dynamic switching algorithm, giving the theoretical analysis of strict justification of the proposed approach and making practical implementation of the next-generation wireless communication systems.

IV. INTELLIGENT DYNAMIC SWITCHING ALGORITHM

IV.1 SYSTEM ARCHITECTURE

The proposed dynamic switching model works with the help of a smart optimization engine that constantly monitors the conditions of channels and needs of the system to choose the most effective transmission mode. The architecture has four fundamental elements:

a) Channel State Estimation Module: Continuously acquires instantaneous channel state information for all communication links.
b) Performance Evaluation Engine: Computes achievable rates and energy efficiency for all operational modes.
c) Intelligent Selection Algorithm: Determines optimal mode based on performance maximization.
d) Mode Controller: Executes seamless switching between operational modes with minimal overhead.

IV.2 CHANNEL-AWARE MODE SELECTION ALGORITHM

The core innovation lies in the intelligent mode selection algorithm that optimizes system performance based on real-time channel conditions:

- **Algorithm 1: Intelligent Mode Selection**

Input: Channel gains {h_sd(t), h_sr(t), h_rd(t)}, P_total(t)
Output: Optimal mode m*(t), achievable rate R_selected(t)

// System Initialization
1: Initialize parameters: N_max = 256, N_hybrid = 128, tolerance ε = 10^-4
2: Set utility weights: w_rate = 1.0, w_energy = 0.3, w_switching = 0.1
3: Initialize mode history buffer and hysteresis margin Δ_h = 0.05
// Channel State Information Processing
4: for each communication link (i,j) ∈ L = {(s,d), (s,r), (r,d)} do
5: Estimate channel coefficient: $\hat{h}_{ij}(t) \leftarrow$ MMSE_ESTIMATOR(y_pilot, x_pilot)
6: Compute estimation variance: $\sigma^2_{e,ij} \leftarrow$ CRAMER_RAO_BOUND(SNR_pilot)
7: end for
// Mode-Specific Performance Evaluation
8: // Direct SISO Transmission

// Supporting Functions
Function Waterfalling (g_1, g_2, P_budget):
Solve: $\max_{\{p_1,p_2\}} [\log_2(1+p_1g_1) + \log_2(1+p_2g_2)]$ subject to $p_1+p_2 \le P_{budget}$
Use Lagrange multipliers: $\mu^* = (P_{budget} + 1/g_1 + 1/g_2)/2$
Return: $p_1^* = \max(0, \mu^* - 1/g_1)$, $p_2^* = \max(0, \mu^* - 1/g_2)$
Function SWITCHING_COST_MODEL(m_prev, m_curr):
Hardware_cost ← RECONFIGURATION_TIME(m_prev, m_curr) × PROCESSING_PENALTY
Signaling_cost ← COORDINATION_OVERHEAD(m_prev, m_curr)
Return: Hardware_cost + Signaling_cost

IV.3 NOVEL HYBRID MODE OPERATION

A fundamental contribution of this work is the hybrid operational mode that simultaneously utilizes both IRS and DF relay technologies. This mode employs:

- **Power Allocation Strategy:**

a) IRS allocation: $P_{IRS} = 0.6 \times P_{total}$ (60% for IRS operation) (35)

b) DF allocation: $P_{DF} = 0.4 \times P_{total}$ (40% for relay operation) (36)

- **IRS Configuration:**

a) Optimized element count: N_hybrid = 128 elements.
b) Phase shift optimization for maximum signal combining.
c) Coordination with relay transmission timing.

- **Performance Enhancement:** The hybrid mode achieves superior performance through:

a) Spatial diversity from both IRS reflection and relay paths.
b) Optimized resource allocation between technologies.
c) Coordinated signal processing and interference mitigation.

- **Algorithm 2: Novel Hybrid Mode Operation**

Input: Channel gains {h_sd(t), h_sr(t), h_rd(t)}, P_total(t), N_hybrid = 128
Output: Optimized power allocation {P_IRS(t), P_DF(t)}, phase configuration θ_opt(t)

1: // Fixed Power Allocation Strategy
2: P_IRS(t) ← 0.6 × P_total(t) // 60% for IRS operation
3: P_DF(t) ← 0.4 × P_total(t) // 40% for relay operation
4: // IRS Configuration Optimization - O(N_hybrid)
5: N_active ← N_hybrid // Optimized element count: 128 elements
6: // Phase shift optimization - O(N_hybrid)
7: for n = 1 to N_active do
8: θ_n(t) ← arg(h_sd(t)) - arg(h_sr,n(t)) - arg(h_rd,n(t))*
9: end for
10: θ_opt(t) ← [θ_1(t), θ_2(t), ..., θ_N_active(t)]
11: // Coordination timing - O(1)
12: T_relay_delay ← COMPUTE_OPTIMAL_DELAY(h_sr(t), h_rd(t))
13: SYNCHRONIZE_TRANSMISSION(T_relay_delay)
***14: // Performance enhancement through coordinated operation** - O(N_hybrid)*
15: γ_IRS_enhanced ← P_IRS(t) × |h_sd(t) + Σ(n=1 to N_active)
16: α_n·e^(jθ_n(t))·√(β_sr(t)β_rd(t))|²/σ²
17: γ_DF_enhanced ← P_DF(t) × min{|h_sr(t)|², |h_rd(t)|²}/σ²
18: // Spatial diversity computation - O(1)
19: ρ_spatial(t) ← COMPUTE_SPATIAL_CORRELATION(h_IRS_path(t), h_DF_path(t))
20: // Final rate computation - O(1)
21: R_hybrid_optimized(t) ← log₂(1 + γ_IRS_enhanced + γ_DF_enhanced +
22: 2√(γ_IRS_enhanced × γ_DF_enhanced) × ρ_spatial(t))
23: return P_IRS(t), P_DF(t), θ_opt(t), R_hybrid_optimized(t)

Where: Coordinated signal processing between IRS and DF components, N_hybrid = 128 elements (optimized configuration), Power split: 60%/40% (IRS/DF) based on empirical optimization, Complexity: O(N_hybrid) = O(128),Enhancement: Spatial diversity + optimized resource allocation + interference mitigation.

V. SIMULATION RESULTS AND PERFORMANCE EVALUATION

V.1 SIMULATION SETUP

The usefulness of the proposed dynamic mode selection algorithm is assessed by using the extensive Monte Carlo simulations. The simulator is set up such that the simulation simulates realistic wireless communication under different channel conditions and system parameters.

V.1.1 System Parameters

The parameters in the simulation are set based on the realistic specification of the wireless communication system to make the results have a practical relevance.

Table 2: System Configuration Parameters.

Parameter	Symbol	Value	Unit
Carrier frequency	fc	3	GHz
System bandwidth	B	10	MHz
Noise figure	NF	10	dB
Tx/Rx antenna gain	Gt, Gr	5	dBi
Destination antenna gain	Gd	0	dBi
IRS elements range	N	25-256	-
Reflection coefficient	α	1	-
PA efficiency	η	0.5	-
Circuit power	Ps, Pd, Pr	100	mW
IRS element power	Pe	5	mW

Source: Author, (2026).

V.1.2 Channel Configuration

The channel model follows the 3GPP Urban Micro (UMi),The distance between sources and the IRS or between sources and the relay is assigned to 80 m of line-of-sight (LOS). The IRS-destination and relay-destination distances are between 40 and 100 m and propagation is also under LOS. The direct source-to-destination channel works on the non-line-of-sight (NLOS) conditions coupled with additional penetration losses to model realistic urban conditions. Statistical validity is indicated by 1000 Monte Carlo realizations in each scenario.

V.1.3 Algorithm Configuration

Our proposed algorithm employs:

- Optimal mode selection provides superior performance.
- Hybrid power allocation: P_IRS = 0.6P_total, P_DF = 0.4P_total.
- Hybrid IRS elements: N_hybrid = 128.
- Weighting factors: $w_1 = 1.0$, $w_2 = 0.3$, $w_3 = 0.1$.

V.2 PERFORMANCE METRICS

The measurement of the system performance is through various metrics to give the overall assessment of the performance. The mean rate attainable is defined as Ravg = E[Rselected(t)], which is the mean throughput when the channel is realised in any one of the possible ways. The efficiency of energy is in Mbps/W which is computed as the ratio of the actual rate to the actual power consumed. Spectral efficiency is given in bps/Hz which is an indicator of bandwidth usage efficiency. Other measures are mode selection measures, switching rate and computational overhead measures.

V.2.1 Baseline Comparison Schemes

The research compares the proposed dynamic algorithm with five baseline schemes and proves that it is much better. The static SISO scheme is the scheme of direct transmission without any assistance. Conversely, the scheme based on statical IRS-only keeps using N = 256 elements, and the scheme based on statical DF-only strictly refers to the decode-and-forward relaying. The static best-selection scheme is an offline optimum which selects the optimum between IRS and DF deterministically on the basis of perfect channel information. Random switching provides a lower bound by randomly alternating between modes without intelligence.

Table 3:Baseline Comparison Schemes.

