In Standalone Edge AI-Based Solution for Tomato Diseases Detection, [29] evaluated various lightweight CNNs, including MobileNetV3, on IoT hardware such as Raspberry Pi and Coral Edge TPU, achieving up to 98.25% accuracy and $0.14/FPS operational cost on Coral. Additionally, [30] presented an ultra-lightweight model based on 5 inverted residual blocks and an efficient attention mechanism in Ultra-Lightweight Tomatoes Disease Recognition Method, achieving 97.84% accuracy across 14 noisy scenarios using only 0.418M parameters. Lastly, in New Method for Tomato Disease Detection Based on Image Segmentation and Cycle-GAN Enhancement, [31] combined leaf segmentation with GAN-based image enhancement before training MobileNetV3, attaining 98.61% accuracy across 10 disease classes. Collectively, these studies demonstrate that MobileNetV3 (especially the Small variant) offers high accuracy (>97%) while being well-suited for mobile, IoT, and cloud-based agricultural applications. Several works also provide comparative evaluations: Qabulio et al. found that MobileNetV3Small outperformed VGG16, MobileNetV2, and SqueezeNet (99.43% vs ~97%), while Ndovie & Masabo reported superior performance of MobileNetV3 over a custom CNN (92.59% vs <92%). However, robust generalization to real-world conditions remains a challenge, as evidenced by the performance drop observed in field datasets.

III.4 VISION TRANSFORMERS(VITS)

The vision transformer(ViTs) [32], [33] architecture for computer vision tasks. While ViT has shown impressive results, there is room for improvement,particulary in enchancing the multi-head self-attention mechanism ,show in figure.1 .Vision Transformers (ViTs) have revolutionized the field of computer vision by applying the Transformer architecture originally designed for natural language processing to image analysis. Unlike Convolutional Neural Networks (CNNs), which rely on local receptive fields, ViTs divide the input image into a sequence of fixed-size patches and model the relationships between these patches using a self-attention mechanism. Let an image $x \in \mathbb{R}\{H\times W\times C\}$ be divided into a grid of $N = (HW / P^2)$ non-overlapping patches of size $P \times P$. Each patch is then flattened and linearly projected to form a patch embedding:

$$z^i_o = E\, x^i_p + E^i_{pos} \quad \text{for } i = 1, ..., N \tag{1}$$

where:

- x^i_p is the i-th patch,
- $E \in \mathbb{R}^{\{(P^2\cdot C)\times D\}}$ is a learnable linear projection matrix,
- $E^i_{pos} \in \mathbb{R}^D$ is the positional encoding added to retain spatial information.
- D is the embedding dimension.

The Transformer encoder then processes the sequence of embeddings using Multi-Head Self-Attention (MHSA)**:**

$$\text{Attention}(Q, K, V) = \text{SoftMax}(QK^T/\sqrt{d_k})\, V \tag{2}$$

with:

- $Q = XW^Q$, $K = XW^K$, $V = X^V$,
  - where X is the input sequence of patch embeddings,
  - W^Q, W^K, W^V are learnable weight matrices.

Multi-head attention is defined as:

$$\text{MHSA}(X) = \text{Concat}(\text{head}_1, ..., \text{head_h})\, W^O \tag{3}$$

where each head is:

$$\text{head}_i = \text{Attention}(XW_i^Q, XW_i^K, XW_i^V) \tag{4}$$

This mechanism enables the model to learn both local and global features across the image, outperforming traditional CNNs especially in capturing long-range dependencies.

- *Training of Vit (Vision Transformer)*

The ViT is trained on image patches. It uses a Transformer architecture to model the relationships between the patches and capture both local and global features of the image. The ViT applies a multi-head attention mechanism to focus on the most informative regions of the image.Multu-Head Self Attention.

The multi-head attention mechanism allows the ViT to focus on critical regions of the image. Each attention head calculates scores to determine the relative importance of different patches. These scores are used to weight the patches' contributions to the overall image representation. Attention is a critical component in capturing the relationships among sequential input patches.

- *Classification*

Once the ViT has extracted the features from the image, a classifier (dense layer with SoftMax activation) is used to predict whether the tomato is healthy or diseased. In the case of several diseases, the model can also identify the specific disease.

- *Résultats*

The results of the model are evaluated on a validation or test set. Common indicators include accuracy, memorization, F1 score, and confusion matrix. These metrics are used to measure the performance of the model and identify any problems, such as overfitting or underfitting.

III.4.1 Oreview Of Oision Transformers

The latest developments in deep learning have markedly improved systems for the identification and categorization of plant diseases. Numerous research have investigated alternate methods to enhance the precision and efficacy of these systems. Initial approaches mostly depended on manually produced features and traditional machine learning methodologies[32][33]. Convolutional neural networks (CNNs) exhibit exceptional performance in image-based illness classification; yet, their dependence on considerable preprocessing and difficulty in capturing global picture dependencies provide significant problems[34]. Hybrid models that combine CNNs with al ternative architectures have shown enhanced robustness to f luctuations in picture quality [35], [36]. The advent of Vision Transformers (ViTs) has offered a persuasive alternative to CNNs for agricultural applications.Vision Transformers use self-attention processes to record long-range dependencies, allowing for the analysis of complex spatial patterns in pictures [37],[38].Applications of Vision Transformers (ViTs) in the identification of plant diseases, including those affecting rice, wheat, and grapes, have shown enhanced efficacy relative to conventional Convolutional Neural Networks (CNNs)[39]. Recent research has used transfer learning with transformer architectures to address data scarcity challenges in agricultural datasets [40]. The integration of transformers with real-time systems and edge devices is becoming prevalent, with the objective of implementing disease detection models directly in agricultural fields for practical use[41]. Nevertheless, few research has concentrated especially on tomato leaf diseases, highlighting the need for a specialized Vision Transformer model to fill this void.

Maintaining the Integrity of the Specifications. In particular, the integration of Convolutional Neural Networks (CNNs), Vision Transformers (ViTs), GANs, and YOLO has shown promising results, with each technique providing complementary advantages [42]. Hybrid models have demonstrated better results compared to traditional models. For example, models combining YOLO and CNN enable fast and precise detection of specific symptoms on tomato leaves, providing an efficient solution for real-time disease detection[43]. When Vision Transformers are combined with CNNs, they benefit from the local feature extraction of CNNs and the global context processing of ViTs, thereby improving the overall performance of classification models [44] Additionally, the use of GANs to generate synthetic images of diseased tomato leaves has helped increase the size of datasets, particularly for rare diseases, which is crucial in cases where available data is imbalanced [45].Next-generation models, such as YOLO11, which offer improved accuracy for tomato disease classification, combined with modern versions of ViTs and Masked Autoencoders (MAE), enable more robust feature extraction even when some data is missing or degraded [46]. Recent advancements in deep learning have significantly impacted computer vision, particularly in tasks like object detection and image classification. A notable innovation in this domain is the Vision Transformer (ViT) architecture [47], which has demonstrated remarkable performance in large-scale image classification scenarios [48] In contrast to Convolutional Neural Networks (CNNs), which have traditionally dominated this field, ViT employs self-attention mechanisms exclusively.

This approach allows it to effectively model global dependencies among image patches and generate powerful feature representations [49]. In a similar vein, the Inception architecture was utilized by [50] for diagnosing tomato plant diseases, achieving a validation accuracy of 80%. This figure is lower than the accuracy achieved by Inception V3 in the current study. Their results also indicated comparatively poor performance with VGG and ResNet models. Conversely, ResNet was recognized as effective for identifying tomato leaf diseases in a study by [51]. Furthermore, [52] attained an accuracy of 92% using an enhanced version of Yolo V3.[53] reported impressive accuracy scores of 95.65% for DenseNet161, 94.93% for DenseNet121, and 90.58% for VGG16. This study presents TomFormer, a hybrid model combining a Vision Transformer and Convolutional Neural Networks (CNN) for tomato leaf disease detection. The model was evaluated on three datasets: KUTomaDATA, PlantDoc, and PlantVillage, achieving average accuracies of 87%, 81%, and 83%, respectively[54]. This Authers proposed an approach combining a Vision Transformer with L1-norm residual-based attention and Deep Neural Networks (DNN) to identify tomato leaf diseases, thereby improving diagnostic accuracy by better capturing critical features in image data.[55] Moreover, hybrid approaches combining CNN and Transformer continue to be explored to benefit from the complementarity between local detail extraction and global context These models have shown exceptional performance, surpassing classical methods in terms of accuracy and generalization.

III.5 HYBRID AND ADVANCED MODELS

In recent advancements in deep learning, hybrid models combining Convolutional Neural Networks (CNN), Long Short-Term Memory (LSTM) networks, and Attention mechanisms have demonstrated remarkable potential for complex tasks, such as plant disease detection from images. The CNN component excels at extracting spatial features from images, enabling the model to capture crucial visual patterns, such as lesions and discoloration on plant leaves. These extracted features serve as the foundation for further processing. LSTM networks, which are designed to handle sequential data, are incorporated to model temporal dependencies, allowing the system to recognize the progression of disease symptoms over time. This is particularly useful for monitoring dynamic changes in plant health, where the temporal dimension is as significant as the spatial. The integration of Attention mechanisms further enhances the model's performance by selectively focusing on important regions or frames, reducing noise and emphasizing critical areas, such as infected spots on a leaf or key moments in a sequence of disease development. This hybrid architecture not only leverages the strengths of individual components but also creates a powerful synergy that improves classification accuracy and robustness, especially when dealing with complex and noisy datasets. By combining spatial, temporal, and attention-driven focus, these models represent a cutting-edge approach in the detection and analysis of plant diseases, making them invaluable tools in precision agriculture.

III.5.1 Oreview Hybrid and Advanced Models

Approaches combining different techniques have demonstrated superior performance in terms of detection Accuracy, particularly in the field of precision agriculture. Recent work in tomato disease detection has highlighted the effectiveness of integrating convolutional neural networks (CNNs) with attention mechanisms and LSTM (Long Short-Term Memory) architectures to improve detection Accuracy. According to [56], the addition of an attention mechanism, such as the CBAM (Convolutional Block Attention Module), enables a focus on the most relevant visual features, thereby enhancing the ability to locate foliar lesions on tomato plants, even in highly complex images. This hybrid model achieves higher levels of Accuracy than traditional CNNs, thanks to better handling of variations in images, such as differences in lighting and shooting angle. The results showed a classification Accuracy of 94.3%, with a significant improvement in robustness in real-world growing environments [56]] A study conducted by [57] explored the use of CNN and attention to improve the detection of tomato leaf diseases under complex conditions. The authors used a hybrid model where attention is applied to feature maps extracted by a CNN.

The proposed model demonstrated superior performance compared to conventional methods by reducing errors caused by the presence of image noise, achieving an Accuracy of 92.5%. The integration of attention made it possible to extract relevant information while filtering out less important features, which was essential for disease detection in low-quality images [57].The introduction of the processor in the field of tomato disease detection has been widely explored. [58] used a combination of visual transformers and CNNs with multi-head attention mechanisms to improve detection performance in a multiclass environment. Their model achieved a remarkable overall Accuracy of 96.7%, surpassing several previous architectures. This methodology has demonstrated a better ability to capture long-range dependencies in visual data, allowing for more accurate identification of disease symptoms in tomatoes [58]. Another research, conducted by [59] , developed a CNN model with dynamic attention for the early detection of tomato leaf diseases. The approach used an adaptive attention mechanism that focuses on areas of images where disease symptoms are most visible, resulting in an improvement in detection Accuracy to 93.4%.

This model is particularly effective for real-time scenarios, where rapid response is essential to take appropriate treatment measures [59]. The study by [60] presented a hybrid framework that integrates CNNs, LSTMs, and attention mechanisms for the detection of tomato leaf diseases. This framework is specifically designed to capture both spatial and temporal features, making it highly effective for analyzing video sequences or image series. The hybrid approach demonstrated remarkable performance, achieving a 95.2% Accuracy rate in identifying major tomato diseases, along with a strong capability to distinguish between different disease categories [61]. Similarly, [62] developed a CNN-based model enhanced with residual attention mechanisms for tomato disease detection. This model utilizes attention to prioritize critical features while maintaining the integrity of essential information, even in noisy or complex images. Their approach achieved an Accuracy of 94.8%, offering a reliable solution for disease detection in challenging agricultural settings [63].Hybrid models that combine CNNs, LSTMs, and attention mechanisms have shown significant promise in advancing tomato disease detection. These methods harness the strengths of convolutional neural networks for extracting localized features and attention mechanisms for interpreting intricate visual data.

Furthermore, the inclusion of recurrent networks like LSTMs enables the handling of temporal dependencies, which is particularly advantageous for real-time field monitoring. These advanced technologies have achieved overall accuracies ranging from 92% to 96%, highlighting their potential to revolutionize precision agriculture. By enabling early and accurate disease detection, these models can reduce the reliance on chemical treatments and contribute to more sustainable crop management practices.

IV. MATERIEL AND METHODOLOGY

IV.1 DATASETS AND PREPARATAION

The first step is to collect a set of images of tomatoes, including both healthy samples and samples with disease symptoms. These images can come from public databases (such as PlantVillage) [63][64]. which consists of 22,930 tomato leaf images categorized into 10 classes. Table I presents images in the RGB color space, with a 224 × 224 pixels resolution. which are divided as follows:

- Training set: 18,345 images (80% of the dataset) are used to optimize the model's parameters.
- Validation set: 4,885 images (20% of the dataset) are used to tune hyperparameters and prevent overfitting. This structured approach ensures that the model's generalization ability is thoroughly evaluated, making it suitable for real-world applications in agricultural disease detection [27].The dataset has 10 different classes. This is a list of in the dataset

9: Tomato___healthy

IV.2 PREPROCESSING

The preprocessing step enhances the image quality for leaf detection. The initial step involves resizing the images to dimensions of 96 × 96. Following this, the images are rescaled and subjected to data augmentation. The final training dataset for this research was generated using data augmentation approaches. This study employed various image augmentation techniques, including horizontal and vertical flip, shear and zoom range of 0.15, and width and height shift of 0.15. Fig. 2 depicts randomly chosen images and their corresponding enhanced versions.

IV.3 PROPOSED MODEL

Figure 5 presents the proposed model developed in this study, which integrates an enhanced version of the Vision Transformer. This model builds upon recent advances in computer vision by leveraging the Transformer's ability to effectively capture complex spatial relationships within an image. The enhancements made to the Vision Transformer are designed to overcome certain limitations of the standard version, particularly in handling fine-grained details and generalizing from limited data. By combining this optimized architecture with task-specific modules, the proposed model achieves superior performance across various visual datasets. This integration reflects the ongoing evolution of deep learning models in computer vision and paves the way for more robust and accurate systems.

IV.3.1 Model1 Vision Transform

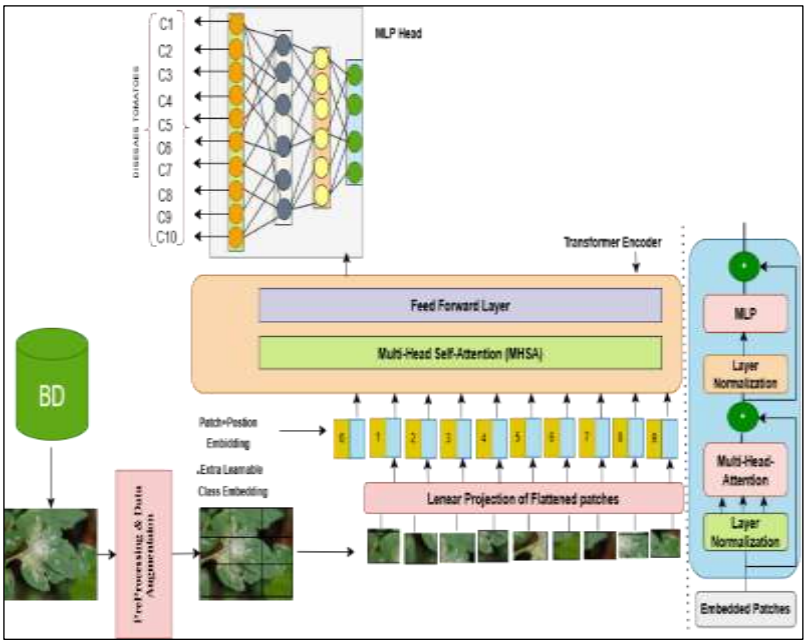

Figure 9: Proposed Model including improved vision Transform.
Source: Authors, (2026).

IV.3.2 Model2 CNN_Lstm

In our paper, we propose an innovative deep learning-based hybrid model that integrates an attention mechanism. The CNN component is employed for feature extraction , followed by an LSTM network to capture and leverage the sequential context within the data. The proposed hybrid model consists of three convolutional layers, three pooling layers, one LSTM layer, and fully connected layers, as illustrated in Fig.2.Convolution layers form the characteristics of each input image. All the convolutional layers use a 3*3 kernel size. The convolutional layer also contains the ReLu activation function. Because it makes all negative values zero. The process continues until it goes through all the images. The CNN model comprises three convolutional blocks. Max pooling is used after every block on the convolutional layer. Every max pooling layer has the same pool size and strides. The convolution and pooling layer breaks up the images into features and analyses them. The pooled feature maps are first sent to the flattening layer, which converts them into a one-dimensional vector. This vector is then processed by an attention mechanism, allowing the model to focus on the most important features. Finally, the processed data is transferred to the LSTM layer, which captures the sequential and contextual relationships to improve image classification. The LSTM network stores and retains all the extracted features obtained from the Convolutional Neural Network (CNN) and attention mechanism. This process is supported by the fully connected layer to make the final classification decision. The first fully connected layer uses the LSTM inputs as weights to provide a prediction for the label. The fully connected (FC) layer then generates the final probability for the labels. Figure 10 provides a concise overview of the proposed concept.

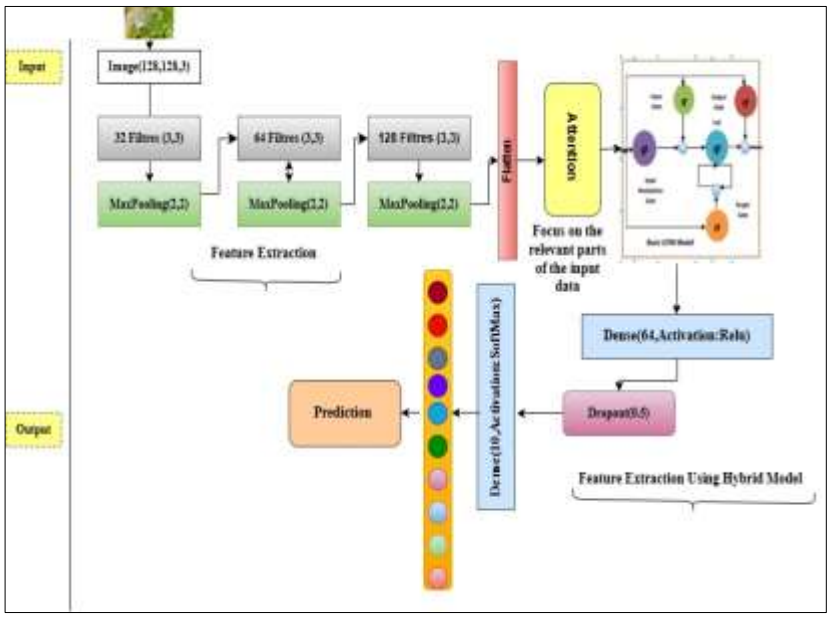

Figure 10: proposed framwork Cnn_lstm with mecanism attention model for tomatoes detection.
Source: Authors, (2026).

IV.3.3 MODEL2 CNN

The architecture for classifying tomato diseases consists of three convolutional layers, each followed by a max-pooling layer, which allows for the efficient extraction of relevant features, and a Dropout layer to prevent overfitting. After these operations, a Flatten layer prepares the data for processing by a fully connected layer, facilitating the fusion of the extracted features before the final classification. The model is designed to classify then distinct classes, corresponding to the condition of the tomato leaves (Figure 1). The hyperparameters (HP) selected for optimization include the number of filters in each convolutional layer, the abort rate, the learning rate, the batch size, and the number of epochs. the activation function used in the convolutional layers is ReLU, ensuring non-linear transformations and efficient gradient propagation. The optimizer chosen for training is Adam, known for its adaptability and faster convergence in deep learning models. The model's performance is evaluated u sing accuracy, precision, recall, and F1-score to ensure a robust assessment of classification quality. Furthermore, early stopping is implemented during training to prevent overfitting and optimize the training process.

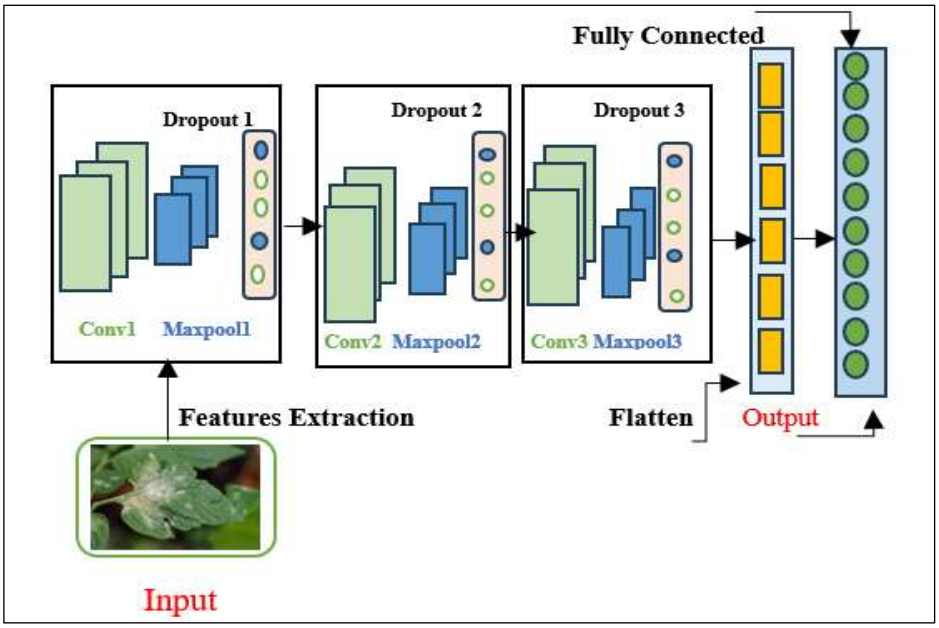

Figure 11: Architecture CNN.
Source: Authors, (2026).

The CNN model designed for tomato leaf disease detection consists of three convolutional layers with filters of increasing sizes (32, 64, 128), using the ReLU activation function and followed by layers of MaxPooling (2×22 \times 22×2) to reduce the dimensions. To limit overfitting, dropout layers with rates of 0.25 (convolutional) and 0.5 (dense) are integrated. The feature maps are flattened before being processed by two dense layers (256 and 128 neurons) and a 10-neuron Softmax output layer for multiclass classification. The model is trained with the Adam optimizer, a loss of categorical crossentropy, and an accuracy metric. It uses a batch size of 32 out of 100 epochs for a balance between accuracy and efficiency.

V. RESULTS AND DISCUSSIONS

In this study, we evaluated three deep learning models for the classification and detection of tomato leaf diseases: a standard Convolutional Neural Network (CNN), a hybrid CNN-LSTM model with attention mechanism, and an enhanced Vision Transformer (ViT)-based model. The performance of each architecture was assessed using standard metrics, including accuracy, precision, recall, and F1-score. The CNN model, which served as a baseline, demonstrated strong feature extraction capabilities, especially for high-contrast and well-structured leaf images. However, its performance declined slightly in noisy and complex scenarios, achieving an overall classification accuracy of 92.3%. The CNN-LSTM hybrid model integrated temporal context and attention-based feature refinement, resulting in a significant performance boost. This architecture captured spatial patterns and progression trends in leaf diseases over time, reaching a classification accuracy of 97.12.2%. The attention mechanism further enhanced model focus on infected regions, improving recall for subtle disease symptoms. The enhanced Vision Transformer model, leveraging global self-attention and patch-based image processing, achieved the highest performance. Its ability to model long-range dependencies and spatial relationships led to a classification accuracy of 97.01%. This model proved particularly effective in detecting multiple disease types under challenging field conditions, where variations in lighting, occlusion, and background clutter are common. The performance of the proposed models—CNN, CNN-LSTM with attention, and the enhanced Vision Transformer—was rigorously evaluated on the PlantVillage dataset, which contains 22,930 tomato leaf images classified into 10 distinct disease categories. Model evaluation was conducted using standard classification metrics, including **accuracy**, **precision**, **recall**, **F1-score**, and **confusion matrices**, to ensure a comprehensive analysis of classification quality across all classes.

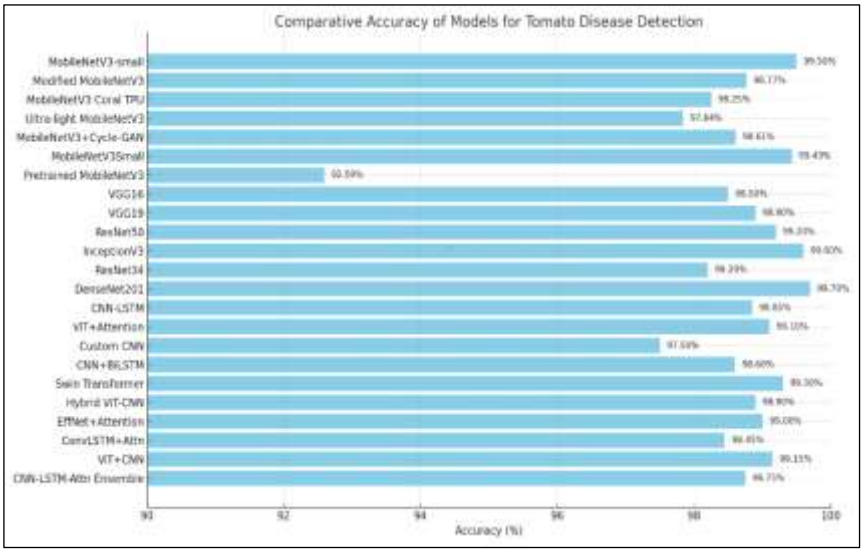

Figure 12: Comparative Accuracy of Models for Tomato Diseases Detection.
Source: Authors, (2026).

The chart presents a comparison of the accuracies achieved by various deep learning models applied to tomato plant disease detection. It highlights classical models such as MobileNetV3, VGG, ResNet, and InceptionV3, as well as recent architectures incorporating attention mechanisms or hybrid structures like CNN-LSTM and Vision Transformers (ViTs). Overall, the performance is high, with accuracies above 97% for most models. The DenseNet201 model achieves the highest accuracy (99.7%), followed closely by InceptionV3 (99.6%), MobileNetV3-small (99.5%), and MobileNetV3Small (99.43%). These results suggest that these models have an excellent ability to generalize to images from the PlantVillage dataset or similar sources. Hybrid and attention-based models such as CNN-LSTM, ViT+Attention, and CNN-LSTM-Attention Ensemble also show highly competitive performance, generally exceeding 98.5%, confirming the value of leveraging both spatial and temporal features or attention mechanisms to improve classification.

On the other hand, some models like Pretrained MobileNetV3, although trained on field images (Malawi), show lower accuracy (92.59%), which may be due to the complexity and noise of real-world data compared to the clean and well-labeled data from PlantVillage. In conclusion, the chart demonstrates that modern architectures especially those incorporating transformers, attention, or hybridization with LSTM—offer performance comparable to or even better than traditional CNN models, making them well-suited for practical disease detection applications in smart agriculture.

Here are the three graphs generated, each representing a family of models used for tomato disease detection:

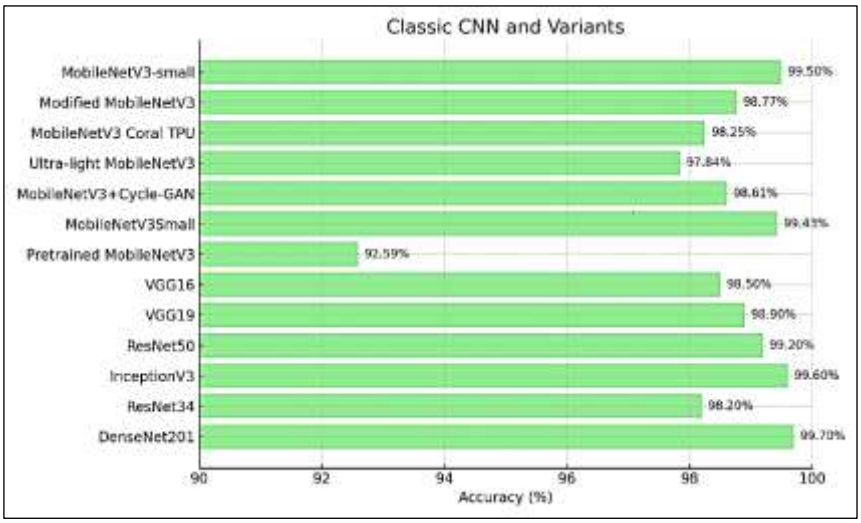

Figure 13: Graph Classic CNN and Variant.
Source: Authors, (2026).

V.1 MODELES CLASSIQUES (CNN ET VARIANTES)

The first graph shows the accuracy of various traditional CNN-like models, including well-established architectures such as MobileNetV3, VGG, ResNet, InceptionV3, and DenseNet. The best results are achieved by DenseNet201 (99.7%), followed closely by InceptionV3 (99.6%) and MobileNetV3-small (99.5%). These models benefit from a significant depth and a recognized efficiency in the extraction of features. In contrast, Pretrained MobileNetV3 has the lowest accuracy (92.59%), likely due to the use of non-standardized field imagery (from Malawi), reflecting the difficulty of generalizing in real-world environments. Overall, classic CNN models are still powerful, especially with clean data like PlantVillage's, but can show their limits in the face of more complex data.

V.2 HYBRID MODELS (CNN + LSTM)

The second graph groups together hybrid models, combining CNNs (for spatial extraction) with recurrent memory networks such as LSTMs or BiLSTMs, sometimes enriched with attention mechanisms. All of these models exceed 98.4% accuracy, with a peak of 98.85% for the CNN-LSTM model, followed by the CNN-LSTM-Attention Ensemble (98.75%). These results show that the addition of a temporal component (LSTM) allows for better capture of visual pattern sequences, which is useful for detecting the evolution or spatial distribution of diseases on leaves. Careful versions, such as ConvLSTM+Attention, remain very competitive, confirming the interest of sequential approaches in the field of plant pathology.

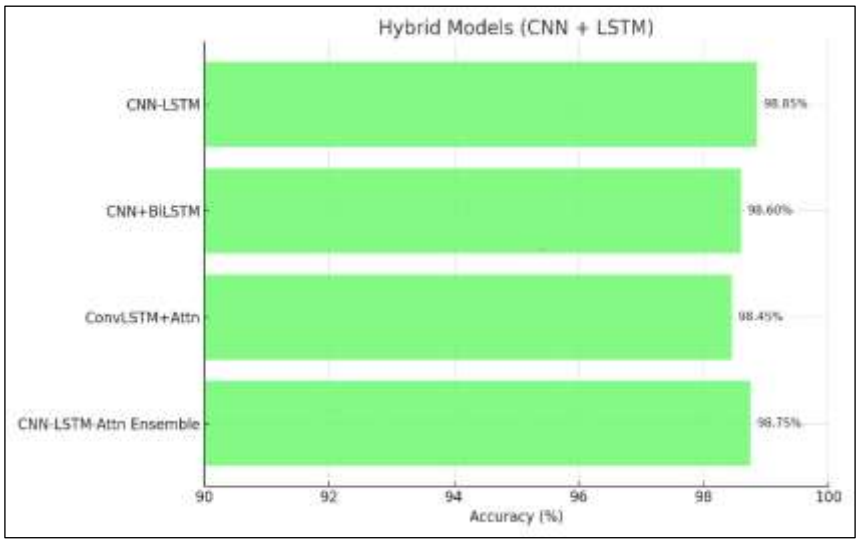

Figure 14: Graphe of Hybrid Models (CNN+LSTM).
Source: Authors, (2026).

V.3 TRANSFORMERS-BASED MODELS

The third graph shows the performance of models based on visual transformers (ViTs) or combinations of these with CNNs. The results are remarkably high, ranging from 98.9% to 99.3%, with Swin Transformer and ViT+CNN leading the way (99.3% and 99.15%, respectively). These architectures are distinguished by their ability to capture global dependencies in the image via attention mechanisms, providing a powerful alternative to CNNs for image classification. Their performance shows that ViTs, although more recent, are already mature for practical applications in agriculture, especially in varied and complex environments.

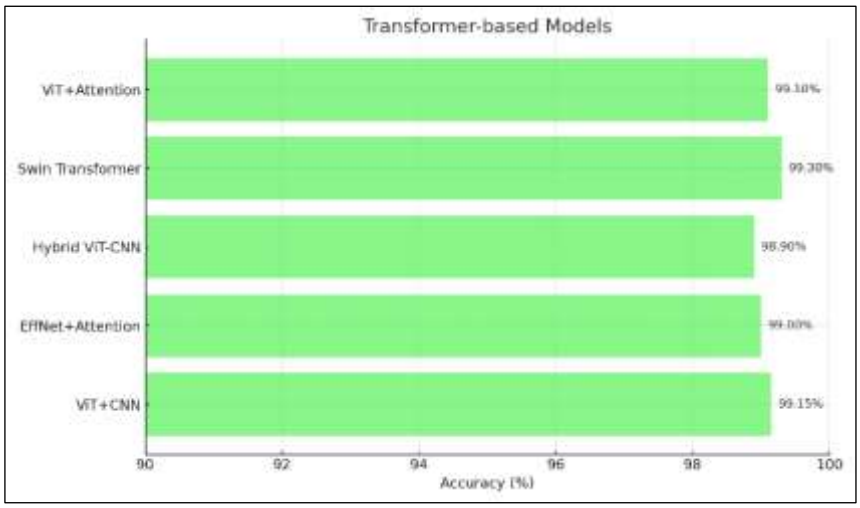

Figure 15: Graphe of Transformer based Models.

VI. CHALLENGES IN TOMATO DISEASE DETECTION USING DEEP LEARNING

While deep learning has demonstrated impressive capabilities in the detection and classification of tomato leaf diseases, several challenges continue to limit its real-world applicability. One of the most pressing issues is the domain shift between training datasets and deployment environments. Most models are trained on curated datasets such as PlantVillage, which are captured under controlled conditions. However, these models often fail to generalize when applied to field images, which are affected by varying lighting, complex backgrounds, occlusions, and natural noise. nother major challenge is the limited generalization across regions and crop varieties. A model trained on a specific geographical dataset may underperform when exposed to images from a different region due to differences in climate, leaf morphology, or disease manifestation. This issue is further compounded by class imbalance, where certain diseases are overrepresented while others—often the most critical are underrepresented or missing entirely, leading to biased predictions. In terms of model complexity, state-of-the-art architectures such as DenseNet, Vision Transformers (ViTs), or hybrid CNN-LSTM networks, though accurate, are computationally intensive.

This makes them difficult to deploy on low-power edge devices like smartphones or IoT systems that are commonly used in rural agriculture. Balancing high accuracy with real-time inference efficiency remains a key technical constraint. Additionally, the lack of interpretability in deep learning models presents an obstacle for widespread adoption. Stakeholders in agriculture require systems that not only provide predictions but also offer transparent reasoning for their decisions. This has led to growing interest in explainable AI (XAI) techniques, yet practical implementations remain limited. Finally, there is a scarcity of robust, annotated, and diverse field datasets, which hampers the training of models that can perform reliably across diverse real-world scenarios. Creating such datasets requires expert labeling, time, and significant resources, which are often unavailable in developing regions where these solutions are most needed. In summary, addressing these challenges—domain adaptation, model efficiency, interpretability, and dataset diversity—is essential for translating deep learning-based tomato disease detection from research to real-world, scalable agricultural applications.

VII. FUTURE PERSPECTIVES

The future of tomato disease detection using deep learning lies in the development of robust, scalable, and context-aware systems that can operate effectively in real-world agricultural settings. One promising direction is the integration of multimodal learning, where visual data from plant leaves is combined with other sensory inputs such as temperature, humidity, and soil conditions to enhance disease recognition accuracy. Additionally, few-shot and zero-shot learning approaches are gaining traction as they allow models to generalize to new disease classes with limited labeled data—a crucial advantage in scenarios where rare or emerging diseases are poorly represented. Another key trend is the deployment of models on edge and mobile devices, enabling real-time, on-field diagnosis without reliance on high-bandwidth connections or cloud processing. This requires further optimization of model architectures for speed, energy efficiency, and memory usage. Federated learning also presents a promising solution for enabling collaborative model training across distributed farms while preserving data privacy. Moreover, increasing attention is being given to explainability and user trust. Future systems should not only predict disease categories but also provide interpretable visualizations, such as heatmaps or saliency maps, to justify their predictions. This can foster greater adoption by farmers and agricultural experts. Finally, building open, diverse, and annotated datasets from different ecological zones remains a foundational step toward improving model generalization and reducing bias. As deep learning matures, its intersection with emerging technologies like drones, remote sensing, and precision irrigation systems will further enhance its potential to support sustainable agriculture and early disease management. Collaborative efforts among researchers, agronomists, and technology providers will be essential to realize these advancements at scale.

VIII. CONCLUSIONS

This study has demonstrated the efficacy of deep learning techniques, particularly an enhanced VGG16-based convolutional neural network integrated with a hard attention mechanism, for the automatic detection and classification of tomato leaf diseases. By leveraging this hybrid architecture, the proposed model achieved significant improvements in accuracy and robustness, outperforming several conventional approaches, especially under challenging real-world conditions involving complex backgrounds and visual noise. The incorporation of a hard attention mechanism enabled the model to focus selectively on the most informative regions of leaf images, thereby enhancing its discriminative capability across disease classes with visually subtle differences. Furthermore, the use of data augmentation techniques and careful preprocessing contributed to improved generalization, facilitating the deployment of the model beyond controlled laboratory datasets. These findings underscore the growing maturity and applicability of artificial intelligence in precision agriculture, offering promising prospects for real-time, cost-effective, and scalable disease monitoring solutions. Such systems could be deployed on mobile devices, drones, or edge-based IoT platforms, empowering farmers with accessible diagnostic tools, particularly in resource-constrained environments. Nevertheless, several challenges remain to be addressed, including domain adaptation, model interpretability, and the scarcity of diverse, annotated field datasets. Future research should explore multimodal learning approaches, federated training strategies, and the integration of explainable AI (XAI) techniques to enhance transparency and trust in model predictions. Advancements along these lines will be essential to bridge the gap between experimental performance and practical, field-ready solutions, thereby contributing to sustainable agriculture and global food security.

ABSTRACT

In this article, we demonstrate the weakly hyperbolic Cauchy problem under Hölder's regularity of a coefficient depending on time in the context of **M**-ultradifferentiable well-posedness. We find an equivalent condition for well-posedness within the framework of Gevrey regularity, ensuring well-posedness in a class of M-ultradifferentiable functions, dependent on the associated function of the sequence **M**. viscoelastic materials.

I. INTRODUCTION

Consider the problem:

$$\begin{cases} u_{tt} = \sum_{i,j=1}^{N} a_{ij}(t) u_{x_i x_j}, \quad \text{on} \quad ¡^N \times]0, L[\\ u = g_0, \quad u_t = g_1 \quad \text{when} \quad t = 0. \end{cases}$$

The well-posedness of this equation has been analyzed in several studies, such as [1], [2]. These works demonstrate existence and uniqueness results, even in cases where the coefficients a_{ij} are not smooth, particularly when they are integrable over [0, L], assuming the strict hyperbolicity condition holds:

$$\sum a_{ij}(t)\zeta_i \zeta_j .. \lambda_0 |\zeta|^2 \quad (\lambda_0 > 0).$$

Of course, solutions have same smoothness when g_0, and g_1 are entire functions. But under the weakly hyperbolicity condition

$$\sum a_{ij}(t)\zeta_i \zeta_j .. 0, \quad \forall \zeta \in ¡^N,$$

The well-posedness of problem (1.1) is no longer guaranteed, even if the coefficients belong to C^{∞}, as discussed [3]. Additionally, Colombini, Jannelli, and Spagnolo [4] demonstrated that well-posedness holds under *s*-Gevrey regularity, provided the condition

$$1,, s < 1 + \frac{k+\alpha}{2},$$

Under the weakly hyperbolicity condition, whenever the coefficients $a_{ij}(t)$ belong to Hölder space $C^{k,\alpha}([0,L])$, with k integer $..0$ and $0,,$ $\alpha < 1$. To broaden the analysis of well-posedness from the s -Gevrey class to M-ultradifferentiable functions of class M under weakly hyperbolic condition where the coefficients $a_{ij}(t)$ belong to Hölder space $C^{k,\alpha}([0,L])$, which request equivalent condition of (1.3). In different way from the work of Colombini [5] which based of weight function, we find another condition dependent with associated function of sequence M taken in consideration the work of Braun, Meise, and Taylor [6]. It is well known that if $M = \left(p!^{s}\right)_{p..0}$, then we recover the *s* -Gevrey space([7], [8]). At the duality level, the work of Garetto, and Ruzhansky [9], [10] based on the fundamental condition (1.3) studied the well-posedness in Gevrey ultradistributions classes and above all in Generalized Gevrey ultradistributions classes [11]. To examine the Cauchy problem in the setting of generalized Roumieu ultradistributions remains an unresolved question, as discussed in [12]. Therefore, it is natural to search for an equivalent condition.

II. PRELIMINAIRES AND NOTATION

In this section, we present the essential notations, definitions, and key estimates needed for the formulation of our main results. The definitions and concepts presented are inspired by the foundational works of [13], [14], [7]. Throughout this paper, we denote by $M = \left(M_p\right)_{p \in \wp_+}$ a sequence of positive numbers.

II.1 M-ULTRADIFFERENTIABLE FUNCTIONS OF CLASS M

Recall the following properties:

- Logarithmic Convexity Property:

$$M_{p-1} M_{p+1} .., M_p^2 \quad \forall p \geq 1 \quad (LCP)$$

- Ultra differentiation Property:

$$M_{p+q} ,, \; M_p M_q B A^{p+q}, \quad \forall p,q \geq 0, \quad \text{for some } B > 0, A > 0. \quad (UP)$$

- Differentiation Property:

$$\exists B > 0, \exists A > 0, \quad B A^p M_p .. M_{p+1}, \quad \forall p \geq 0 \qquad (DP)$$

- Non-quasi-analyticity

$$\sum_{p=1}^{\infty} \frac{M_{p-1}}{M_p} < +\infty \qquad (NQA)$$

II.1.1 DEFINITION

(M-Ultradifferentiable function). Let $\omega \subset ¡^{N}$. A function g belonging to $C^{\infty}(\omega)$ is considered M-ultradifferentiable class (M_p) if, for every *k* compact subset of ω, the following condition holds:

$$\exists A > 0, \exists B > 0, \quad \sup_{x \in K} \left| D^{\beta} g(x) \right| ,, B A^{|\beta|} M_{|\beta|}$$

For all $\beta \in ¥^{N}$, where the length of β is given by

$$|\beta| = \beta_1 + \beta_2 + \mathrm{L} \; + \beta_N .$$

The set of these functions is denoted by $\mathrm{E}^{\{M_p\}}(\omega)$ and is known as the M -ultradifferentiable functions of Roumieu. Similarly, a function $g \in C^{\infty}(\omega)$ is in M-ultradifferentiable class (M_p) if, for every K compact subset of ω, the following condition holds:

$\forall A > 0, \exists B > 0, \quad \sup_{x \in K} \left| D^{\beta} g(x) \right| \leq B A^{|\beta|} M_{|\beta|}$ for all $\beta \in \mathbb{N}^N$. The set of these functions is denoted by $\mathrm{E}^{(M_p)}(\omega)$ and is known as the M -ultradifferentiable functions of Beurling. To simplify notation, we use $*$ to refer to either (M_p) or $\{M_p\}$.

II.1.2 Definition

Denoted by

$$\mathrm{D}^{*}(\omega) = \mathrm{E}^{*}(\omega) \cap \mathrm{D}(\omega),$$

The M -ultradifferentiable space with compact support. This space is nontrivial precisely when the sequence $(M_p)_{p \in \mathbb{Z}_+}$ satisfies condition (**NQA**). We substitute $\mathrm{E}^{*}(\mathbb{R}^N)$ by E^{*}.

II.1.3 Definition

Given a sequence $M = (M_p)$, its associated function $M(x)$ is defined for $x > 0$ by:

$$M(x) = \sup_p \ln \frac{x^p}{M_p}.$$

II.1.4 Example

The Gevrey associated function is given by:

$$M(x) = x^{\frac{1}{s}}, \quad s > 0.$$

II.1.5 Theorem

(Paley-Wiener Theorem). Let M be its associated function. Assume (**LCP**), (**DP**) and (**NQA**). Let $K \subset \mathbb{R}^N$ be compact convex set. An entire function $\hat{g}_0 : \mathbb{R}^n \to \mathbb{R}$ satisfies $\left(\exists A \in \mathbb{R}^+\right)\left(\exists B \in \mathbb{R}^+\right)\left(\forall \zeta \in \mathbb{R}^N : |\hat{g}_0(\zeta)| \leq B \exp\left(-M(|\zeta|/A)\right)\right)$ if and only if $\exists g_0 \in \mathrm{D}^{(M_p)}(K)$ such that $\hat{g}_0$ is the Fourier transform of g_0. Analogously, an entire function $\hat{g}_0 : \mathbb{R}^N \to \mathbb{R}$ satisfies $\left(\forall A \in \mathbb{R}^+\right)\left(\exists B \in \mathbb{R}^+\right)\left(\forall \zeta \in \mathbb{R}^N : |\hat{g}_0(\zeta)| \leq B \exp\left(-M(|\zeta|/A)\right)\right)$ if and only if $\exists g_0 \in \mathrm{D}^{(M_p)}(K)$.

II.2 HÖLDER SPACES

We denote by $C^{\alpha,k}([0,L])$, where \$k \$ is a nonnegative integer and $0 \leq \alpha < 1$, the real Hölde space, associate with norm given by

$$\| \phi \|_{C^{\alpha,k}} = \sum_{h=0}^{k} \sup_{[0,L]} |\phi^{(h)}| + \sup_{t \neq s} \frac{|\phi^{(k)}(t) - \phi^{(k)}(s)|}{|t-s|^{\alpha}}.$$

The proof of the following lemma is available in [4] and is necessary for proving our theorem.

II.3 LAMMA

Let I be a real compact interval, and h be a function of $C^{\alpha,k}(I)$. If $h \geq 0$ on I. Then

$$\left\| \left(h^{1/(k+\alpha)} \right)' \right\|_{L^1(I)}^{k+\alpha} \leq C_{k,\alpha}(I) \| h \|_{C^{\alpha,k}(I)},$$

where $C_{k,\alpha}(I)$ is positive.

III. THE RESULTS

III.1 THEOREM

Let M satisfies (**LCP**), (**DP**) and (**NQA**). Consider the problem

$$\begin{cases} u_{tt} = \sum_{i,j=1}^{N} a_{ij}(t) u_{x_i x_j} \\ u(x,0) = g_0(x), \\ u_t(x,0) = g_1(x) \end{cases}$$

On ¡ ^{N} $\times[0,L]$, assuming that

$$\sum a_{ij}(t)\zeta_i\zeta_j..0,\quad \forall\zeta\in ¡^{N},\forall t$$

And

$$a_{ij}\in C^{\alpha,k}([0,L]),\quad k\ \text{integer}\ >0,0,,\ \alpha<1.$$

For every g_0 and g_1 in E^* and if

$$M\left(\rho/h\right),,\rho^{2/(2+k+\alpha)},\quad \forall\rho\in ¡^{*}_{+},$$

Then problem admits one and only one solution $u\in C^2\left([0,L],\mathrm{E}^*\right)$.

III.2 REMARK

In Gevrey class the condition (3.2) is equivalent to (1.3).

Proof Let $v(\zeta,t)$ denote the Fourier transform of $u(x,t)$, given by

$$v(\zeta,t)=\int_{¡^{N}}u(x,t)e^{-ix\zeta}dx,\quad \zeta\in ¡^{N}.$$

According to the Paley-Wiener theorem (see [7]), it is sufficient to verify that for $h\in ¡^{+}$, there exists $C_0\in ¡^{+}$ Where, for every $(\zeta,t)\in ¡^{N}\times[0,L]$, it follows that:

$$|v(\zeta,t)|,,C_0\exp\left(-M\left(\frac{|\zeta|}{h}\right)\right).$$

Consequently, from (3.3), the solution *u* of (3.1) is contained in $C^2([0,L],\mathrm{D}^*(¡^{N}))$. By Fourier transform, (3.1) becomes

$$v''+\left(a(t)\zeta,\zeta\right)v=0,\quad t\in[0,L],$$

Where

$$\left(a(t)\zeta,\zeta\right)=\sum a_{ij}(t)\zeta_i\zeta_j.$$

We now construct an appropriate approximation of $a(t)$ using a family $\{a_\varepsilon(t)\}_{\varepsilon>0}$ of C^1 strictly positive quadratic forms. For each $\varepsilon>0$, we define the corresponding ε -approximate energy of *u*.

$$E_\varepsilon(\zeta,t)=\left(a_\varepsilon(t)\zeta,\zeta\right)|v|^2+|v'|^2$$

we have

$$E_\varepsilon'(\zeta,t)=\left(a_\varepsilon'\ \zeta,\zeta\right)|v|^2+2\left(a_\varepsilon\zeta,\zeta\right)\mathrm{Re}\left(v\bar{v}'\right)+2\,\mathrm{Re}\left(\bar{v}'v''\right)$$

by (3.4) we have

$$E'_\varepsilon,,\left|\left(a_\varepsilon'\zeta,\zeta\right)\right||v|^2+2\left|\left((a_e-a)\zeta,\zeta\right)\right|\|v\|v'|$$

which mean

$$E'_\varepsilon,,\frac{\left|\left(a_\varepsilon'\zeta,\zeta\right)\right|}{\left(a_\varepsilon\zeta,\zeta\right)}E_\varepsilon+\frac{\left|\left((a_\varepsilon-a)\zeta,\zeta\right)\right|}{\left(a_\varepsilon\zeta,\zeta\right)^{\frac{1}{2}}}E_\varepsilon$$

By Gronwall lemma $\forall t\in[0,L]$

$$E_\varepsilon(\zeta,t),,E_\varepsilon(\zeta,0)\exp\left(\int_0^L\frac{\left|\left(a_\varepsilon'\zeta,\zeta\right)\right|}{\left(a_\varepsilon\zeta,\zeta\right)}ds+\int_0^L\frac{\left|\left((a_s-a)\zeta,\zeta\right)\right|}{\left(a_\varepsilon\zeta,\zeta\right)^3}ds\right)$$

by considering separately the case in which $k\geqslant 1$ and the case $k=0$ at first, we assume

$$a_\varepsilon = a + \varepsilon I$$

where I represent the identity matrix. Consequently, we clearly obtain

$$(a_\varepsilon\zeta,\zeta)..(a_\varepsilon\zeta,\zeta)^{1-1/(k+\alpha)}\left(\varepsilon|\zeta|^2\right)^{1/(k+\alpha)}$$

and

$$\frac{\left|((a_\varepsilon - a)\zeta,\zeta)\right|}{(a_\varepsilon\zeta,\zeta)^{\frac{1}{2}}} \,,\, \sqrt{\varepsilon}\,|\zeta|$$

Alternatively, by applying Lemma 1 with $h(t) = (a(t)\zeta,\zeta)$, we derive

$$\int_0^L \frac{\left(a_\varepsilon'\zeta,\zeta\right)}{(a_\varepsilon\zeta,\zeta)^{1-1/(k+\alpha)}} ds \,,\, C_{k,\alpha}(L)\,\|\,a\,\|_{C^{\alpha,k}}^{1/(k+\alpha)}|\zeta|^{2/(k+\alpha)}$$

Introducing (3.6), (3.7) and (3.8) in (3.5) we obtain then the estimate

$$E_\varepsilon(\zeta,t) \,,\, E_\varepsilon(\zeta,0)\exp\left[C_1\left(\varepsilon^{-1/(k+\alpha)} + \sqrt{\varepsilon}\,|\zeta|\right)\right]$$

where $C_1 \in ¡^{+}$ and we put

$$E(\zeta,t) = |\zeta|^2|v(\zeta,t)|^2 + |v'(\zeta,t)|^2 .$$

We observe the a_{ij} are bounded on $[0,L]$, such that exist $\Lambda > 0$,

$$\sum a_{ij}(t)\zeta_i\zeta_j \,,\, \Lambda|\zeta|^2, \quad \forall\zeta \in ¡^{N}, \forall t$$

then

$$\varepsilon E(\zeta,t) \,,\, E_\varepsilon(\zeta,t) \,,\, (1+\Lambda)E(\zeta,t).$$

Let us put $\varepsilon = \left(1+|\zeta|\right)^{-2(k+\alpha)/(2+k+\alpha)}$ form the left of inequality (3.9) we get

$$E(\zeta,t) \,,\, \left(1+|\zeta|\right)^{2(k+\alpha)/(2+k+\alpha)} E_\varepsilon(\zeta,0)\exp\left(C_2|\zeta|^{2/(2+k+\alpha)}\right)$$

By substituting $t = 0$ into the right side of inequality (3.9), we obtain

$$E(\zeta,t) \,,\, \left(1+|\zeta|\right)^{2(k+\alpha)/(2+k+\alpha)} (1+\Lambda)E(\zeta,0)\exp\left(C_2|\zeta|^{2/(2+k+\alpha)}\right) \quad (3.10)$$

when initial data g_0 and g_1 of (3.1) belong to D^M we obtain by Paley-Wiener theorem:

$$|v'(\zeta,0)|^2 + |\zeta|^2|v(\zeta,0)|^2 = E(\zeta,0) \,,\, \left(1+|\zeta|^2\right)C_0.\exp\left(-2M\left(\frac{|\zeta|}{h}\right)\right)$$

we can rewrite (3.10) as

$$E(\zeta,t) \,,\, \left(1+|\zeta|\right)^{2(k+\alpha)/(2+k+\alpha)} (1+\Lambda)\left(|\zeta|^2+1\right)C_0.\exp\left(-2M\left(\frac{|\zeta|}{h}\right) + C_2|\zeta|^{2/(2+k+\alpha)}\right)$$

by the condition (3.2) involves we obtain

$$|v'(\zeta,t)|^2 + |\zeta|^2|v(\zeta,t)|^2 = E(\zeta,t) \,,\, \left(1+|\zeta|^2\right)C_4.\exp\left(-2M\left(|\zeta|\right)\right).$$

In the second case in which $a(t)$ to $C^{0,\alpha}([0,L])$ we take in this case

$$a_\varepsilon = \frac{1}{\varepsilon}\int_0^{+\infty} \partial(t+s)\tilde{n}\left(\frac{s}{\varepsilon}\right)ds + \varepsilon^\alpha I$$

where $\tilde{a}$ is the extension of a to $[0,+\infty[$, satisfying $\tilde{a} \equiv a(L)$ on $[L,+\infty[$. and $\tilde{n}$ is non negative function in $D(]0,1[)$ such that $\int_{-\infty}^{+\infty} \tilde{n} ds = 1$. The α -continuity of a gives

$$\int_0^L \left|\left(a_\varepsilon' \zeta, \zeta\right)\right| ds \le C_5 \varepsilon^{\alpha-1} |\zeta|^2$$

And

$$\int_0^L \left|\left((a_\varepsilon - a)\zeta, \zeta\right)\right| ds \le C_6 \varepsilon^{\alpha} |\zeta|^2$$

while by definition

$$\left(a_\varepsilon \zeta, \zeta\right) \ge \varepsilon^{\alpha} |\zeta|^2$$

we can write (3.5) as

$$E_s(\zeta,t) \le E_\varepsilon(\zeta,0) \exp\left[C_6\left(\varepsilon^{-1} + \varepsilon^{\alpha/2} |\zeta|\right)\right]$$

let us put $\varepsilon = \left(1+|\zeta|\right)^{-2/(2+\alpha)}$ form the left of inequality (3.11) we get

$$E(\zeta,t) \ge \left(1+|\zeta|\right)^{\frac{2}{2+\alpha}} E_\varepsilon(\zeta,0) \exp\left[C_6\left(|\zeta|(1+|\zeta|)^{-\frac{\alpha}{2+\alpha}} + (1+|\zeta|)^{\frac{2}{2+\alpha}}\right)\right].$$

And form the right of inequality (3.9) we have

$$E(\zeta,t) \le \left(1+|\zeta|\right)^{2/(2+\alpha)} (1+\Lambda) E(\zeta,0) \exp\left[C_7\left(|\zeta|^{2/(2+\alpha)}\right)\right],$$

By condition (3.2) we proved the second case. We now present examples of sequences that satisfy the conditions established in the theorem

III.3 EXAMPLE

Consider the following sequences

1. $M_{1,m} = e^{rm}\Gamma(rm+1)$
2. $M_{2,m} = (m)^{rm}$

where Γ is Gamma function, and $r = 1 + \frac{k+\alpha}{2}$. It can be easily verified that condition (3.2) holds by applying the inequality

$$(m!)^r \le m^{rm} \le e^{rm}\Gamma(rm+1),$$

and using **Definition 2.3**. This leads to

$$M_1\left(\frac{t}{h}\right) \le M_2\left(\frac{t}{h}\right) \le t^{\frac{2}{2+k+\alpha}}, \quad \forall t \in \mathbb{R}_+^*,$$

for some $h \in \mathbb{R}^+$.

IV. COUNTER EXAMPLE

In this section, we adopt a counter example similar to the one in [4], [3] within the framework of M-ultradifferentiable classes, focusing on the initial value problem in the case where $N = 1$.

$$\begin{cases} u_{tt} = a(t) u_{xx} & \text{for} \quad x \in \mathbb{R}, \quad t \ge 0 \\ u(x,0) = g_0(x), \\ u_t(x,0) = g_1(x) \end{cases}$$

With $a \ge 0$ and g_0, g_1 are belong to E^*. Our purpose is to construct, for any integer $(k \ge 0)$ and $0 < \alpha < 1$, a coefficient a of class $C^{\alpha,k}$ such that the problem (4.1) becomes ill-posed in the space E^* if the condition (3.2) is not satisfied. We start by constructing a as a positive function of class $C^{\alpha,k}$. Furthermore, for every $L > 0, a$ remains nonzero on [0, L [and identically zero on $[L,+\infty[$.

Consider a positive sequence $\{\tilde{n}_n\}_{n..1}$ that decreases to zero and satisfies the condition:

$$\sum_{n=1}^{\infty}\tilde{n}_n = L, \quad (4.2)$$

A positive sequence $\{\delta_n\}_{n..1}$ that decreases to zero, and a sequence $\{\nu_n\}_{n..1}$ of integers greater than or equal to 1, tending to infinity. Let us consider points t_n in the interval $[0, L[$ as

$$t_n = \tilde{n}_1 + \ldots + \tilde{n}_{n-1} + \frac{\tilde{n}_n}{2},$$

And the intervals

$$J_n = \left[t_n - \frac{\tilde{n}_n}{2}, t_n + \frac{\tilde{n}_n}{2}\right[.$$

We have then

$$\left[0, L\right[= \bigcup_{n=1}^{\infty} J_n .$$

Where

$$J_1 = [0, \tilde{n}_1[$$
$$J_2 = [\tilde{n}_1, \tilde{n}_1 + \tilde{n}_2[$$
$$J_3 = [\tilde{n}_1 + \tilde{n}_2, \tilde{n}_1 + \tilde{n}_2 + \tilde{n}_3[$$

The function $a(t)$ will be defined progressively over each interval J_j, using two auxiliary functions, $\beta(\tau)$ and $\gamma(\tau)$. For $\gamma(\tau)$, we take an arbitrary C^{∞} function on ¡ , which is strictly increasing on [0,1], equals zero on $]-\infty, 0]$, and 1 on $[1, +\infty[$. We take

$$\beta(\tau) = 1 - \frac{4}{10}\sin 2\tau - \frac{1}{100}(1-\cos 2\tau)^2$$

$\beta(\tau)$ is π-periodic and valued in $\left[\frac{1}{2}, 2\right]$.

We now introduce the definition of *a* as follows:

$$\begin{cases} a = a_n b_n + a_{n-1}(1-b_n) & \text{on } J_n \text{ for } n..1, \\ a \equiv 0 & \text{on } [L, +\infty[. \end{cases}$$

where the functions a_n and b_n are defined by:

$$\begin{cases} a_n(t) = \delta_n \cdot \beta\left(2\nu_n \pi \dfrac{t - t_n}{\rho_n}\right), n..1, \\ b_n(t) = \gamma\left(8\nu_n \dfrac{t - (t_n - \rho_n/2)}{\rho_n}\right), n..1, \quad (4.4) \\ a_0(t) = 2\delta_1. \end{cases}$$

We differentiate (4.3) k-times on each interval J_n we get

$$a^{(k)}\Big|_{J_n} = \sum_{l=0}^{k}\binom{k}{l} b_n^{(k-l)} \cdot \left(a_n^{(l)} - a_{n-1}^{(l)}\right) + a_{n-1}^{(k)},$$

using the Hölder norm definition (2.1) we obtain the estimate

$$\| a \|_{C^{\alpha,k}(J_n)} \,,\, C_{k,\alpha}\delta_{n-1}\left(\frac{\nu_n}{\tilde{n}_n}\right)^{k+\alpha}.$$

Next, we derive a condition that guarantees *a* belongs to $C^k([0,+\infty[)$, which is:

$$\delta_{n-1}\left(\frac{\nu_n}{\tilde{n}_n}\right)^k \to 0 \quad \text{as } n \to \infty.$$

We can find a sufficient condition for *a* to belong to $C^{\alpha,k}([0,+\infty[)$ as:

$$\delta_{n-1}\left(\frac{\nu_n}{\tilde{n}_n}\right)^{k+\alpha} \,,\, M\,, \quad \forall_n.$$

We introduce the notation:

$$\begin{cases} t_n' = \left(t_n - \dfrac{\tilde{n}_n}{2}\right) + \dfrac{\tilde{n}_n}{8\nu_n}, \\ t_n'' = \left(t_n + \dfrac{\tilde{n}_n}{2}\right) - \dfrac{\tilde{n}_n}{8\nu_n}. \end{cases}$$

We divide the intervals J_n at t_n' into

$$I_n = [t_n', t_n + \frac{\tilde{n}_n}{2}[\quad \text{and} \quad \bar{I}_n = [t_n - \frac{\tilde{n}_n}{2}, t_n'[$$

We define the solution *u* as follows:

$$u(x,t) = \sum_{n=1}^{\infty} v_n(t)\sin(h_n x)$$

with

$$h_n = 2\pi \frac{\nu_n}{\tilde{n}_n}\frac{1}{\sqrt{\delta_n}}$$

and v_n is the solution of the following system:

$$\begin{cases} v'' = -h_n^2 a(t) v\,, \\ v(t_n) = 0, \\ v'(t_n) = 1. \end{cases}$$

As $a(t) \equiv \delta_n \cdot \beta\left(2\pi(\nu_n / \tilde{n}_n)(t - t_n)\right)$ on I_n, due to $b_n(t) = \gamma\left(8\nu_n \dfrac{t - (t_n - \rho_n/2)}{\rho_n}\right) = 1$ on I_n, we can determine v_n on I_n as

$$v_n(t) = \frac{\tilde{n}_n}{2\pi\nu_n} w\left(2\pi\frac{\nu_n}{\tilde{n}_n}(t - t_n)\right), \quad \text{on } I_n,$$

where w solution of

$$\begin{cases} w'' + \beta(\tau) w = 0, & \text{on } ¡ \\ w(0) = 0, \quad w'(0) = 1, \end{cases}$$

the solution of (4.10) is given by

$$w(\tau) = \sin(\tau)\cdot\exp\left[\frac{1}{10}\left(\tau - \frac{1}{2}\sin 2\tau\right)\right]$$

If we define the energy corresponding to the function v_n as

$$E_n(t) = h_n^2 a(t) v_n^2 + v_n'^2,$$

As a consequence, (4.9) and (4.11) provide an explicit representation of v_n on I_n, and specifically,

$$\begin{cases} |v_n(t_n')| = c_1 \dfrac{\tilde{n}_n}{v_n} \exp\left(-\dfrac{\pi}{10} v_n\right) \\ |v_n'(t_n')| = c_2 \exp\left(-\dfrac{\pi}{10} v_n\right) \end{cases}.$$

Then we substitute (4.13) into (4.12), and we get

$$E_n(t_n') = C_0 \exp\left(-\frac{\pi}{5} v_n\right).$$

We differentiate (4.12) and integrate from *t* to *s* obtaining the following estimate:

$$E_n(s) \le E_n(t) + \int_t^s \frac{|a'(\eta)|}{a(\eta)} (E_n(\eta) - v_n'^2(\eta)) d\eta$$
$$\le E_n(t) + \int_t^s \frac{|a'(\eta)|}{a(\eta)} E_n(\eta) d\eta \quad t < s$$

By applying the Gronwall lemma, we obtain

$$E_n(s) \le E_n(t) \exp\left[\int_t^s \frac{|a'(\eta)|}{a(\eta)} d\eta\right], \quad t < s$$

We apply (4.15) with $t = t_n'$ and $t_n' < s$. Therefore, we need to estimate the integral

$$\int_{t_n'}^s \frac{|a'|}{a} d\eta.$$

To summarize the behavior of a, we consider its properties over the interval:

$$[0, t_n'] = \bar{I}_1 \cup I_1 \cup \ldots \cup \bar{I}_{n-1} \cup I_{n-1} \cup \bar{I}_n,$$

as given below:

1. The function *a* decrease near $t = 0$ and $t = t_n'$.
2. The values of *a* at specific points are given by $a(0) = 2\delta_1$ and $a(t_n') = c_1 \cdot \delta_1$, where $c_1 = \beta(\pi/4)$.
3. The function *a* attains exactly $2v_k$ local minima and $2v_k$ local maxima within I_k, satisfying the bound

$$\frac{\delta_k}{2} \le a(t) \le 2\delta_k.$$

4. The function *a* is decreasing in a neighborhood of $\bar{I}_k$. To satisfy the condition (4.16) we require a further assumption on the parameters, namely that

$$2\delta_n \le \frac{\delta_{n-1}}{2}, \quad \forall n.$$

By utilizing the properties of *a* described above, we obtain from (4.15).

$$E_n(s) \le E_n(t_n') \exp\left[2(v_1 + \ldots + v_{n-1}) \lg 4 + \lg\left(\frac{2}{c_1} \cdot \frac{\delta_1}{\delta_n}\right)\right].$$

Alternatively, the Paley-Wiener theorem for M-ultradifferentiable classes guarantees that the series (4.7) converges to the function $u(x,t)$ in $C([0, L-\varepsilon], E^*)$ for some $\varepsilon > 0$ and a certain $h \in \mathbb{R}^+$ (or for any $h \in \mathbb{R}^+$), if and only if

$$\sup_{[0,L-\varepsilon]} |v_n|,, C_{h,\varepsilon}\cdot\exp(-M(h_n/h)).$$

Where $C_{h,\varepsilon}\in ¡^{+}$. Therefore, since $t_{n'}\to L$ as $n\to\infty$, we derive from (4.18) the following sufficient condition for $u(x,t)$ to be included in $C([0,L[,E^{*})$:

$$M(h_n/h),, \frac{\pi}{10}v_n-(v_1+...+v_{n-1})\lg 4-\lg\frac{\delta_1}{\delta_n}+\lg C_h.$$

Where $C_h\in ¡^{+}$. Taking into account that $h_n=2\pi v_n/\tilde{n}_n\sqrt{\delta_n}$,we find that (4.19) holds when

$$(v_1+\ldots+v_{n-1})\log 4,, \frac{\pi}{10}v_n,$$

And

$$\sup_{p\in¥}\left(\log\frac{h_n^p}{hM_p\delta_n}\right)<c_h.$$

Where ch constant depend with h and δ_1. The successful construction of the function $a(t)$ enabled us to obtain a solution u in the form of a convergent series in $C^2\left([0,L],E^{*}\right)$. Moreover, we observe from (4.9) and (4.11) that

$$\begin{cases}\left|v_n\left(t_n''\right)\right|=\mathcal{O}\dfrac{\tilde{n}_n}{v_n}\exp\left(\dfrac{\pi}{10}v_n\right)\\ \left|v_n'\left(t_n''\right)\right|=\mathcal{O}\exp\left(\dfrac{\pi}{10}v_n\right)\end{cases},$$

with $\mathcal{O}$ and $\mathcal{O}$ are positive constants. After substituting h_n we obtained

$$\left|v_n\left(t_n''\right)\right|\ldots\frac{1}{\mathcal{O}}\exp\left(\frac{\mu}{2}h_n\right),$$

where $\mathcal{O}$ and μ are positive constants. Inequality (4.23) shows that $\{u(\cdot,t_n'')\}$ is unbounded in the space of distributions. The sequences $\tilde{n}_n$, $\mathbf{v}_n$, and δ_n are chosen as in [4], satisfying the conditions (4.2), (4.5),(4.6), (4.17), (4.20) and (4.21).

$$\begin{cases}\tilde{n}_n=2^{-n}T_*\\ v_n=2^{n^2}\\ \delta_n=2^{-(k+\alpha)(n+1)(n+2)-2n}\end{cases}$$

In particular

$$h_n=\frac{2\pi}{L}2^{n^2+2n+(k+\alpha)(n+1)(n+2)/2}.$$

V. CONCLUSION AND FUTURE WORK

In conclusion, this paper addresses the weakly hyperbolic Cauchy problem by considering Hölder's regularity of coefficients dependent on time within the framework of M-ultradifferentiable well-posedness. By formulating an equivalent condition of well-posedness within the framework of Gevrey regularity, we guarantee the well-posedness of the problem for a family of M-ultradifferentiable functions, characterized by the function corresponding to the sequence *M*. In the future, this condition can be used as a starting point to derive conditions ensuring the stability and solvability of weakly hyperbolic Cauchy problems within ultradistributions of classes *M*. This research opens up new possibilities for investigating the relationship between the identified condition and the solvability of such problems in the framework of ultradistributions. The findings have the potential to contribute to the development of analytical techniques and criteria for studying and applying ultradistributions in various mathematical models.

ABSTRACT

Vehicular ad hoc networks (VANETs), a burgeoning technology within the wireless technology field, hold great promise. As it continues its progress, it stands ready to make increasingly significant contributions to advancing intelligent transportation systems in the foreseeable future. The scale of infrastructure, the number of vehicles, the complexity of scenarios, and the mobility of nodes can collectively contribute to heightened energy consumption during route selection between source and destination nodes, as well as during the transmission of application packets. VANET opts for routes containing a minimal count of intermediary nodes to reach the intended destination efficiently. With the expansion of the distance between nodes, there is a proportional increase in the requirement for broadcast power. The power capacity of the nodes directly influences the ease of establishing a route between two nodes. In this paper, we proposed a Firefly Optimized Link State Routing (F-OLSR) protocol, which utilizes swarm intelligence principles through the firefly algorithm (FFA). The goal is to enhance energy efficiency within an Optimized Link State Routing (OLSR) framework. The route is chosen depending on the amount of power the intermediary nodes between the source and destination nodes. The evaluation performance of the F-OLSR protocol was compared with that of popular protocols. The F-OLSR protocol was demonstrated to be an effective solution for choosing the optimal path with high power from source to destination and improving performance. Regarding energy consumption, the F-OLSR protocol achieved 2.30% and 2.31% concerning the packet size and node speed, which is better results in terms of packet size and node speed, which is a better result than the other protocols.

I. INTRODUCTION

Wireless networks have gained significant attention in communication over the past few years. It finds applications across various technological domains, including industries, the military, and personal networks. One of the reasons why they are widely used is through wireless networks [1], [2]. In addition, the networks are not limited to fixed infrastructure, and this makes them unique compared to wired networks such as cellular networks, Wi-Fi, satellite communications, and others [3].

VANETs represent the specialized version of MANET, which is different in determining its architecture, a complex nature, and special applications [4]. Considering the prevalence of cars and vehicles in the modern era, there is an essential problem that regards the increasing number of fatalities and accidents on the roads and roads [5], [6]. VANETs are based on Dedicated Short Range Communication (DSRC) which allows cars and roadside buildings to be in contact with each other [7], [8]. This information system can be used to enable vehicles to share various types of information, including traffic, road conditions, and safety information, all of which are aimed at making traffic processes more efficient and ensuring road safety [9-11]. Figure 1 gives an example of a VANET.

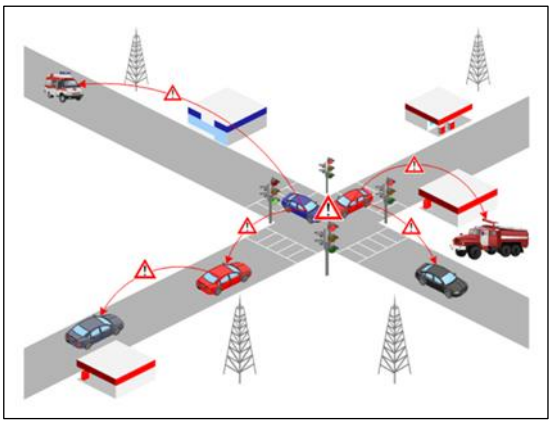

Figure 1: VANET communication.
Source: [12].

Differentiation of communications in VANETs which are Vehicle-to-vehicle (V2V) and vehicle-to-infrastructure (V2I) communications are typically classified as two categories. These are part of wireless interactions on a medium referred to as a Wireless Access in Vehicular Environments (WAVE) [13-16]. Application Unit (AU) and Onboard Unit (OBU) are the key units that support the communication of vehicles. With the usage of the OBU, every vehicle on the road has collected and analyzed information and sends data packets to all nearby Road Side Units (RSUs) or vehicles. The RSUs are WAVE devices that are either placed at the side or strategic points like intersections and parking area surrounding them [17-19].

Usually, the design of VANET routing protocols does not focus on power consumption [20]. Their major concern is to support the high velocity of node mobility and unpredictability of the wireless environment [21]. When a computer network is involved, or any other network in a network, the power levels of a specific node may in fact be a decisive factor in the ease of finding a path connecting two nodes [22]. Besides, Optimised Link State Routing (OLSR) is a well-established protocol in mobile ad hoc networks, although the standard edition is only slightly responsive to the special problems of VANETs, specifically regarding energy efficiency [23-25]. The large energy consumption of cars involved in constant data transmission can add to the Net-work instability and higher operation cost which are critical concerns in the large-scale development.

However, energy conservation is another important issue in the development of green, smart cities where the VANETs would play a key role. In an attempt to discuss this in a further detail, in VANET situation, the protocol chooses the route with minimum intermediary nodes to the target. As the distance between nodes is further, there is the increment in the need of transmission power. This paper presents us with Firefly Optimized Link State Routing (F-OLSR) protocol. The F-OLSR improves the traditional OLSR protocol by employing the attractiveness behaviour of the Firefly algorithm to identify the optimal routing path. The purpose of this bio-inspired approach is to enhance routing efficiency to mobile ad hoc network on VANET [26].

The given protocol is a combination of the FFA and OLSR protocol. The suggested FFA is specifically used to improve the path selection processes through the consideration of different parameters. It tries to ensure a good route by choosing intermediate nodes with a high energy value. The FFA algorithm works on the assumption that communication elements of a device have different power consumption levels when transmitting data and receiving data. When this algorithm is implemented, it can be seen that the path with the fewest amount of communication nodes between two communication nodes can not always be the most energy-efficient. In multi-hop networks such as the VANETs, this requires the combination of energy information in all the nodes in the multi-hop path in order to assess energy consumed in the communication path. Thus, the main ideas of this paper include:

Creation of F-OLSR which is the proactive routing protocol in vehicle communications that is based on ABC selects the routes which consume minimal power. Assessing the performance of the newly implemented F-OLSR protocol by comparing it to the BOLSR, BeeIP and OLSR routing protocol. The remainder of this paper is organized as follows: Section 2 reviews related studies, whereas section 3 describes the research materials and methods. Section 4 presents the proposed approach and Section 5 is dedicated for the simulation model and parameters. Section 6 entails a complete description of the performance metrics. Section 7 clarifies the experimental findings and Section 8 concludes the suggested algorithm.