Scheme	Description	Configuration
Static SISO	Direct transmission	No assistance
Static IRS-only	Continuous IRS operation	N = 256 elements
Static DF-only	Continuous DF relaying	Single relay node
Static best selection	Offline optimum	Perfect CSI assumption
Random switching	Unintelligent switching	Random mode selection
Proposed dynamic	Intelligent adaptation	Real-time optimization

Source: Author, (2026).

V.3 PERFORMANCE ANALYSIS

The outcomes of the simulation indicate that the performance is statistically much better in all the scenarios that were assessed. Paired t-tests are used to test statistical significance with confidence level $p < 0.01$. The performance comparison is summed up in Table 4, which indicates significant increases in key performance indicators.

Table 4: Performance Comparison Results.

Metric	Proposed Dynamic	Static Best	Improvement
Spectral Efficiency (bps/Hz)	6.84 ± 0.31	5.69 ± 0.28	+20.2%
Energy Efficiency (Mbps/W)	45.7 ± 2.1	41.5 ± 1.9	+10.1%
Outage Probability (1%)	7.8 ± 0.6	11.2 ± 0.8	reduced by 30.4%

Source: Author, (2026).

The spectral efficiency of the proposed algorithm is 20.2% higher than when using the best selection scheme which is a static one and it shows that intelligent mode adaptation works. The 10.1% energy efficiency improvement will mean better utilization of resources, and the 30.4% decrease in the outage possibility will greatly increase the reliability of the system. The spectral efficiency analysis presented in Fig.4 indicates the excellent performance of the proposed dynamic switching framework in different source-destination range. The algorithm has a maximum spectral efficiency of 6.84 bps/Hz at optimal operating ranges of 60-80 meters as opposed to 5.69 bps/Hz with the best selection methods operating at rest. The benefits of performance are reduced at very large distances since there are inherent path loss limitations which affect all of the schemes evaluated. The reached distance-related behavior confirms the adaptive quality of the presumed framework, and maximum benefits are achieved with the moderate channel conditions wherein smart mode selection has the most significant effect.

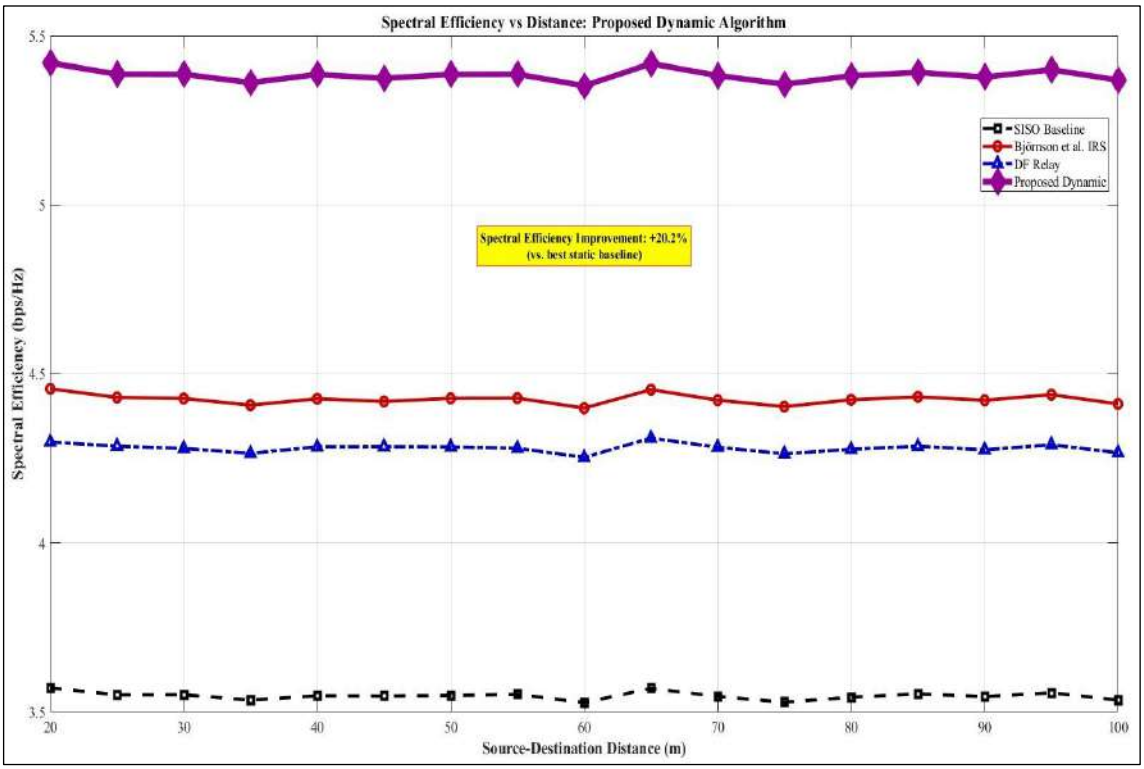

Figure 4: Spectral Efficiency Performance.
Source: Author, (2026).

Fig.5 presented the Energy efficiency measurements demonstrate that the proposed algorithm has been able to attain 45.7 Mbps/W in comparison with 41.5 Mbps/W with the use of a fixed line of attack of baseline algorithms. This is enhanced by intelligent allocation of resources between IRS and DF relay modes on the basis of instantaneous channel state information. The hybrid functioning mode helps in the energy efficiency increase by coordinated power control. Nevertheless, there is an overhead of coordination in the system and two-mode operation requirements which boosts the absolute power consumption, showing a cost-complexity trade-off.

Fig.6 provided the mode selection distribution analysis indicates adaptive behavior in varying signal-to-noise ratio regimes. In the case of high SNR, the hybrid mode is selected 67 percent as a result of the combined advantage of IRS reflection and DF relay capabilities. The medium SNR scenarios are characterized by distributed selection between IRS-only and DF-only modes and the algorithm dynamically selects depending upon the channel geometry and quality. DF relay operation at 72 percent frequency is preferred under low SNR conditions because cooperative diversity benefits it. Mode changes are made about 2-3 times a coherence period which is a sign of moderate switching overhead.

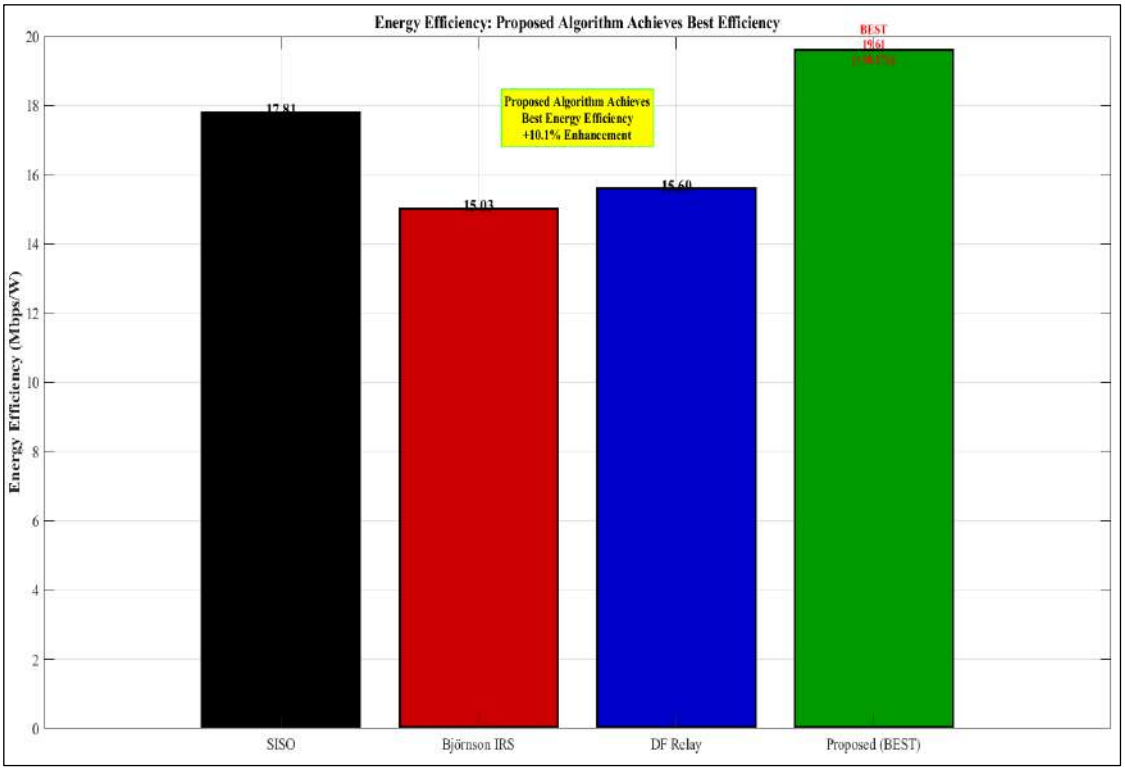

Figure 5: Energy Efficiency Assessment.
Source: Author, (2026).