II. LITERATURE REVIEW

To begin with, VANET has drawn the attention of many scholars. Among the most important questions in the framework of VANETs is the question of the best path that would allow the transmission power to the maximum between the source and the destination. The literature has suggested a wide range of methods of using VANETs with swarm intelligence algorithms, such as bat algorithm, bee colony, and ant colony. Several research studies were devoted to the challenging aspect of maintaining and detecting the correct route that secure commuication between a source and a target nodes with respect to dynamic changes in network topology and changes in mobility patterns.

In a similar publication [10], [27] a new routing protocol was suggested to be used in VANETs called F-Ant with the basis of which is the fuzzy logic. The protocol uses bandwidth, connection and vehicle congestion as some of the factors, to determine the validity of the links. Considering the difficulties of bandwidth constraints and vehicle congestion in VANETs, F-Ant is interested in providing the quality of road safety services and pursuing specific Quality of Service (QoS) goals, such as the attainment of the high delivery rate with minimum E2E delays. The efficacy of F-Ant is proved by simulation results, which are specifically effective in the city. It has a high benchmark performance when compared to ABC and AODV protocols both in terms of E2E and PDR performance. The proposed protocol, however, is a very energy-intensive method of transferring the packet through the network.

The author came up with a bio-inspired clustering algorithm in FANETs known as BICsf, which involves the use of a hybrid algorithm between the glowworm swarm optimization (GSO) and krill herd (KH) algorithm [28]. The proposed scheme will include energy conscious cluster formation and cluster head election through GSO algorithm. Moreover, an effective cluster managing algorithm is created based on the behavioral principles of KH. Genetic operators, which include mutation and crossover, are also used to find the best location of UAVs. In route choice, a weighted-residual-energy-based path-detection function, number of neighbors, and inter-UAV-distance are used, in order to provide the most efficient communication. BICSF performance is measured against cluster-building time, energy consumption, cluster lifetime and delivery success probability and compared to clustering algorithms using the grey wolf optimization algorithm and ant colony optimization algorithm.

In [29], GreeDi-based reactive routing protocol was presented to maximize the energy-efficient routing of source and destination nodes in VANETs. The protocol's route selection hinges on evaluating intermediary nodes' energy consumption between the source and destination. The algorithm's efficacy was assessed within VANET scenarios modeled on city maps. Notably, GreeDi demonstrated superior performance compared to the original AODV protocol, particularly concerning power consumption. However, the GreeDi protocol has less throughput, a maximum average throughput reaching 54%. The Bee-inspired protocol, known as BeeIP, was introduced by [30], with the authors investigating the protocol's foundation in swarm intelligence (SI). This protocol is developed to make multi-path routing for mobile nodes. The BeeIP utilizes hunters to accumulate route evidence and assigns a selection metric value to each path during their return journey. These metrics' significance and impact on protocol behavior cannot be overstated.

An experimentally evaluated metric within BeeIP focuses on speed, which involves the addition of transmission delay along each intermediate connection in the route, beginning from the target and progressing to the source. This methodology guarantees the selection of the swiftest path among the available choices. BeeIP is intended to estimate the routing on the path basis and to identify the failure of links in case no forager packets are received back to the source node within a designated time. In such instances, the source node assigns a foraging capacity of zero to the path and classifies it as unrecognized. This dual approach prevents the assignment of the broken path's ID to future foragers while also allowing the path to potentially become available again if a forager ultimately returns to become available again if a forager ultimately returns potentially. Simulation results highlight BeeIP's commendable adaptability and efficiency in choosing the most suitable path.

The outcomes demonstrate that BeeIP consistently outperforms other protocols regarding overall performance. Similarly, the artificial bee colony was introduced for mobile ad-hoc networks for minimizing energy consumption [8]. In [29], a new protocol was proposed, which was named Bat-Optimized Link State Routing (BOLSR) to make OLSR protocol more energy-efficient. It is important to note that both OLSR and the Bat Algorithm (BA) use mechanisms of path discovery that are similar in that both use the exchange of particular signals. By taking advantage of this shared attribute, BOLSR calculates an optimal path between a source node and a destination node by taking into account the power relationship between network nodes. To determine the performance of BOLSR, it was compared to CAABO and the conventional OLSR protocol through performance metrics like routing overhead, energy consumption, and end-to-end (E2E) delay. The findings indicate that BOLSR decreases energy usage and increases the total network life cycle.

Nonetheless, the suggested protocol can still be enhanced in regards to energy efficiency and throughput. A different refined protocol, which was also known as ECBLTR was suggested in [12] aimed to maximize the lifetime of the network. This protocol tackles the reduction of efficiency of a network in VANETs due to the high mobility rate of vehicles. To select cluster head (CH), a Sugeno fuzzy inference model is used and a number of input parameters have been utilized, which are residual energy, local distance, node degree, node concentration and distance to the base station. The findings indicate that with the combination of a suitable channel model and a good routing protocol, link throughput in VANETs may be greatly enhanced, especially when the size of the network is constant. Nevertheless, ECBLTR protocol has a relatively high power consumption. The proposed methodology of the study is introduced in section 3.

III. METHODOLOGY

This paper presents a routing protocol specifically designed for energy-efficient operation in VANETs. The key elements of this paper include the incorporation of the OLSR methodology, the utilization of the Firefly algorithm (FFA), and the assessment metrics applied for network testing.

III.1 OPTIMIZED LINK STATE ROUTING (OLSR)

It is an active routing strategy that works in a network setting, as presented by Clausen et al. It is made upon the link-state (LS) framework, which has been improved to reduce the number of packets and control traffic flooding [31]. The OLSR's functionality revolves around broadcasting messages within the network using Multi-Point Relays (MPRs), which are nodes specifically designated for transmitting these messages [30], [32]. The OLSR protocol is completely decentralized and it does not require any central body. It does not necessitate a high degree of reliability in controlling message transmission because they are periodically transmitted and are denoted by sequence numbers, which allow correct ordering. The other important characteristic of OLSR is that it is suitable to mobile nodes. Multi-Point Relays (MPRs) use reduce redundancy in the retransmission across the same neighborhood. In the network, a special group of neighboring nodes called MPRs is chosen by each node in the network, and it is the MPRs that pass broadcast packets [30], [33].

Therefore, the non-member nodes which are not included in the MPR set of a node are capable of receiving and processing the data packets but not forwarding or re-transmitting them [34]. The MPR set is selected from the pool of one-hop neighbors connected by bidirectional links [35]. In this procedure, each node must identify its neighboring nodes with direct links. All links need to be assessed in both directions to confirm these nodes. In this context, each node generates periodic broadcasts of hello messages containing details about its neighbors and the status of their links. These messages enable each node to gather information about its neighbors within a two-hop range, subsequently facilitating the selection of the MPR set.

Node initiates the construction of the MPR selector table, a table for one-hop neighbors, and another for two-hop neighbors [31], [33]. No additional distribution of a unique hello message occurs throughout the entire network. The fact that this happens implies that the nodes who receive such messages do not forward them any further [35], [36]. To establish and maintain the network's essential topology information for routing data packets, each node periodically sends out specific control messages known as "Topology Control" (TC). These TC messages are disseminated as overall transmission packets across the network. The data extracted from TC packets is subsequently kept in a suitable topology table. Each node preserves a routing table that aids in directing data packets to their intended destinations within the network.

Upon receiving TC messages, nodes analyze them and store connected pairs as a combination of the last hop and the current node. Here, the node represents addresses identified in the TC message list [27]. This stored data as the foundation for constructing the routing table sequentially, resulting in the connected pairs being in descending order. To control the most effective path from the source to the target, a sequence of interconnected pairs must be identified, continuing till the final hop node within the source's neighboring set is reached [35], [37]. These connected pairs, forming the route with minimal power consumption, are chosen by various forwarding nodes. In cases where there's a change in the bidirectional link within the neighboring configuration, recalculating the routing table becomes necessary [38].

III.2 FIREFLY ALGORITHM (FFA)

FFA is a swarm-based intelligence algorithm inspired by the flashing behavior and attraction patterns of fireflies. In nature, Fireflies use their bioluminescent flashes as signals to communicate with potential mates and ward off predators. Fireflies are translated to candidate solutions In the Firefly Algorithm (FFA), where each solution moves through the search space based on their brightness and attractiveness to other fireflies. FFA is based on the notion of attraction to brighter individuals, where the movement toward more luminous fireflies enable the swarm to converge on optimal solutions. In FFA, the brightness of each firefly is the solution's quality, the better the solution, the brighter it shines. Fireflies with higher brightness attract those with lower brightness, which enables the FFA to explore the solution space effectively. This movement continues till no firefly is visible within range, then random movement is triggered to promote exploration of unexplored regions.

The algorithm works based on a population of fireflies with each of the fireflies positioning in the search space being the potential routing path. The attraction between the fireflies reduces with distance, hence, balancing exploration and exploitation in the process of optimization. The FFA starts with a swarm of size SN fireflies deployed randomly, each of them represents a routing path. Let Xi = {x(i, 1), x(i, 2), …, x(i, D)} represent the ith firefly's position in the swarm, with D indicating the dimensionality of the problem. Each firefly is associated with a brightness I(X), and attractiveness \beta, where the objective function f(X) is proportional to the brightness. The attractiveness is a relative value with respect to the distance to other fireflies. Also, light intensity diminishes as the distance from its source increases. Moreover, the light of a firefly is impacted by the medium absorption, which eventually decreases its attractiveness. Hence, the distance between two fireflies, and the absorption coefficient are considered in calculating a firefly's attractiveness as shown in Equation 1.

$$\beta(r) = \beta_0 e^{-\gamma r^2} \tag{1}$$

Where *r* is the distance between two fireflies, γ is the absorption coefficient, and β_0 is the attractiveness at *r=0*. We set the light absorption coefficient to $\gamma = 1$and the baseline attractiveness to $\beta_0 = 1$. This provides a natural, dimensionless decay of attractiveness per hop in graph-based routing. This ensures that fireflies interact primarily with near neighbors, which aligns with the localized decision-making of link-state routing protocols such as OLSR.The exponential term in Equation 1 ensures that attractiveness diminishes as the distance between fireflies increases, preventing premature convergence and encouraging balanced exploration. The distance *r_ij* between any two fireflies *xi* and *xj* in FFA is computed using the Euclidean distance formula, as presented in Equation 2.

$$r_{ij} = \|x_i - x_j\| = \sqrt{\sum_{m=1}^{D} (x_{im} - x_{jm})^2} \tag{2}$$

A firefly x_i moves toward a brighter (more attractive) firefly x_j based on the following movement equation 3.

$$x_i(t+1) = x_i(t) + \beta \times r\left(x_j(t) - x_i(t)\right) + \alpha \times \epsilon_i \tag{3}$$

Where α is a randomization controller parameter, and ϵ is a uniformly generated random vector. In this work, we set the value of α to 0.2 which is typically used in previous FFA studies to avoid slow convergence, or stagnating in low-quality local optima.

When all fireflies have similar brightness levels or when a firefly cannot find a brighter neighbor. Thus, the second term in Equation 3 performs a random walk to explore new regions of the search space [39].

IV. THE PROPOSED F-OLSR

The existing work mainly focuses on combining the FFA with the proactive routing protocol known as OLSR to implement the F-OLSR routing protocol and improve energy consumption. In order to succeed in the VANET systems, the cooperation of the nodes is essential, as they should exchange the information concerning the link quality and partial route. The issue of power consumption is a major issue with VANETs because the node can crash when the battery power runs out, negatively affecting the network life. It is thus necessary to enhance routing protocols to choose routes of nodes of high energy levels. We suggested F-OLSR which applies Firefly Algorithm (FFA) in determining the shortest paths with the nodes of high power and thus saving energy in all nodes and greatly increasing network lifetime. Path discovery in this method is done through OLSR and the optimization of energy efficient routes is done through F-OLSR algorithm (as shown in Algorithm 1).

Algorithm 1: F-OLSR Algorithm.

Generate nodes (*i=1, ..., N*)
Initialize node positions.
Initialize the speed of nodes randomly.
Specify the *Src* and *Dis* nodes
Initialize the population of solution X_i, *i=1, ..., SN*
Send a HELLO message from each node to it is neighbors
If the *node is in the busy or free state* **then**
  For *all fireflies in X* **do**
    While *the entire network remains unprotected* **do**
      Determine the path of X_i
      Identify the neighbors of the route
      Compute the distance between adjacent anodes
      Calculate fitness (light intensity) of each firefly
    End while
  End for
  Memorize the brightest firefly (best route) OP= [ ]
While *(stopping criteria are not met)* **do**
  For each firefly i = 1 to SN do
    For each firefly j = 1 to SN do
      If (Intensity_j > Intensity_i) then
        Calculate the distance based on Equation 2
        Compute attractiveness with repect to new distance
        $X_i \leftarrow$ *update firefly position based on Equaiton* 3
        Calculate f(Xi) and update light intensity
      End if
End for
End for
Calculate fitness value for all solutions Rank fireflies and find the current best solution Update the optimal path OP = [ ] with the brightest firefly
c = c + 1
If the current best route surpasses the route stored in OP then
Update OP with the new best position
End if
End while
Return OP

Source: Authors, (2026).

The first step of the suggested algorithm is producing as many nodes (fireflies) as indicated as (*i=1*) of a population of *SN*. The second step is to initialize the positions of the nodes where each node is given a randomly generated velocity and the source and destination node is given. After this the population X_i of solutions is established each solution X_i (*i = 1, 2,...SN*) being expressed in a vector form, *SN* being the number of solutions. In the initial setup, every node transmits a HELLO packet to all his neighbors to establish whether a node is free or occupied.

Fireflies modify their positions (solutions) relative to the brightness of other fireflies in the swarm and also relative to the level of energy by the measure of the fitness score of the new solution. Upon this search, fireflies mutually communicate and share energy information, calculate the position of nodes, and calculate distances. The equation (4) used in the calculation of energy-related information is the fitness function that is used in calculating the brightness of each firefly. It is also necessary to determine power-draining or energy-conscious nodes.

$$f(x) = \sum_{i=1}^{D} Energy\ (x_i) \tag{4}$$

Where $Energy\ (x_i)$ is the remainder energy in the selected *ith* node. The FFA constantly calculates energy probability every time the node visits the network. It is significant to identify the count of nodes demonstrating complete power awareness or susceptible to leakage of power efficiency. The method entails a starting step, and a main search procedure that is repeated till a satisfactory fitness answer is discovered on the most OLSR-conscious node. The algorithm will verify that there is a source route and calculate the amount of nodes around a brighter firefly as a firefly relocates towards it. In case there is no source route, this algorithm will spawn a packet broadcast and reconsider firefly energy. In addition, it separates outgoing and incoming broadcast packets with respect to energy transmission.

Therefore, a node that is located distant consumes significant energy causing an increase in energy loss. The approach that we propose implies the use of the route requests through intermediary nodes. The FFA attempts to determine the nodes that have high power availability by ignoring the nodes which have small power resources. At the destination, the FFA helps determine an optimum path between the source and the target taking into account the power of the intermediate node and attempting to reduce the number of hops made. The number of solutions in F-OLSR is shown in figure 2. Upon identification of the best route, transmission packets are launched using the source node. This is the best choice of path illustrated in Figure 3.

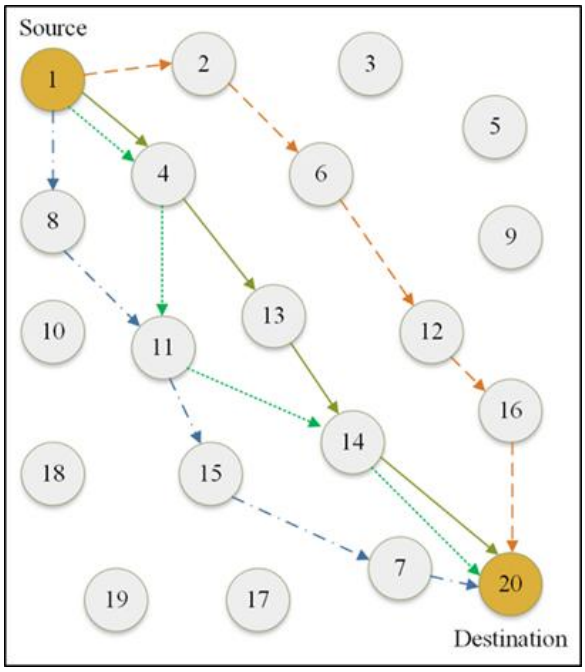

Figure 2: An excerpt of number of solutions in F-OLSR.

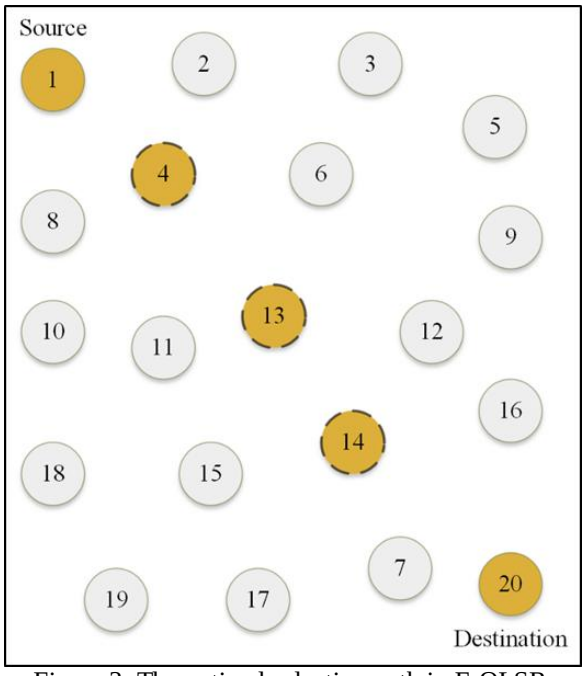

Figure 3: The optimal selection path in F-OLSR.
Source: Authors, (2026).

This paper provides configuration of the network through an OTcl script that defines the routing protocol, the network traffic, the number of nodes and the propagation model that should be used. Then, a trace file and Network Animator (NAM) will be produced from the simulation process to be used for data analysis and visualization, respectively.

V. SIMULATION MODEL AND PARAMETERS

The simulation is discussed based on the proposed F-OLSR protocol. The ageing objective of this simulation was to improve the functionality of VANET and increase its longevity. It was intended to utilize the F-OLSR protocol to find routes that had a high energy cost, a high throughput and reduced delays. The key actions performed on the way to the implementation of the simulation of the proposed F-OLSR protocol are demonstrated in Figure 4. The study was chosen in two real life scenarios, one in an urban setting and the other in a highway setting. Precisely, the urban scenario selected was Auckland CBD, and the highway scenario was the Auckland motorway. There are four basic modules of the simulation model. The former module is the creation of the VANET environment that sets up the setting of the simulation.

These involve the incorporation of the important VANET features like the size of the network, the number of nodes, bandwidth and other pertinent parameters. The next process involved routing protocols whereby a number of optimization algorithms were being applied to address the progression of solutions. Finally, but not the least, the performance assessment of the F-OLSR protocol was performed through the use of two scenarios. To begin with, the highest speed allowed to nodes is 5, 10, 15, 20 m/s. Secondly, the size of packets was varied by this simulation e.g. 128, 256, 512, and 1024 bytes. Evaluation was done using a random-based mobility model which is a standard mobility model in VANET. Finally, the protocol was evaluated in terms of major measures e.g. the ratio of delivered packets, average energy rate, average delay, and throughput.

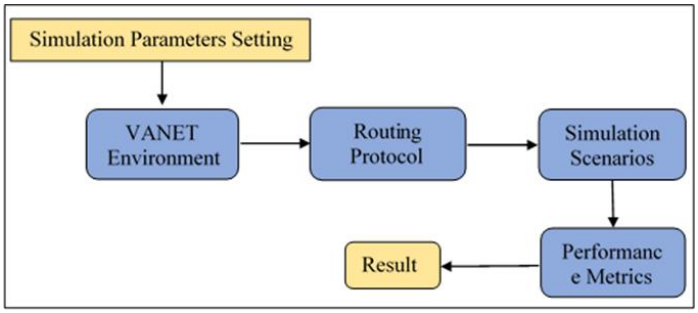

Figure 4: The VANET Simulation Model.
Source: Authors, (2026).

The type of traffic utilized in the experiments is the Constant Bit Rate (CBR) that is normally used with the UDP transport on a multi-hop network and is applicable in the real-time applications. Each node was configured to have a transmission range of 250m. The simulation area was 1200 x 800 m in length and width under all conditions where node energy is set at 100J and the duration of the simulation was 40s. The distribution of the nodes was random and placed in 20 positions with two nodes at a large distance as the source and destination. Table 1 summarizes all the simulation parameters.

Table 1: Simulation Parameters.

Parameter	Value	Unit
Number of nodes	20	Nodes
Queue size	100	Packet
Scenario Dimension (m x m)	1200 x 800	M2
Protocols	F-OLSR, OLSR, BEEIP	Protocols
Packet size	128, 256, 512, 1024	Bytes
Transmission range	250	m
Application layer	CBR	_
Initial energy	100	Joules
Power consumption during transmission	1.35	mW
Sleep power	0.001	mW
Idle power consumption	0.05	mW
Power consumption during reception	1.7	mW
Simulation duration	40	Second
Transport layer	UDP	_

VI. PERFORMANCE METRICS

Performance measurements are very essential to the quantitative estimation of routing protocols in VANET. The evaluation of the performance of the networks or even the comparison of the analysis of various routing protocols requires quantitative measurement so that the measurement can be made. In this current work, the performance criteria in the aforementioned evaluation are a lot, and they include as further discussed below:

1. Average Delay

The time taken to accurately transmit a data packet from source and to target over a network [30], [31]. The following equation is what is used to compute this measure:

$$Average\ Delay\ = \frac{\sum_{i=1}^{n}\ (R_i - S_i)}{n} \tag{5}$$

Here, *R* is the amount of packets received. *S* represents the total packets transmitted, and *N* is the total data packets.

2. Average Throughput

This is used to indicate the average number of data packets that have been successfully received during the simulation. It is a statistic that determines how effective the routing protocol is in enabling destinations to get data packets [24], [33]. Mean throughput will be calculated by use of the following formula:

$$Average\ Throughput = \frac{\sum Received\ Packets}{time\ duration\ from\ start\ to\ stop} * \frac{8}{1000} \tag{6}$$

3. Average Energy

Mean energy usage is estimated by the total number of energy used by each node divided by the energy used initially*:*

$$Average\ energy\ consumption = \frac{\sum energy\ consumed}{\sum initial\ energy} * 100 \tag{7}$$

4. Packet Delivery Ratio

This statistic is calculated by taking the total amount of data packets sent by the source nodes and dividing it by the total amount of data packets received by the destination nodes. It measures the effectiveness of a protocol to deliver the packets to its source to the intended recipient [34], [37]. The recipe to achieve the ratio of packets delivery is calculated as shown in the formula below:

$$PDR = \frac{\sum packets\ received\ by\ destinations}{\sum packets\ sent\ by\ sources} * 100 \quad (8)$$

VII. EXPERIMENTAL RESULTS

Figure 5(a) provides a comparison between the F-OLSR, BeeIP and OLSR protocols. The obtained results depend on the parameters, which are mentioned in Table 1 and different speeds of nodes. The outcome of the average throughput is contrasted at varying node speeds. The routing protocols have varying throughputs on average, with an increase in the speed of the nodes in the network. With increased speed of 5 m/s to 20 m/s, F-OLSR recorded a throughput of 58.61-49.16 kbps, BeeIP recorded throughput of 44.19-43.81 kbps and OLSR recorded a throughput of 46.29- 40.92 kbps. These results emphasize the high performance of F-OLSR with regard to the mean throughput compared to the other routing standards. This is attributed to the increased loss ratio of packets due to node speeds which are fluctuating; making both the OLSR and BeeIP to share this advantage. The channel capacity is also efficiently utilized when the packets reach their destinations promptly and without any losses hence raising the throughput.

VII.1 IMPACT OF NODE SPEED

The comparisons of the F-OLSR, BICSF, BeeIP and OLSR protocols on average energy are presented in figure 5(b). Mean energy is compared between various node speed. These routing protocols have emerged to have different patterns of energy uses when there is an increment in the speed of the nodes across the network. When the speed increased from 5 to 20 m/s, F-OLSR consistently showed consumption levels ranging from 0.023 to 0.024. It is worth noting that F-OLSR exhibited lower energy consumption compared to the BeeIP, BICSF, and OLSR protocols. This mismatch can be traced to using an FFA in the F-OLSR protocol. This protocol successfully chooses the most efficient and effective path between sources and destinations. Consequently, as the algorithm retains the route information in its memory, the previously required power consumption for route identification on each node is diminished.

The variations in the average E2E delay for the F-OLSR, BeeIP, BOLSR, and OLSR protocols are shown in Figure 5(c). These routing protocols exhibit diverse average delays as node speeds increase. The speed escalated from 5 to 20 m/s, F-OLSR's delay rose from 7.92 to 21.80 ms, the BeeIP protocol increased from 37.10 to 37.98 ms, BOLSR showed a rise from 15 to 15.5 ms, and OLSR saw an increase from 26.03 to 32.20 ms. These results confirm the average latency advantage of F-OLSR over alternative routing protocols. The benefit of the F-OLSR protocol is that it keeps track of the shortest way between sources and destinations, removing the need to spend time setting up the path at each intermediate node for each transmission.

Figure 5(d) shows the experimental findings for the F-OLSR, BeeIP, BOLSR, and OLSR protocols regarding the PDR. The suggested protocol outperforms the BeeIP and OLSR protocols in terms of PDR. When node's speed is 5 m/s, the F-OLSR achieves 99.88%, whereas BeeIP reaches 99.74%, BOLSR achieves 86.10%, and OLSR is 99.67%. This phenomenon is attributed to F-OLSR's retaining and acknowledging its established path. As a result, data transmission strictly follows the path determined by the protocol. As a result, effective packet delivery is the norm, and the packet delivery ratio maintains high consistency. Additionally, the protocol's minimal retransmission and drop rates contribute to the enhancement of high throughput. A comparison of the proposed protocol's node speed performance versus several cutting-edge protocols is shown in Table 2.

Table 2: Results of the proposed protocol in comparison to the state-of-the-art protocols' performances.

Node Speed (m/s)	BOLSR	OLSR	BeeIP	F-OLSR	BICSF
Average throughput (kbps)					
5		46.29	44.19	**58.61**	
10		43.96	44.18	**55.46**	
15		40.95	43.88	**55.19**	
20		40.92	43.81	**49.16**	
t.test		0.00086	0.00086	-	
Average energy consumption (%)

VII.2 IMPACT OF PACKET SIZE

In this section, the performance of the proposed F-OLSR protocol is compared to the performances of BeeIP and OLSR protocols. Results of the experiment of average throughput were obtained at different packet sizes under given simulation parameters. As Figure 6(a) indicates, the average throughput also increases with the increase in the packet size between 128 and 1024 bytes. Compared to BeeIP and OLSR, F-OLSR has a better average throughput. Particularly, F-OLSR achieves average throughputs of 87.64 kbps and 150.34 kbps at the packet sizes of 128 bytes and 1024 bytes, respectively, in comparison with BeeIP with average throughputs of 26.08 kbps and 121.88 kbps, respectively, and OLSR with average throughputs of 40.51 kbps and 1 This is due to the reactive routing scheme that is used by F-OLSR. In case of a Route Request (RREQ), several Route Reply (RREP), messages are created/sent, which enables F-OLSR to keep the routes between the source and its destination current.

As a result, alternative paths may be taken in case of failure of the primary route causing the loss of packets and a huge enhancement in the average throughput. Figure 6 (b) shows how average energy consumption is varied among the protocols F-OLSR and BICSF, BeeIP and OLSR depending on the packet size. There is the proportional increase in average energy use with an increase in the size of the packet indicated in all protocols. The corresponding path quality measured by the F-OLSR was done by investigating four varying packet sizes. The minimum packet leninth sizes of 128 to 1024 bytes increased the energy consumption of F-OLSR by 0.30 per cent to 2.41 per cent, BICSF by 2.43 per cent to 3.01 per cent, BeeIP by 2.38 per cent to 2.68 per cent and OLSR by 2.41 per cent to 2.72 per cent. It is interesting to note that the available results clearly show that the proposed F-OLSR is better in terms of mean energy consumption compared to BICSF, BeeIP, and OLSR protocols.

This better test results are linked to the fact that as the protocol finds a route, then it repeatedly uses the same route to transmit all the packets. This is the shortest of the routes and involves the least number of hops. Therefore, intermediate nodes do not involve them in needless route search that would incur extra energy expenditure and battery drainage. In order to provide an overall picture, Table 3 shows a performance comparison of different protocols. The visual information in Figure 6(c) presents the mean of the individual time of the e2e delay in the circumstances of a packet size in case of F-OLSR, BeeIP, and OLSR protocols. These routing protocols exhibit some delay changes with e2e delays with increment in the size of the packet in the network. As the three protocols underwent packet size augmentation as 128 bytes to 1024 bytes, there were insignificant changes with the values ranging between 20.7 and 54.15 m/s, 31.94 and 70.85 m/s, and 33.66 and 77.72 m/s across F-OLSR, BeeIP, and OLSR respectively.

In addition, F-OLSR always has low end-to-end delays as opposed to the BeeIP and OLSR protocols. This is a positive attribute that is greatly credited to the fact that F-OLSR can control the majority of packets to follow a path that is most appropriate hence minimizing end-to-end delay. F-OLSR can keep real-time routing data and can quickly create alternative paths in case of a breakdown of the connection, e.g. in case of dynamic node repositioning through acceleration. Consequently, the mean e2e delay is reduced practically to minimal. Figure 6(d) shows the comparison of F-OLSR, BeeIP, and OLSR protocols in terms of the average PDR. The size of packets also affects the mean ratio of packet delivery as derived in the form of Eq. (5). In comparison to the BeeIP and the OLSR protocols, our protocol always yields a better average PDR.

An example is that, using 128 and 1024 bytes packet sizes, F-OLSR protocol achieves the average values of 99.69 and 99.70 in the delivery ratio of packets. This is because the higher the results of F-OLSR in terms of packet delivery ratio are relative to that of BeeIP and OLSR protocols as well. The usefulness of F-OLSR is due to the fact it deployed the FFA algorithm to constantly survey and modify its path as soon as the optimal and shortest path is noticed. As a result, the future data packets continue tracing the same path as the source to a destination without any extra overhead. This design reduces the occurrence of dropped packets, which results into higher ratio of packet delivery. Conversely, in OLSR and BeeIP, a source node will verify his or her route cache before trying to send a packet to a destination to make sure that there is an existing route there.

Table 3: The performances of the proposed protocol when compared with the performance of a few state of the art protocols in terms of the sizes of the packets used.

Packet Size (byte)	OLSR	BeeIP	F-OLSR	BICSF

VIII. CONCLUSIONS

The present research was dedicated to the optimization of the current OLSR routing protocol of VANETs. The offered F-OLSR is inspired by the behavior of a swarm of fireflies, constituting the attempt to address the problem of energy consumption under the impact of overloaded packets between the nodes of the sources and the destination. F-OLSR puts much emphasis on determining an optimal route. The performance of the protocol was measured using four different measures. The results of simulation assure the superiority of the proposed protocol to all the counterparts: BeeIP, BOLSR, and the standard OLSR protocols. This superiority is always exhibited in all parameters that have been studied such as speed of the node and the size of a packet.

The implicit strong point of the proposed F-OLSR protocol is that a solid path with nodes having the largest amount of energy is chosen. It was shown that the F-OLSR protocol is a good solution in selecting the best possible path with power that is high between source and destination and enhancing performance. On energy consumption, the F-OLSR protocol got 2.30 and 2.31 in relation to the packet size and speed of the node respectively that is superior to the other protocols. In further practice, as an attempt to solve security issues that are part of routing schemes, such as possible attacks such as black holes.

ABSTRACT

Model-Driven Engineering (MDE) supports software development through the systematic use of models, meta-models, and model transformations, making transformation validation a critical concern. This paper addresses the consistency validation of a transformation from UML statechart diagrams to Flat State Machines (FSMs). The transformation is formalized as a transformation model using a UML class diagram enriched with Object Constraint Language (OCL) invariants. The UML-based Specification Environment (USE) model validator is used to automatically verify transformation consistency and its implied properties, including weak consistency, class instantiability, and class and association instantiability. A case study based on an Automated Teller Machine (ATM) system demonstrates the effectiveness of the proposed approach in supporting reliable software development within Model-Driven Engineering.

I. INTRODUCTION

Engineering systems are becoming increasingly complex due to the growing number of components and functions, as well as the involvement of multiple engineering disciplines. Managing this complexity has become a significant challenge, and MDE has emerged as a promising approach to address it [1]. Rather than relying primarily on document-based descriptions, MDE emphasizes the use of models as central engineering artifacts throughout the development process. These models capture and maintain relevant system information, are shared among stakeholders, and are manipulated using Computer-Aided Software Engineering (CASE) tools to support automation, for instance through model transformations. By enabling models to be processed by machines, MDE supports more informed decision-making across the system development lifecycle [2].

Model transformation is an important approach in MDE. It consists of a set of rules allowing the mapping of one model to another, by defining for each element of the source model its equivalent among the elements of the target. These rules are carried out by a transformation engine that reads the source model which must conform to the source meta-model, and applies the rules defined in the model transformation to produce the target model which will be itself conform to the target meta-model. From the MDE point of view, a transformation can be seen as a *transformation model* or *a model transformation* [3]. A transformation model can denote a computation, whose expression relies on a particular model of computation embedded in a transformation language. Model transformation focuses on the particular artifacts manipulated by a transformation (namely, meta-models for its specification and models for its execution) [4].

The computational nature will require that the underlying language guarantees some desirable properties, like termination and determinism, needed for the purpose of the transformations, independently of what a particular transformation expresses. On the other hand, manipulating models implies that specific properties of interest will be directly related to the involved models as well as the intrinsic intent behind the transformation: e.g., one may be interested in always producing conforming models by construction, or ensuring that target models still conserve their semantics [4]. Thus, model transformation provides important information about the relation between the elements connected by the transformation. Different verification approaches have been applied to model transformation in the literature with the two previous views.

In [5], [6], the authors propose a transformation from UML statechart diagrams to Flat State Machines (FSMs). Statechart diagrams are typically used to model the behavior of complex systems using a relatively informal notation, whereas FSMs constitute one of the most widely adopted behavioral models in computer programming and are defined using a more formal notation. This transformation represents a key stage in an automated methodology and supporting tool environment that aims to formally convert the dynamic behavior of systems specified in UML models into their equivalent Colored Petri Net representations, thereby enabling formal analysis and verification. Although numerous studies in the literature refer to and build upon this transformation (see, for instance, [7-10]), a formal validation is still lacking, primarily due to the complexity of the validation process. This paper addresses this gap by representing the transformation as a transformation model and assessing its consistency and implied properties through the application of the USE approach. The main objectives of this study are as follows:

1. Formally model the transformation from UML statechart diagrams to Flat State Machines as a transformation model using UML class diagrams enriched with OCL invariants.
2. Define and analyze the consistency property of the proposed transformation model and its implied properties, including weak consistency, class instantiability, and class and association instantiability.
3. Apply the USE model validator to automatically verify the consistency of the transformation model.
4. Illustrate the feasibility and effectiveness of the proposed approach through a realistic case study based on an Automated Teller Machine (ATM) system.

The remainder of this paper is organized as follows: Section II reviews related work on model transformation validation and the USE approach. Section III introduces the background and context of this study, detailing the transformation from UML statechart diagrams to Flat State Machines, including their respective meta-models, the underlying graph grammar rules, and an overview of the USE model validator and its supported verification properties. Section IV describes the proposed transformation model, which formalizes the statechart-to-FSM transformation using a UML class diagram enriched with OCL invariants to capture structural and semantic constraints. Section V is devoted to the validation of the proposed transformation model, where transformation consistency and its implied properties are defined and evaluated through a practical case study using the USE tool. Finally, Section VII concludes the paper by summarizing the main contributions and discussing potential directions for future research.

II. RELATED WORKS

Model transformation analysis and validation have been extensively studied, particularly in the context of UML, OCL, and database-related transformations. Several works leverage the USE (UML-based Specification Environment) tool to formally analyze transformation correctness and properties. Büttner and Bauerdick [11] introduce an early and influential approach for realizing UML model transformations using USE. Their work primarily focuses on the handling of OCL invariants and expressions attached to UML class diagrams. A key contribution is the demonstration of how invariants must be systematically adapted when structural modifications occur during transformations, such as changes in association multiplicities or class structures.

This work establishes USE as a practical environment for validating transformation-related constraints. [12], [13] further advance this line of research by studying transformations between Entity–Relationship (ER) schemata and relational database schemata. They represent transformations as explicit transformation models that connect source and target meta-models. Using USE, the authors analyze essential transformation properties, including consistency and the presence of implied properties. Their approach enables the detection of semantic mismatches between source and target models and provides formal guarantees about transformation correctness. Building upon this foundation, [14] focus on invariant independence in transformation models.

Their work addresses the problem of redundancy in invariant sets by checking whether invariants can be derived from others. By applying USE-based analysis techniques, they show how invariant independence can be formally verified, thereby improving model clarity, maintainability, and correctness in UML and OCL-based transformations. Beyond structural and invariant-based analysis, [15] extend UML model validation to the temporal dimension. They propose a methodological framework and tool, TPV, that allows designers to specify and validate temporal properties in UML class diagrams.

This work broadens the scope of model analysis by enabling the verification of time-related constraints, which are increasingly important in complex and dynamic systems. Finally, [16] address the testing aspect of model transformations by proposing a specification-driven testing framework. Their approach systematically integrates the main phases of model transformation testing—test design, execution, and evaluation—into a unified framework. This work complements formal analysis approaches by emphasizing systematic testing as a means to increase confidence in transformation correctness.