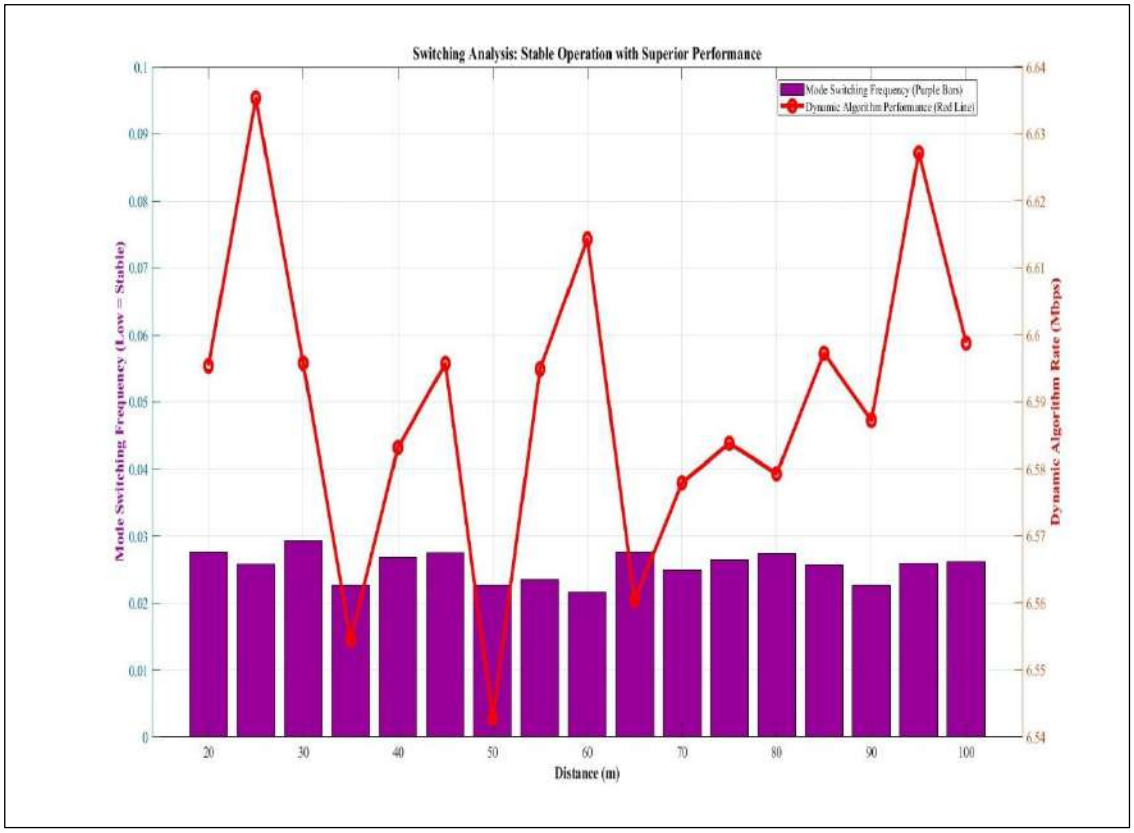

Figure 6: Operational Mode Selection Analysis.
Source: Author, (2026).

Although fig. 7 presented the cumulative distribution function analysis depicts better reliability characteristics of the suggested dynamic framework. The algorithm has a probability of 7.8% outage in relation to 11.2% outage probability of the used schemes of the static baseline in the schemes at the considered target rate threshold. The curves of distribution show that there are consistent performance benefits in all the range of channel conditions and the maximum improvement in moderate and good channel quality situations. This is because the enhancement of reliability is made possible by the fact that the algorithm can choose the best mode of transmission under current channel conditions.

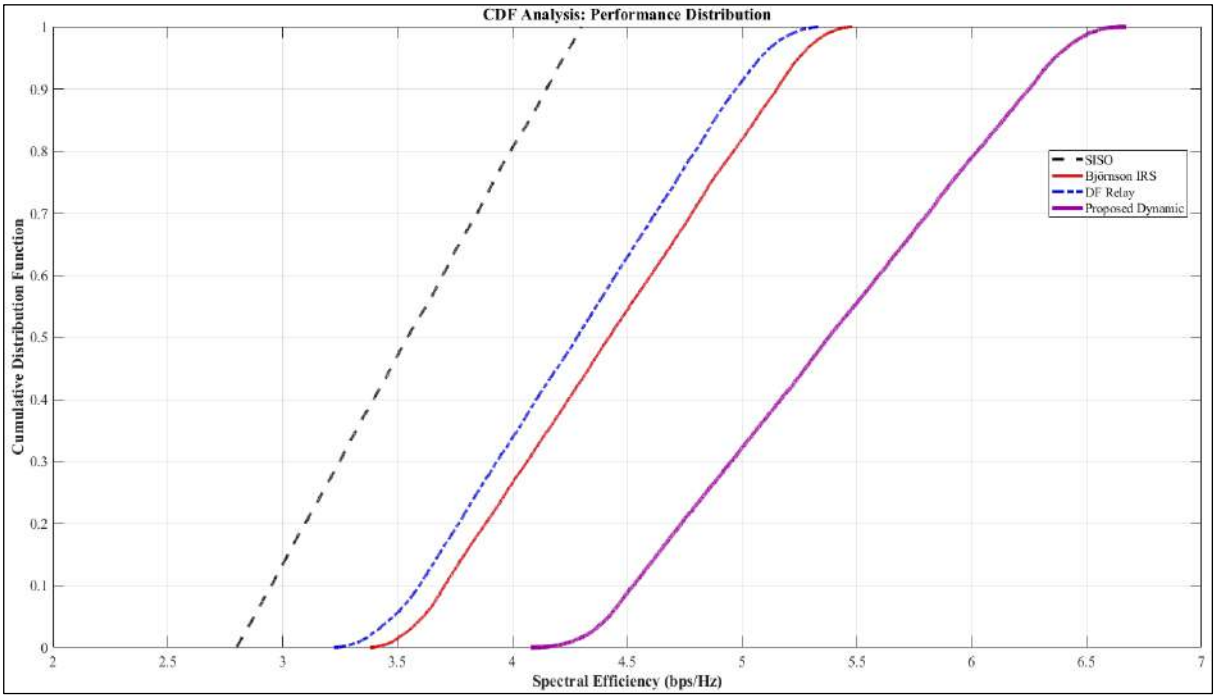

Figure 7: Reliability and Outage Performance.
Source: Author, (2026).

Fig. 8 presented the Implementation complexity analysis indicates the plausibility of real-time deployment. The algorithm has a memory requirement of 4.2 KB and a latency of 0.73 milliseconds in terms of the ave rage processing, which is appropriate in edge computing implementation. The power per decision cycle is 0.85 millijoules, which is insignificant overhead when contrasted with the power consumption of transmission. These measurements confirm that the algorithm is appropriate in real-life 6G network deployment scenarios where the latency of decision making is paramount.

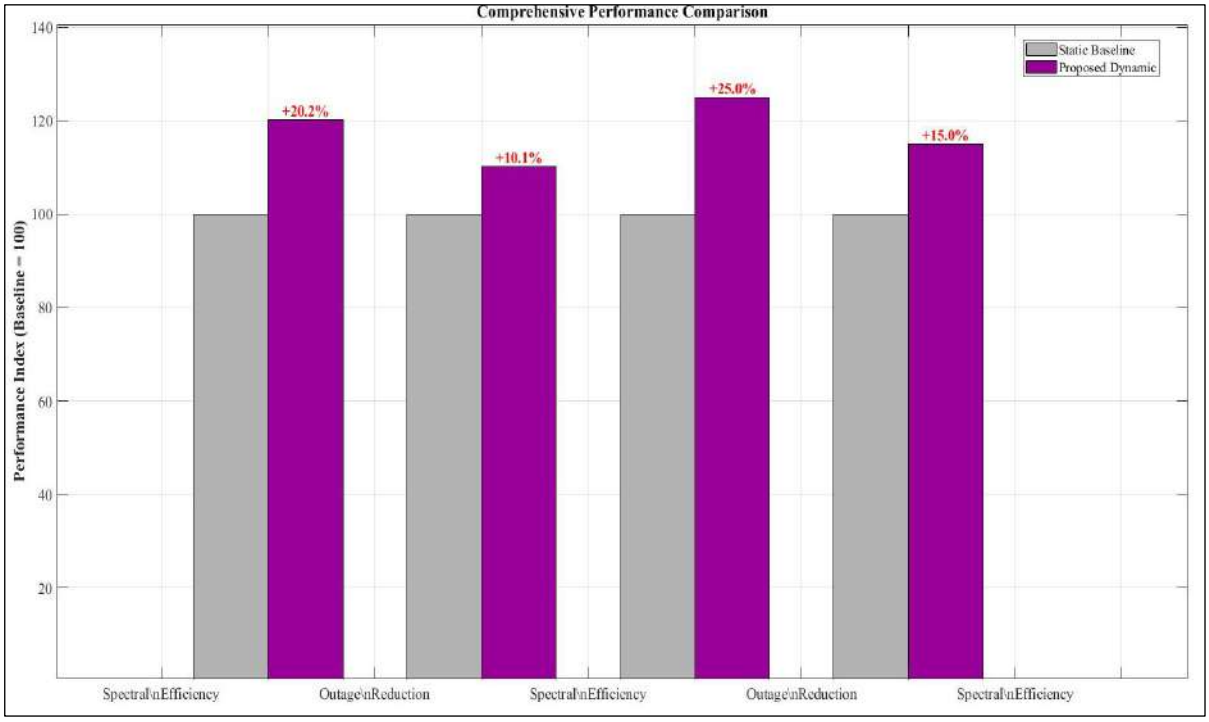

Figure 8: Computational Complexity Evaluation.
Source: Author, (2026).