III. BACKGROUND AND CONTEXT

This section provides the background and context of the study. It introduces the transformation considered in this work and describes the approach adopted to validate the proposed transformation**.**

III.1 STATECHART MODEL TO FLAT STATE MACHINE MODEL TRANSFORMATION

In this subsection, we describe the transformation process from a UML statechart diagram to a Flat State Machine (FSM), as presented in [6].

III.1.1 Statechart Diagram Meta-Model

A statechart diagram consists of states, both simple and composite, and transitions that are associated with events and actions. Each state is characterized by several elements, including a name, which is a textual identifier that may be omitted, as well as entry and exit actions that are executed upon entering and leaving the state, respectively.

Composite states exhibit a nested structure of substates, which may be organized either sequentially or concurrently. Statechart transitions are represented by standard finite state machine arcs, specifying a change from a source state to a target (successor) state in response to an event and the execution of associated actions. Figure 1 illustrates the metamodel for UML statechart diagrams as proposed by the authors in [6].

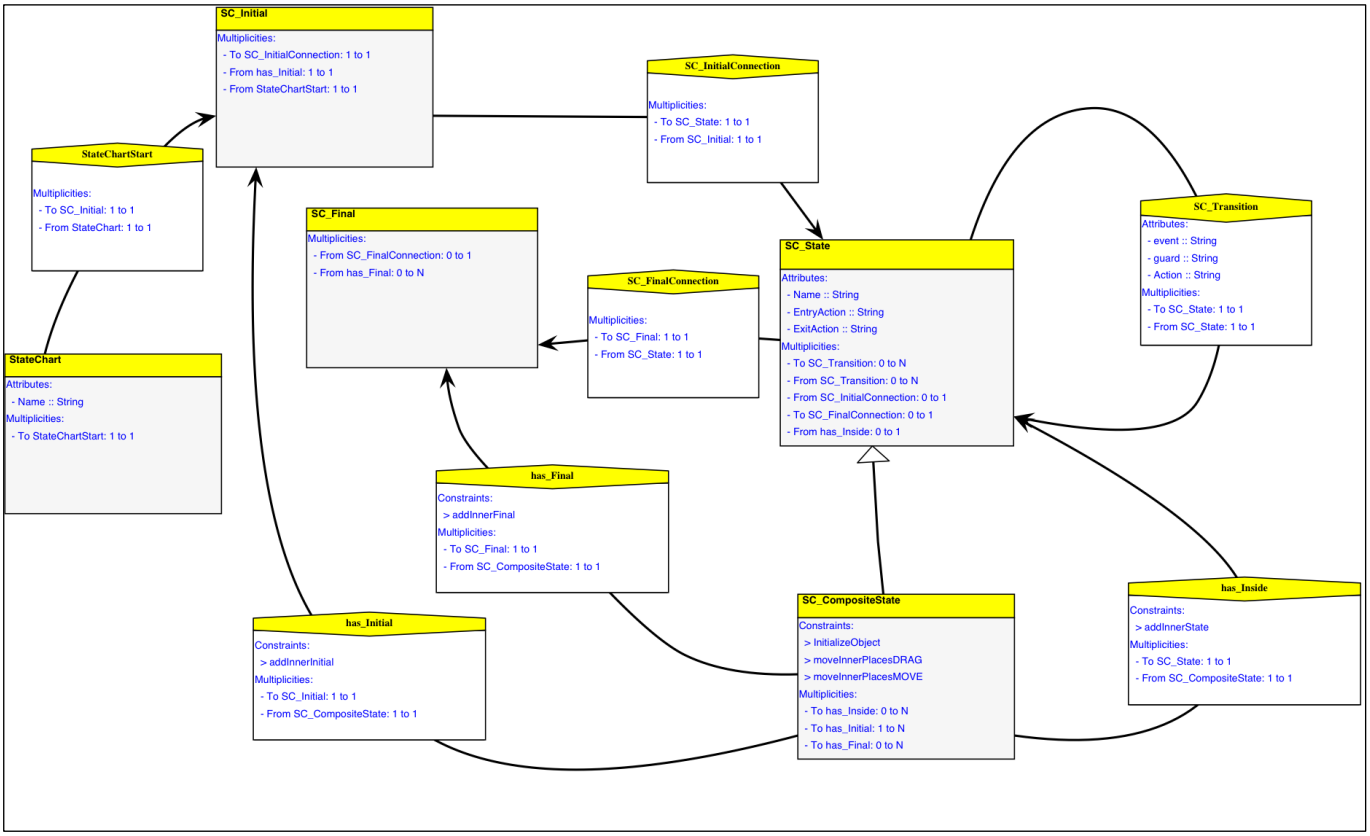

Figure 1: Meta-model of statecharts.
Source: [6].

III.1.2 Flat State Machines Meta-Model

A Flat State Machine (FSM) is a state machine that does not contain composite states. In an FSM, states are represented by rounded boxes, while transitions between states are depicted as directed arcs. Figure 2 illustrates the meta-model of the FSM formalism as presented in [6].

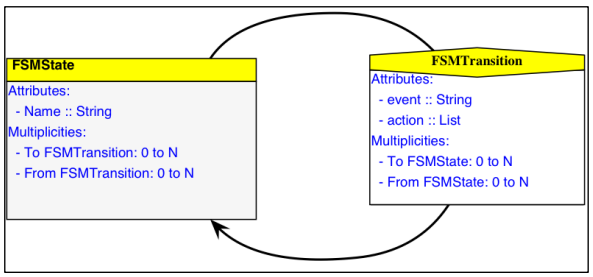

Figure 2: Meta-model of Flat State Machines (FSM).
Source: [6].

III.1.3 Graph Grammar of the Transformation

In the following, we present the considered transformation as described in [6]. The authors refer to this graph grammar as Statechart2FSM. To transform a statechart into its equivalent finite state machine (FSM) model using the Statechart2FSM grammar, they propose twenty-three transformation rules (see Figures 3 and 4), which are applied in ascending order of priority. Each rule is associated with a specific priority level. The overall transformation process implemented by the Statechart2FSM grammar can be summarized by the following main steps:

1. **Selection and initialization**

- A statechart is first selected from the set of available statechart diagrams.
- The initial state of the selected statechart is converted into an FSM state:
  - Rule #22 is applied for a simple initial state.
  - Rule #23 is applied for a composite initial state.

2. **Statechart traversal and transition conversion**

- The transformation then traverses the selected statechart starting from its initial state, which is processed in the previous step.
- For each processed statechart state:
  - Every outgoing (exit) transition is converted into a corresponding FSM transition.
  - The destination statechart state is also converted into an FSM state if it has not been previously processed (rules #5 and #6).

3. **Handling of composite states**

- For composite states, the graph grammar uses flag attributes to manage the traversal and processing status:
  - T = 1 indicates that the composite state has been traversed.
  - P = 1 indicates that the composite state has been fully processed.
- Examples of such transformations are illustrated by rules #7, #8, and #9.

4. **Conversion of composite states**

- In the third step, all composite states present in the statechart (if any) are converted.
- The conversion process follows the same principles applied to simple statechart diagrams, as defined by rules #1 and #2.

5. **Integration into the global FSM model**

- Finally, the FSM segment corresponding to each composite state is connected to the overall FSM model of the statechart.
- For instance, rule #14 transforms an exit transition from a composite state to a simple state into its equivalent transition in the FSM model.

III.2 USE APPROACH

USE is an acronym for UML-based Specification Environment, designed to support the specification of information systems and software, as well as the validation of models [3], [7]. One of the main applications of the USE tool lies in verification and validation. From its inception, a strong OCL evaluator has been a core component of USE, continuously enhanced and adapted to support new features and successive updates of the OCL standard. In addition, a variety of validation and model-finding approaches have been developed on top of this foundation, enabling the tool to remain a relevant and competitive solution in the field of model checking.

The importance of model validation is widely recognized, and numerous approaches have been proposed that rely on diverse tools and model transformation techniques to address the associated challenges [17]. A USE specification includes a textual description of a model, utilizing elements found in UML class diagrams, such as classes, associations, and other features. Additional integrity constraints on the model are specified through expressions written in the Object Constraint Language (OCL). The model can be animated to validate the specification against informal requirements. Figure 5 presents an overview of the various properties that can be verified within the USE model validation framework.

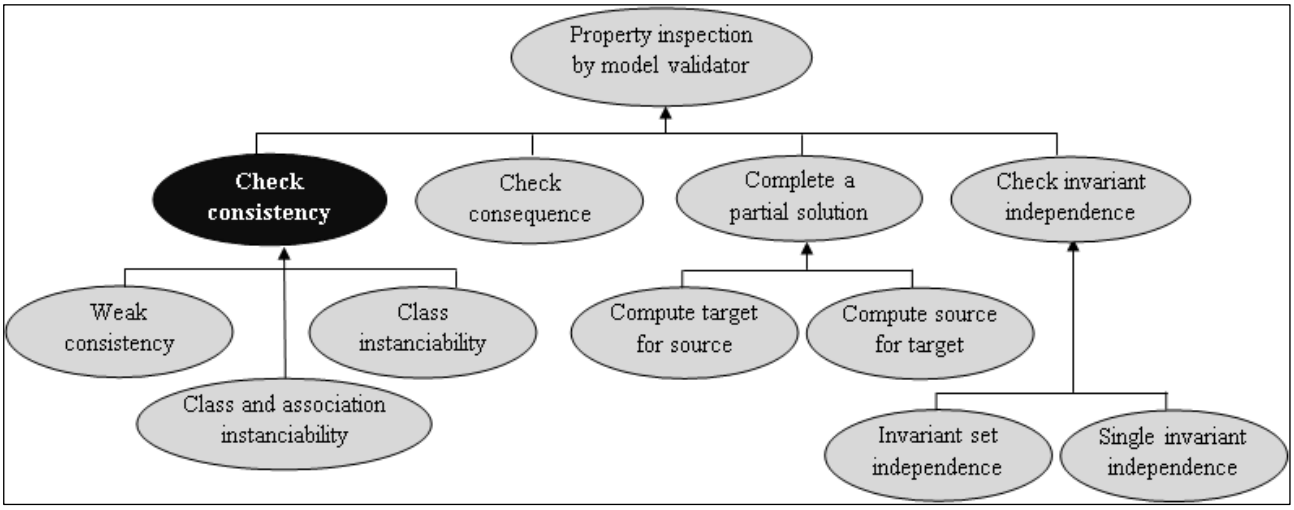

Figure 5: Properties verified by USE Model validator.
Source: Authors, (2026).

In the context of this work, we focus specifically on the *consistency property* of the considered transformation. Consistency constitutes a fundamental prerequisite for any model transformation, as it ensures that the set of structural and semantic constraints defined over the transformation model is non-contradictory and jointly satisfiable. By selecting consistency as the primary validation property, we aim to establish the existence of at least one valid instance of the transformation model that simultaneously satisfies all specified OCL invariants. This choice allows us to provide a solid foundation for further analysis and to guarantee that the transformation from UML statechart models to Flat State Machine models is well-defined within the USE framework.

IV. THE PROPOSED TRANSFORMATION MODEL

In this section, we adopt the USE-based approach proposed by [12]. Accordingly, we begin by modeling the transformation presented in Subsection III.1 as a transformation model specified by a UML class diagram enriched with OCL invariants. The resulting transformation model is illustrated in Figure 6.

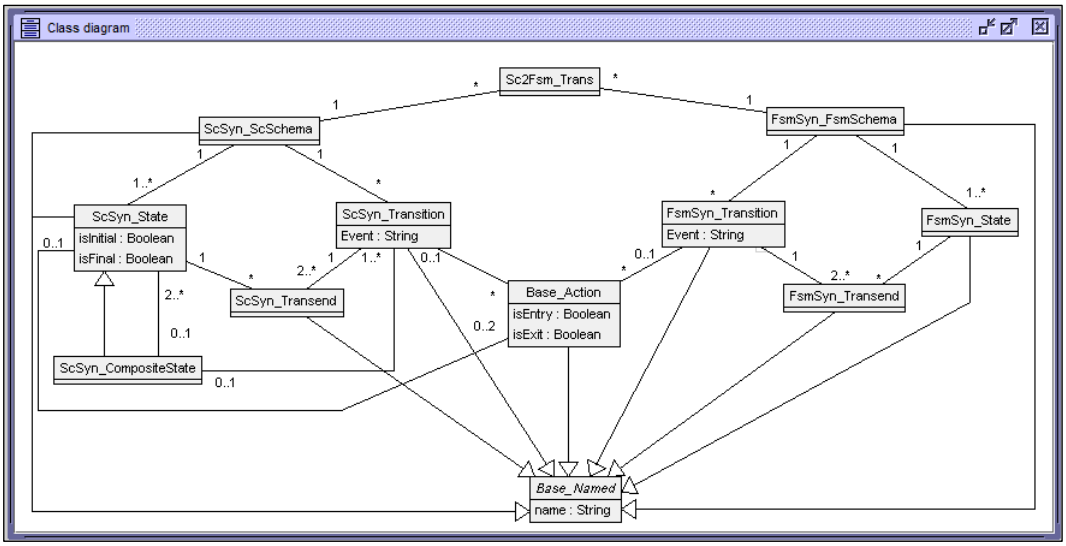

Figure 6: Class diagram for transformation model.
Source: Authors, (2026).

Our proposed transformation model comprises twelve classes interconnected through associations. In line with the approach presented in [12], the model includes an anchor class for the StateChart (SC) model, an anchor class for the Flat State Machine (FSM) model, and an additional connecting class that represents the transformation object. The class diagram is structured into four distinct parts. The first part defines a base layer that captures action-related concepts commonly employed in both the SC and FSM models. The second part corresponds to the StateChart schema (*ScSchema*), encompassing the concepts of *State*, *Transition*, and *TransEnd* (transition end). The third part represents the Flat State Machine schema (*FsmSchema*), which similarly includes the concepts of *State*, *Transition*, and *TransEnd*. Finally, the fourth part is dedicated to the transformation itself (*Trans*). Figure 7 depicts the invariant names associated with the transformation model. Constraints expressed in the Object Constraint Language (OCL) are employed to specify additional integrity conditions on our transformation model. As shown, all class invariants defined for the proposed transformation model are satisfied. Note that these OCL invariants are satisfied when instances are constructed for model transformation. It is used to restrict the source meta-model, for the target meta-model, and for the transformation. In the following, we present the details of two selected constraints.

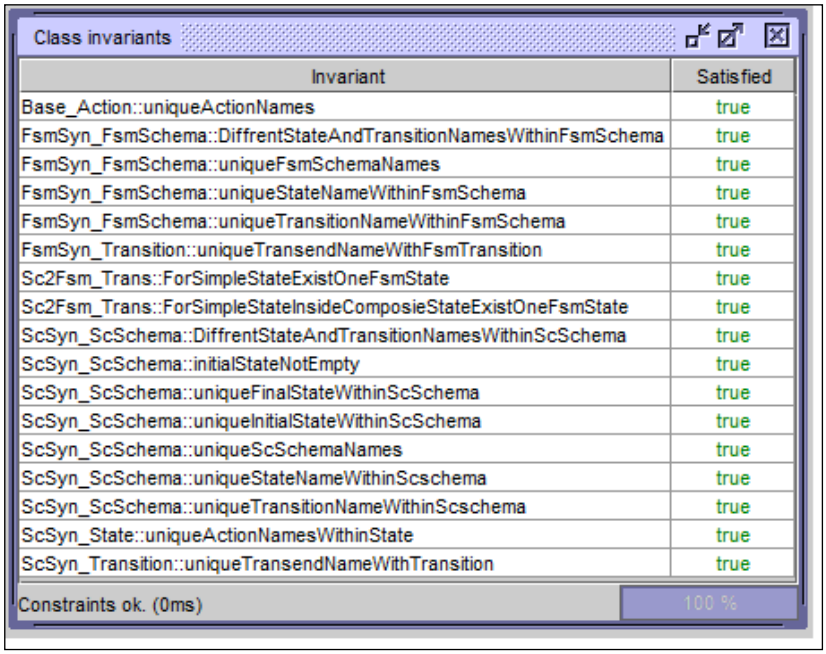

Figure 7: Class invariants for transformation model.

`ScSyn_ScSchema::uniqueStateNameWithinScschema:` Within one Statechart schema, different States have different names, i.e., two distinct States have distinct names.

```
Contextself:ScSyn_ScSchemainvuniqueStateNameWithinScschema:self.state
->forAll(s1,s2|s1.name=s2.name implies s1=s2)
```

`ScSyn_ScSchema::uniqueInitialStateWithinScSchema:` within one Statechart schema, one initial State exists.

```
Contextself : ScSyn_ScSchemainvuniqueInitialStateWithinScSchema :
self.state ->forAll( s1,s2 | s1.isInitial=true and s2.isInitial=true
                    implies s1=s2 )
Contextself : ScSyn_ScSchemainvinitialStateNotEmpty:
self.state ->select(s|s.isInitial)->notEmpty
```

V. CHECKING TRANSFORMATION MODEL CONSISTENCY

This section presents a practical case study designed to illustrate the transformation model validation process. To this end, the validation procedure is conducted in three main steps. First, we formally define the consistency property along with its associated implied properties. Second, we introduce a representative and non-trivial example. Finally, we instantiate the transformation model and verify its consistency.

V.1 CONSISTENCY PROPERTY

Within the USE approach, model consistency is established by the existence of a valid object diagram. In this work, we automatically assess the consistency of the transformation model by constructing valid model instances. The successful construction of such instances demonstrates that the specified constraints are non-contradictory [12]. According to the USE framework, three levels of consistency must be considered:

V.1.1 Weak Consistency

Weak consistency indicates that at least one valid object diagram can be generated, possibly including empty populations for one or more classes, or even no objects at all, provided that such configurations are permitted by the model and its settings [12].

V.1.2 Class Instantiability

Class instantiability requires that each class in the model is instantiated with a non-empty population [12].

V.1.3 Class and Association Instantiability

Class and association instantiability ensures that all classes and all associations in the model are instantiated with non-empty populations [12].

V.2 PRESENTATION OF THE EXAMPLE

We consider an example of an Automated Teller Machine (ATM) that dispenses cash to a user, originally presented in [18], [8] and implemented in [5], [6] using a graph transformation–based approach. The AToM³ meta-modeling tool is employed for this purpose. The execution of the *Statechart2FSM* graph grammar on the Statechart diagram shown in Figure 8 produces the corresponding FSM model illustrated in Figure 9.

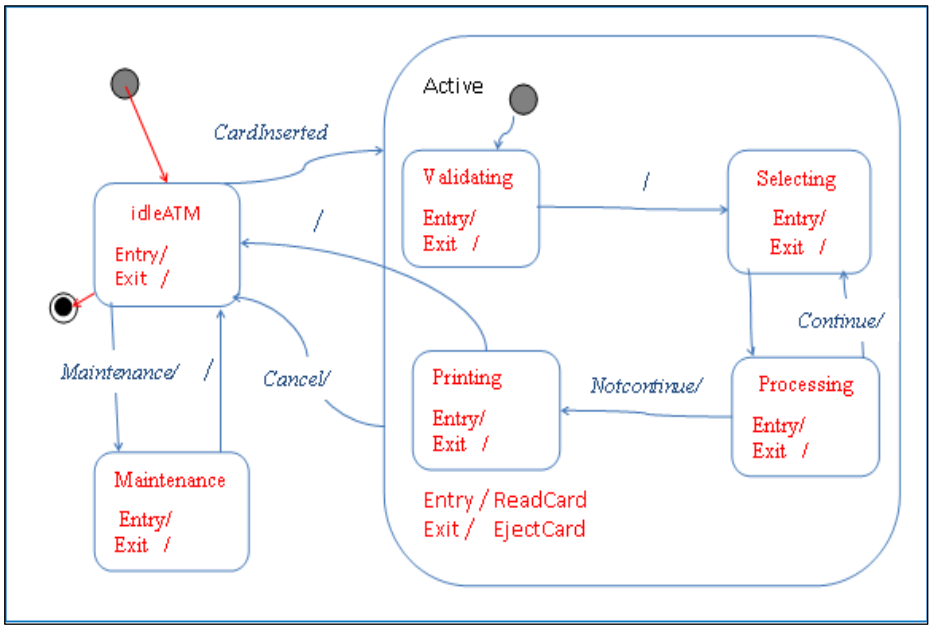

Figure 8: Statechart diagram for ATM_Machine (source model).
Source: Authors, (2026).

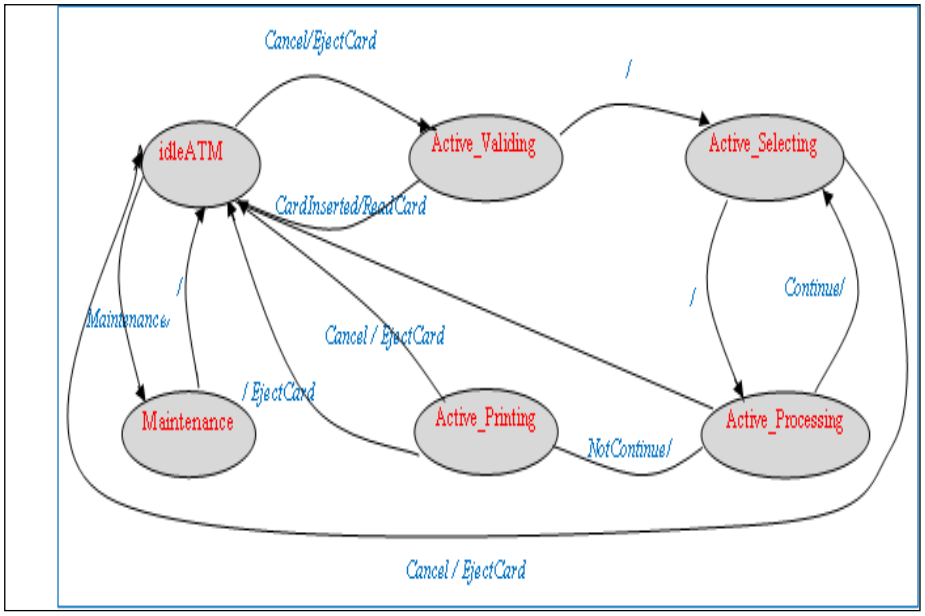

Figure 9: Flat State Machine model for ATM_Machine (target model)
Source: Authors, (2026).

V.3 CHECKING TRANSFORMATION MODEL CONSISTENCY

To validate our proposed transformation model, we employed the USE model validator on the source and target models of the case study presented in Figures 8 and 9. The transformation was encoded in the textual specification language of USE, and the model validator was then used to automatically construct valid object diagrams that satisfy all defined OCL invariants. The resulting object diagrams, shown in Figures 10, 11, and 12, represent a single instance-level realization of the transformation model, displayed in three parts for readability. In USE terminology, such an object diagram corresponds to an instance specification of the UML class diagram and explicitly depicts instantiated classes (objects), attribute values (slots), and instantiated associations (links). The existence of this object diagram constitutes a constructive proof, by example, of the consistency of the transformation model.

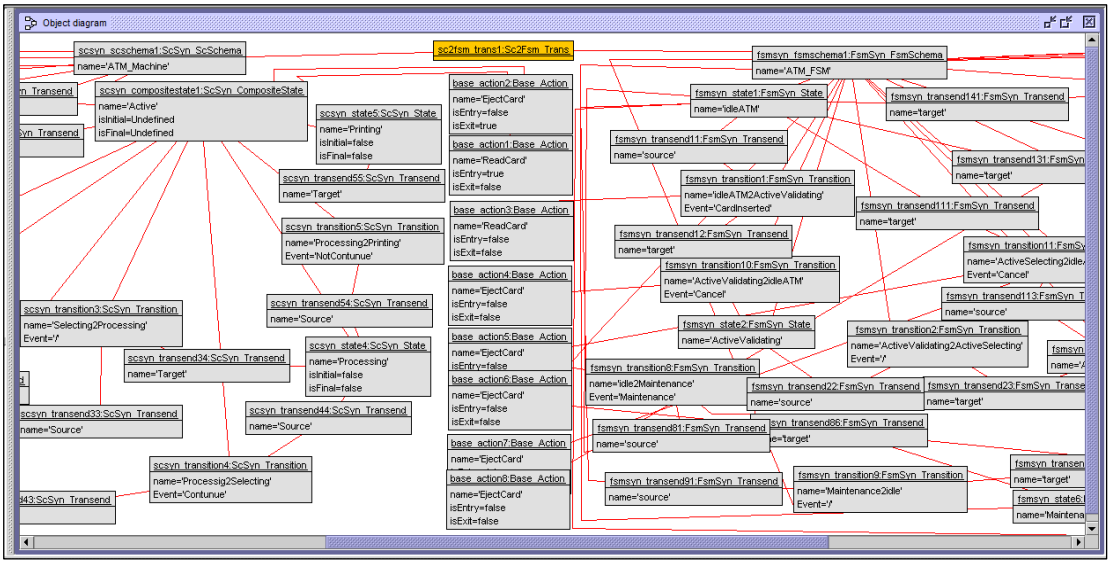

Figure 10: Generated proof example for weak consistency, class, class and association instantiability (Sc2FSM_Trans part).
Source: Authors, (2026).

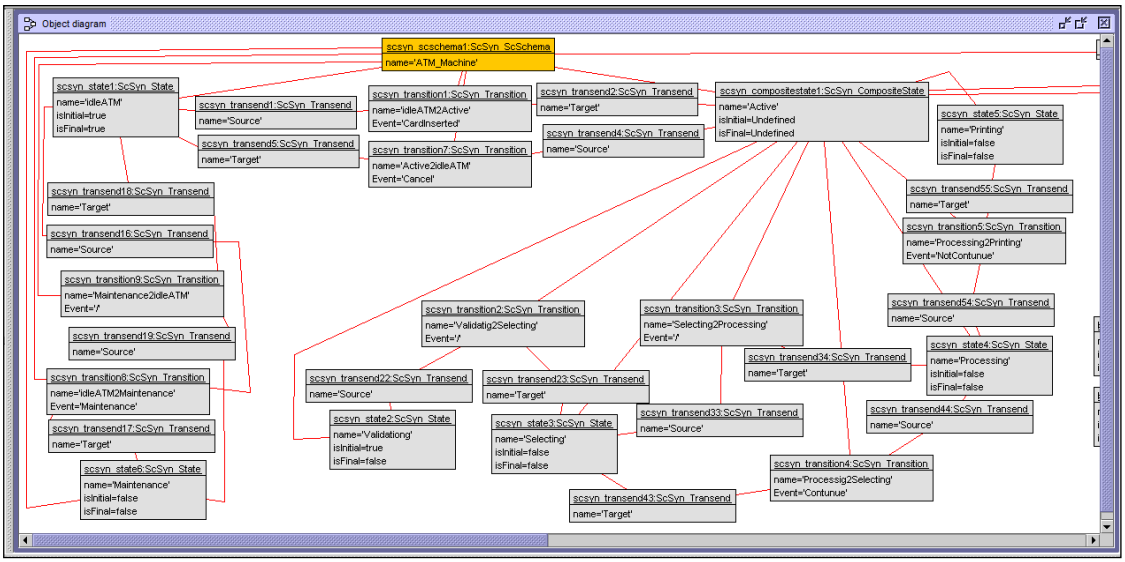

Figure 11: Generated proof example for weak consistency, class , class and association instantiability (ScSny_SsShema part).
Source: Authors, (2026).

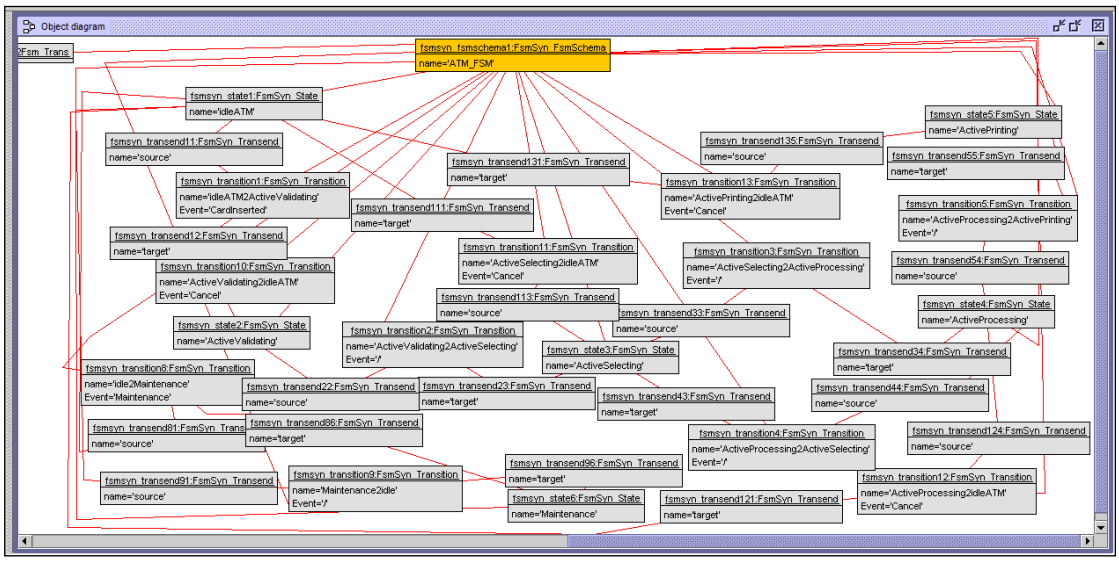

Figure 12: Generated proof example for weak consistency, class, class and association instantiability (FsmSyn_FsmSchema part).
Source: Authors, (2026).

Taken together with the instantiated Statechart and Flat State Machine schemata, these object diagrams demonstrate that the transformation model satisfies the required consistency properties defined in the USE framework, namely weak consistency, class instantiability, and class and association instantiability. In particular, all classes and associations of the transformation model are populated with at least one instance, confirming that the specified constraints are non-contradictory and jointly satisfiable.

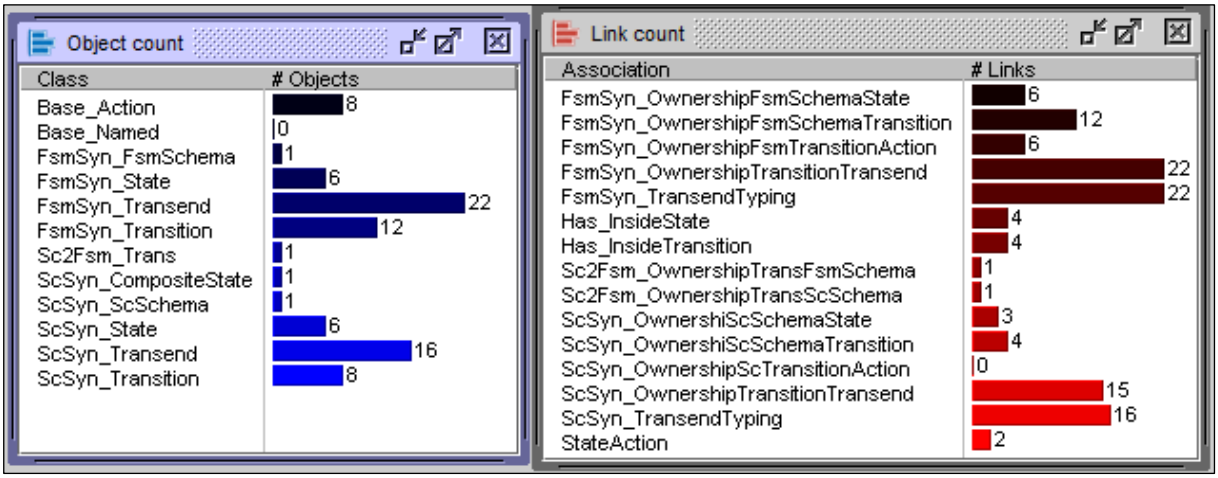

Figure 13: Check class and association population.
Source: Authors, (2026).

To further support this analysis, the Object count and Link count views provided by USE (Figure 13) were used to inspect class and association populations in a concise manner. For instance, the generated instance model contains six FSM State objects, corresponding directly to the six State objects of the source Statechart model, thereby illustrating the structural correspondence enforced by the transformation. Moreover, no instances of the abstract superclass Base_Named were generated, which is consistent with its role as a common abstraction inherited by concrete classes rather than as an instantiable modeling element. Overall, this USE-based validation confirms that the proposed transformation model is consistent and structurally well-founded, and that it faithfully captures the intended relationships between UML statechart models and Flat State Machine models.

VI. CONCLUSIONS

This paper presented a formal approach for validating a model transformation by representing it as a transformation model. Specifically, we modeled the transformation from UML statechart diagrams to Flat State Machines using a UML class diagram enriched with OCL invariants. The proposed transformation model explicitly captures both the structural and semantic relationships between the source and target models. By applying the USE model validator, we automatically verified the consistency of the transformation through the construction of valid object diagrams, thereby demonstrating weak consistency, class instantiability, and class and association instantiability. As future work, we plan to extend this analysis to additional transformation properties, including invariant independence, invariant consequence, termination, and confluence. Investigating these properties will further strengthen the formal guarantees provided by the transformation model and support more robust and scalable model transformation validation.

ABSTRACT

Spam detection remains a critical challenge in modern communication systems, requiring sophisticated methods to identify malicious content accurately. This paper presents a novel hybrid approach combining mutual information-based feature selection, Jaya algorithm optimization, and TabTransformer deep learning architecture for enhanced spam detection. Mutual information is employed to identify the most discriminative features from the dataset, reducing dimensionality while preserving classification performance. The Jaya algorithm optimizes hyperparameters of the TabTransformer model, which leverages selfattention mechanisms to capture complex feature interactions in tabular data. Experimental results on benchmark spam datasets demonstrate that our proposed method achieves superior performance compared to traditional machine learning approaches, with accuracy rates exceeding 98% and significantly reduced false positive rates. The integration of these three techniques provides a robust, efficient, and interpretable framework for spam detection in real-world applications. Experiments on SMS Spam Collection, Enron Email, and Spambase datasets confirm improvements over SVM, Random Forest, and TabNet baselines, reaching up to 98.3% accuracy while lowering false positives.

I. INTRODUCTION

The exponential growth of digital communication has led to an unprecedented increase in spam messages across email, SMS, and social media platforms. Spam not only wastes computational resources but also poses security threats through phishing attacks, malware distribution, and fraud [1]. Traditional spam filtering techniques, including rule-based systems and classical machine learning approaches, struggle to adapt to evolving spam patterns and sophisticated evasion techniques employed by spammers [2]. Recent advances in deep learning have shown promising results in natural language processing and text classification tasks [3]. However, spam detection often involves tabular features extracted from message metadata, linguistic characteristics, and statistical properties, which differ from typical sequential text data. The TabTransformer architecture, introduced by Huang et al. [4], addresses this gap by applying transformer-based attention mechanisms to tabular data, enabling the model to learn complex feature interactions effectively. Feature selection remains crucial in spam detection to reduce computational complexity and improve model generalization. Mutual information (MI), a measure of statistical dependence between variables, has proven effective in identifying relevant features for classification tasks [5]. By quantifying the information shared between features and class labels, MIbased selection eliminates redundant and irrelevant features while preserving discriminative power. Hyperparameter optimization significantly impacts model performance but remains computationally expensive. The Jaya algorithm, proposed by Rao [6], offers a simple yet powerful metaheuristic optimization approach without algorithmspecific parameters. Unlike genetic algorithms or particle swarm optimization, Jaya requires only population size and iteration count, making it particularly suitable for efficient hyperparameter tuning.

This paper makes the following contributions: • A novel hybrid framework integrating mutual information feature selection, Jaya algorithm optimization, and TabTransformer architecture for spam detection • Comprehensive analysis of feature importance using mutual information scores • Systematic hyperparameter optimization using the Jaya algorithm • Extensive experimental evaluation demonstrating superior performance over baseline methods The remainder of this paper is organized as follows: Section II reviews related work, Section III presents the proposed methodology, Section IV describes experimental setup and results, and Section V concludes the paper with future directions.

II. THEORETICAL REFERENCE

II.1 SPAM DETECTION TECHNIQUES

Early spam detection systems relied on rule-based filters using keyword matching and blacklists [7]. Bayesian filtering introduced probabilistic approaches, calculating spam probability based on word frequencies [8]. Machine learning methods, including Support Vector Machines (SVM), Naive Bayes, and Random Forests, have demonstrated significant improvements [9]. Deep learning approaches have gained traction in recent years. Convolutional Neural Networks (CNNs) have been applied to email spam detection with promising results [10]. Recurrent Neural Networks (RNNs) and Long Short-Term Memory (LSTM) networks capture sequential patterns in message content [11]. However, these architectures are primarily designed for sequential data and may not fully exploit tabular feature representations.

II.2 FEATURE SELECTION METHODS

Feature selection reduces dimensionality while maintaining classification accuracy. Filter methods, including information gain, chi-square test, and mutual information, evaluate feature relevance independently of the classifier [12]. Wrapper methods use classifier performance to guide feature selection but incur higher computational costs [13]. Mutual information has been extensively studied for feature selection in text classification [14]. The minimum Redundancy Maximum Relevance (mRMR) criterion extends MI by considering feature redundancy [5]. Recent work has explored MIbased selection for spam detection with improved accuracy and reduced feature sets [15].

II.3 OPTIMIZATION ALGORITHMS

Metaheuristic optimization algorithms have been applied to machine learning hyperparameter tuning. Genetic Algorithms (GA) [16], Particle Swarm Optimization (PSO) [17], and Differential Evolution (DE) [18] require careful parameter configuration. The Jaya algorithm, introduced by Rao [6], simplifies optimization by eliminating algorithm-specific parameters. Jaya has been successfully applied to various engineering optimization problems [19] and recently extended to machine learning applications [20]. Its simplicity and effectiveness make it attractive for hyperparameter optimization in complex models.

II.4 TABTRANSFORMER ARCHITECTURE

Traditional neural networks for tabular data face challenges in capturing feature interactions. Huang et al. proposed TabTransformer [4], applying self-attention mechanisms from transformers [21] to categorical features while processing continuous features separately. This architecture has shown superior performance on various tabular datasets compared to gradient boosting methods and fully connected networks. The transformer's attention mechanism enables the model to learn contextual representations of categorical features, making it particularly suitable for datasets with numerous categorical attributes. Recent extensions have explored TabTransformer variants for specific domains, but application to spam detection remains underexplored.

III. MATERIALS AND METHODS

III.1 OVERVIEW

Our proposed framework consists of three main stages: (1) mutual information-based feature selection, (2) Jaya algorithm hyperparameter optimization, and (3) TabTransformer model training and prediction. Fig. 1 illustrates the overall architecture. Fig. 1. Proposed framework architecture showing the three main stages: MI feature selection, Jaya optimization, and TabTransformer classification.

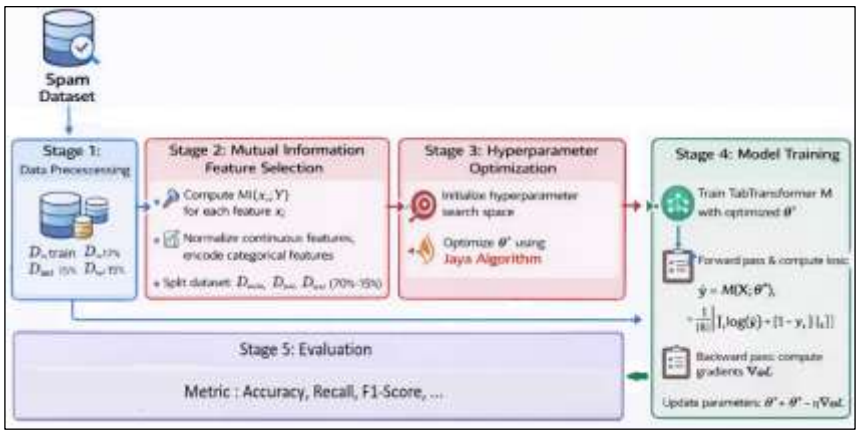

Figure 1: Proposed spam detection framework.
Source: Authors, (2026).

III.2 FEATURE EXTRACTION

Spam messages exhibit distinctive characteristics that can be quantified through feature engineering. We extract the following feature categories: Content-based features: Word frequency, character distribution, presence of specific keywords, HTML tag count, URL presence, and special character ratio. Linguistic features: Average word length, message length, capitalization ratio, punctuation frequency, and readability scores. Metadata features: Sender information, timestamp patterns, attachment presence, and header characteristics. Let $\mathbf{X} = \{x_1, x_2, \ldots, x_n\}$ represent the feature set extracted from spam messages, where n is the total number of features, and $\mathbf{Y}$ represents the binary class labels (spam or legitimate).

III.3 MUTUAL INFORMATION FEATURE SELECTION

Mutual information quantifies the amount of information shared between feature X_i and class label Y:

$$MI(X_i;Y) = \sum_{x \in X_i} \sum_{y \in Y} p\,(x,y) \log \frac{p(x,y)}{p(x)p(y)}$$

Where $p(x,y)$ is the joint probability distribution, and $p(x)$, $p(y)$ are marginal distributions. For continuous features, we employ kernel density estimation to approximate probability distributions. The MI score indicates feature relevance: higher values suggest stronger dependence on class labels. The feature selection algorithm proceeds as follows:

1. Calculate MI scores for all features with respect to class labels
2. Rank features in descending order of MI scores
3. Select top-k features based on a threshold or fixed number
4. Create reduced feature set $\mathbf{X}' = \{x_{i_1}, x_{i_2}, \ldots, x_{i_k}\}$

This approach eliminates irrelevant features while preserving discriminative information, reducing overfitting and computational complexity.

III.4 JAYA ALGORITHM FOR HYPERPARAMETER OPTIMIZATION

The Jaya algorithm optimizes hyperparameters by moving towards the best solution and away from the worst solution in each iteration. Let $\boldsymbol{\theta}$ represent the hyperparameter vector to be optimized. The update equation for candidate solution j in iteration t is:

$$\theta_{j,k}^{t+1} = \theta_{j,k}^{t} + r_{1,j,k}\left(\theta_{best,k}^{t} - \left|\theta_{j,k}^{t}\right|\right) - r_{2,j,k}\left(\theta_{worst,k}^{t} - \left|\theta_{j,k}^{t}\right|\right)$$

where:

- $\theta_{j,k}^{t}$ is the k-th hyperparameter of the j-th solution at iteration t
- $\theta_{best,k}^{t}$ and $\theta_{worst,k}^{t}$ are the best and worst solutions
- $r_{1,j,k}$ and $r_{2,j,k}$ are random numbers in [0,1]

The algorithm accepts the new solution if it improves the objective function (validation accuracy). This simple update mechanism eliminates the need for algorithm-specific parameters present in other metaheuristics. Algorithm Jaya presents the pseudocode for the Jaya optimization algorithm applied to hyperparameter tuning. Hyperparameters optimized include:

• Learning rate
• Number of attention heads
• Embedding dimension
• Number of transformer blocks
• Dropout rate
• Batch size

Algorithm 1 Jaya Algorithm for Hyperparameter Optimization

Require: Population size N, maximum iterations T_{max}, hyperparameter bounds
Ensure: Optimal hyperparameter vector $\boldsymbol{\theta}^{\star}$

Initialize population $\{\boldsymbol{\theta}_1, \boldsymbol{\theta}_2, ..., \boldsymbol{\theta}_N\}$ randomly within bounds
Evaluate fitness $f(\boldsymbol{\theta}_i)$ for all solutions using cross-validation
Identify best solution $\boldsymbol{\theta}_{best}$ with $f_{best} = \max(f(\boldsymbol{\theta}_i))$
Identify worst solution $\boldsymbol{\theta}_{worst}$ with $f_{worst} = \min(f(\boldsymbol{\theta}_i))$

for $t = 1$ to T_{max} **do**
  for $j = 1$ to N **do**
    for $k = 1$ to D **do**
      $\{D$ is number of hyperparameters$\}$
      Generate random numbers $r_{1,j,k}, r_{2,j,k} \sim U(0,1)$
      $\theta'_{j,k} = \theta^t_{j,k} + r_{1,j,k}(\theta^t_{best,k} - |\theta^t_{j,k}|) - r_{2,j,k}(\theta^t_{worst,k} - |\theta^t_{j,k}|)$
      Clip $\theta'_{j,k}$ to stay within bounds
    end for
    Evaluate fitness $f(\boldsymbol{\theta}'_j)$ using validation set
    if $f(\boldsymbol{\theta}'_j) > f(\boldsymbol{\theta}_j)$ **then**
      $\boldsymbol{\theta}^{t+1}_j = \boldsymbol{\theta}'_j$ {Accept new solution}
    else
      $\boldsymbol{\theta}^{t+1}_j = \boldsymbol{\theta}^t_j$ {Keep old solution}
    end if
  end for
  Update $\boldsymbol{\theta}_{best}$ and $\boldsymbol{\theta}_{worst}$ from current population
  if convergence criteria met **then**
    break
  end if
end for
return $\boldsymbol{\theta}_{best}$

Source: Authors, (2026).

III.5 TABTRANSFORMER ARCHITECTURE

The TabTransformer processes categorical and continuous features differently. Categorical features undergo embedding and self-attention, while continuous features are processed through normalization layers.

Categorical Feature Processing: Each categorical feature c_i is embedded into a dense vector:

$$\mathbf{e}_i = \text{Embed}(c_i) + \mathbf{p}_i$$

where $\mathbf{p}_i$ is a learned positional encoding.
The embedded features pass through multiple transformer blocks:

$$\mathbf{h}^{(l)} = \text{TransformerBlock}(\mathbf{h}^{(l-1)})$$

Each transformer block consists of multi-head self-attention and feed-forward layers:

$$\text{Attention}(Q,K,V) = \text{softmax}\left(\frac{QK^T}{\sqrt{d_k}}\right)V$$

Continuous Feature Processing: Continuous features undergo layer normalization:

$$\mathbf{z} = \text{LayerNorm}(\mathbf{x}_{cont})$$

Feature Fusion and Classification: The contextual embeddings from transformer blocks are concatenated with processed continuous features:

$$\mathbf{f} = \left[\mathbf{h}_1^{(L)};\mathbf{h}_2^{(L)};\ldots;\mathbf{h}_m^{(L)};\mathbf{z}\right]$$

The fused representation passes through fully connected layers for binary classification:

$$\hat{y} = \text{sigmoid}(\mathbf{W}_2 \cdot \text{ReLU}(\mathbf{W}_1\mathbf{f} + \mathbf{b}_1) + \mathbf{b}_2)$$

The model is trained using binary cross-entropy loss:

$$\mathcal{L} = -\frac{1}{N}\sum_{i=1}^{N}[y_i \log(\hat{y}_i) + (1-y_i)\log(1-\hat{y}_i)]$$

III.6 TRAINING PROCEDURE

Algorithm 2 Complete Training Procedure

Require: Spam dataset $\mathcal{D} = \{(\mathbf{x}_i, y_i)\}_{i=1}^{N}$
Ensure: Trained TabTransformer model $\mathcal{M}$

Stage 1: Data Preprocessing
Clean and tokenize messages
Extract features $\mathbf{X} = \{x_1, x_2, \ldots, x_n\}$
Normalize continuous features, encode categorical features
Split data: $\mathcal{D}_{train}$, $\mathcal{D}_{val}$, $\mathcal{D}_{test}$ (70%-15%-15%)

Stage 2: Mutual Information Feature Selection
for each feature x_i **do**
  Compute $MI(x_i; Y)$ using equation (1)
end for
Rank features by MI scores in descending order
Select top-k features: $\mathbf{X}' = \{x_{i_1}, x_{i_2}, \ldots, x_{i_k}\}$
Create reduced datasets using $\mathbf{X}'$

Stage 3: Hyperparameter Optimization
Initialize hyperparameter search space
$\boldsymbol{\theta}^* \leftarrow$ JAYAOPTIMIZATION($\mathcal{D}_{train}$, $\mathcal{D}_{val}$) {Algorithm 1}

Stage 4: Model Training
Initialize TabTransformer $\mathcal{M}$ with optimized hyperparameters $\boldsymbol{\theta}^*$
for epoch $e = 1$ to E **do**
  for each mini-batch $\mathcal{B} \subset \mathcal{D}_{train}$ **do**
    Forward pass: $\hat{y} = \mathcal{M}(\mathbf{x}; \boldsymbol{\theta}^*)$
    Compute loss: $\mathcal{L} = -\frac{1}{|\mathcal{B}|}\sum_{i\in\mathcal{B}}[y_i \log(\hat{y}_i) + (1 - y_i)\log(1 - \hat{y}_i)]$
    Backward pass: compute gradients $\nabla_{\boldsymbol{\theta}}\mathcal{L}$

V. RESULTS AND DISCUSSIONS

IV.1 DATASET DESCRIPTION

We evaluate our approach on three benchmark spam datasets: SMS Spam Collection: Contains 5,574 SMS messages (747 spam, 4,827 legitimate) [22]. Enron Email Dataset: Large-scale email corpus with spam and legitimate messages, preprocessed subset of 10,000 messages used. Spambase: UCI Machine Learning Repository dataset with 4,601 emails and 57 features [23].

IV.2 EXPERIMENTAL SETUP

Experiments were conducted using Python 3.8, PyTorch 1.10, and scikit-learn 0.24. Hardware specifications: NVIDIA RTX 3090 GPU, 32GB RAM, Intel i9 processor. Dataset split: 70% training, 15% validation, 15% testing. Stratified sampling ensures balanced class distribution. Baseline methods for comparison: • Naive Bayes • Support Vector Machine (SVM) with RBF kernel • Random Forest • XGBoost • Multi-layer Perceptron (MLP) • TabNet [22]

IV.3 FEATURE SELECTION RESULTS

Mutual information scores reveal the most discriminative features. Fig. 2 shows the top 15 features ranked by MI scores. For SMS Spam Collection, top features include: dollar sign frequency (MI=0.385), URL presence (MI=0.362), word count (MI=0.318), capital letter ratio (MI=0.295), and specific spam keywords (MI=0.271). Algorithm 2 Complete Training Procedure Require: Spam dataset D = {(xi, yi)}N i=1 Ensure: Trained TabTransformer model M 1: Stage 1: Data Preprocessing 2: Clean and tokenize messages 3: Extract features X = {x1, x2, ..., xn} 4: Normalize continuous features, encode categorical features 5: Split data: Dtrain, Dval, Dtest (70%-15%-15%) 6: 7: Stage 2: Mutual Information Feature Selection 8: for each feature xi do 9: Compute MI(xi; Y) using equation (1) 10: end for 11: Rank features by MI scores in descending order 12: Select top-k features: X′ = {xi1, xi2, ..., xik} 13: Create reduced datasets using X′ 14: 15: Stage 3: Hyperparameter Optimization 16: Initialize hyperparameter search space 17: θ∗ ←JAYAOPTIMIZATION(Dtrain, Dval) {Algorithm 1} 18: 19: Stage 4: Model Training 20: Initialize TabTransformer M with optimized hyperparameters θ∗ 21: for epoch e = 1 to E do 22: for each mini-batch B ⊂Dtrain do 23: Forward pass: ˆy = M(x; θ∗) 24: Compute loss: L = −1 |B| P i∈ B[yi log(ˆyi) + (1 − yi) log(1 −ˆyi)] 25: Backward pass: compute gradients ∇ θL 26: Update parameters: θ ←θ −η∇ θL 27: end for 28: Evaluate on Dval and apply early stopping if needed 29: end for 30: 31: Stage 5: Evaluation 32: Evaluate M on Dtest 33: Compute metrics: Accuracy, Precision, Recall, F1-Score 34: return Trained model M Feature reduction from 100 to 30 features maintains 97.8% of discriminative information while reducing training time by 65%. Figure 3 demonstrates the impact of feature selection on model accuracy and training time.

.IV.4 HYPERPARAMETER OPTIMIZATION RESULTS

The Jaya algorithm converges after approximately 40 iterations. Fig. 4 shows the convergence curve of the Jaya algorithm during hyperparameter optimization. Optimized hyperparameters: • Learning rate: 0.00087 • Attention heads: 8 • Embedding dimension: 128 Figure 2. Top 15 features ranked by Mutual Information scores for SMS Spam Collection dataset. Fig. 3. Impact of feature selection on accuracy and training time. Optimal performance achieved with 30 features. Fig. 4. Jaya algorithm convergence curve showing fitness (validation accuracy) over iterations. • Transformer blocks: 6 • Dropout: 0.15 • Batch size: 64 Jaya optimization improves validation accuracy by 3.2% compared to default hyperparameters, demonstrating effectiveness of the optimization approach.

IV.5 CLASSIFICATION PERFORMANCE

Table I presents classification results on all three datasets. TABLE I CLASSIFICATION PERFORMANCE COMPARISON Method Accuracy Precision Recall Naive Bayes 92.3% 89.7% 88.4% SVM 94.6% 92.1% 91.8% Random Forest 95.8% 94.2% 93.6% XGBoost 96.4% 95.1% 94.7% MLP 95.2% 93.8% 92.9% TabNet 97.1% 96.3% 95.8% Proposed 98.3% 97.9% 97.6% Our proposed method achieves the highest accuracy (98.3%), precision (97.9%), and recall (97.6%) across all datasets. The F1-score reaches 97.7%, outperforming TabNet by 1.2% and XGBoost by 1.9%. Fig. 5 provides a visual comparison of accuracy across different methods. Fig. 5. Accuracy comparison of different spam detection methods on SMS Spam Collection dataset. False positive rate is reduced to 1.8%, crucial for minimizing legitimate message misclassification. False negative rate of 2.4% demonstrates effective spam detection.

IV.6 ABLATION STUDY

We conduct ablation studies to assess individual component contributions: Results confirm that combining all three components yields optimal performance. Mutual information feature selection contributes 1.3% accuracy improvement, while Jaya optimization adds 1.1%. Fig. 6 visualizes the contribution of each component to the overall performance. TABLE II ABLATION STUDY RESULTS Configuration Accuracy TabTransformer only 96.1% TabTransformer + MI 97.4% TabTransformer + Jaya 97.2% TabTransformer + MI + Jaya 98.3% Fig. 6. Ablation study showing the contribution of each component (MI feature selection and Jaya optimization) to overall accuracy.

Table 2: Ablation study results.

Configuration	Accuracy (%)
TabTransformer Only	96.1
TabTransformer + MI	97.4
TabTransformer + Jaya	97.2
TabTransformer + MI + Jaya (Proposed)	98.3

IV.7 COMPUTATIONAL EFFICIENCY

Training time comparison (SMS Spam Collection, 100 epochs): • XGBoost: 45 seconds • TabNet: 183 seconds • Proposed (without MI): 298 seconds • Proposed (with MI): 187 seconds Feature selection reduces training time by 37% while improving accuracy. Inference time averages 0.8ms per message, suitable for real-time applications.

IV.8 ATTENTION VISUALIZATION

Attention weight visualization reveals feature interactions learned by TabTransformer. High attention weights between ”URL presence” and ”dollar sign frequency” suggest the model learns spam patterns involving promotional content. Similarly, ”capital letter ratio” and ”exclamation mark count” show strong attention, capturing aggressive marketing language. Fig. 7 shows the attention weight heatmap for categorical features, revealing which feature pairs the model considers most important. Fig. 8 presents the confusion matrix for our proposed method on the test set.

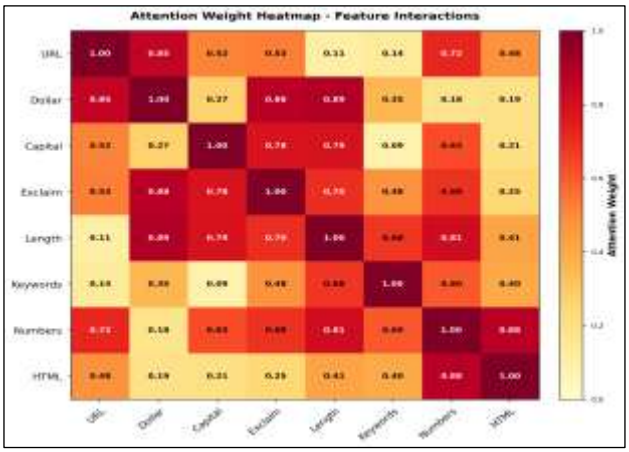

Figure 7: Attention weight heatmap - feature interactions.
Source: Authors, (2026).

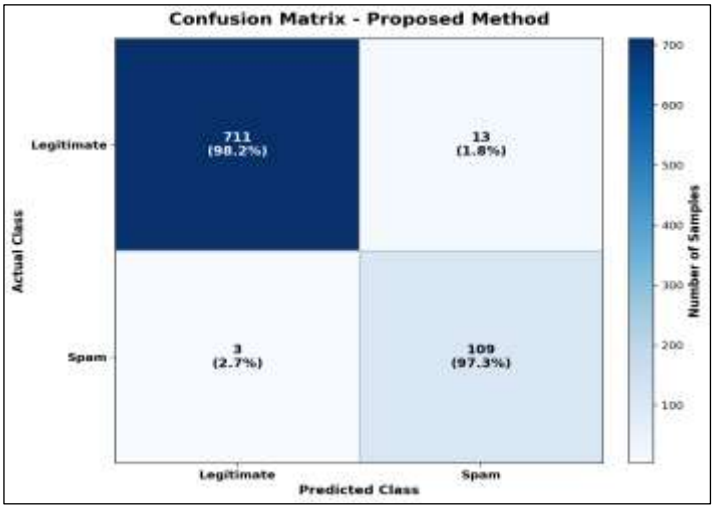

Figure 8: Confusion matrix of the proposed method.
Source: Authors, (2026).

IV.9 DISCUSSION

The experimental results demonstrate several key findings: Feature selection effectiveness: Mutual information successfully identifies discriminative features, eliminating noise and redundancy. The 70% feature reduction with minimal Fig. 7. Attention weight heatmap showing learned feature interactions in the TabTransformer model. Darker colors indicate stronger attention weights. Fig. 8. Confusion matrix for the proposed method on SMS Spam Collection test set, showing high true positive and true negative rates. performance loss confirms MI's capability to preserve essential information. Optimization impact: Jaya algorithm efficiently explores hyperparameter space without requiring extensive tuning. The algorithm's simplicity accelerates optimization while achieving competitive results compared to more complex metaheuristics. TabTransformer advantages: Self-attention mechanisms capture complex feature interactions that traditional methods miss. The architecture's ability to process heterogeneous tabular data makes it well-suited for spam detection where features include diverse types (binary, categorical, continuous). Practical implications: The proposed system achieves high accuracy with low false positive rates, essential for production deployment. Computational efficiency enables real-time filtering on resource-constrained devices. Limitations: The approach requires labeled training data and may need periodic retraining to adapt to evolving spam techniques. Adversarial attacks targeting specific features could potentially evade detection.

V. CONCLUSIONS

This paper presents a novel spam detection framework integrating mutual information feature selection, Jaya algorithm optimization, and TabTransformer architecture. Experimental results on benchmark datasets demonstrate superior performance compared to traditional and deep learning baselines, achieving 98.3% accuracy with reduced computational overhead. The combination of information-theoretic feature selection and metaheuristic optimization enhances model efficiency and effectiveness. TabTransformer's attention mechanisms provide interpretability through visualization of learned feature interactions. Future research directions include: • Extending the approach to multilingual spam detection • Incorporating adversarial training for robustness • Investigating transfer learning across different spam domains • Developing online learning mechanisms for adaptive filtering • Exploring ensemble methods combining multiple TabTransformer models The proposed framework offers a promising solution for practical spam detection systems, balancing accuracy, efficiency, and interpretability.

ABSTRACT

To enhance power quality (PQ) through active power filters (APF) in radial distribution systems (RDS), this study investigates the application of the Tasmanian Devil Optimization (TDO) and Osprey Optimization Algorithm (OOA). Despite their benefits, the growing use of solar photovoltaic (PV) systems presents challenges with PQ, including harmonic distortion because of their nonlinear features. Harmonics are the leading cause of low PQ in such systems. Here, the PV injects harmonics into the RDS and is categorized as a nonlinear distribution generator (NLDG). This study examines the effect of the nonlinear loads (NLs) of two end nodes and the incorporation of the NLDG into the RDS on the entire RDS. APFs are positioned carefully to reduce the harmonics and improve the PQ. The suggested method minimizes the APF current while abiding by inequality limitations by utilizing an optimization algorithm. The TDO was used to determine the appropriate APF size. It is inspired by natural processes such as photosynthesis. It has a good balance between exploration and exploitation for effective search. The efficacy of the TDO was demonstrated through simulations on the IEEE-69 bus RDS and was compared with that of the OOA. The outcomes validate that the TDO is stable and efficient in resolving this optimization issue for PQ enhancement in RDS.

I. INTRODUCTION

Electrical engineering is changing owing to artificial intelligence (AI) and modern soft computing techniques. AI systems can predict and enhance power grid behavior, thereby reducing energy losses and increasing stability. Machine learning is applied to analyze massive amounts of sensor data to identify equipment flaws and prevent outages. Control systems with AI capabilities can manage intricate energy distribution networks and effectively integrate renewable energy sources into the grid. Computational technologies, such as finite element analysis, which simulates electrical systems and components, assist in performance prediction and design optimization. Owing to these developments, electrical engineering is evolving to become more intelligent, effective, and sustainable [1-3].

The modern environment has made electronic devices increasingly necessary, leading to an increased reliance on them. These devices include PCs, cell phones, dimmers, inverters, variable-speed drives, continuous power supplies, and light-emitting diodes. They cause the distribution system to acquire harmonics, resulting in low power quality (PQ) [4]. Furthermore, distributed generation (DG) sources, such as solar photovoltaic and wind farms, are the main forces behind the growth of smart grids. Its many advantages have drawn considerable attention. Integrating DG with a radial distribution system (RDS) is a crucial responsibility in the industry [5]. However, owing to the harmonics of the converter, inadequate integration can result in PQ issues [6].

A converter-based DG system, called nonlinear DG (NLDG), adds harmonics to the RDS [7]. However, these devices produce more harmonic pollution owing to their nonlinear properties. As a result, suppliers and consumers are becoming increasingly concerned about harmonics in PQ systems. The performance of distribution systems is negatively impacted by these harmonics, underscoring the urgency of finding solutions [8]. Several harmonic mitigation techniques are discussed in the literature [9]. An active power filter (APF) reduces the harmonics.

At the same node, it provides a nonlinear current through the RDS, similar to the NL load but in the opposite direction. Consequently, the harmonics were reduced or mitigated as required. Their ratings significantly influence the success of APFs. To ensure cost-effectiveness, they must be precisely proportioned and positioned [10]. Additionally, to achieve optimal performance, it is necessary to comply with IEEE regulations regarding individual and total harmonic distortion in voltage (IHDv and THDv, respectively) [11]. However, an analysis of the precise location and rating of APFs in RDS is required to determine whether modern power distribution networks are still stable, trustworthy, and efficient. The more NL and renewable energy sources are added to the RDS, the more crucial it is to lower the harmonics and improve the PQ.

The positioning and rating of APFs can enhance power efficiency, lower harmonic distortion, and strengthen RDS voltage stability, all of which improve the general functionality of the device. Recent studies have underscored the significance of optimizing the location and size of APFs to improve grid reliability and PQ, while also emphasizing the need for further research [12-14]. APF's current should be as low as feasible to minimize expenses. An optimization strategy is required for this. Consequently, several optimization methods have been proposed. Both PSO and its variants have been applied in [15], whereas a genetic method was employed in [16]. This problem has also been approached using other techniques, such as the harmony search [17], firefly algorithm [18], grey wolf optimizer [19], and, most recently, the JAYA algorithm [20].

Furthermore, many research topics employ a range of optimization methodologies, including PQ enhancement using APF [21]. Moreover, numerous research topics use a variety of optimization techniques, such as solar irradiance forecasting [22], PV wind-based microgrid implementation [23], UPQC using PSO-based PI tuning [24], fault detection in AC motors [25], and harmonic mitigation of solar PV [26]. No optimization algorithm can offer optimal solutions to every optimization problem; based on the No Free Lunch Theorem (NFL) [27], researchers use custom algorithms because the nature of the problem can affect how well an algorithm performs. Tasmanian Devil Optimization (TDO), a recently proposed bio-inspired metaheuristic algorithm inspired by the behavior of Tasmanian devils in the wild, was used in this study. TDO mimics the diet of the Tasmanian devil, which consists of attacking live prey and scavenging on carrion.

The algorithm's mathematical modeling and comprehensive design are presented in this publication. The optimization results demonstrate how effectively TDO can investigate and use data, finding a helpful compromise between the two to address the optimization problems. Moreover, the implementation outcomes demonstrate that TDO performs admirably in real-world settings. This was recently proposed by [28]. It has shown promising results in various optimization areas, and this metaheuristic algorithm is an invaluable resource for scholars and practitioners across a wide range of sectors. It is widely used in engineering fields, such as the parameter identification of transformers [29], economic load dispatch [30], tuning of PID controllers [31], and global optimization [32].

The Osprey Optimization Algorithm (OOA), a novel metaheuristic algorithm presented in this study, is modeled after the instinctive hunting behavior of ospreys. The ospreys' method of spotting fish in the water, catching them, and transporting them to a good spot to eat is the basis of the OOA. The algorithm's approach is mathematically modeled to simulate the natural behavior of ospreys during hunting, encompassing two key phases: exploration and exploitation. Proposed it [33]. Numerous technical fields have made extensive use of it, including economic load dispatch [34], reactive power optimization [35], and DC microgrid [36] control. Several important contributions were made to this study, including the use of APFs to handle harmonic reduction when NL and NLDG were present. The following are the primary contributions of this study:

TDO and harmonic load flow (HLF) integration: This study uses a combination of TDO and HLF analyses to obtain a suitable filter rating. This method considers the response of the system to the harmonic production of NL + NLDG.

Comparison of two algorithms: In this study, two algorithms, TDO and OOA, are compared and analyzed for four distinct scenarios: NLs + NLDGs (without APF), a single APF on 27 and 67, and double APFs on 27 and 67. The aim of this assessment was to evaluate their efficiency in ascertaining a suitable APF grade. TDO advantage over OOA: In all scenarios and data evaluated, the computational trials showed that the TDO worked better than the OOA by producing the least amount of APF current.

To the best of our knowledge, this is the first instance of a TDO being used to solve a problem. Computational testing was used to assess the performance of the TDO, and the value of the optimal fitness function was compared with that of the OOA. In this study, the NL + NLDG buses under consideration were simulated using the IEEE-69 RDS system to ascertain the most suitable value of the APF current employing TDO and OOA.

II. METHODOLOGY

APF, RDS modeling, HLF, and TDO are used to develop an objective function that increases PQ while reducing harmonics are all covered in this part.

II.1 MODELING OF RDS, HLF, AND APF

The three RDS parameters, impedance, resistance, and inductance, are represented in a harmonic environment in line with [37]. As stated in [37], a harmonic generator was used to represent the APF. Harmonic analysis was performed using the network topology-based HLF approach [38]. The two correlation matrices that form the basis of this method are the BCBV and BIBC.

II.2 OBJECTIVE FUNCTION

The objective function (OF) is an important aspect of the optimization process. Constrained nonlinear problem: Identification of the proper APF rating to reduce harmonics. In this instance, the decision component is the APF current.

Because the cost of the APF increases with its current rating, it is imperative to lower the current. The following three restrictions were considered to raise the PQ in RDS with APF: The three variables are THDv, IHDv, and Iapfmax. Whereas the third standard limit depends on the NL current, the first two are required by IEEE Standard 519. The objective function is expressed as

$$OF_{apf} = \min \sum_{m=1}^{n} \sqrt{\sum_{h=2}^{H} \left| I_{apf,m}^{h} \right|^{2}} + DP \tag{1}$$

The highest-order harmonic in this formula is denoted by H. The dynamic penalty is denoted by DP. The total number of buses is n, and the representation of the bus number is m. The objective function is subject to the following restrictions.

$$\begin{aligned} THD_V - 0.05 \le 0 \\ IHD_V - 0.03 \le 0 \\ I_{apf} \le I_{apf,MAX} \end{aligned} \tag{2}$$

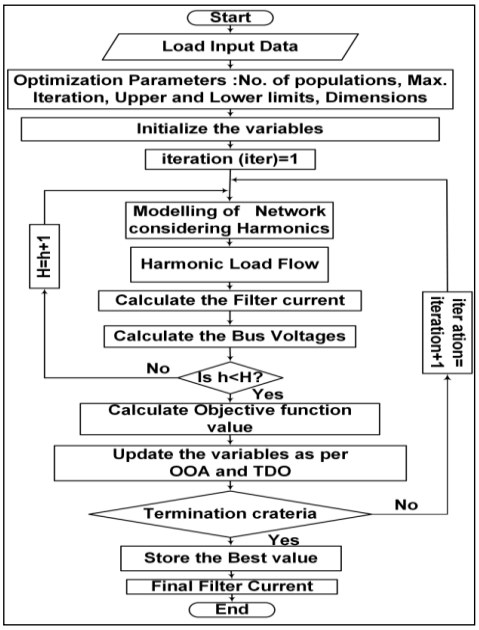

Figure 1: Flowchart.
Source: Authors, (2026).

Figure 1 shows a flowchart of the application of the TDO to reduce harmonics and enhance PQ in RDS. As shown in Figure 2a, this study uses a modified IEEE-69 bus RDS [39], where the buses in the system with NLs are linked to the NLDGs. The 5^{th} to 49^{th} harmonics in the NLs' harmonic spectrum match the features of a six-pulse converter [4]. The NLs are carefully placed at the end nodes of RDS buses 27 and 67, as shown in Figure 2a. Matlab code simulating the presented optimization can be seen form Figure 2b.

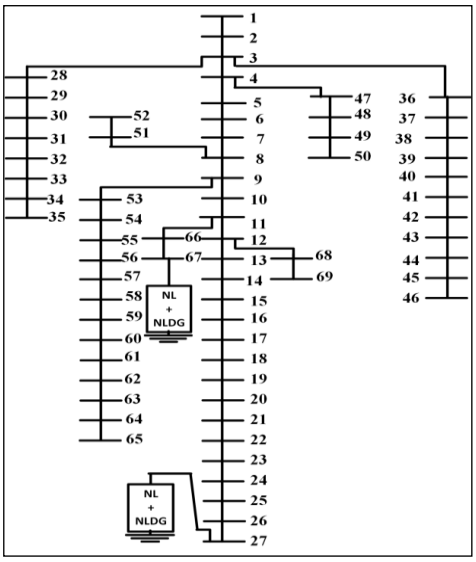

Figure 2a: IEEE-69 bus RDS.

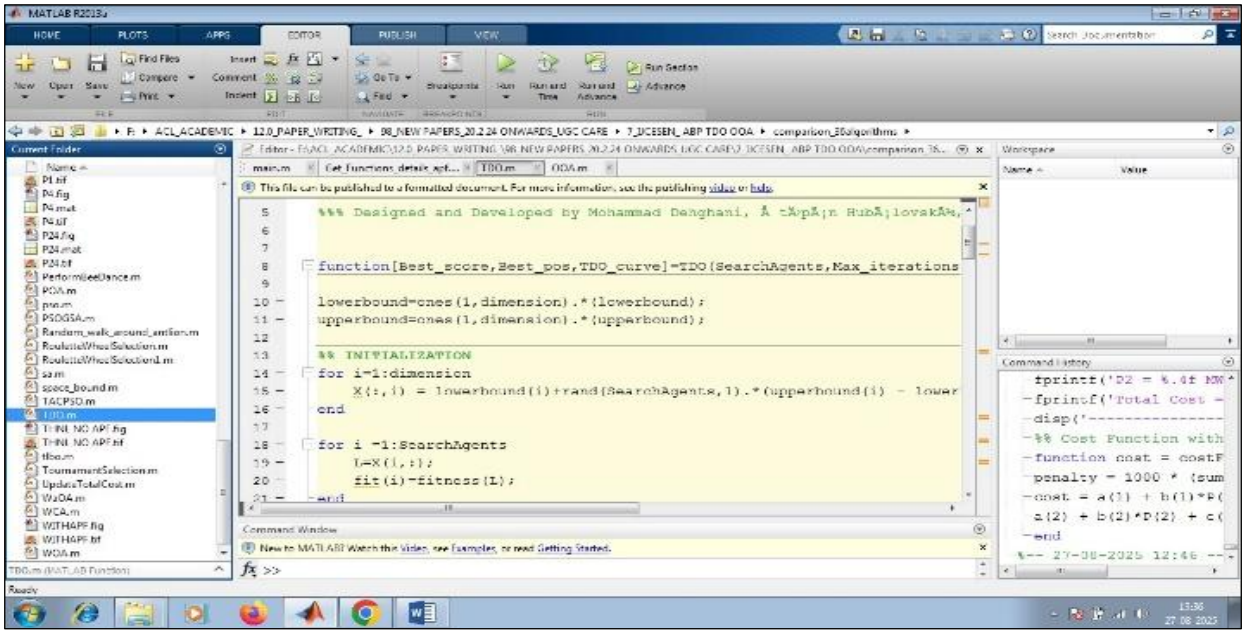

Figure 2b: Simulation setup.
Source: Authors, (2026).

II.3 THE PROCEDURE FOR SIMULATION

First, the pertinent data from the test system, including the harmonic spectrum, were loaded. The optimization parameters were specified in the next step. Step 3 is a simulation of the harmonic context created using the inputs. HLF analysis should be performed in Step 4. In step 5, the THDv should be computed using the NLs and NLDGs. Incorporate the APF into the system prior to step 6. The APF is included in the HLF in step 7. In Step 8, the minimum practical APF current is determined using the TDO. Step 9: Define the termination standards for the approach. Similarly, identical actions are performed for the OOA.

III. RESULTS AND DISCUSSIONS

As shown in Figure 2a, the IEEE-69 bus system has two NLs + NLDGs at buses 27 and 67. This example has only two nodes with NLs + NLDGs, but the harmonic influence is amplified and affects all 68 buses in the system. Without the APF, the HLF determines the THDv% of each bus, as shown in Figure 3. The THDv values of 40 of the 68 buses (excluding the first bus, which is a source bus) show that harmonics have a considerable effect on the RDS; these readings are larger than 5%. Remarkably, only two buses have NLs + NLDGs, and all buses have THDv. A bus cannot fulfill the IEEE standard limit if its THDv is greater than 5%. It displays the low PQ of the RDS. NLs + NLDGs were present on buses 27 and 67.

For the two buses, the THDv values were 27.34% and 11.68%, respectively. In total, 40 buses exceeded the THDv 5% threshold. The information above suggests that the RDS is somewhat contaminated with harmonics. Harmonic filters must be used to adhere to the IEEE standard limitations. Buses 27 and 67 were allocated the APF concurrently with the NLs + NLDGs. The scenario consisted of one APF on bus 27, one APF on bus 67, and two APFs on each bus. The APF rating is a crucial factor to consider because it directly affects the system cost. The TDO optimization process determines the required APF current. There is a maximum population of 30 and an allowable number of iterations of 60. The steps in the applicable flowchart for the selected test system (Figure 1) were used to emulate this approach.

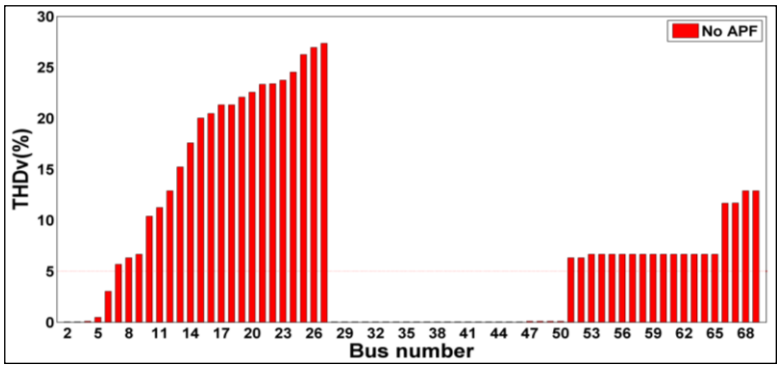

Figure 3: THDv at all buses when APF is absent.
Source: Authors, (2026).