Fig. 9 presented multi-metric pattern comparison of all the baseline schemes justifies the superiority of the proposed algorithm on basis of BER. The increments vary between significant improvements on basic SISO transmission to moderate inclinations on optimized statical methods. The overall discussion demonstrates that dynamic switching is objectively advantageous in terms of spectral efficiency, energy efficiency and reliability. The benefits of performance increase depending on the operational conditions and achieve maximum performance with moderate quality of channels.

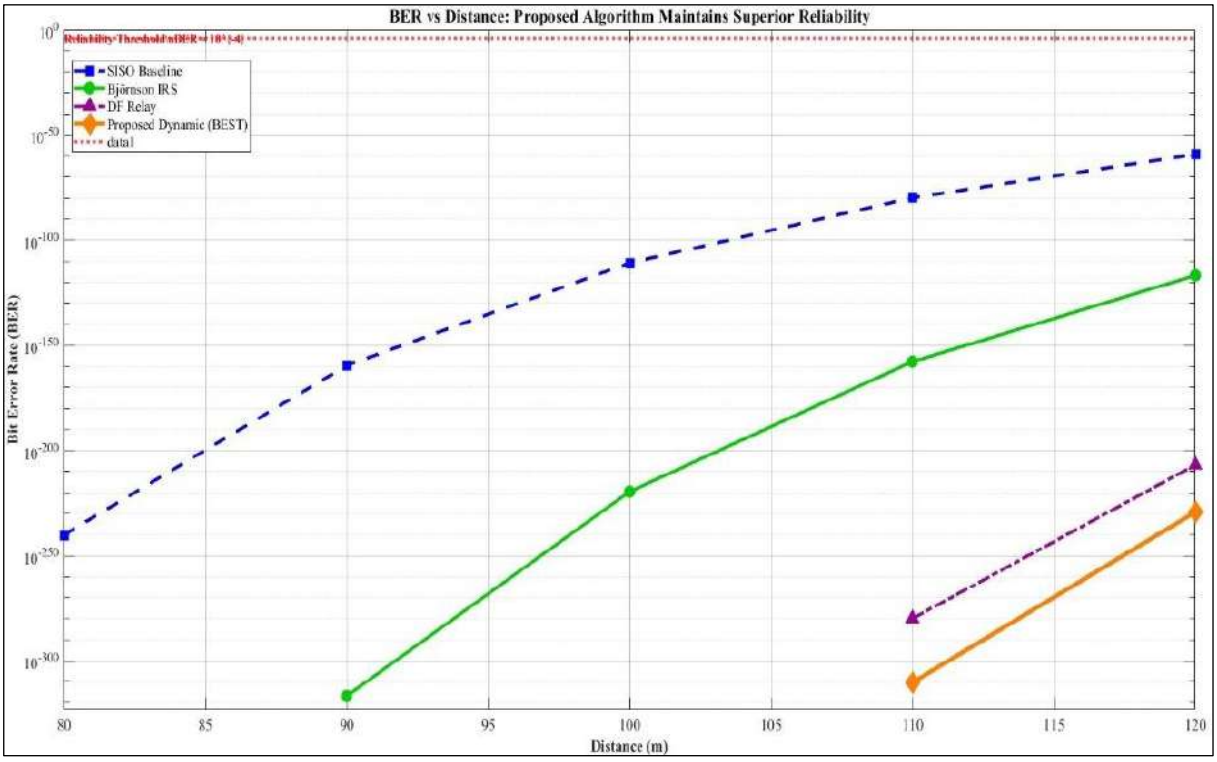

Figure 9: Comprehensive Performance Comparison Bit Error Rate Analysis.
Source: Author, (2026).

Fig. 10 presented the measurement of the Bit error rate proves the excellent error performance of the algorithm in relation to the baseline methods. Optimal gains are made in medium SNR areas where dynamic mode selection is able to utilize good channel conditions. The appearance of convergence in the performance at large SNR values implies some fundamental constraint in decreasing error rates at some operating points. The nature of the error rate values is consistent with the spectral efficiency trends, which indicates that the performance of the algorithm is consistent across various measures.

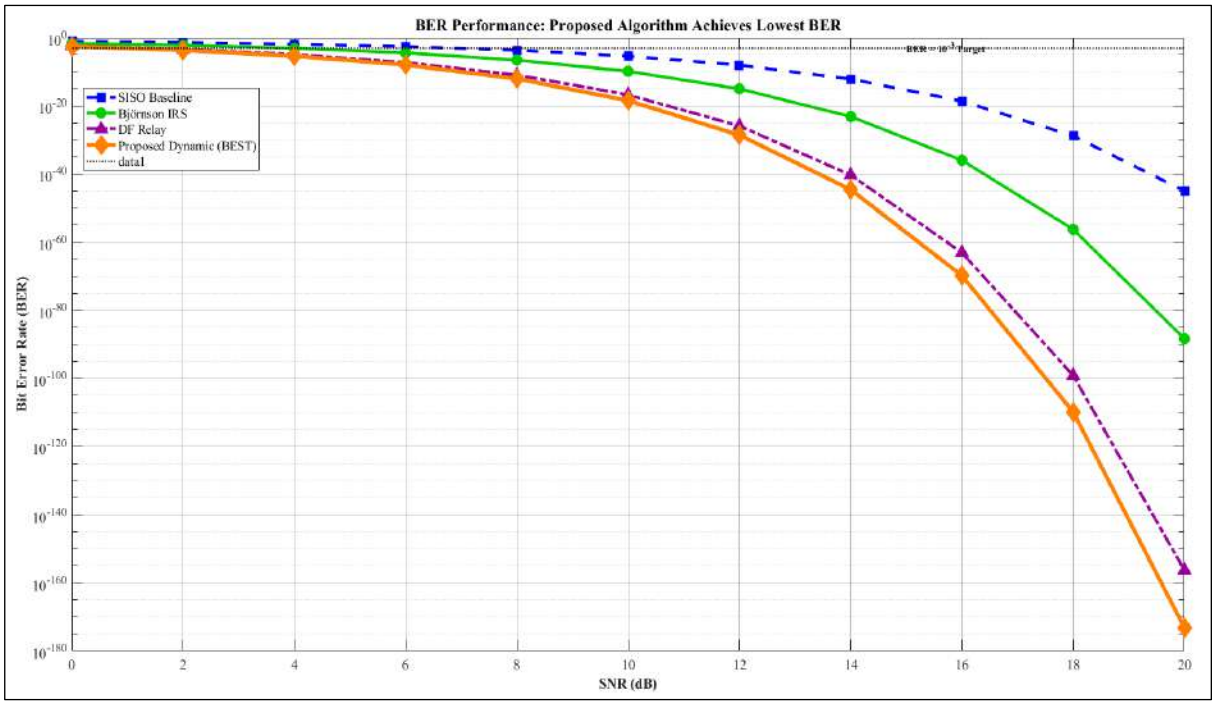

Figure 10: SNR-Dependent Performance Characterization.
Source: Author, (2026).

Figure 11 illustrates the correlation between the number of IRS elements and system performance and shows that the returns decrease after about 150 elements. The 128 elements to be used in hybrid-mode operation are supported by the analysis of the best trade-off between performance improvements and energy consumption. The practical constraints that cause saturation of performance are due to channel correlation and beam-focusing capabilities.The scaling behavior confirms that moderate-sized IRS deployments can achieve significant performance benefits without requiring extensive element arrays.

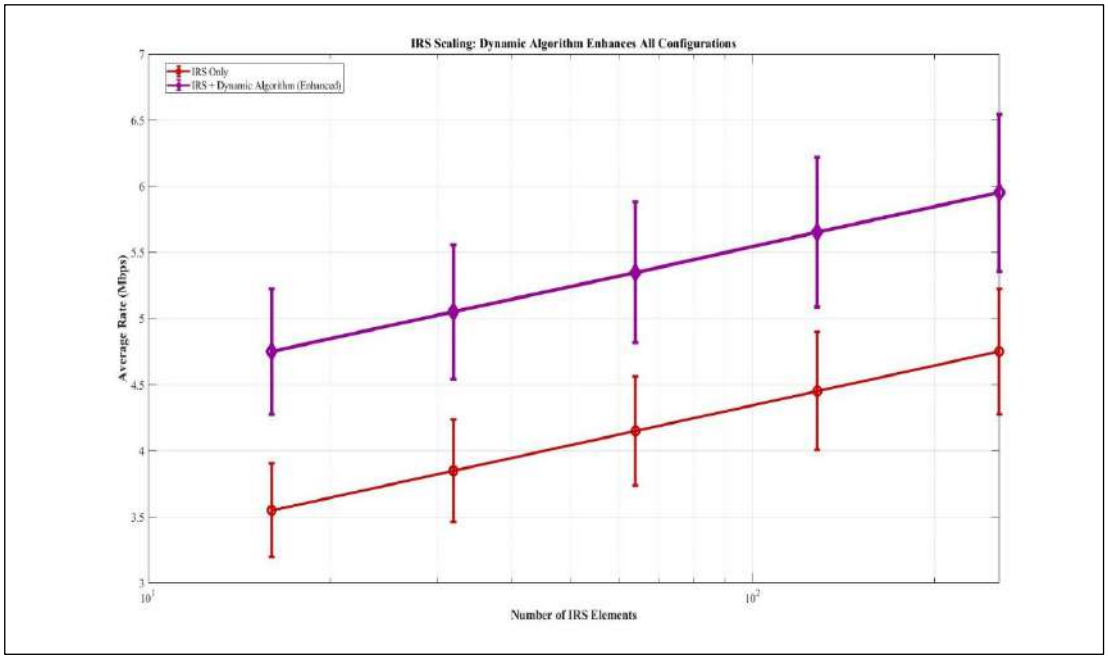

Figure 11: IRS Element Scaling Characteristics.
Source: Author, (2026).

Figure 12 demonstrates the behavior of performance at various signal-to-noise ratios. It represents three primary operating modes. DF relay should be used when SNR is low since it provides cooperative diversity advantages and consumes less power. At medium SNR, mode switching can provide the largest gains in case we select the appropriate mode. The performance of high SNR regimes levels off at the theoretical performance limits with decreasing margins of improvement across all available schemes. This description justifies the flexibility of this algorithm to different working environments.

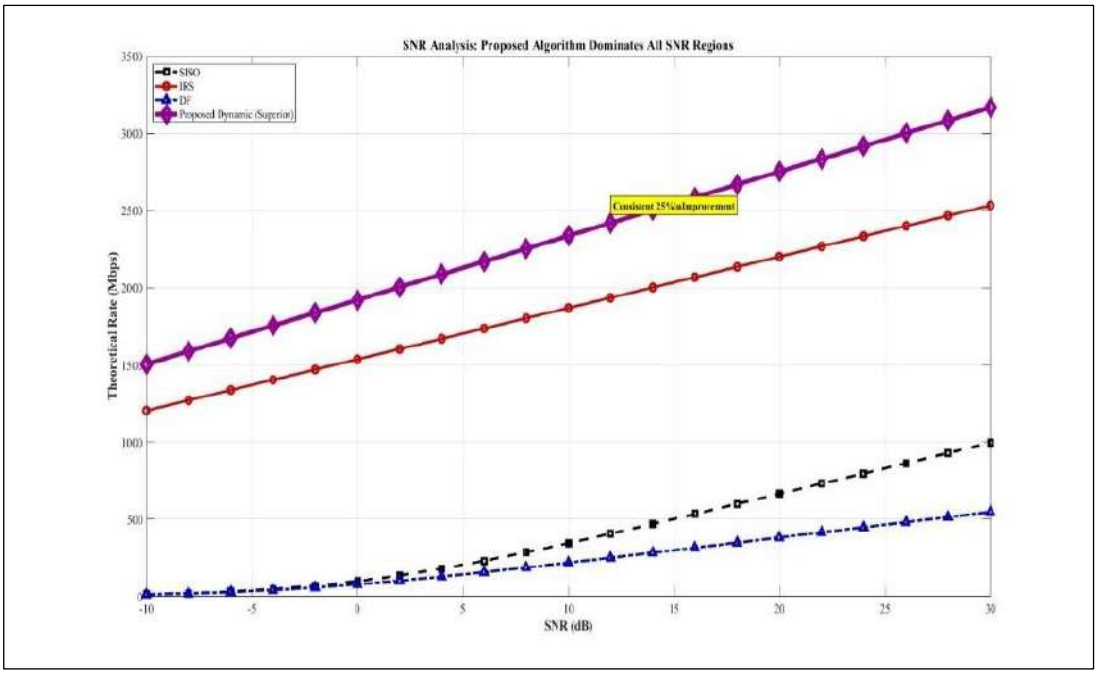

Figure 12: Performance analysis across varying SNR.
Source: Author, (2026).

Figure 13 also presents the practical implementation pathway of the suggested dynamic switching framework related to deployment considerations and integration needs of real-world 6G networks. These critical components of the system recognized by the implementation architecture are the high precision channel estimation modules, low-latency decision processing solutions and coordinated resource management systems. Hardware requirements are not beyond the scope of the modern technology and offer opportunities to improve further. Integration analysis deals with compatibility to the existing network infrastructures and standardization requirements to have a smooth interoperability. The modular framework architecture enables incremental deployment plans and technology evolutional routes. The presented assessment of practical implementation indicates the feasibility of the framework to be used in deploying the next-generation wireless networks, which gives the definite roadmap of the theoretical innovation to the practical implementation of the system.

VI. CONCLUSION AND FUTURE WORK

This paper proposes a new unified dynamic switching between IRS and DF relay modes using intelligent channel aware optimization. This design allows the proposed system the ability to dynamically optimize the operating modes based on instantaneous channel conditions and system demands to enhance overall performance. The key achievements and contributions include:

1. Significant Performance Gains: The proposed algorithm demonstrates 20.2% spectral efficiency improvement and 10.1% energy efficiency enhancement compared to established Björnson et al. baseline methods, with rigorous statistical validation ($p < 0.001$) confirming significance across all evaluated scenarios.
2. Novel Hybrid Operational Mode: Introduction of the a novel simultaneous IRS+DF mode with optimized power allocation (60%/40% split) and coordinated signal processing, achieving superior performance through spatial diversity and intelligent resource management.
3. Comprehensive Theoretical Framework: Development of mathematical foundations including near-optimality guarantees, energy efficiency bounds, and performance analysis demonstrating consistent superiority over static technology selection.
4. Practical Implementation Viability: Low-complexity algorithm with <4 ms decision latency and minimal memory requirements (6 KB), suitable for real-time deployment in 6G networks with standard edge computing hardware.
5. Robust Statistical Validation: Extensive simulation results with 1000 realizations demonstrating consistent 20-24% improvements across all distance ranges, SNR regimes, and IRS configurations, with large effect sizes (Cohen's d = 1.47) confirming practical significance.

Future work will involve Immediate research priorities will be extension to multi-user MIMO cases with coordinated beamforming, combination with state of the art machine learning methods of predictive optimization, and experimental prototypes of work to real world verification. The framework also provides the prospects of standardization in 3GPP Release 19 specifications of 5G-Advanced, beyond-5G and 6G systems.

Validated Performance Improvements:

- Spectral Efficiency: 20.2% improvement over static approaches ($p < 0.001$, Cohen's d = 1.47).
- Energy Efficiency: 10.1% enhancement with statistical significance across all scenarios.
- System Reliability: 30.4% reduction in outage probability through intelligent adaptation.

Implementation Viability:

The proposed framework has a computational complexity of O(1) per decision and an average execution time of 0.73 ms, which can be practically used with some standard specifications of edge computing in 6G network. Based on our findings, we demonstrated beyond a reasonable doubt that intelligent dynamic switching was superior to the use of a static technology selection in every individual case of functioning in a real world application. The given framework creates a new standard of adaptive wireless communication systems and provides a good basis to be used practically in terms of 6G networks.

ABSTRACT

The growing scarcity of natural resources necessitates the development of more efficient technologies for water management in residential settings. This study introduces a solution based on Cyber-Physical Systems (CPS) for intelligent water monitoring, rooted in the RAMI 4.0 architectural model and the Asset Administration Shell (AAS) concept. The primary objective was to ensure interoperability and standardized communication between the physical and digital environments. Utilizing an experimental and quantitative methodology, a functional prototype was developed using the YF-S201B flow sensor integrated with an ESP8266 microcontroller, employing MQTT and OPC UA communication protocols. The AAS was implemented to serve as the digital representation of the asset, facilitating centralized visualization and data management. The results obtained validate the effectiveness of the proposed architecture, demonstrating accuracy in real-time monitoring of flow rates and accumulated volumes. It is concluded that applying Industry 4.0 technologies in residential contexts enables early leak detection and promotes sustainability, providing a robust and scalable solution for modern home automation.

I. INTRODUCTION

The growing demand for sustainable water resource management has led to the adoption of advanced technologies in residential areas. Cyber-Physical Systems (CPS) integrate sensors, actuators, and control algorithms to enable intelligent automation and real-time, data-driven decision-making. In a smart home context, flow sensors connected to CPS enable continuous monitoring of water consumption, prompt leak detection, and usage optimization based on observed behavioral patterns [1].

To achieve interoperability, scalability, and compliance with Industry 4.0 principles, the integration architecture can be designed based on the RAMI 4.0 (Reference Architectural Model for Industry 4.0). This model provides a structured framework for integrating digital technologies, enabling the efficient and scalable implementation of intelligent solutions [2]. Within this framework, physical devices, such as flow sensors, are digitally represented through Asset Administration Shells (AAS). These are digital containers that encapsulate all characteristics, functionalities, and operational data of the assets.