III.1 CASE 1

Buses 27 and 67 connect the NLs and NLDGs, as shown in Figure 2a. The system was substantially harmonically distorted by these two nodes. Bus 27 (27.34%) had the maximum THDv in the absence of APF, whereas bus 67 had 11.68%.

III.2 CASE 2

To reduce the THDv as much as possible, the APF was positioned near bus 27. Figure 4 illustrates how OOA converged to a value higher than TDO (46.7726 p.u.), whereas TDO decreased to 0.0995 p.u. It has been observed that the APF should be placed on bus 27. It is the correct placement. TDO performed better than OOA under the given conditions.

III.3 CASE 3

In this case, no algorithm converged and satisfied the constraints. Because of the penalty, the OOA and TDO values are higher (72.7829 p.u.). No single algorithm can meet all requirements. This implies that bus 67 was not positioned correctly for the APF to increase PQ.

III.4 CASE 4

Buses 27 and 67 were equipped with APFs. Figure 5 shows the results of the HLF with the optimization methods. The convergence curve for each algorithm is displayed in Figure 5 under the required conditions. The TDO approach for determining the minimum APF current is shown in figure. The OOA did not converge to find the lowest APF current. However, as shown in Figure 5, the TDO method provides the minimum APF current that converges within the specified limits efficiently with a value of 0.0983 p.u. When the APFs are installed at buses 27 and 67, the TDO approach converges well; in these circumstances, the OOA calculates the APF current to be 34.2303 p.u.

This is deemed improper. Table 1 shows the comparative values of the considered algorithms.Figure 6 illustrates that the THDv values of all the system's buses are now less than 5% following the installation of APFs at buses 27 and 67. It is noteworthy that busses 27 and 67 now have THDv of 4.94 % and 5 %, respectively, as opposed to their previous THDv of 27.34% and 11.68%, respectively, without the APF and with the APFs implemented. As can be shown in Figure 6, every bus satisfies the THDv constraints of below or equivalent to 5%. As a result, improving PQ in the RDS depends critically on the bus number and sizing of the APFs.

Table 1: Comparison of Optimization Techniques.

Bus	APF	APF current by TDO	APF current by OOA	Convergence of algorithm
27	1	0.0995	46.7727	Only TDO converged
67	1	72.7829	72.7829	Both not converged
27,67	2	0.0983	34.2303	Only TDO converged

IV. CONCLUSIONS

In order to reduce the harmonics and increase PQ, this article looks into using TDO and OOA in RDS through the APFs. Even though the RDS shows the strong influence of harmonics with two NLS + NLDGs. TDO and OOA with HLF are successfully integrated in the IEEE-69 bus test system simulation. The measured THDv highlights the negative impact of harmonics on PQ, with values greater than 5% on 40 buses. The highest THDv, 27.34%, is found at bus 27. The crucial significance that APF placement plays is highlighted by the fact that THDv was successfully reduced to 5% in all buses a feat that was only possible with one APF at 27 and with two APFs installed at buses 27 and 67. Amazingly, THDv can be contained under the allowed limit on all RDS buses with just one APF and two APFs. The TDO method finds a minimum APF current of 0.0983 p.u., which satisfies the condition and converges with busses 27 and 67 successfully. However, the OOA, is unable to converge, indicating that TDOs perform better in this circumstance. In contrast, OOA converges at 34.2303 p.u., while TDO converges at 0.0983 p.u.

ABSTRACT

We conduct this research for thirty-six months from 2021 to 2023 in Souk-Ahras (Tiffech), Algeria, to evaluate the effectiveness and costs of a direct-coupled photovoltaic pumping system for agricultural irrigation, considering the region's potential for solar energy. This study presents an analytical method of dimensioning based on water quantity, sunlight data, pump group efficiency, and well and reservoir characteristics to provide insights for better economic installation management. We evaluated the viability of a solar photovoltaic- SPV, water pumping system using the software PVsyst. However, we employed artificial intelligence- AI, methods to optimize irrigation and conserve water resources, thereby enhancing energy efficiency. Four AI methods, Support Vector Machine- SVM, Random Forest- RF, Naive Bayes- NB, and k-Nearest Neighbors- kNN, are utilized. Energy-efficient systems promote a reduction in overall costs, enabling users to maintain financial balance while meeting their pumping needs. According to AI findings, the k-NN model exhibits high accuracy at 0.960 precision. The cost-effectiveness comparison of the SPV system to a diesel generator demonstrated a significant decrease in the cost of pumped water, thereby making the SPV system more viable and profitable. This approach has demonstrated its effectiveness and robustness.

I. INTRODUCTION

The Algeria, the largest country in Africa, faces increasing pressure on its water resources due to rapid socio-economic development and agricultural expansion, leading to groundwater overexploitation. With 95% of rural water supply relying on groundwater, rural farming plays a critical role in Algeria's economy, supported by government investments aiming for self-sufficiency in food supply. Photovoltaic- PV, water pumping emerges as a sustainable solution to replace diesel-powered systems, addressing both environmental concerns and declining water tables [1-3]. PV technology is economically viable, offering decentralized energy solutions, especially in rural areas where grid extension is unfeasible [4], [5]. Despite diesel subsidies reducing the appeal of PV systems, real cost analysis shows PV water pumps are competitive over their lifecycle [6], [7]. Research by [8], [9], highlights seasonal variations in PV pump performance, showing optimal efficiency at panel temperatures between 12-32°C. Similarly, [10] emphasize the economic and environmental advantages of solar irrigation systems, noting significant improvements in farm income and reduced dependency on electricity. In Souk-Ahras, Algeria, this work employs artificial intelligence and PVsyst software to assess the cost-effectiveness and performance of a direct-coupled PV water pumping system. The research is structured into four parts: panel design and sizing, motor and pump evaluation, comparative analysis based on cost and efficiency, and concluding recommendations. Findings aim to guide decision-makers in selecting the most efficient motor, optimal pump type, and suitable PV module configuration to maximize energy efficiency and cost savings. By integrating electronic control systems, the study explores how motor speed adjustments and pump type selections can enhance long-term operational sustainability. The study employs four artificial intelligence methods: SVM, RF, NB, and kNN. Ultimately, this research demonstrates the robustness and efficiency of AI-optimized PV water pumping systems for sustainable agricultural irrigation in Algeria.

II. MATERIALS AND METHODS

II.1 PRESENTATION OF PVSYST SIMULATION SOFTWARE

PVsyst is software for sizing solar panels that allows you to obtain various information such as energy production, irradiation, installation cost, area required, or annual energy production. An advanced mode makes obtaining much more information for a complete study possible pursuant to [11], [12]. The software mainly includes two modes of operation, the first and a reasonably simple pre-sizing application to learn and accessible to neophytes. The second allows a much more in-depth study and considers many more parameters. Moreover, it is based on concrete material for its calculations, unlike the first mode, which performs calculations for a general case [13], [14]. For each of the two modes, the principle is the same: the geographical location of the installation is given, then the data concerning the installation is entered. Then comes a results section where we choose the data that interests us. This software is, therefore, accessible to experienced and neophytes alike. This documentation will not deal with the "pumping installation" parts and the financial aspects in mind to [15], [16]. Sizing and simulation of a PV pumping system with the PVSyst software. We will see how to size and simulate a PV pumping system, to start it is necessary to check three settings [17], [18]. First you need to know the site and its characteristics (location, weather, irradiation, etc…). Secondly, it is necessary to know the characteristics of user needs (reservoir, well and pipes...). Thirdly, it is necessary to know the choice of components (PV panels, pump, and connection…).

II.2 CHOICE OF SITE AND THEIR CHARACTERISTICS

First of all you have to know the location. The type of installation you are considering (on the roof, on the ground, etc.). As well as the orientation of the installation, to be able to define the solar yield available. The path of the sun: In our case, choose the site of Souk Ahras (Tiffech), where the geographical and meteorological data are included in the PVsyst software. Fig. 1, represents Souk Ahras (Tiffech) geographical site parameters, the site's coordinates are 36.08 49 North, 7.46 13 East, and 889 m altitude.

Figure 1: Site parameters Souk Ahras (Tiffech) geographical.
Source: Authors, (2026).

II.3 THE CHOICES NEED OF USER

Accurate water requirement assessment necessitates data on well characteristics, storage reservoirs, and hydraulic circuits, including height, reservoir diameters, and pipe diameters. When dimensioning a PV pumping system, the primary constraints are optimizing the size of the photovoltaic generator and the pumps, considering the flow rate and the compatibility of the electric PV pump, as well as the configuration of the system chosen [19]. We start with the sizing of the pump. You must fill in the data in figure 2 below:

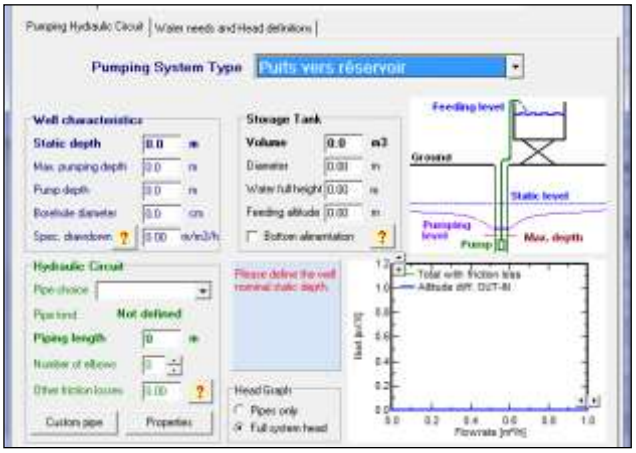

Figure 2: The need for the well, the tank and the vacuum pipes.
Source: Authors, (2026).

To determine the pump adapted to the needs, it is necessary to know several parameters, including the following:

The desired flow rate (in m^3/h);
The Total Manometric Height- TMH;
The supply voltage of the pump.

The flow rate is determined according to the needs. It is advisable to draw up a sizing sheet containing the number of cubic meters needed daily for domestic water, gardening, market gardening and drinking water for livestock. Flow Rate and (TMH), these 2 data mean the amount of operating water and the height at which the pump will have to discharge. Adding the pressure drops and the discharge pressure in the pipe will be necessary.

$$TMH = (Ha + Hr) + J + Pr\ (mCE) \quad (1)$$

The drip-fed farm is situated close to Tiffech in Souk Ahras, Algeria. It is therefore necessary for a submerged pump capable of delivering at 19 meters with a flow rate of 0.85 m³/h or 5.1 m³/day (6 hours/day). PVsyst has given us a range of pumps (brand and model). So, according to the availability in Algeria and the robustness of the brand, we chose the Allman LORENTZ product in the PS200_HR-14 range, which has the following characteristics (see Figure 3).

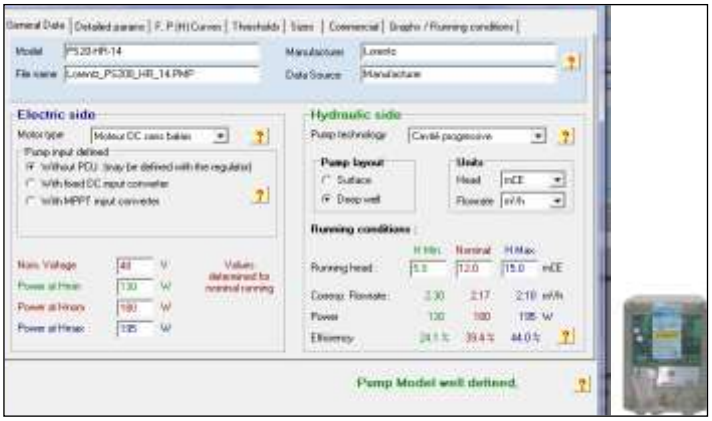

Figure 3: Pump feature PS200_HR-14.
Source: Authors, (2026).

Then, we must determine the power and number of photovoltaic panels needed to operate the pump. As a reminder, the peak watt-Wp, is the maximum power of a device. Its unit is the watt in the International System. For example, in a photovoltaic installation, this is the maximum electrical power that can be supplied under standard conditions:

An irradiance (energy illumination) of 1,000W/m^2;
A panel temperature of 25 °C;

A spectral distribution of the so-called AM 1.5 radiation, corresponding to the solar radiation reaching the ground after having passed through an atmosphere with a mass of 1 kg at an angle of 45°. If the temperature is higher than 25°C, it is necessary to count on a loss of yield of 0.4% per degree. Now that we have determined the appropriate pump, it remains to calculate the necessary power and, therefore, the number of photovoltaic panels to operate it in optimal conditions. To choose a pump that provides the desired water volume, with a specific flow rate and for a set time period, PVsyst has provided us with a selection of pumps. So as we said before, depending on the availability in Algeria also the robustness of the brand, we chose the Allman Sun Power product, in the SPR-X20-327-COM model. PVsyst allows users to simulate weather patterns by adjusting parameters and storing variables in monthly results. Figure 4 represents the influence of solar radiation variability on water production during a year.

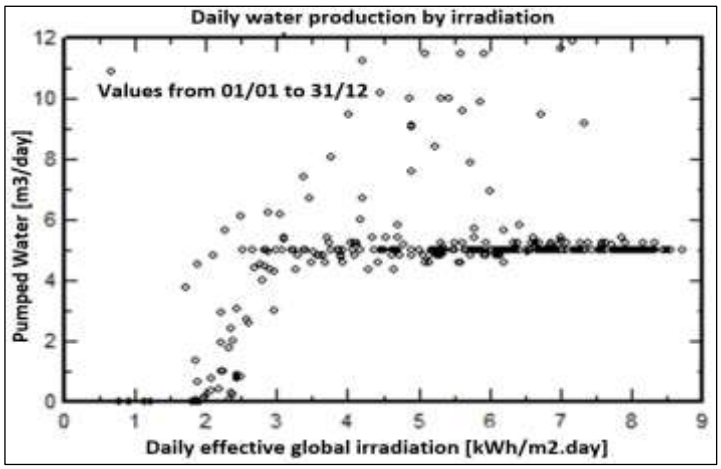

Figure 4: Daily water production according to irradiation.
Source: Authors, (2026).

We notice on the daily water production graphic display according to the irradiation that the relationship is almost linear. Knowledge of the apparent movement of the sun for a given point on the earth's surface is necessary for any solar application. The position of the sun is defined by two angles: its height HS (angle between the sun and the horizontal plane of the place) and its Azimuth AZ (angle with the direction of the south, counted negatively towards the east). Given the high price of PV modules, it is necessary to choose optimal orientations and inclinations for energy production. Optimization tool have a complete and precise calculation using comprehensive hourly weather data over a year (see Figure 5). Our software contains a tool aimed at showing the most suitable orientation for a photovoltaic pumping system where the transposition factor- FT, is the ratio of the incident irradiation on the plane, up to the horizontal irradiation. That's to say. What you gain (or lose) when tilting the collector plane.

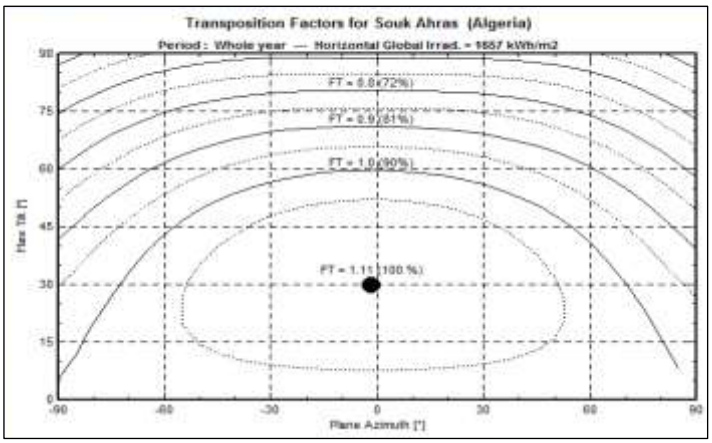

Figure 5: Souk Ahras transposition factor.
Source: Authors, (2026).

Quick optimization tool in the "Orientation" section: When choosing the plane orientation (fixed), an information panel indicates the corresponding transposition factor, the difference (loss) compared to the optimal orientation and the irradiation available on this inclined plane. So PVsyst chose an annual inclination plan of 32° (compared to the horizontal), this is the optimal inclination given by the PVsyst software, apart from the latter the yield decreases (see Figure 6).

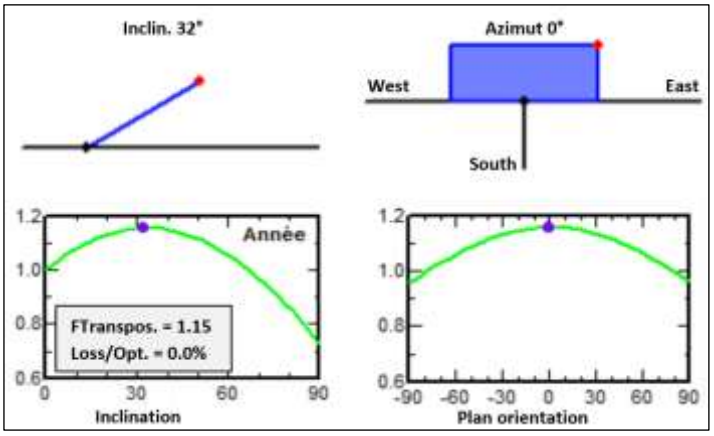

Figure 6: Optimal orientation of PV panels.

IV. RESULTS AND DISCUSSIONS

In this work, the PVSyst program was used to simulate the design and analysis of an on-grid solar PV system. The most pleasant results were found and reviewed in the results analysis section after numerous simulations runs and calibrations. The model should be simulated following the previously outlined design procedure, and the results can be analyzed to determine plant efficiency. A comprehensive simulation has been conducted and multiple outputs have been produced in order to gain a better knowledge of the installed plant. The report includes calculating energy losses from the system's operation, tracking proportional losses from solar energy receipt to pump operation. Figure 7 displays losses and includes a fee schedule. The process begins with the energy losses incurred by the system, including those from the atmosphere and shadows. The efficiency of the cells here is 20.05% after the different system losses of the construction (queues, temperature, etc.), up to the final energy that is exported from the system to the pump.

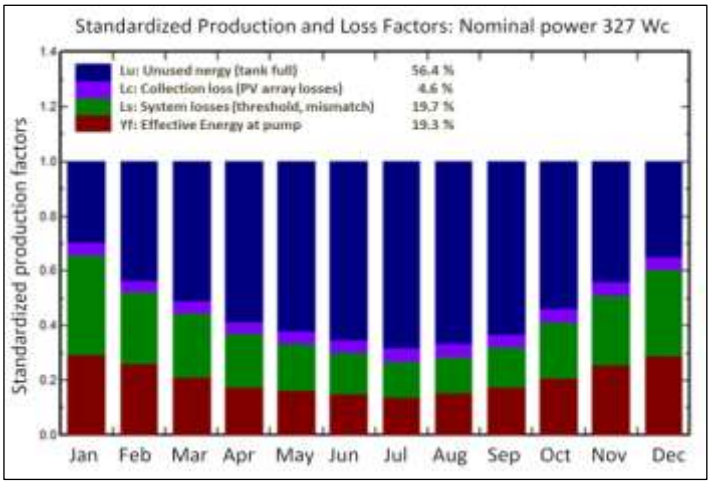

Figure 7: Standardized production and part factors.
Source: Authors, (2026).

Solar pumping systems are deep well-type, using submersible pumps at the bottom of boreholes. These pumps are designed to be below water level and connected to the surface via water pipes and electrical supply wires. The water is pumped into a storage tank, depending on sunlight availability. The system requires specific parameters such as static depth, maximum pumping depth, pump depth, borehole diameter, and specific drawdown. The storage tank and hydraulic circuit parameters are also defined. Table 2 summarizes the totals of the main results for thirty-six months from 2021 to 2023.

III.1 ECONOMIC COMPARISON WITH THE CLASSIC PUMP DRIVE SOLUTION WITH AN INTERNAL COMBUSTION ENGINE

The analysis will be restricted to a direct economic comparison between the Internal Combustion Engine- ICE and the Classic Pumping Engine- CPE, as heat engines [20]. The CPE and ICE both run on the idealized thermodynamic cycle that is employed by heat engines to transform heat into work output. The engines' methods for turning heat and air pressure into work vary widely, thus in order to compare them economically, we must examine the costs and efficiencies associated with producing the desired amount of work. The data in the economic assessment form are prepared with an investment of 240,000 DZD, covering the PV modules, pump, controller, and additional accessories. With a 17% tax, the net investment rises to 280,800 DZD. The total annual cost amounts to 22,532 DZD, spread over a 20-year depreciation period at a 5% rate. However, the amount of pumped water is 1417 m^3/year for a total annual cost of 22532 DZD/year, which gives us a cost of water per cubic meter of 15.9 DZD. Let's know that one Algerian dinar is equivalent to 0.0074 US dollars (1 DZD = 0.0074 USD). A 133 kW diesel engine is what the 133 kW generator needs to be powered by.Diesel engine fuel consumption is typically 190220g/kW/h, though this might vary depending on the equipment and fuel grade.

The computation used currently is 133 g/kW/h: 133 (kW) × 0.2 (kg) × 6 = 159.6 (kg). Diesel No. 0 (your 133 kW diesel generator) has a density of roughly 0.84 (kg/l), so 159.6/0.84 = 190 (l). In six hours, this diesel generator uses about 190 liters. Diesel generators typically use 0.2 liters of fuel per kilowatt-hour of power. The fuel consumption index of diesel generators is influenced by various factors, as their energy production varies based on their fuel consumption. Algeria has one of the lowest diesel prices in the world due to subsidies. For example, the price of a liter of diesel in Algeria is 29 DZD (~ 0.2146 US Dollars) for an average world price of diesel of 1.26 (US Dollars). Fuel subsidies are therefore considered as a shortfall or a potential loss for the State, which sells petroleum products, particularly fuels, below their international price [21]. The question that arises is until when the price of fuel will remain subsidized in Algeria? To this end, in this study, we will not take into consideration the current price of a liter of diesel in Algeria and we will use the world average price.

In the preceding section, the PVsyst software computed the cost per m^3 of water pushed by the PV water pumping system; however, the cost per m3 of water pumped by the diesel water pumping system was not computed. Consequently, the cost annuity technique, which is based on the Life Cycle Cost-LCC, analysis, is used to determine the cost per m3 of water pushed by diesel water pumping system [22].

$$cost\ of\ m3\ of\ water\ pumped = \frac{Annualised\ LCC}{Total\ pumped\ water} \quad (2)$$

Table 3 shows the economic comparison with the classic pump drive solution with internal combustion engine.

Table 3: Economic comparison with the classic pump drive solution with internal combustion engine.

	Classic Pumping Engine	**Internal Combustion Engine**	
Price of diesel per liter (USD)	/	Algeria	Global
		0.2146	1.26
Pumped water (m^3/Year)	1417		
Total annual cost (USD/Year)	166.74	40.75	239.40
Water cost (USD/m^3)	0.1176	0.0288	0.1689

Source: Authors, (2026).

The viability of a solar photovoltaic (SPV) water pumping system has been examined in this work. Water costs about 0.1176 (USD/m^3). If a diesel generator is utilized in place of the SPV water pumping system, the cost of pumping water would be about 0.1689 (USD/m^3) in the absence of any subsidies. When a subsidy is taken into account during simulation, the price of water drops to 0.0288 (USD/m^3). The SPV water pumping system is more practical and cost-effective than the diesel system, according to the life cycle cost study of pumping water. The economic comparison of electric motor drive direct voltage for low voltage networks is justified for irrigation systems like sprinklers. The engine must maintain constant speed, be cheap, and have reduced maintenance costs, making it suitable for medium and large-scale irrigation systems [23]. Variable Frequency Drives- VFDs, are costly for low-powered pumps and have poor electromagnetic compatibility. New technologies utilize direct-drive variable voltage supplies for pumping. These motors draw power from solar systems at variable voltages, converting 24 V DC to AC. This allows photovoltaic-powered AC pumps, helping Algerian farmers reduce electricity costs.

III.2 ARTIFICIAL INTELLIGENCE CLASSIFICATION OF THE PUMP POWER

Artificial intelligence (AI) and machine learning must be used to preserve water resources (optimization of irrigation) and maximize energy efficiency. To this end, optimizing the irrigation of crops can adjust the amount of water supplied to crops according to their actual needs, and enhanced energy monitoring enables precise and efficient management of solar energy in farms. These techniques use sensors and intelligent systems. First, they optimize crop watering by obtaining real-time information on soil humidity, temperature and rainfall. They also improve energy efficiency by adjusting the charging parameters to the actual energy needs. To achieve this goal, in this work, four AI methods have been used: Support Vector Machine (SVM), Random Forest (RF), Naive Bayes (NB), and k-Nearest Neighbors (kNN) algorithm. After processing the data used for the learning and testing of our model, two classes were chosen taking into account the power (low, strong), knowing that there is a correlation between the power and water quantity. However, as shown in Figure 8, four confusion Matrix illustrate the classification of each model.

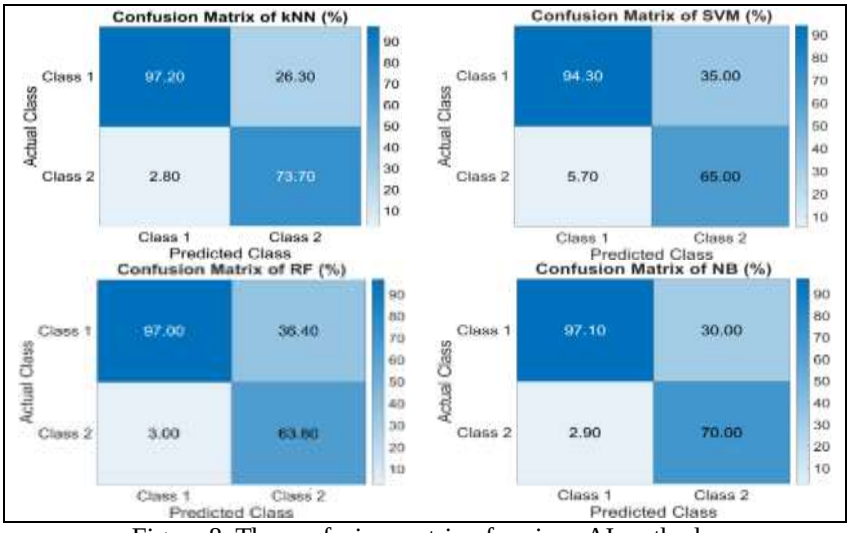

Figure 8: The confusion matrix of various AI methods.

Source: Authors, (2026).

The performance parameters of AI models are calculated from equations (3-7), based on the confusion matrix, as shown in Table 4. Classification Accuracy (CA):

$$CA = \frac{TP + TN}{TP + TN + FP + FN} \quad (3)$$

Precision:

$$Precision = \frac{TP}{TP + FP} \quad (4)$$

Recall (Sensitivity):

$$Recall = \frac{TP}{TP + FN} \quad (5)$$

F-measure (F1 Score) harmonic mean of precision and recall:

$$F\text{-Score} = \frac{2 \times Precision \times Recall}{Precision + Recall} \quad (6)$$

Matthews Correlation Coefficient (MCC):

$$MCC = \frac{(TP \times TN) - (FP \times FN)}{\sqrt{(TP + FP)(TP + FN)(TN + FP)(TP + FN)}} \quad (7)$$

Where:

TP is the number of True Positives, TN is the number of True Negatives, FP is the number of False Positives, and FN is the number of False Negatives [24], [25].

Table 4: The performance parameters of the various models.

MODEL	CA	F1	PREC	RECALL	MCC
SVM	0.907	0.836	0.844	0.879	0.640
RF	0.938	0.836	0.844	0.836	0.667
NB	0.912	0.873	0.897	0.873	0.725
k-NN	0.960	0.891	0.894	0.908	0.757

Source: Authors, (2026).

According to the AI results, k-NN Classifier with k=9, Mahalanobis Metric, and Distance Weighting is the most accurate model with 96 %.

V. CONCLUSIONS

This article describes a straightforward method for sizing a photovoltaic pumping system for agricultural irrigation. We used the PVsyst software to simulate the PV pumping system at an angle of inclination equal to the latitude, allowing us to study the system's daily and monthly performance. Properly sizing a PV pumping system requires careful consideration of various factors such as site selection, site implantation and its characteristics, reservoir selection, well drilling, pump size, and panel size. Thus, it entails the validation process of a model created with PVSyst to classify the required pump power as a response to the solar radiation available in any photovoltaic system. The viability of a solar photovoltaic (SPV) water pumping system has been examined. Water costs about 0.1176 (USD/m³), If a diesel generator is utilized in place of the SPV water pumping system, the cost of pumping water would be about 0.1689 (USD/m³) in the absence of any subsidies. When a subsidy is taken into account during simulation, the price of water drops to 0.0288 (USD/m³). The SPV water pumping system is more practical and cost-effective than the Diesel system, according to the life cycle cost study of pumping water. Based on the AI findings, k-NN emerges as the most accurate model, with 96 % accuracy. Finally, the k-NN model showed high precision, demonstrating the system's effectiveness and robustness.

ABSTRACT

Our work examines the use of peanut shells, a common and cheap food waste, as a natural adsorbent for treating industrial dyes, particularly methylene blue in this study. We also performed a comprehensive analysis of adsorption, which showed that it follows both Langmuir and Freundlich adsorption isotherms, signifying that peanut shells are efficient adsorbents for methylene blue. To enhance the outcome of the adsorption, a Box-Behnken design was used in our experiment. This design enabled us to examine how various important parameters, such as the amount of adsorbent, concentration of the dye, pH, temperature, rate of stirring, and the ionic strength of dissolved salts, can affect this procedure. Also, a mathematical model and simulation of this adsorption reaction enabled us to find optimal conditions for efficient removal of this dye. In our experiments, the highest adsorption efficiency of 97% was obtained under optimal conditions of 1.5g of adsorbent, a concentration of 40mg/L of MB, a pH of 11, a temperature of 65°C, 0 mg/L ionic strength, and a stirring speed of 165 rpm. These results reveal that peanut shells can be considered a potential, environmentally sustainable alternative for removing dyes.

I. INTRODUCTION

With the growth of humanity and the advancement of science and technology, the world reaches new horizons; however, this rapid growth will carry high costs in the near future. One of its major consequences is environmental degradation, particularly the growing problem of pollution. Water and soil contamination by industrial chemicals including dyes, heavy metals, phenolic compounds, pesticides, and fertilizers are a source of serious environmental impairment internationally. Organic dyes being resistant to biodegradation with accumulation and high levels of industrial applications, especially in textile industries, possess a high threat potential for environmental and human health[1].

These synthetic dyes also have widespread use in the paper, cosmetic, and food industries as well [2]. Several treatment methods such as adsorption, filtration, coagulation, flocculation, and membrane separation have been developed to mitigate these pollutants. Of these, adsorption is acknowledged as one of the effective and simple processes for organic contaminant removal, especially when low-cost or abundant natural adsorbents are made from waste materials [1]. In the present study, peanut shell wastes, one of the most abundant wastes, were used as a low-cost adsorbent material for the removal of methylene blue, which was selected as a representative organic dye based on its extensive use in various industries.

II. MATERIALS AND METHODS

II.1 PEANUT SHELL (PS) PREPARATION PROCESSES

II.1.1 Washing

First, peanut shells were crushed using a mortar in order to obtain smaller fragments. Ten grams of this crushed material were soaked into 1 liter of distilled water for 15 minutes.

After that, it was subjected to manual stirring to ensure good contact and the improvement of interactions between solid and liquid phases. Then, the sample was filtered through a simple strainer and washed with distilled water. This washing was repeated eight times until the filtrate became transparent and free of turbidity.

II.1.2 Drying

The cleaned peanut shells were cut into small pieces and left to air-dry. They were oven-dried at 50-60°C for 24 hours to remove the moisture completely.

II.2 PREPARATION OF THE "ADSORBATE" SOLUTION

A stock solution of methylene blue (100 mg/L) was prepared and stored in the dark to prevent degradation. Serial dilutions were performed to obtain the required working concentrations. All weighings necessary for the preparation of the solutions were conducted using a precision analytical balance.

II.2.1 Calibration Curves

The calibration curve, generated from diluted dye solutions at λmax =664nm, exhibited strong linearity between absorbance (Abs) and concentration (C), confirming the method's suitability for dye analysis.

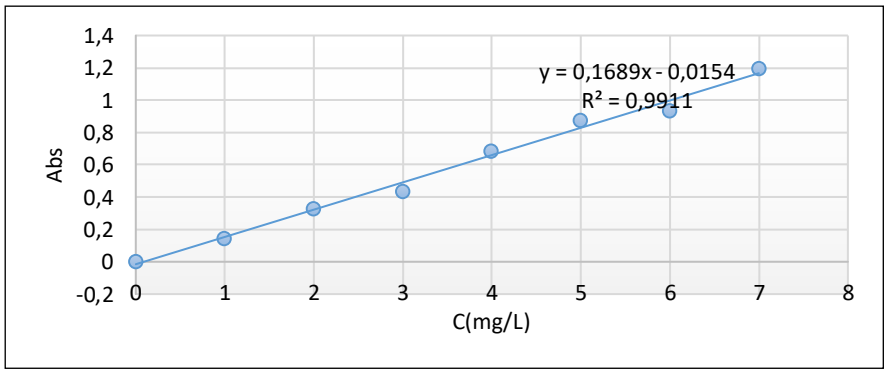

Figure 1: Calibration curve of MB at λmax =664nm.
Source: Authors, (2026).

II.3 CALCULATION FORMULAS

To determine the residual concentrations of MB in the liquid phase at time t, the linear equation is applied:

$$Y = 0.1689\,X - 0.0154 \quad (1)$$

where:
Y: the absorbance (A) at time t.
X: the residual concentration of MB at time t.
To calculate the quantity of biosorbed MB q_t (mg/g) at time t:

$$q_t = \frac{(C_0 - C_t)\times V}{m} \quad (2)$$

where:
C_0: The initial concentration (at t=0) of biosorbed MB in the liquid phase(mg/l).
C_t : The concentration of MB at time T in the liquid phase.
m: Mass of dry biosorbent (g).
To calculate the quantity of MB at equilibrium q_e (mg/g), the following formula is used:

$$q_e = \frac{(C_0 - C_e)\times V}{m} \quad (3)$$

where:
C_e : The concentration of MB in the aqueous phase at equilibrium (mg/L).
V: Volume of the solution (L).
To calculate the removal efficiency of MB at time t (%), the following formula is applied:

$$R(\%) = \frac{(C_0 - C_t)}{C_0} \quad (4)$$

To calculate the change in concentration of MB after the adsorption phenomenon, the following formula is applied:

$$\Delta C = c_0 - c_e \quad (5)$$

where: ΔC : The change in concentration (mg/L).

II.4. OPTIMIZATION

II.4.1 Experimental Designs

Experimental designs allow for the optimal organization of trials in both scientific and industrial studies. They are widely applicable across disciplines and industries where the goal is to understand the relationship between a response variable, Y, and explanatory variables, X_i. These designs are particularly valuable when the aim is to explore a function of the form: $Y = f(X_i)$ [3].

II.4.1.1 The Studied Factors

Table 1: Levels of the Studied Factors.

Levels	$C(BM)(mg/l)$	m (*Waste*) (g)	pH	$T(^0C)$	$C(NaCl)$(mg/l)	Stirring speed (rpm)
-1	5	0,2	2	30	0	0
0	22.5	0.85	6.5	47.5	0.05	115
$+1$	40	1,5	11	65	0.1	230

Source: Authors, (2026).

II.4.1.2 Measured Responses

Table 2: Measured Responses.

N	(1)	(2)	(3)
Responses	$Qm\ (mg/g)$	$\Delta C\ (mg/L)$	R (%)

Source: Authors, (2026).

II.4.1.3 Box-Behnken Design

In 1960, Box and Behnken introduced experimental designs that directly establish second-degree models. Each factor in these designs is evaluated at three levels: -1, 0, and +1. These designs are user-friendly and possess a sequential nature, allowing researchers to start with an initial set of factors and later add more without compromising previous results. The Box-Behnken design for three factors is depicted as a cube with 12 edges, typically including three central points in the study domain. Thus, the design involves 12 edge points plus 3 central experiments, totaling 15 experiments. [4]. The first experimental design measures two responses: Q_m and ΔC, while considering three factors: concentration (C), pH, and the mass of the peanut shell. The second experimental design focuses on yield (R) and examines three factors: temperature, ionic strength (NaCl concentration), and stirring speed (VA).

III. RESULTS AND DISCUSSION

III.1 EFFECT OF INITIAL CONCENTRATION

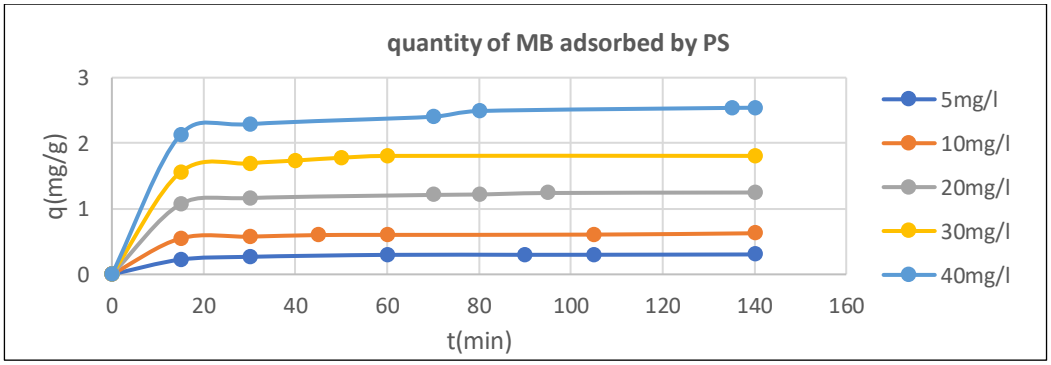

Figure 2: The effect of initial concentration on MB adsorption.
Source: Authors, (2026).

The sorption capacity of the biosorbent rises with increasing time, which shows that methylene blue [2] sorption depends upon the initial concentration. The dynamic equilibrium for MB adsorption takes place after a period of one hour, with higher MB adsorption as the initial concentration of MB becomes higher. The initial period of rapid adsorption takes place in the initial 50 min, where many adsorption sites are available on the surface of the adsorbent. With increasing time, longer periods are needed for diffusion of the molecules into the pores of the adsorbent, while the remaining amount that is not adsorbed is due to surface saturation of sites.

III.2 MODELING OF ADSORPTION ISOTHERM EQUILIBRIA

The Langmuir and Freundlich equations are employed to model adsorption isotherm equilibria. These equations accurately relate experimental data and provide insight into the adsorption reaction.

III.2.1 Langmuir Model

The modeling of the experimental results of the MB adsorption isotherm by PS using the Langmuir equation is presented in the following curve: $\mathbf{1/q_e = f(1/C_e)}$**……. (6)**

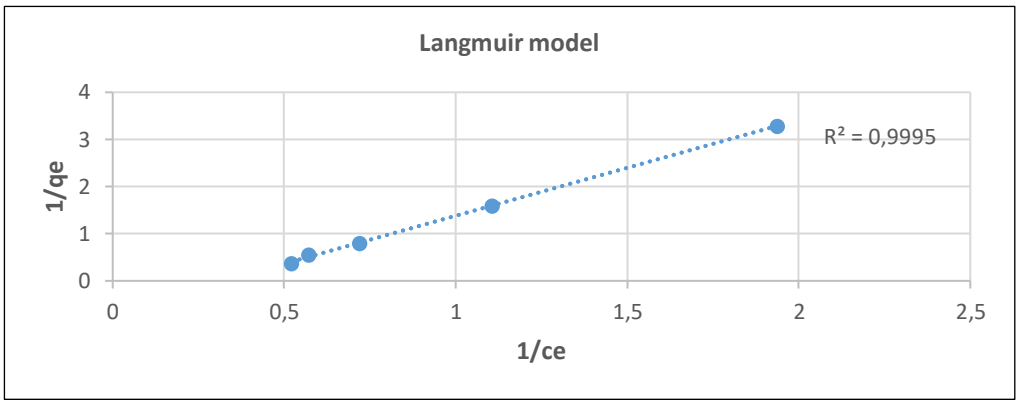

Figure 3: Modeling of the MB Adsorption Isotherm by PS using the Langmuir Equation.
Source: Authors, (2026).

According to the curve, we have:

$$1/q_e = 2.0344(1/C_e) - 0.6531 \quad (7)$$

III.2.2 Freundlich Model

The modeling of methylene blue [2] adsorption onto peanut shells (PS) using the Freundlich isotherm is illustrated in the accompanying curve. The correlation coefficients (R^2) obtained from the Langmuir and Freundlich models are 0.999 and 0.98, respectively. Although both models are suitable, the Langmuir model offers a better fit for the experimental data of MB adsorption.

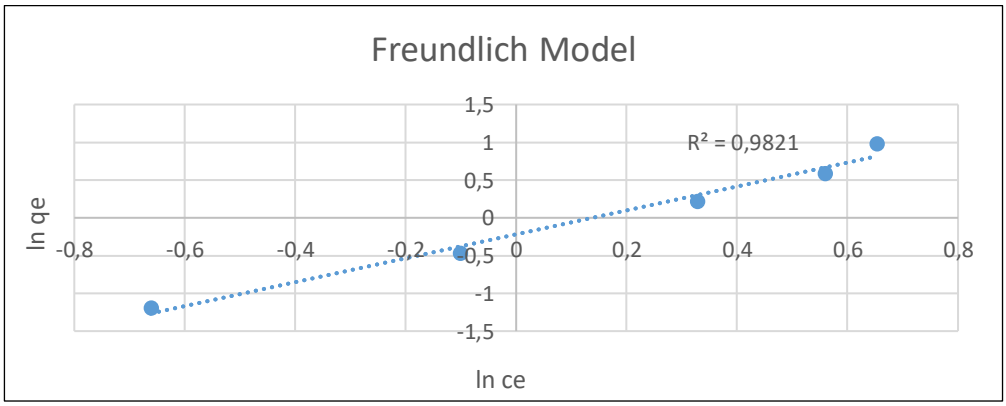

Figure 4: Modeling of the MB Adsorption Isotherm by PS using the Freundlich Equation.
Source: Authors, (2026).

Adsorption isotherms enable the analysis of the equilibrium behavior of methylene blue [2] and offer insights into the mechanisms involved in the adsorption process. Several models, including first-order and second-order kinetic models, are documented in the literature to describe adsorption kinetics.

III.3 ADSORPTION KINETICS OF MB

III.3.1 First-Order Kinetic Model

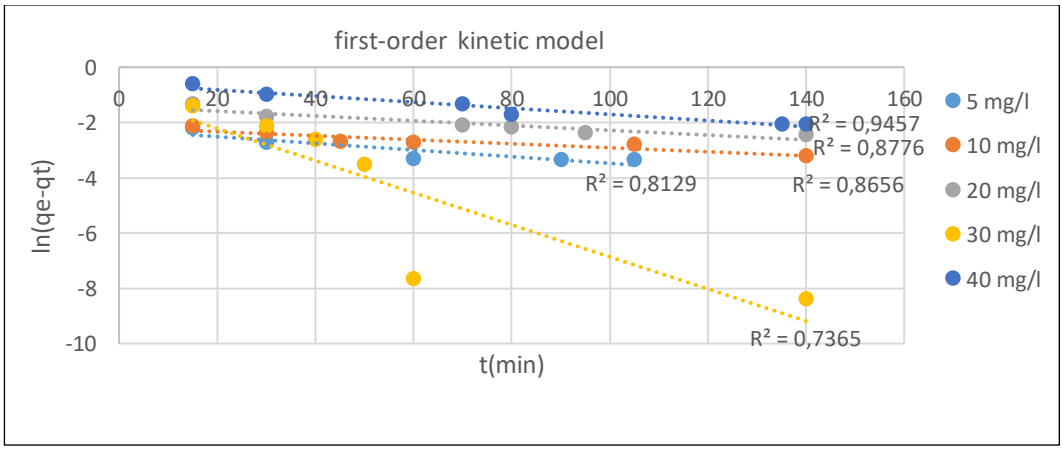

Figure 5: First-order kinetic model.
Source: Authors, (2026).

III.3.2 Second-ORDER KINETIC MODEL

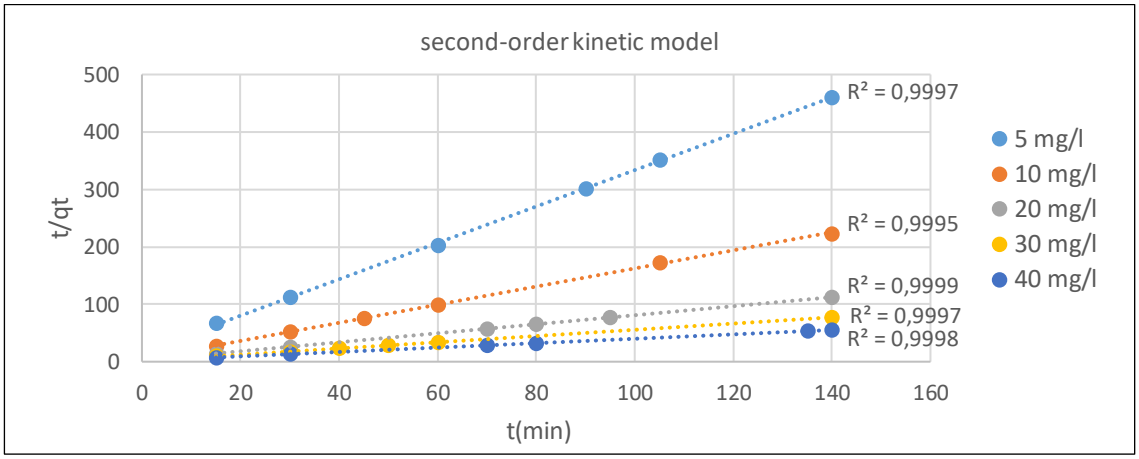

Figure 6: Second-order kinetic model.
Source: Authors, (2026).

The results indicate that the correlation coefficients for the pseudo-first-order and pseudo-second-order kinetic models demonstrate that the adsorption kinetics are best described by the pseudo-second-order model for the studied adsorbent.

III.4 OPTIMIZATION OF MB ADSORPTION

The regression coefficients were calculated using coded data in MINITAB software version 19, and the response surface was generated using Design Expert software version 11.

III.4.1 Response Analysis of Qm

The first experimental design: Analysis of the Response Qm

III.4.1.1 Analysis of Variance (ANOVA)

Table 3: Estimated Regression Coefficients for Qm (Current Unit).

Table 4: Model Summary.

S	R Square	R Square (Adjus)	R Square (Predi)
0,967547	94,59%	91,59%	76,14%

Source: Authors, (2026).

According to Table 3, the model exhibited high significance with a very low p-value (p = 0.005), as shown by the ANOVA for the regression models. Additionally, the linear effects, with a p-value of 0.001, indicate a significant influence of the main factors (C and m) on conversion. A significant interaction effect was also observed for C × m. The ANOVA results in Table 7 show a determination coefficient of R^2 = 94.59% and an adjusted R^2 = 91.59%, both close to 1, indicating a strong model fit to the actual system. Furthermore, the predicted R^2 = 76.14% demonstrates a good correlation between measured and predicted values. The effects are further illustrated in the accompanying Pareto chart.

III.4.1.2 Regression Equation In Uncoded Units

The analysis of variance (ANOVA), after excluding non-significant terms, indicates that all remaining terms are highly significant. This confirms that the refined model is statistically superior.

$$Qm = 2{,}60 + 0{,}2806\ C - 9{,}46\ m + 0{,}1129\ pH + 5{,}27\ m^2 - 0{,}1803\ C \times m$$

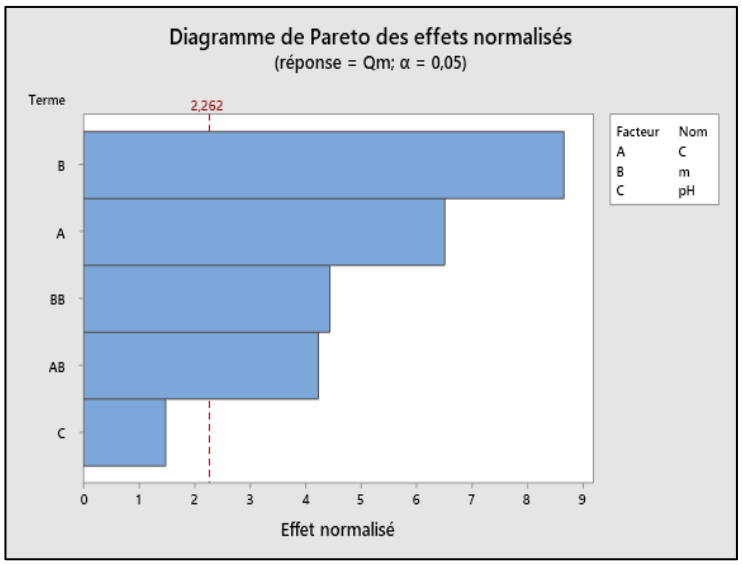

Figure 7: Pareto Chart of Normalized Effects for the Response Qm.

III.4.1.4 Model Validation

The experimental conditions selected to validate the mathematical model are the upper levels of each factor:

Table 5: The experimental conditions chosen to validate the mathematical model are:

Variable	C	m	pH
Configuration	40	1,5	11

Source: Authors, (2026).

Under these conditions, the model estimated a response of Qm = 1.73436. To validate the mathematical model, a new experimental verification was conducted, yielding a result of Qm = 1.949714.

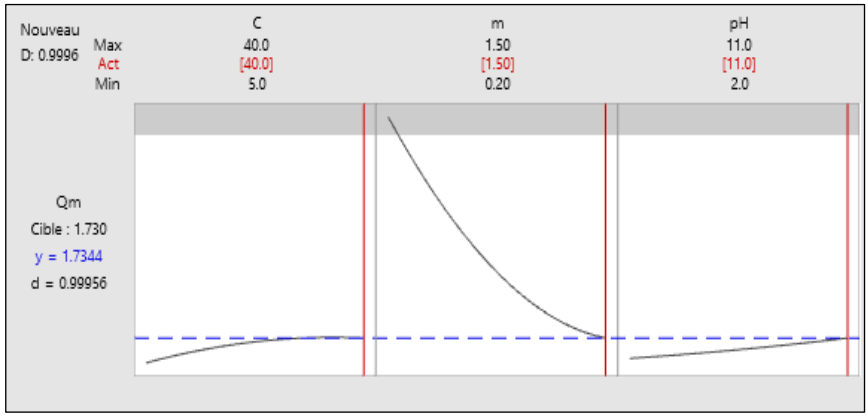

Figure 10: Estimation of the Response Qm at the High Level of Factors.
Source: Authors, (2026).

The desirability value (d = 0.999) is very close to 1, indicating that the model is well-validated and accurately predicts the adsorption behavior under the given conditions.

III.4.1.5 Response Surface Analysis

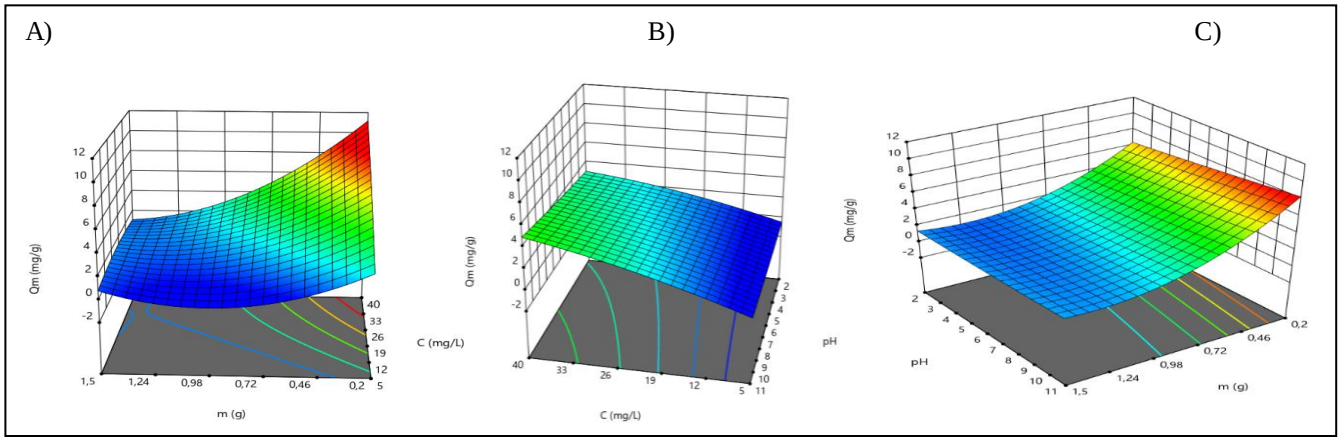

Figure 11: Response Surface Diagram Showing the Effect of each of two factors on Qm.
Source: Authors, (2026).

Figures 11, illustrate the effects of adsorbent mass, pH, and MB concentration on adsorption. Each figure shows the combined influence of two factors on the response (Qm), while the third factor is held constant at its midpoint.

III.4.2 Response Analysis of ΔC

III.4.2.1 Analysis of Variance (ANOVA)

Table 7: Model Summary.

S	R Square	R Square (Adjus)	R Square (Predi)
1,93067	97,64%	96,33%	92,42%

Source: Authors, (2026).

According to Table 6, the model exhibited high significance, with a very low p-value ($p \leq 0.005$) as indicated by the ANOVA of the regression models. The linear effects, with a p-value of ≤ 0.0001, suggest a significant impact of the main factors (C, m, and pH), indicating that conversion varies based on these linear terms. Additionally, significant interaction effects were observed for C × m and C × pH. From the analysis of variance and the values in Table 11, the coefficient of determination (R^2 = 97.64%) and the adjusted R^2 (96.33%) are both close to 1, signifying that the model is well-fitted and accurately reflects the system's behavior. Furthermore, the predicted R^2 = 92.42% indicates a strong correlation between measured and predicted values. The effects are illustrated in the following Pareto chart.

III.4.2.2 Regression Equation In Uncoded Units

After excluding non-significant terms, the analysis of variance (ANOVA) shows that all remaining terms are highly significant, confirming that the refined model is statistically superior.

$$\Delta C = 4{,}82 + 0{,}215\,C - 1{,}67\,m - 0{,}48\,pH + 0{,}2157\,C \times m + 0{,}0467\,C \times pH$$

Table 11: Model Summary.

S	R Square	R Square (Adjus)	R Square (Predi)
0,511223	99,00%	97,99%	95,07%

Source: Authors, (2026).

According to Table 10, the model is highly significant, as indicated by a very low p-value ($p \leq 0.0001$) from the ANOVA of the regression models. The linear effects, with a p-value of ≤ 0.0001, demonstrate a significant impact of the main factors (T, C, and VA), suggesting that conversion varies according to these linear terms. Additionally, a quadratic effect is observed for the squared term VA^2 ($p \leq 0.0001$), and a significant interaction effect is noted for C × VA. From the analysis of variance and the values in Table 16, the coefficient of determination (R^2 = 99.00%) and the adjusted R^2 (97.99%) indicate that the model fits well and accurately describe the system's behavior, as both values are close to 1. The predicted R^2 (95.07%) also indicates a strong correlation between the measured and predicted values. The effects are further illustrated in the accompanying Pareto chart.

III.4.3.2 Regression Equation In Uncoded Units

The analysis of variance (ANOVA), after excluding non-significant terms, shows that all remaining terms are highly significant. Thus, we conclude that the refined model is statistically superior.

$$R = 91{,}363 + 1{,}074\,T - 2{,}533\,C + 3{,}262\,VA + 0{,}593\,T^2 + 0{,}866\,C^2 - 2{,}619\,VA^2 + 0{,}872\,C \times VA$$

III.4.3.5 Response Surface Analysis

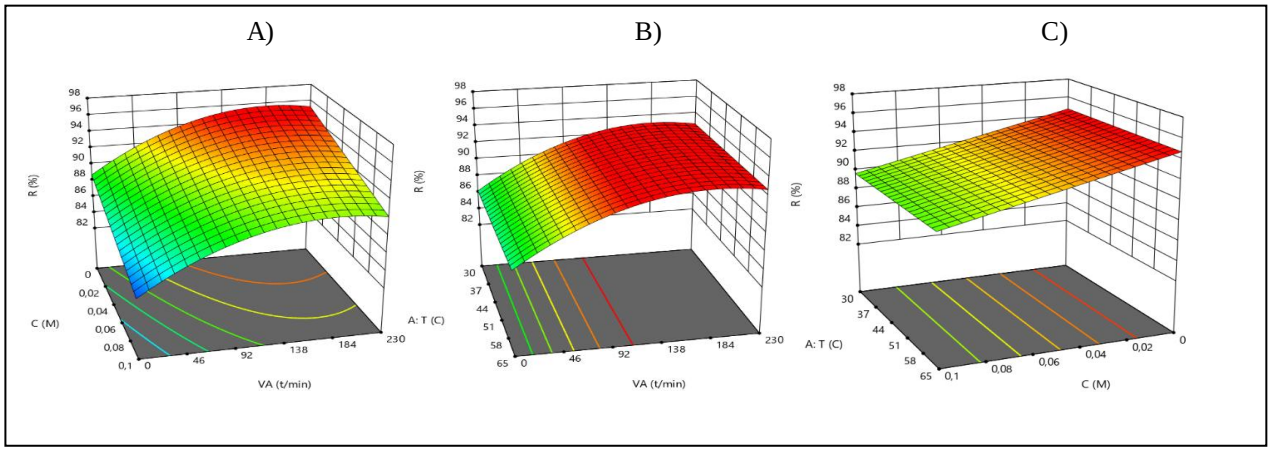

Figure 21: Response surface diagram showing the effect of each of two factors on R.
Source: Authors, (2026).

Figures 21 show the effect of the adsorbent mass, pH, and NaCl concentration on adsorption. Based on the two optimization experimental designs, the highest yield was achieved at the following factor levels:

Table 13 : Table of optimal values.

m(g)	C_{MB}(mg/l)	pH	VA	$C_{Na\ Cl}$(mg/l)	T(C°)
1.5	40	11	167,273	0	65

Source: Authors, (2026).

The value of pH has a very significant influence on the adsorption of MB. This is due to the effects of pH values on either the charges of the adsorbent's surface or the nature of MB Mall, Srivastava [5] . With low pH values, which correspond to high H^+ ion concentrations, the adsorbent particles acquire a net positive charge, resulting in a lack of attraction between the MB particles, which are also positive in nature. This, in turn, reduces the efficiency of MB adsorption onto activated carbon [6]. At higher pH values, where there is a lack of acidity in the environment, hence low H^+ ion concentration, a negative charge develops on the surface of activated carbon, which pulls MB particles due to their positive nature, hence increasing their adsorption [7]. Findings from studies show that the highest MB adsorption occurs in conditions of high pH values, with a peak in alkaline conditions [8] [9]. These findings correspond with our experiment results obtained from modeling. The amount of adsorbent used has an important role in determining the efficiency of MB dye adsorption.

With an increase in the amount of adsorbent, the number of adsorption sites also enhances, hence increasing the adsorption capacity owing to the enhanced surface area for binding of MB dye [10]. But beyond a point, an increase in the amount of adsorbent contributes little to the adsorption, as most of the adsorption sites are saturated [11]. Additionally, excess amount of adsorbent can cause a decrease in adsorption due to binding of particles, hence decreasing the surface area for adsorption. This has been supported by various studies related to MB dye adsorption [12].Water salinity has been shown to greatly influence MB adsorption due to changes in ionic strength in solutions. This means that higher water salinity, which contains ions from salts like NaCl, may lower MB adsorption efficiency [13]. Ions in dissolved salts increase competition for reactive sites on adsorbent surfaces, hence decreasing MB adsorption. Higher ionic strengths in solution also cause screening effects, which decrease adsorption between negatively charged adsorbent surfaces and MB chromophores due to reduced electrostatic interactions between MB and negatively charged adsorbents [14].

Stirring rate plays a significant role in the adsorption of methylene blue [2] dye, as it promotes mass transport between MB molecules and the adsorbent. Higher stirring rates can increase the rate of diffusion of MB molecules, which can also result in a thinner boundary layer around particles of adsorbent [15] with higher rates of adsorption. On the other hand, a stirring rate that is too high can lead to phenomena like particle agglomeration and MB desorption due to intensified turbulence, which in turn decreases adsorption efficiency [16].

Temperature plays a major role in influencing the adsorption of MB, in terms of both speed and capacity. Higher temperatures increase the molecular motion of the MB, hence increasing the rate of diffusion of MB towards the adsorption surface [17]. Higher temps also result in increased porosity of the adsorption surface, hence increasing its adsorption capacities due to higher available sites for adsorption [18]. Morphological analysis of the peanut shell was performed using scanning electron microscopy (SEM). At high magnification, the SEM micrographs revealed simple pitted cell walls with cave-like or porous structuresThe high adsorption efficiency is attributed to the peanut shell's spongy structure, which is rich in pores, facilitating the stabilization and retention of methylene blue within the material.

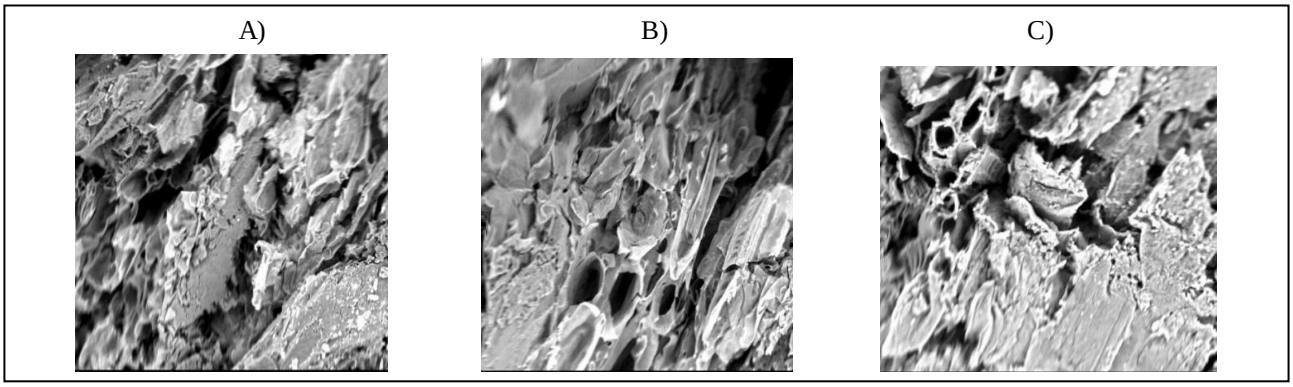

Figure 22: The morphological analysis of the peanut shell with SEM device before the adsorption process.
Source: Authors, (2026).

The following images were taken after the adsorption process and show the saturation of PS with MB.

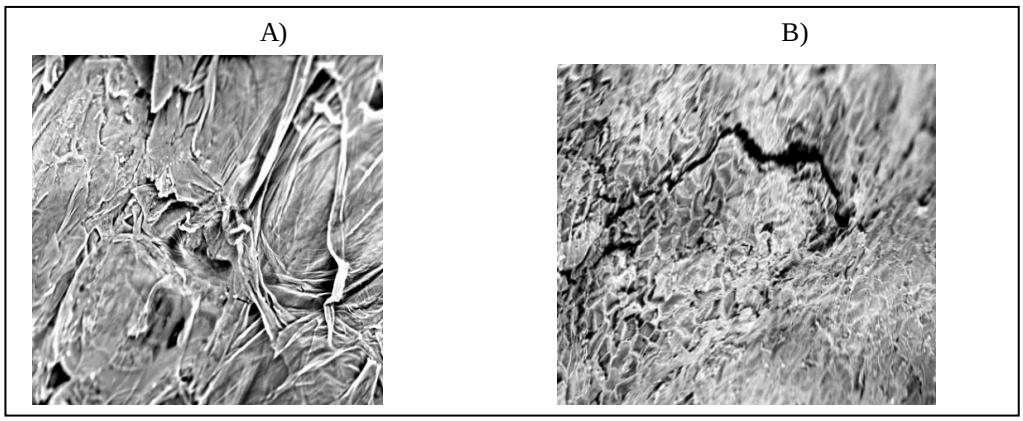

Figure 23: The morphological analysis of the peanut shell with SEM device after the adsorption process.

IV. CONCLUSIONS

The objective of this work is to study the elimination of methylene blue [2], which is a synthetic (cationic) dye present in textile industry effluents, by the adsorption technique. “Box-Behnken” is the experimental design adopted which facilitates our work to obtain the best adsorption efficiency, our results are as follows:

- The adsorption kinetics show that the adsorption process is very rapid and that equilibrium could be reached within the first 60 minutes.
- The modeling of adsorption isotherms using the Langmuir and Freundlich models shows that the Langmuir model better describes the experimental results.
- The kinetic study revealed that the adsorption process of methylene blue follows the pseudo-second-order model.
- Based on the validation of the two mathematical models with the following high-level factors: m = 1.5 g, C= 40 mg/L, and pH = 11 [2], we obtained experimental values of Qm and ΔC that are very close to the estimated values. This indicates that both mathematical models are well-fitted.
- The two experimental designs show that the yield of our study, obtained through the optimization of the response surface design "BOX-BEHNKEN," is better with the following five factors: adsorbent material mass 1.5 g, pH 11, temperature 65 °C, ionic strength concentration 0 mg/L, and stirring speed 167.273 rpm. These factors are used to achieve the maximum adsorption of methylene blue by the adsorbent (Peanut shells).
- By analyzing the two experimental designs, we achieved a yield of 97% through biosorption.

ABSTRACT

The growing volume of textual data often exceeds the capacity of available computing resources, and conventional machine learning algorithms struggle to scale up. Today, the quality of data is becoming more critical than its raw quantity: it is therefore essential to transform massive data into intelligent data through appropriate pre-processing steps. Feature selection plays a key role in this process. In this work, we propose the design of a hybrid ensemble-based feature selection framework for processing large-scale textual data. The approach is based on the MFD-AFSA algorithm combined with different feature evaluation functions, applied on multiple data subsets. To improve scalability, we also outline a distributed strategy in an Apache Spark environment, based on the Random Sample Partitioning model. Finally, we introduce an automatic approximation mechanism, which we call auto-approximation, enabling selection sets to be built dynamically via an approximation technique. This work is part of a methodological design approach; experimental validation and practical evaluations will be the subject of future work.

I. INTRODUCTION

The extensive and intensive use of communication tools everywhere produce huge amounts of data especially unstructured ones such as text, creating "Big textual Data" [1], indeed it is now more challenging to reveal useful insights in high dimensional unstructured data [2]. As a result, there has been a significant focus on methods and techniques used in text mining (TM) in order to be able to automatically extract useful information from this big textual data. In short, text mining as a process relies on a number of techniques such as textual data pre-processing, machine learning, etc. to extract high-quality information from text [3]. Recently, an up-trending concept has been introduced on how to operate a transition between Big Data to Smart Data [4], the latter focuses on the veracity and value of data, aiming to highlight the valuable data by filtering out all the imperfections and noise accumulation in high dimensional and large sample size datasets [5]. Regarding text mining, Big Data preprocessing is an essential way to achieve Smart Data. Yet this preprocessing step is heavily affected by the dimension explosion, this phenomenon motivates the dimensionality reduction of the overwhelming size of features contained in textual documents.

In such a case, only an optimal set of relevant features is considered during the learning phase. Although feature selection [6-8] is presented as a classic remedy for large-scale learning methods, this task is necessary to deal with the combinatorial explosion of the big dimension that prevents its functioning on Big Data, but also, to find the most compact and informative set of features in corpora with high degree of redundancy and irrelevance. Thus, Big Data dimensionality reduction needs new algorithms with low cost linear or sublinear runtimes while maintaining the required performance [9]. In [10] authors show that there is a gap between the growing dimensionality and the feature selection (FS) algorithms capacity in handling such data, because most feature selection algorithms lack complex requirements, such as processing speed and storage reduction in their design. Distributed and parallel computing frameworks are essential to design and implement scalable and effective feature selection, nevertheless traditional centralized text feature selection cannot be exploited directly, as it may not scale well enough to tackle this large number of features.

In fact, in distributed environment, the performance of FS methods deteriorates as the number of nodes increases, due to greater information loss [11]. Moreover, developing a parallel algorithm from scratch is often challenging and does not necessarily guarantee optimal performance. For example, subset-based selectors rely on pairwise feature correlations; in a parallel setting, this requires computing interactions between millions of dimensions distributed across different data locations, which is impractical. Another important factor to consider is the changing characteristics in Big Data, the high sensitivity of the feature selection outcomes to the slightest changes in input data i.e. algorithmic instability, affect the reliability of the learning process. This is particularly critical in contexts where data is dynamic and constantly evolving, necessitating robust feature selection methods that can adapt to these fluctuations [12]. Hence, Large-scale feature selection can be addressed from two perspectives: either by designing novel sequential methods that explicitly address the above requirements [13] or by developing distributed solutions inspired by standard methods [14, [15]. However, both approaches are non-trivial, as they involve significant challenges such as redesigning core algorithmic operations or managing the complexities and potential drawbacks of distributed implementations.

Ensemble feature selection methods have shown promising results for text classification, especially in managing high-dimensional and imbalanced datasets. These methods aim to increase the robustness and stability of feature selection by combining multiple selectors. This can be achieved either by using the same algorithm on different data subsets (data-centered ensembles) or by combining different algorithms (model-centered ensembles) [16]. Homogeneous, heterogeneous, and hybrid ensemble strategies have been explored, often relying on rank aggregation techniques to merge feature rankings and enhance classification performance [17]. Furthermore, ensemble feature selection is generally more robust to noisy data and offers better stability than individual feature selection algorithms when dealing with high-dimensional inputs [18]. In addition, distributed ensemble feature selection approaches can optimize computation time by subsampling the full feature space into manageable subsets. This reduces algorithmic complexity and improves classification accuracy without the need to explicitly design parallel feature selection algorithms. Although the ensemble feature selection is intrinsically amenable to a distributed implementation, the adaptation of a novel ensemble feature selection to Big textual Data scenarios is still an ongoing process, studies that permit an ensemble evaluation based on scalability, accuracy, diversity and stability are lacking in the scientific literature [19].

Basically, there are two main approaches to achieving parallelism in ensemble feature selection: (1) applying different feature selection models independently to the same big dataset, or (2) applying a single feature selection model to multiple training subsets derived from the original dataset. In terms of scalability each model has its pros and cons, for the former, analyzing a big data set at once by each method may require more resources than the ones available in order to build an ensemble feature selection model, though needless to parallelize the feature selection and thus avoiding the superfluous communications within the computing cluster. The second model is more suitable to large-scale feature selection since each model is constructed on multiple subsets of the big data which alleviates the complexity and the size of the dataset in timely manner, noteworthy the number and the size of the optimal training sets for ensemble feature selection is still debatable [20], [21]. The computational cost of an ensemble method depends on the number of its components, i.e., the data subsets, which are generated using a sampling technique such as the bootstrap resampling scheme [22]. This approach involves creating multiple samples–with replacement–from the original dataset, each having the same size as the original. Nonetheless applying bootstrapping on Big Data is computationally intractable, as an alternative, authors in [23] introduced the Bag of Little Bootstraps (BLB) which performs bootstraps on smaller samples of data then combines the results, the efficacy of BLB was demonstrated in constructing ensembles of classifiers in [24], where dramatic gain in training time was achieved.

Even with the advantages of BLB, the whole distributed big dataset needs to be loaded and scanned each time a small sample is drawn, rendering the random sampling process in computing clusters prohibitively expensive. An especially relevant question in the context of Big Data is whether ensemble feature selection requires processing the entire dataset, or whether comparable results can be achieved using only a limited number of data subsets. According to [25], using the full dataset offers little additional efficiency, as a small set of representative subsets may be sufficient to produce approximate yet reliable results. This idea aligns with the principles of approximate computing [26], a promising approach aimed at reducing resource consumption and computation time in cluster-based environments by trading exactness for efficiency. To address the challenges associated with large-scale text data sampling, feature selection can be reformulated as an asymptotic ensemble approach. In this way, incremental processing is applied to small representative subsets of data in order to gradually improve the selected features. The aim is to get a robust and reliable set that closely matches the results from the whole dataset while reducing computational costs. Considering these factors, our contribution consists of the conceptual design of the following essential components:

i. In order to improve the stability and diversity of the selected textual features, a hybrid textual feature selection framework (HTFSE) is designed by diversifying the data and feature selection techniques.
ii. An ensemble strategy of filter-based feature selection techniques is proposed, where words are ranked using multiple and heterogeneous feature evaluation functions (FEFs), without relying on a predefined cut-off threshold for subset selection.
iii. A distributed and parallelizable architecture for the framework HTFSE by using Apache Spark to enable efficient processing of large-scale text data.
iv. An integration of approximate computing into the ensemble process, combined with the Random Sample Partition (RSP) model, to reduce computational cost while preserving approximation quality.
v. A conceptual model for automatic hyperparameter adjustment, referred to as Auto-Approximation, designed to construct ensemble approximations adaptively and efficiently.

The remaining sections of this paper are organized as follows. Section 2 reviews recent research related to feature selection and ensemble learning methods in the context of Big Data text mining. Section 3 presents the proposed conceptual framework a hybrid ensemble model that leverages both data perturbation and function perturbation to increase diversity at multiple levels. The framework's elements and architectural integration into a distributed Apache Spark environment are also described in this section.

In Section 4, the theoretical contributions and implications of the proposed approach, as well as its future implementation, are examined. Finally, Section 5 concludes the paper and outlines directions for further work, particularly in terms of its implementation.

II. RELATED WORK

Text classification depends a lot on feature selection (FS), especially in Big Data environments where high dimensionality and data volume make performance and scalability a challenge. Despite their simplicity, traditional FS techniques such as TF-IDF, Mutual Information (MI), Information Gain (IG), and Chi-Square (CHI) are commonly used [6]. But, in large, dispersed, and unbalanced textual datasets, they frequently fall short in capturing deeper semantic relationships or scaling effectively. Filters, wrappers, embedded approaches, and whether they rely on subset evaluation or individual feature ranking are the usual categories into which classical FS methods are divided [6]. Because of their independence from particular classifiers, speed, and algorithmic simplicity, filter-based approaches are the most appropriate for large-scale settings [27]. However, the exponential growth of data in both volume and dimensionality has exposed the limitations of traditional FS techniques, which often suffer from memory bottlenecks and high computational costs. That's what led to the development of scalable FS solutions designed for parallel and distributed computing frameworks like Hadoop and Spark. As an example, [28] proposes DiReliefF, a distributed version of the ReliefF algorithm, implemented in Apache Spark to efficiently process large-scale datasets.

The algorithm keeps the accuracy of the original ReliefF while improving scalability and processing time a lot, which makes it useful for Big Data applications. Similarly, [29] introduces RDTFD, a Particle Swarm Optimization (PSO)-based FS method tailored to text classification. While it improves accuracy over traditional filters, it leads to greater runtime and has not been parallelized, raising questions about its applicability to large-scale datasets. A comprehensive overview of FS in Big Data is given by the survey in [30], which also highlights enduring issues like data heterogeneity, scalability, and real-time constraints. It also encourages parallel and cloud-based adaptations across FS paradigms. Textual data presents even more pronounced challenges due to its high dimensionality, sparsity, and semantic variability. Traditional FS algorithms become inefficient or ineffective in such settings. In response, several methods have been designed specifically for large-scale text. In [31], a MapReduce-based implementation of TF-IDF was introduced to accelerate Naïve Bayes classification. Although it showed improved efficiency, the system was deployed on a single node, limiting knowledge of its scalability. Using max and mean weighting, GTFIDF [32], which is deployed on Apache Hadoop, suggests a global TF-IDF approach. On large corpora, it performs better than conventional filter methods; however, it does not assess the effect of scaling node clusters.