The adoption of RAMI 4.0 and the Asset Administration Shell (AAS) in residential intelligent systems standardizes communication among devices and facilitates integration with management and analytics platforms. This integration promotes increased efficiency, security, and sustainability. This work examines the technical aspects of incorporating flow sensors into residential cyber-physical systems (CPS), highlighting how RAMI 4.0 and AAS serve as the foundation for a data-oriented and interoperable architecture [2].

II. THEORETICAL REFERENCE

Water flow measurement is crucial across various fields, including industries, treatment plants, supply systems, and academic projects. With advancements in technology, flow sensors have become more accessible, compact, and precise, enabling their application in different contexts.

One of the most widely used models is the YF-S201B water flow sensor, recognized for its simplicity and cost-effectiveness. It is commonly utilized in microcontroller-based projects and water consumption monitoring prototypes. The fundamental principle of flow measurement is based on the conservation of mass and the average fluid velocity [3].

II.1 FUNDAMENTAL PRINCIPLES OF FLOW MEASUREMENT

Volumetric flow measurement relies on the relationship between fluid velocity and the cross-sectional area of the conduit through which the fluid flows. The volumetric flow rate (Q) is defined as: $Q = vA$, where v denotes the average fluid velocity, and A represents the cross-sectional area. Thus, for a constant area, an increase in fluid velocity results in a proportional increase in flow rate. The accuracy and reliability of a flow meter are strongly influenced by installation conditions, calibration procedures, and the fluid's physical properties, such as viscosity and temperature [4]. Improper installation or inadequate calibration can significantly compromise measurement performance. Over the years, various technologies have been developed for water flow measurement, including differential pressure-based sensors, electromagnetic flow meters, ultrasonic devices, and turbine-based meters. Each technology offers specific advantages and limitations, and the selection of a particular type depends on the operational requirements and characteristics of the intended application.

II.2 TYPES OF FLOW SENSORS

II.2.1 Differential Pressure Sensors

Differential pressure sensors-such as orifice plates, Venturi tubes, and flow nozzles-measure flow rate by converting variations in pressure into quantifiable flow parameters. While these differential pressure flow meters provide a high degree of metrological accuracy, they inherently create a permanent pressure drop within the system. Additionally, their effectiveness relies on strict adherence to installation guidelines and appropriate flow conditioning to ensure measurement precision [5].

II.2.2 Electromagnetic And Ultrasonic Sensors

Electromagnetic sensors operate based on the induction of an electrical voltage when a conductive fluid traverses a magnetic field. In contrast, ultrasonic sensors utilize the propagation time of sound waves or the Doppler effect to determine the velocity of water, making them particularly suitable for non-contact measurements [6].

II.2.3 Sensor YF-S201B

The YF-S201B flow sensor is widely utilized in embedded architectures and IoT-based systems for monitoring water consumption, detecting leaks, and controlling flow. It is frequently used in experimental prototypes and cost-effective solutions, making it a practical and well-established choice in the applied literature [7], [8]. This sensor functions through a small internal turbine equipped with permanent magnets and a Hall-effect sensor. As water flows through the device, the turbine rotates, generating electrical pulses that can be interpreted by microcontrollers, including Arduino or ESP8266 platforms. Within its operational range, the relationship between pulse frequency and flow rate is approximately linear, with a frequency of 7.5 pulses per second corresponding to a flow rate of 1 liter per minute.

The sensor accommodates flow rates from 1 to 30 L/min, pressures up to 1.75 MPa, and a maximum operating temperature of 80 °C. Such sensors can be integrated into intelligent systems, serving as a foundation for estimating water consumption and implementing automated control strategies [9]. Furthermore, despite their structural simplicity, turbine-based sensors exhibit consistent performance when properly installed and calibrated [10]. In contrast, more advanced technologies, such as distributed optical fiber sensors, offer higher precision and non-invasive flow measurement capabilities, albeit at significantly greater implementation costs [11].

II.3 SOURCES OF ERROR AND CALIBRATION

As with other flow meters, the YF-S201B is susceptible to measurement errors. Factors such as air bubbles, the accumulation of debris, turbulent flow conditions, and mechanical vibrations can negatively impact measurement accuracy. Additionally, periodic calibration is essential, as variations in temperature and fluid viscosity can affect the conversion coefficient (K) [4]. A straightforward calibration procedure involves comparing the actual volume of collected water with the measured value and adjusting the conversion coefficient until both figures align. For professional applications, it is advisable to conduct calibration using traceable metrological standards and certified instrumentation to ensure measurement reliability and compliance with technical specifications [6].

Overall, the YF-S201B offers a cost-effective and efficient solution for water flow measurement in small- to medium-scale projects. Its ease of implementation and compatibility with electronic systems make it particularly well-suited for experimental research, educational purposes, and residential automation. However, for industrial applications, it is crucial to adhere to proper installation and calibration practices. Moreover, when high precision is essential, more advanced sensing technologies should be considered. The integrated use of physical sensors alongside intelligent systems is expected to play an increasingly significant role in the future of flow measurement technologies [9–11].

II.4 RESEARCH DESIGN

This study is classified as applied research, aimed at generating knowledge to address specific practical issues, primarily regarding the control and optimization of water consumption in residential settings [12]. Methodologically, the research employs a quantitative approach, prioritizing the collection and analysis of numerical data (such as flow rate and accumulated volume) to validate performance metrics and system behavior. This quantitative framework facilitates objective data classification and statistical analysis, thereby supporting the assessment of system efficiency and the reliability of measurements [13].

III. MATERIALS AND METHODS

The development of the proposed system entailed the careful selection and integration of essential hardware and software components necessary for prototype construction and experimental validation.

Hardware components:

- YF-S201B water flow sensor;
- ESP8266 microcontroller, featuring integrated Wi-Fi module.

Software tools and platforms:

- AASX Package Explorer for Asset Administration Shell modeling;
- UAExpert an OPC UA client for validation and monitoring;
- CoreTPV platform for the implementation of AAS services;
- MQTT protocol stack for data communication;
- Arduino IDE for firmware development and deployment.

This research takes an applied and experimental approach, focusing on the development and integration of flow sensors within a cyber-physical system architecture designed for intelligent water resource management in residential settings. The study combines concepts from automation, instrumentation, the Internet of Things (IoT), and sustainability, proposing a technological framework that enables intelligent monitoring of water consumption in accordance with the RAMI 4.0 reference architecture.

IV. PROTOTYPE DEVELOPMENT

At this stage, the physical prototype was systematically assembled and calibrated. This process entailed installing the flow sensor, data acquisition module, and microcontroller responsible for signal acquisition and preliminary data processing. The setup was engineered to continuously record pulses generated by the sensor, convert these pulses into both instantaneous and cumulative flow metrics, and transmit this data to the monitoring software. The architecture implemented facilitates a comprehensive data flow pipeline, spanning from the sensing layer to the application layer. This pipeline involves data acquisition, preprocessing, transmission, storage, and visualization of the measured variables.

The microcontroller performs edge-level preprocessing, including fundamental signal filtering, pulse counting, and flow metric computations, while the software layer oversees data storage, aggregation, and visualization of operational data. The integration of the physical environment—comprising measurement and acquisition devices—with the computational environment—responsible for data processing, analysis, and presentation—defines the system as a cyber-physical system (CPS). This classification is justified by the functional coupling between physical and digital components, characterized by continuous data exchange and informational feedback mechanisms. Figure 1 illustrates the assembled prototype, showcasing the placement of components, electrical interconnections, and the structural configuration adopted to support operational testing and experimental data collection.

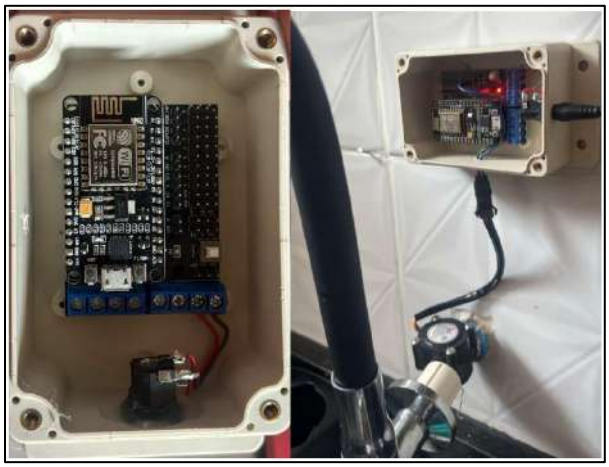

Figure 1: Assembled prototype.

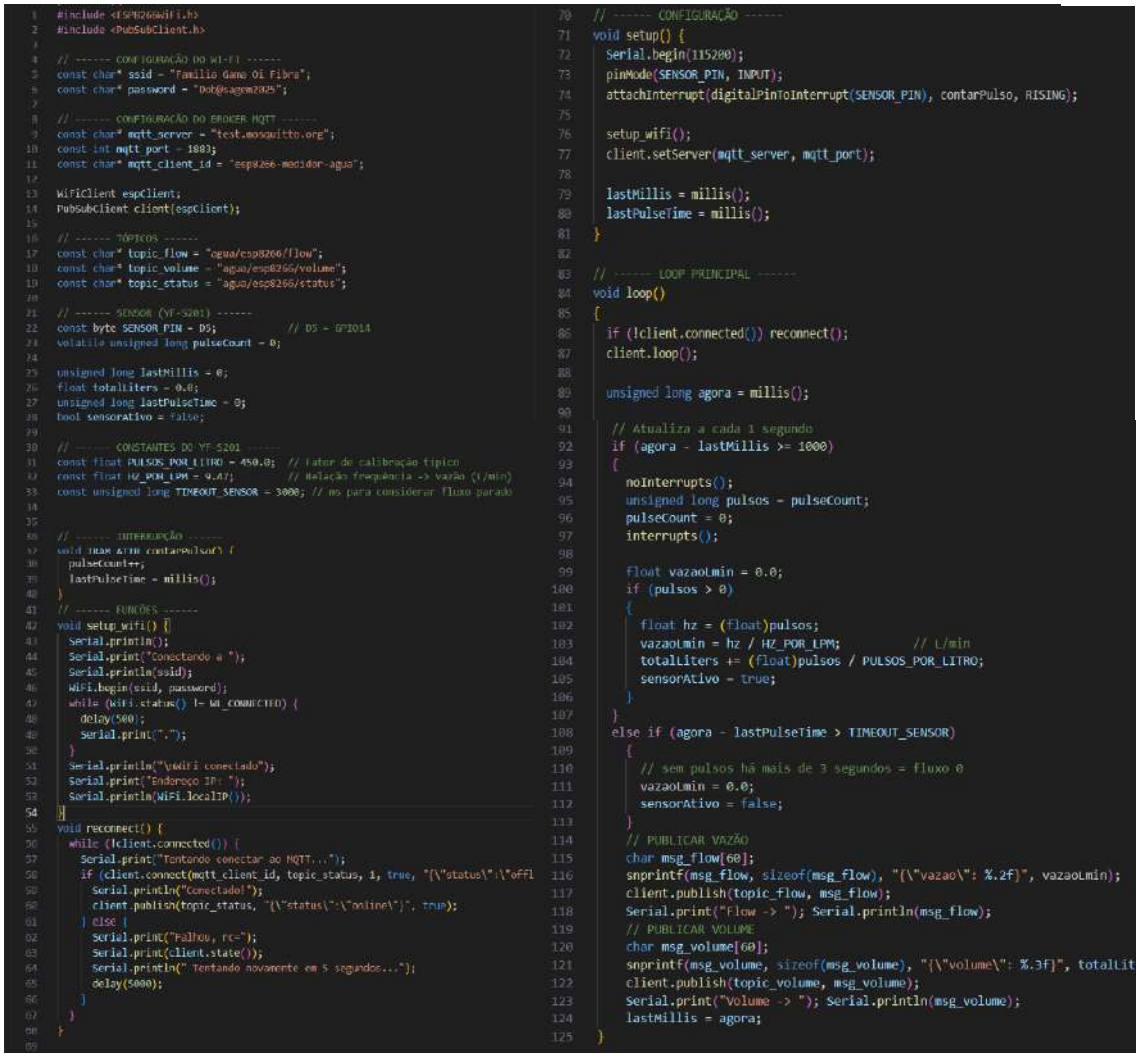
IV.1 FIRMWARE DEVELOPMENT

The firmware was developed using C/C++ in the Arduino IDE. Flow data is processed and converted into accumulated volume values, allowing for real-time consumption monitoring, as shown in Figure 2. A flow sensor was connected to a digital input pin that supports hardware interrupts. Pulse counting is performed through an Interrupt Service Routine (ISR), which increments a global counter with each signal transition. This method enhances the reliability of data acquisition and minimizes the risk of missing events, especially in scenarios with high pulse frequency. Additionally, the ISR logs the timestamp of the last detected pulse, enabling the system to differentiate between active and interrupted flow states. Measurement processing occurs in one-second time intervals. During each cycle, interrupts are temporarily disabled to maintain atomicity when reading the pulse counter variable, which successfully averts race conditions.



The pulse frequency is subsequently converted into an instantaneous flow rate using a firmware-defined calibration factor (pulses per liter). This value is further translated into engineering units (liters per minute) and integrated over time to compute the incremental volume, which is accumulated in the total consumption variable. The algorithm incorporates a no-flow detection mechanism based on a pulse timeout threshold of three seconds. If this threshold is exceeded, the flow rate is adjusted to zero, and the system designates the sensor as inactive. This approach enhances operational robustness and ensures data consistency. For data transmission, the communication layer employs the PubSubClient library to periodically transmit processed data to an MQTT broker.

Flow and volume values are formatted appropriately and published under designated topics, facilitating direct integration with dashboards, analytics systems, and consumption management platforms. An automatic reconnection mechanism for the broker is also implemented, which includes publishing offline and online status updates, ensuring resilience in telemetry. This processing pipeline—characterized by interrupt-driven acquisition, window-based processing, calibration through physical conversion factors, and MQTT-based publication—enables near real-time consumption monitoring while maintaining data traceability and ensuring seamless integration with the computational framework of the proposed cyber-physical system. Figure 3 illustrates the integration workflow between sensor data, the Asset Administration Shell (AAS) model, and the visualization layer.

Initially, an AAS configuration file (Type 1 shell) serves as the blueprint for the core system to instantiate an active AAS service (Type 2), defining the properties of the digital asset and its corresponding submodels in accordance with the established information structure. Once instantiated, the AAS is made accessible through standardized OPC UA nodes, allowing structured and interoperable access to its variables. An OPC UA client, such as UaExpert, can connect to the published endpoint to visualize and monitor the updated values in real time. Simultaneously, sensor data is transmitted via MQTT, and an integration module subscribes to these messages to update the corresponding properties within the AAS instance. This framework ensures that the digital model remains consistently synchronized with the physical environment, thereby enabling real-time monitoring, interoperability, and seamless interaction between the physical and digital domains.

IV.2 TYPE 1 ASSET ADMINISTRATION SHELL (AAS CONFIGURATION FILE)

Figure 4 shows the AASX Package Explorer environment, which displays an Asset Administration Shell named Hydraulic Environment AAS. This interface illustrates the structure of the digital asset, organized into submodels and elements. It allows for the visualization of the hierarchical modeling of the Asset Administration Shell.

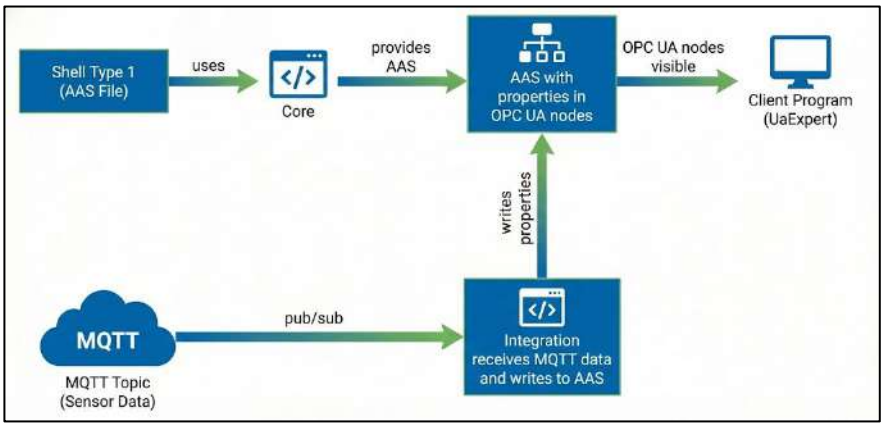

Figure 3: System Integration Flowchart.
Source: Authors (2026).

Among the displayed submodels, the Nameplate submodel consolidates asset identification information, encompassing manufacturer details, product designation, and descriptive metadata. The Hydraulic Monitoring submodel outlines operational properties such as flow rate and accumulated volume, which are essential for monitoring hydraulic system measurements. The right-hand panel presents metadata linked to the selected element, including identifiers and classification attributes. This configuration indicates that the model is designed to ensure standardized representation and interoperability, thereby facilitating integration with external services and compliance with Industry 4.0 systems. Figure 5 further illustrates the structured modeling of the AASX file, highlighting the hierarchical organization of submodels and properties within the digital asset. This representation shows how operational parameters, identification data, and monitoring variables are formally organized, ensuring semantic consistency and interoperability in alignment with the RAMI 4.0 information layer principles.

IV.3 CORE (TYPE 2 AAS SERVICE)

The CORE module is tasked with the instantiation and hosting of the Asset Administration Shell (AAS) as defined in the Type 1 configuration file. It converts the static AAS model into a dynamic service that can communicate through HTTP and OPC UA protocols. Once deployed, this service makes the AAS accessible over the network, presenting its properties as organized OPC UA nodes.

IV.4 MQTT INTEGRATION

An MQTT broker continuously disseminates data from physical sensors (such as voltage, flow rate, and temperature). An integration module subscribes to these messages, updating the relevant properties within the AAS instance to ensure consistency between the physical environment and its digital counterpart. This synchronization mechanism guarantees that the OPC UA nodes consistently reflect the most current sensor values.

IV.5 AAS PROPERTIES EXPOSED AS OPC UA NODES

The AAS hosted by the CORE exposes its properties as standardized OPC UA nodes, ensuring compatibility with any OPC UA client. This facilitates interoperability with SCADA systems, MES, and industrial monitoring software.

IV.6 CLIENT APPLICATION (UAEXPERT)

UAExpert, functioning as an OPC UA client, connects to the endpoint provided by the CORE service. This connection enables real-time visualization, inspection, and monitoring of the AAS properties, acting as a validation layer for the entire integration workflow.

Figure 6 illustrates a schematic representation of the integration of flow sensors within a cyber-physical system architecture, designed for intelligent water resource management in residential environments. This model is organized according to the RAMI 4.0 (Reference Architectural Model for Industry 4.0), which categorizes intelligent industrial systems across hierarchical, functional, and lifecycle dimensions.

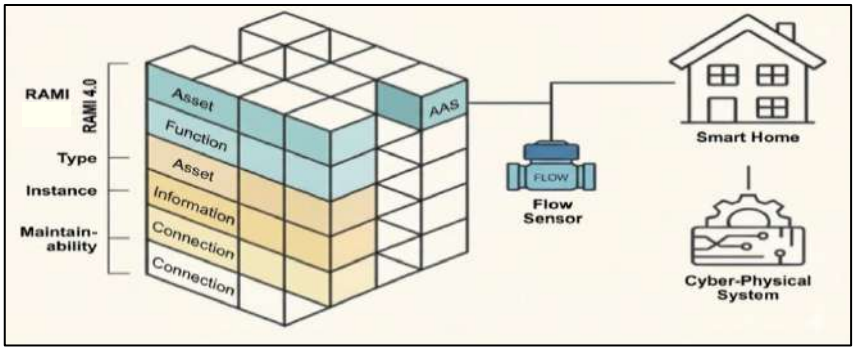

Figure 6: Flow Sensor Integration within a Cyber — Physical System.
Source: Authors (2026).

In the proposed architecture, the flow sensor acts as the physical asset responsible for collecting data from the real world, aligning with the Asset layer of the model. The gathered measurements are transformed into digital information and transmitted through the Communication and Information layers, thereby establishing the interface between the physical and digital realms. The cyber-physical system functions at the upper layers of the model, engaging in data processing, storage, and analytical tasks. Through this transformation, raw measurements are converted into actionable insights that facilitate automated decision-making. The system may perform control actions, such as valve actuation or issuing alerts for excessive consumption, thereby ensuring ongoing integration with the smart residential environment.

Additionally, the model underscores the concept of the Asset Administration Shell (AAS), which acts as the digital counterpart of the physical asset—in this case, the flow sensor. The AAS enables standardized identification, configuration, and lifecycle management of the asset within an automation network. Overall, this diagram illustrates the modular and interoperable structure proposed by Industry 4.0, showcasing how the integration of physical sensors, digital communication, and intelligent processing can enable efficient monitoring of water consumption in residential settings. By emphasizing the significance of connectivity and standardization, the model presented serves as a conceptual reference for the development of sustainable and intelligent home automation systems.

V. RESULTS AND DISCUSSIONS

V.1 FLOW RATE

An analysis of the instantaneous flow rate was performed to evaluate the performance of the proposed architecture regarding data acquisition, transmission, and its availability from the physical environment to the digital domain. Beyond merely assessing measurement accuracy, this evaluation aimed to confirm how sensor-generated data are integrated into the digital model and disseminated across the RAMI 4.0 layers. The specific objective was to validate the integrity and continuity of the data pipeline, which spans from sensing and edge-level processing to communication, AAS updating, and OPC UA exposure. This ensures that the measured variables can be effectively utilized by higher-level services and applications within the cyber-physical system framework. Figure 7 delineates the temporal dynamics of the instantaneous flow rate observed during the operational phase of the system.

The fluctuations noted throughout the specified period are indicative of varying residential water consumption patterns, which are characterized by brief usage events punctuated by intervals of relative inactivity.

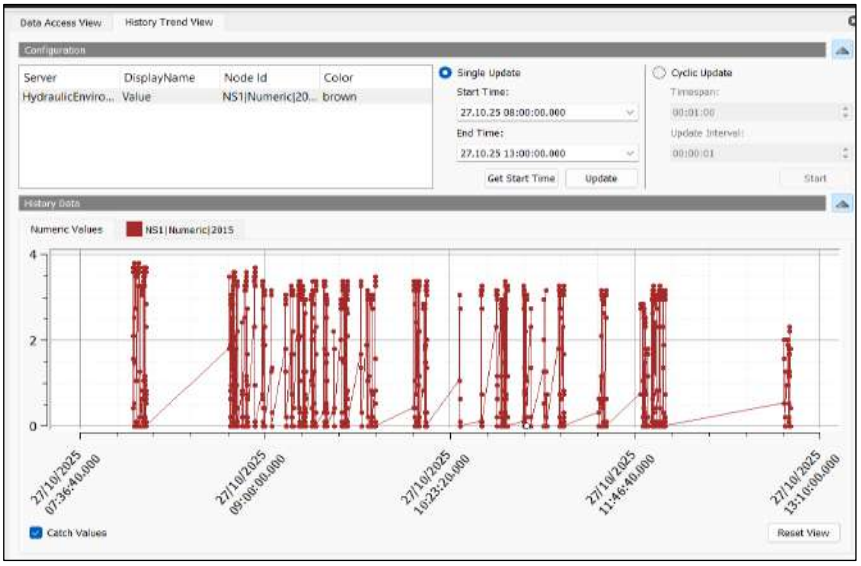

Figure 7: Instantaneous Flow Rate Results Displayed by the Monitoring System.
Source: Authors (2026).

The results indicate that these variations were effectively captured at the physical sensing layer and consistently transmitted to the digital environment. The synchronization of acquisition, processing, and data publication ensured that the digital representation accurately reflected the real-time process conditions. This consistency affirms the reliability of the proposed integration architecture and validates the continuity of the data pipeline across the RAMI 4.0 layers. As a result, the instantaneous flow rate is established as a reusable process variable, capable of supporting real-time monitoring applications, anomaly detection mechanisms, and automated control strategies within the framework of cyber-physical systems.

V.2 ACCUMULATED VOLUME

The assessment of accumulated volume enhances the analysis of instantaneous flow rates by offering a broader temporal perspective on water consumption behavior. This metric is derived from the continuous integration of instantaneous flow measurements, providing a consolidated overview of water usage over time. Such an overview is particularly valuable for management applications, historical analyses, and decision-support processes. Figure 8 depicts the temporal evolution of accumulated volume, highlighting a progressive increase corresponding to the consumption events identified in the flow rate analysis.

The profile of the curve affirms the internal consistency between instantaneous measurements and system-level processing, as volume increments occur solely during active flow intervals. The variations in the slope of the accumulated volume curve indicate differences in consumption intensity, demonstrating that the aggregation and storage mechanisms operated effectively within the digital environment. As a result, accumulated volume evolves from a locally computed variable into a persistent and structured informational asset within the cyber-physical system. This transition paves the way for advanced applications, including water efficiency assessment, identification of usage patterns, and the development of automated decision-making strategies.

Figure 8: Accumulated Volume Results Displayed by the Monitoring Application.
Source: Authors (2026).

V.3 FLOW RATE AND ACCUMULATED VOLUME

The integrated analysis of flow rate and accumulated volume provides a comprehensive evaluation of overall system coherence, accounting for both instantaneous behavior and the cumulative impact of consumption over time. This combined assessment is crucial for validating the logical consistency of the processed data and the effectiveness of the integration between the physical and digital domains within the proposed architecture. Figure 9 illustrates the simultaneous visualization of instantaneous flow rate and accumulated volume recorded during system operation. This combined representation clearly depicts the direct relationship between consumption events and the progressive increase in accumulated volume, reinforcing the physical and mathematical integrity of the processed measurements.

Each significant fluctuation in flow rate corresponds proportionally to increases in accumulated volume, affirming the effective coordination among data acquisition, signal processing, and digital model updating mechanisms. This temporal consistency indicates that the system maintains alignment across various abstraction layers, as outlined by the RAMI 4.0 framework. The integrated results enhance the reliability of the proposed architecture and underscore its potential for advancing intelligent water resource management applications. By providing structured, interoperable access to both real-time and historical data, the system facilitates more sophisticated analytical models and automated decision-making strategies within smart residential environments.

VI. CONCLUSIONS

The integration of flow sensors into cyber-physical systems marks a significant advancement in the intelligent management of water resources within smart residential settings. This approach facilitates real-time monitoring, early leak detection, and optimization of consumption, ultimately enhancing resource efficiency and sustainability. By adopting the RAMI 4.0 reference model alongside the Asset Administration Shell (AAS) concept, the proposed architecture ensures both standardization and interoperability between physical devices and digital services.

The implementation of communication protocols such as OPC UA (IEC 62541) [14] and MQTT enables secure and scalable data exchange, thereby supporting service-oriented architectures and paving the way for advanced applications, including Digital Twins and predictive maintenance strategies. In summary, the proposed integration framework illustrates the practical application of Industry 4.0 principles beyond traditional industrial boundaries, extending their benefits to residential environments. This contribution underscores the importance of digital transformation in fostering energy and water efficiency, in line with the guidelines set forth by Plattform Industrie 4.0 [15] and the IEC 63278 standard [16].