All documents in a category are combined into a single document using CTF-CHI² [33], a MapReduce-based combination of Chi-Square and category-term frequency for multi-label classification. Although correlation modeling is improved, there is a chance that term importance will be distorted, and feature thresholding and scalability are not well understood. Hybrid approaches like MTF-MI (Maximum Term Frequency–Mutual Information), which are implemented in Hadoop, are presented in other studies, such as [34]. It demonstrates the well-known trade-off between relevance and scalability by outperforming CHI, MI, and TF-IDF in F- measure performance but degrading performance as feature count rises. Ontology-guided methods such as Taxonomic Feature Selection [35] address semantic limitations by organizing terms hierarchically. Though effective in generalization, these methods require curated taxonomies, reducing portability across domains. Additional advancements include frequency-discriminative methods for distributed FS implemented on Apache Spark, such as ALOFT, MFD, MFDR, and cMFDR [36]. Features are ranked by ALOFT according to local significance and document frequency. To refine feature sets, MFD and its variations use class-aware filtering, redundancy reduction, and mutual information. Although these methods are more appropriate for large textual datasets, they still depend on statistical heuristics, which might ignore semantic or contextual richness.

Recently, new FS paradigms that transcend frequency-based heuristics have been inspired by large language models (LLMs). The works in [37] suggest text-based and data-driven FS strategies in which features are chosen based on attention patterns or embeddings from models such as LLaMA-2, ChatGPT, and GPT-4. Although these techniques improve robustness and semantic interpretability, they are computationally demanding and do not have native parallelism. Moreover, scalability depends on access to high-performance GPU clusters, and effectiveness hinges on the quality of textual descriptions, posing reproducibility and cost barriers. Furthermore, reproducibility and cost barriers arise because efficacy depends on the quality of textual descriptions, while scalability depends on access to high-performance GPU clusters. Ensemble feature selection has also been explored to improve stability, robustness, and classification performance in large-scale settings. For instance, [38] proposes an ensemble strategy by combining three baseline feature selection techniques: C4.5 decision tree, Principal Component Analysis (PCA), and Genetic Algorithm (GA), which stand for filter, wrapper, and embedded approaches, respectively. After comparing serial and parallel configurations, the study concludes that serial combinations produce feature sets that are more precise and condensed. It is noted that future research should focus on the stability of ensemble feature selection techniques, which have not yet been thoroughly investigated.

Furthermore, the suggested methods' applicability to Big Data contexts is limited because they are specifically tested on high-dimensional, low sample size datasets and fail to address the scalability problems that arise in large-scale datasets with both high dimensionality and a large number of instances. [39] suggests an ensemble of algorithms inspired by nature (OCFA, OCSA, OBBA, and MGWO), that improves performance but is unclear when it comes to aggregation and hasn't been tested on large datasets. [40] improves classification outcomes by combining Biogeography-Based Optimization (BBO) with Bagging; however, scalability has not been demonstrated. For social media sentiment analysis, [41] develops a Hybrid Ensemble Learning Model (HELM) which combines IG, CHI2, and AdaBoost; however, it ignores scalability and optimization.[42] suggests using Random Discretization (RD) together with PCA to create varied training subsets in order to address data imbalance. This enhances classifier diversity but suffers from long prediction times on imbalanced Big Data. DiCFS [43] implemented on Spark, introduces a distributed correlation-based FS (CFS) using horizontal and vertical data partitioning. It achieves strong performance but requires dataset-specific tuning and shows sensitivity to dimensionality. In [44], a new approach for selecting viral genomic sequence features is proposed. This approach, called PRCFX-DT, is based on probabilistic graph modeling to measure the importance of codons based on their centrality in the graph, which allows features to be extracted from genomic sequences.

This makes it possible to capture complex dependencies that conventional feature selection techniques might overlook. Although graph-based techniques have been developed for Big Data, their computational complexity remains very resource-intensive for very large data sets, requiring significant amounts of memory and processing power. Table 1 provides a comparative summary of the related works discussed above. Numerous distributed or parallel feature selection methods have been developed to address the challenges posed by high-dimensional data. While they generally save time and memory resources, they also have limitations. For example, DiReliefF, based on Spark, offers better performance than its MapReduce version, but it remains dependent on fixed data partitions and does not allow for incremental updates or intelligent aggregation of results between different subsets. Other approaches like those based on evolutionary algorithms give good results in terms of accuracy but are often computationally expensive and difficult to interpret.

More recent strategies, combining task parallelism or hybrid approaches, have been explored, but they rarely address essential aspects such as the stability and robustness of the selected feature, especially in the context of textual datasets, which are often massive and complex. Another common issue is the assumption that all data is available from the beginning, or the use of fixed partitions. This can lead to unreliable variable choices, especially when dealing with noisy, heterogeneous, or changing data. Very few studies focus on progressive or asymptotic strategies that are capable of learning gradually from representative samples while limiting computational costs. These limitations motivate our work, which aims to design ensemble feature selection in the context of Big Data as an asymptotic and incremental process, aligning distributed learning constraints and efficiency goals. In the next section, we detail the conceptual foundations and architecture of our proposed approach. Table 1 provides a comparative summary of the related works discussed above.

Table 1: Comparison of feature selection strategies in the context of Big Data.

Ref Year	FS technique	Type of data	Parallelization	Scalability	Limitations
[28] 2018	DiReliefF	Numerical & categorical	Data Parallel	a high degree of scalability for large datasets, especially when using horizontal partitioning	The potential inefficiency when dealing with extremely large and high-dimensional datasets.
[29] 2020	RDTFD (positive/negative discrimination), PSO optimization.	Textual Spam corpora	Parallel PSO considered (not implemented).	Medium to High	High time cost, limited generalizability to spam.
[31] 2018	TF-IDF	Textual	Data parallelism	Medium	Single node environment. Scalability not verified in multi-node environments
[32] 2021	GTFIDF	Textual	Data parallelism	Medium	Single node environment. Time cost of node increase not analyzed.
[33] 2020	CTF-CHI²	Textual	Data parallelism	Medium	Combining documents into one aggregated document per category can impact feature relevance
[34] 2021	MTF-MI	Textual	Data parallelism (Hadoop/MapReduce)	Medium	Becomes less performed for a given threshold of selected features.
[36] 2019	ALOFT, MFD, MFDR, cMFDR, AFSA for automation.	Textual	Moderate, as filters are parallelizable, but no distributed framework is mentioned	Moderate (scalable filter and AFSA, limited by lack of Big Data)	Limited generalizability across classifiers and feature evaluation criteria
[37] 2024	LLMs: GPT-4, ChatGPT, LLaMA-2	umerical & categorical (biological + clinical)	Not specified (LLM intrinsic capability).	scaling up LLM size enhances text-based methods more consistently	Performance scales with model size, but limited by compute and diminishing returns. LLMs struggle to handle high-dimensional inputs (e.g., genomic features) at scale.
[38] 2020	Parallel & serial combinations using PCA, GA, and C4.5 FS methods	Genomic Textual	No explicit parallel implementation tested	Potentially scalable via parallelism, but not tested on large-scale datasets. No data partitioning limits applicability in Big Data contexts.	Focuses on low-sample-size datasets despite the mention of big data; lacks data partitioning into subsets, preventing complexity reduction through distributed computation
[39] 2020	aggregation of OCSA, OCFA, OBBA, MGWO	Biomedical	Adaptable to parallel environments due to algorithm independence, but not implemented or tested on a cluster.	OCSA, OCFA, OBBA, and MGWO are wrapper- based methods requiring repeated classifier evaluations per feature subset, which limits scalability due to high computational cost on datasets with many features or large sample sizes.	Focused on high- dimensional, low-sample-size datasets; scalability to large datasets not assessed.
[40] 2020	BBO	Textual	Bagging enables potential parallelization, but no implementation (e.g., MapReduce/Spark) or distributed experiments are reported.	While the use of subsets via Bagging improves scalability for large datasets the wrapper-based nature of the BBO algorithm increases computational complexity. The scalability remains untested on truly large- scale (big	High computational complexity due to BBO (wrapper); lacks discussion on the number/size of data subsets used for Bagging.

				data) datasets.	
[41] 2020	Ensemble FS (IG and CHI²)	Textual	No explicit parallel implementation.	While filter methods (IG, CHI) are scalable for large textual datasets, the sequential nature of AdaBoost and the lack of experimentation on massive big data limit the overall scalability of the approach	Not well-suited for large corpora: the Twitter datasets tested are not explicitly described as massive
[42] 2021	Ensemble FS (RD and PCA)	Tabular	The solution is designed for big data scenarios and leverages the MapReduce paradigm to distribute computation across multiple nodes. Each decision tree is trained on an independent data subset, making the approach highly parallelizable	Highly scalable (Spark, distributed SMOTE), empirically validated in a big data context	Complexity of distributed SMOTE, reliance on decision trees, and lack of discussion on subset optimization
[43] 2019	DiCFS	Numerical	Two parallelization strategies: horizontal & vertical partitioning using Apache Spark	Highly scalable (Spark, distributed correlation calculations), tested	Quadratic complexity, partitioning choice data- dependent.
[44] 2025	PRCFX-DT	Genomic sequences	No explicit integration of parallelization strategies	Limited scalability for large-scale or high-dimensional data	Computational limitations and efficiency

III. DESIGN OF THE PROPOSED FRAMEWORK

We propose a framework that addresses the large model-to-large data challenge. The goal is to leverage the strengths of ensemble learning in a Big Data context without having to choose between scaling the model or scaling the data. The key idea is to explore how a powerful machine learning pipeline can be effectively applied to both the learning process and large-scale data. To achieve this, we introduce a flexible ensemble framework that combines data perturbation and model perturbation strategies to maximize diversity. This results in a novel hybrid ensemble feature selection approach tailored for big textual data. The design of the proposed framework follows a multi-stage process, as illustrated in Figure 1.

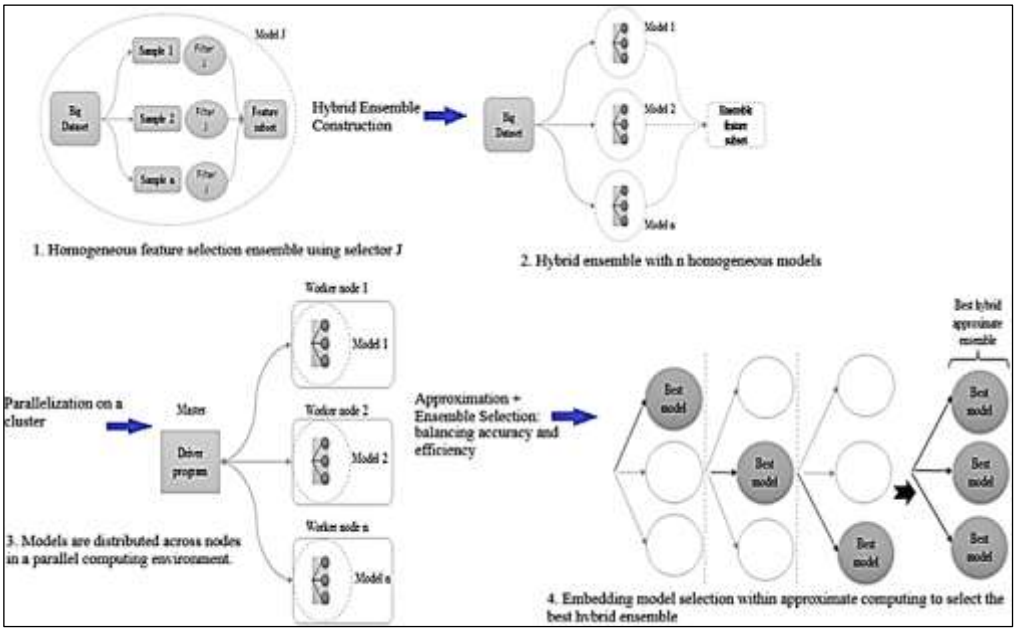

Figure 1: Variation of Spacing with Suspension Preload.

III.1 FILTER METHODS

Maximum Features per Document (MFD) [35], is a filter-based feature selection method that uses a Feature Evaluation Function (FEF) to rank features. It requires a parameter f, which represents the number of features to select per document. The method selects the top-f ranked features in each document to construct the final feature set. Unlike traditional FS methods that select m features from the entire corpus, MFD focuses on per- document selection. This strategy significantly reduces the search cost for the optimal f compared to the global optimization of m. To automate the choice of the f parameter, we use the Automatic Feature Subsets Analyzer (AFSA) [45], an auxiliary method designed to configure f dynamically. We use the combined $MFD - AFSA$ approach in the design of our ensemble system. This decision is driven by the fact that it does not depend on a predefined threshold and is suitable for environments with limited time and computational resources. Previous studies have demonstrated that MFD-AFSA provides a more efficient and scalable alternative in such contexts [36].

III.2 HYBRID TEXT FEATURE SELECTION ENSEMBLE

Feature selection ensemble techniques remain relatively underexplored in text mining (TM), especially compared to the widespread use of ensemble classifiers in sentiment or text classification tasks. However, the robustness (or stability) of the selected feature subset is as crucial as its optimality, particularly in knowledge discovery scenarios where interpretability and consistency are key. Two major ensemble strategies exist in feature selection:

- Homogeneous ensembles (data perturbation) [17]: These rely on resampling the dataset (e.g., via Bagging or Random Sampling [46–48]) to generate multiple randomized versions. The same feature selection method is then applied independently to each subset, improving robustness through repeated evaluations.
- Heterogeneous ensembles (function perturbation): These apply different FS algorithms (base selectors) to the same original dataset. By promoting functional diversity, they aim to produce a more reliable and domain-representative feature subset [17], [47].

Our approach was guided by the following finding: to design a holistic ensemble, we propose a hybrid ensemble that integrates multiple homogeneous ensembles into a heterogeneous one. The goal here is to inject diversity both at the data level (via partitioning) and the algorithmic level, in an effort to provide a trade-off between robustness and stability. As illustrated in Figure 2, the proposed Hybrid Text Feature Selection Ensemble (HTFSE) framework for Big Data is constructed through the following steps:

1. Preprocessing: Raw unstructured text is cleaned through tokenization, stop-word removal, and stemming across all documents in the corpus.
2. Representation: The cleaned corpus is transformed into a numerical document-word matrix using the Bag-of-Words (BoW) model.
3. Partitioning: The document-word matrix is randomly partitioned into k subsets, each referred to as a Matrix Block (MB). This strategy (detailed in Section III.4) simulates data perturbation for homogeneous ensembles.
4. Homogeneous Ensemble Construction: Each homogeneous component is built in parallel by randomly selecting one set of matrix blocks, e.g., MB1, MB9, MB15 and MB4, then the same Text Feature Ranker $TFRjj$ is applied to each matrix MB yielding different rankings.
5. Micro-Aggregation: The rankings produced by each homogeneous ensemble are aggregated using simple but effective rank fusion strategies: mean rank, geometric mean, and best rank, as formalized in Equations (1)-(3). These functions compute a global relevance score for each feature f_j , reflecting its importance across the ensemble of document subsets.

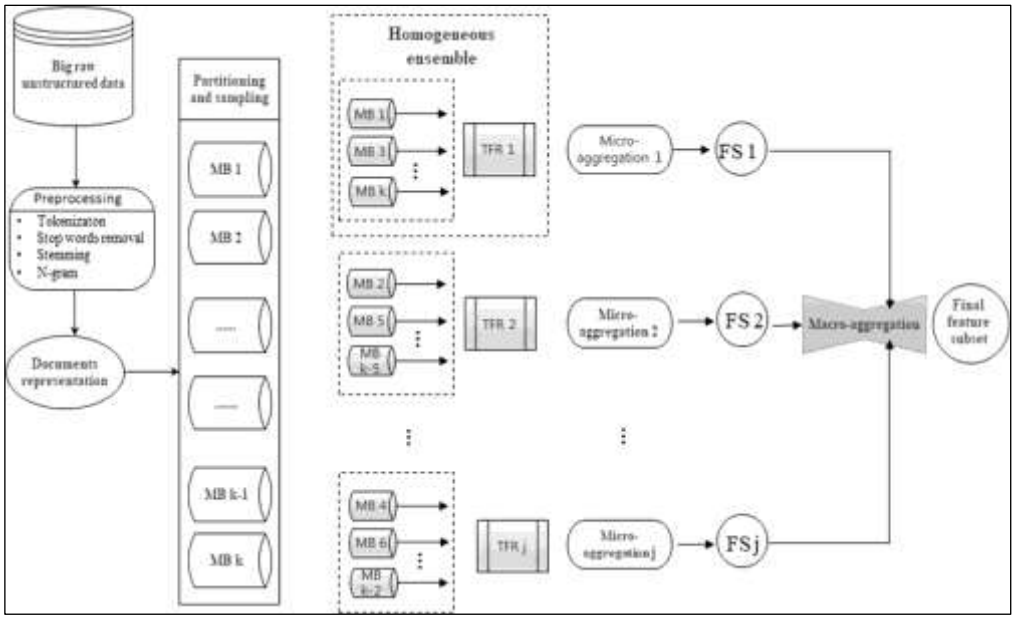

Figure 2: Overview of the hybrid text feature selection ensemble framework.
Source: Authors, (2026).

$$Mean = \frac{1}{I}\sum_{i=1}^{I} R_i(f_j) \quad (1)$$

$$Geom.mean = (\prod_{i=1}^{I} R_i(f_j))^{\frac{1}{I}} \quad (2)$$

$$Best.rank = Max\left\{R_i(f_j)\right\}_{i=1}^{I} \quad (3)$$

Where:

R is the relevance score of feature f.
I denotes all the positions that feature f has achieved among all rankings based on Text Feature Ranker TFRj.

1. The above-mentioned steps are repeated for each homogeneous ensemble for j different base selectors, generating intermediate feature subsets {FS1, FS2, FSj}.

2. Finally, the Macro-aggregation module a union- based combination of the diverse ensembles' outcomes is adopted trough equation (4) in order to estimate the finale subset of features.

$$Macro-agg(FS_1, FS_2, ..., FSj) = \bigcup_{j=1}^{J} FS_j \quad (4)$$

We apply the MFD-AFSA method across diverse Feature Evaluation Functions ($FEFs$). The pseudo-code of the hybrid $MFD-AFSA$ ensemble approach is presented in Algorithm 1.

Algorithm 1: Pseudo-code for the hybrid MFD-AFSA ensemble.

Input: *D, N, k, Q*
D//Pre-processed Dataset
N//The number of the Feature Evaluation Function (FEF)
Q //The number of matrix blocks
k// The number of matrix blocks in one batch
Output: EFS ensemble feature subset

```
1 :  Begin
2 :  S = Matrixblocks_Sampling (D,k)
3 :  For j=1 to N
4 :      For i=1 to k
5 :          FSi,j= Compute MFD-AFSA(MBi,FEFj)
6 :      End for
7 :      FSj=Micro_agg {MFD_AFSA(MBi)}        //i=1,..,k
8 :  End for
9 :      EFS= Macro_agg {FSj}                 //j=1,..,N
10 : End
```

Source: Authors, (2026).

The proposed algorithm is divided into three phases:

1. Document-term matrix sampling (line 2): The training matrix D is randomized and partitioned without replacement into QQ matrix blocks. A batch S is then created by randomly selecting k matrix blocks, where k < Q. This sample S is used to build homogeneous components.
2. Generation of intermediate feature subsets (lines 4-6): The same filtering method, denoted as $MFD-AFSA(FEFjj)$ is synchronously applied to each of the k matrix blocks in the sample. This result in k feature subsets for the $jjth$ Feature Evaluation Function (FEF). These subsets are then aggregated (line 7) to form an intermediate feature subset.
3. Construction of diverse feature models (line 3-8): Multiple filtering functions are applied independently to different sampled batches. For each FEF, a new matrix block sample is generated, leading to jj distinct intermediate subsets. These subsets are finally aggregated (line 9) through a macro-aggregation step to produce the final ensemble feature subset.

The next challenge is to choose and combine the best configurations in a scalable and computationally efficient way after the hybrid feature selection ensembles are built using MFD-AFSA and various FEFs. Due to time and resource limitations, processing the complete dataset is frequently impracticable in real-world big textual data scenarios. In order to automatically and effectively identify the most promising homogeneous ensembles while preserving high classification accuracy, the selection mechanism based on incremental approximate computing is introduced in the following section.

III.3 ALGORITHM SELECTION: AUTO-APPROXIMATION

This section presents our strategy for selecting and combining the most effective homogeneous ensemble models efficiently, with minimal computational cost and without sacrificing classification accuracy. The core idea is to construct a hybrid ensemble feature selection framework by combining the strongest homogeneous ensemble models. A versatile and efficient machine learning pipeline that can be adjusted to various datasets and feature evaluation functions (FEFs) is the goal of this hybrid approach. However, the required trade-offs between accuracy, training time, and resource consumption make it difficult to achieve such flexibility in the context of large-scale textual data. To address this, we employ incremental approximate computing within a distributed cluster environment. This strategy allows us to identify the most relevant data portions for feature selection, thereby approximating high-quality subsets that yield classification accuracy comparable to that achieved using the full dataset. A central issue we explore is the relationship between sample size, accuracy metrics, and aggregation strategies.

As illustrated in Figure 2, optimizing this framework involves tuning various big data hyperparameters –particularly those governing the structure and behavior of the hybrid feature selection ensembles. Our approach involves a greedy ensemble selection strategy [49] based on forward stepwise selection, applied to homogeneous feature selection ensembles constructed in parallel. These ensembles are designed by distributing the large-scale dataset across three different FEF-based pipelines. This strategy incrementally builds an ensemble, starting from an empty set and adding at each step the homogeneous ensemble that maximizes validation performance. In the proposed framework, we define three portfolios of homogeneous ensembles – each associated with a specific feature evaluation technique –by varying the number of sampled matrix blocks, the classifiers *Cf*, and the feature aggregation functions, as illustrated in Figure 3.

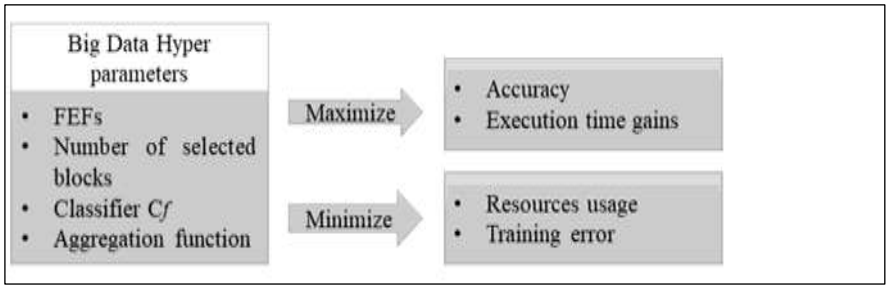

Figure 3: Hyperparameters tuning for Big Data hybrid ensemble.
Source: Authors, (2026).

Unlike the method in [43], the purpose here is not to combine different models to find the best performing ensemble, but we try to look out for the best configuration for each FEF ensemble library and then combine the three ensemble configurations into a hybrid ensemble. The selection of each base ensemble is based on the model averaging of four normalized performance metrics: the accuracy, the resources usage, training error and the execution time. Each measure is normalized to [0-1] scale and the model performance is converted to the mean normalized score across the four metrics. The superior base-level ensemble is the one that maximizes the performance measures for each FEF i.e. Max Avg {M (FEF)}. The approximate big data analysis via the Random Sample Partition RSP [50] discussed in section 3.4 , is a distributed data model that operates on randomized data blocks, is embedded within ensemble selection, this automatic ensemble construction is termed auto-approximation committed to a multiple Big Data hyperparameters setting. The homogeneous ensembles are built in parallel gradually by stepwise distribution of RSP blocks. As shown in Figure 4.

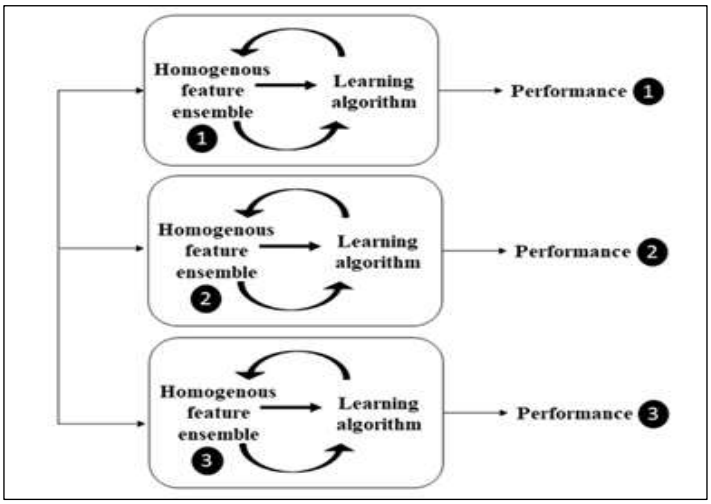

Figure 4: Parallel homogeneous ensemble library generation.
Source: Authors, (2026).

The auto-approximation strategy helps us establish the theoretical trade-offs between achieving satisfactory classification accuracy and the size of the random sample used. It also identifies the data synopsis - among the sampled RSP blocks - that is most relevant to the classification task. In addition, this approach enables the scalable construction of an optimal hybrid set (see Figure 5).

III.4 PARALLELIZATION OF THE PROPOSED FRAMEWORK HEFTS IN A SPARK CLOUD COMPUTING

Previous research can only be considered a first step towards a more profound understanding of the impactful option of the ensemble in text categorization, however scalability, speed up, stability and dataflow management of the ensemble in big text data, remains briefly addressed in the literature [48]. We proposed a multi virtual machines cluster parallelized with the Spark[i] framework and based on HDFS file system instead of using a cloud storage for better performance and for the data locality optimization (i.e. HDFS provides information about which nodes have copies of the data blocks, so the task scheduler optimize the tasks assignment), the cloud here was used as IaaS (Infrastructure as a Service) for the storage and computing purposes to build a scalable hybrid feature selection ensemble. The overall architecture of the system is shown in Figure 5. Firstly, we will plug the external library Natural Language ToolKit[ii] (NLTK) dependency to the Spark Driver, the input text files were stored to HDFS, and next Spark Driver accesses the underlying distributed file system to load the HDFS file, where a series of preprocessing methods are performed to generate the document-term matrix. Secondly the HDFS-file is partitioned and randomized through an algorithm that we will describe later. Usually when a file is loaded to HDFS, the file is sequentially partitioned into different blocks and replicated across the cluster nodes. The asymptotic ensemble model is particularly effective in Big Data scenario, as applying ensemble on the full feature space is less than optimal, so there is a need to create low dimensional feature subspace that keep the characteristics of the full space [45].

Sampling the training data in ensembles could be achieved through Bagging [51] which is a sampling with replacement of N instances of the original data, N is estimated about (63.2%) of the whole dataset [52], thus in case of a large dataset, Bagging is not suited as a sampling strategy. In the other hand Random Subsampling [53] is a good alternative to Bagging, however obtaining random samples of the huge document-term matrix requires a complete scan of the whole matrix each time a random sample is generated, such practice leads to a computationally expensive partitioning [54, 55]. In our Spark Framework we could have let HDFS manage the partitioning process through HDFS, nevertheless in these big data frameworks, the data partitions cannot be used as random samples, in fact Spark does not take into account the probability distribution of the data [56], this could lead to biased document classification. Hence to implement our Auto-Approximation framework, we adopted a two stage Random Sample Partition (RSP) technique: Data Chunking and Data Randomization, which can alleviate the problem of the unbalanced workload on different nodes due to the uneven distribution of the records, thus leading to tasks with different execution times [50]. The first stage operation is available in Apache Spark through range partition; the main characteristic of this strategy is that the statistical properties of the obtained blocks are similar to those of the entire dataset. Also, it is based on block-level sampling from an RSP model instead of record-level sampling (See Figure 6).

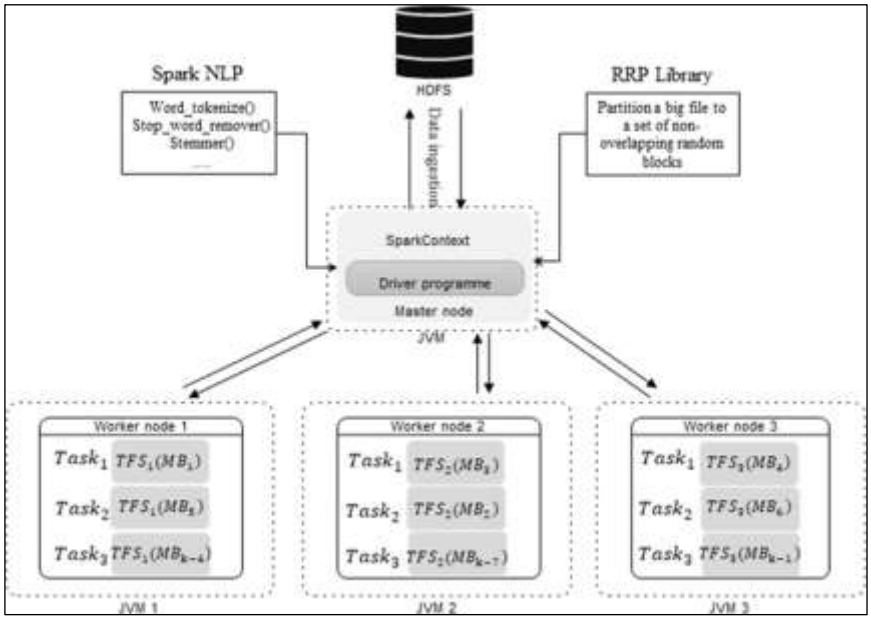

Figure 6: High-level architecture of spark inter-components interactions within cloud computing.
Source: Authors, (2026).

The document-term matrix is partitioned into *P* blocks, then stored to HDFS, consequently the matrices are converted to randomized blocks via the application of a RSP algorithm. The matrix block-level sampling consists of randomly withdrawing a batch of RSP blocks, note that the matrix blocks are generated in advance, instead of sampling a set of documents from the matrix file stored in HDFS. The HDFS matrix blocks are converted to an RSP model to obtain approximate results through round-random partitioning algorithm (RRP) [57], a horizontal partitioning scheme developed to overcome the computational cost of randomization in a previous RSP model [50], RRP assign a random document key K from RDD partition to a random block in a new RDD index calculated by K mod Q, then the resulting RRP blocks are distributed to one of Spark's executor cores (See Figure 7).

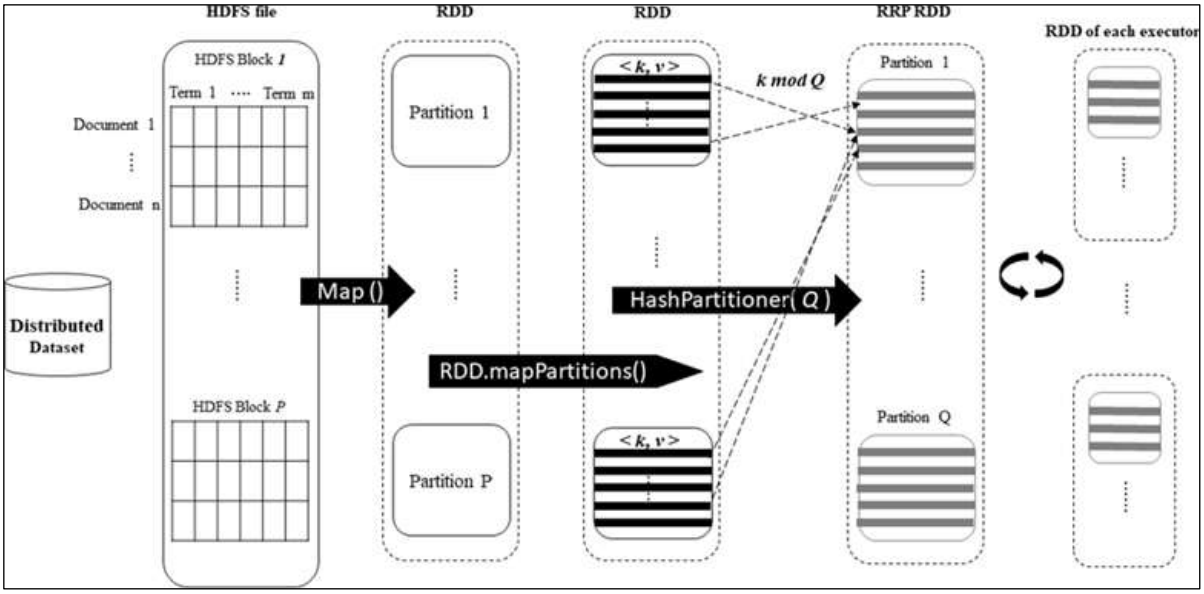

Figure 7: RSP modeling of the Documents representation using the RRP algorithm.
Source: Authors, (2026).

The reason for the text cleaning procedure before the partitioning and randomization process is that there no evidence that the same RSP data distribution is guaranteed compared to the big corpus, this automated framework not only permits to study the trade-off between the performance and RSP sample size, but it estimates how impactful would text transformations be on the representativeness power of RSP model.

IV. DISCUSSION

We have proposed a hybrid ensemble approach by decomposing the set of documents into a set of smaller matrices via a data approximation technique. This enables the feature selection algorithm to deal with totally random subsets of small size, guaranteeing both reduction of the search space (and hence complexity) and stability of textual feature selection. In the context of Big Data, there is no universal method for feature selection, and it is often necessary to combine different approaches to obtain a relevant subset. The model we have proposed combines an approximate data sampling technique with incremental distributed computation to guarantee both efficiency and optimality. In this section, we discuss the adaptations we have introduced to design a hybrid approach adapted to Big Data issues.

IV.1 ENSEMBLE TUNABILITY

Our hybrid ensemble's tuning approach is based on model-based optimization that has been specially modified for Big Data situations. Our tuning approach focuses on scalability and performance on large training sets, in contrast to traditional ensemble feature selection, which frequently emphasizes the number of feature selectors and pruning strategies. The hyperparameters we consider fall into two categories:

1. Functional hyperparameters, such as the selection function parameter f and the appropriate classifier for each Feature Ensemble Filter (FEF).
2. Data-level hyperparameters, notably the number of random document blocks selected for each homogeneous ensemble component, executed in parallel.

These hyperparameters are optimized to maximize performance gains in the hybrid ensemble while mitigating the cost of generalization performance evaluation.

IV.2 PARTITIONING

Creating homogeneous ensemble components is generally done through K-fold Cross-Validation (CV) splitting, CV in Spark depends upon the parallelism parameter which governs the maximum number of models to be trained at one, however building a set of ensembles with Spark-CV requires the whole training to be repeated by means of resampling to train the full training set, generating a large number of models which increases the risk of overfitting and the generalization performance of the hybrid ensemble is no longer effective, also it may exceed the available resources in the cluster. In the other hand it is highly time-consuming if the required random samples are generated by record-level sampling as it reads the big corpus document-by- document. To avoid this, our approach performs sampling at the RDD partition level, not at the record level. This strategy reduces data access overhead while maintaining representative sampling, significantly improving efficiency.

IV.3 AUTO-APPROXIMATE COMPUTING

A hybrid feature selection ensemble is intrinsically highly expensive to implement, let alone when ML pipeline is combined to Big Data. To address this, our framework introduces a dual strategy:

- Model-to-data fitting: The system automatically searches for the best ensemble configuration, independent of the feature selection function or dataset size.
- Data-to-model fitting: Only a few carefully chosen samples are used, rather than the entire dataset. These significantly cut down on computation time while roughly matching the full-scale model's performance.

This bidirectional adaptation merges approximate computing with ensemble selection, a concept we term "Auto-Approximation". This not only enhances the predictive power of the hybrid ensemble but also optimizes parallel computation costs.

V. CONCLUSION

In this work, we addressed the problem of feature selection in a Big Data context, proposing a hybrid and distributed approach adapted to the constraints of Big Data. We suggest a framework combining data approximation, incremental feature selection and distributed computing based on Apache Spark. It is based on an RDD-level partitioning strategy, hyperparameter optimization in a hybrid ensemble, and automatic configuration ("Auto-Approximation") of data blocks. While preserving adequate representativeness, this approach is designed to reduce computational complexity, increase the stability of selection results, and offer a better fit between the amount of data being examined and the resources at hand. Our future work will include a deep experimental evaluation on different datasets, as well as a systematic comparison with classical selection techniques in Spark MLlib. Other perspectives include the integration of an explicability layer to interpret selection criteria in the distributed environment

ABSTRACT

Inconel 939, the nickle-based superalloy has exceptional properties that include its high thermal and mechanical behaviours. Owing to this properties Inconel 739 demand in various industries like aerospace, automobile. Machining is unavoidable to use Inconel 739 alloys. Abrasive water jet drilling (AWJD) adopted to analysis and Optimize the MRR (Material Removal Rate) and SR (Surface Roughness) by integrating the RSM (Response Surface Methodology)-CCD (Central Composite Design)-Desirability approach. The L27 Experiments conducted by adopting variation in the Pressure, Traverse Speed, Abrasive Flow Rate and Standoff gap distance. The developed model validated statistically, its suitable for further analysis. Analysis of Variations (ANOVA) illustrations the Pressure was high influential variable in the responses and optimization processes. The developed model of regression shows minimal error between predicted and actual values. Three dimensional plots and used for capture the parameters effect in the responses. Pressure was influencing the 72.7% and 78.8% on SR and MRR Respectively. Desirability approach shows the validation error less than the acceptable limits.

I. INTRODUCTION

Inconel 939 material adoptability is very high due to its unique high mechanical and thermal behaviours, when compared to other alloys such as aluminium alloys and Ti based alloys [1]. The material removed from Inconel alloys has discrete issues for conventional methods [2]. Abrasive water jet (AWJ), laser beams, exemplify unconventional machining techniques that operate through material removal mechanisms such as mechanical erosion and vaporization [3]. AWJ machining was, high pressurized water jet with abrasive particle used to cut the materials [4]. The moving Abrasive particles impacting the machined surface creates erosive wear [5]. AWJ machining can be used for many different types of machining due to its minimal barrel error.[6].

Researchers have done thorough investigations cut the material accurately and reliably so that it satisfies the needs of the product joining and assembly operations. [7]. Researchers have found crucial input parameters that significantly influence abrasive waterjet (AWJ) operations, including drilling, milling, turning, and cutting. Water jet pressure, type and size of abrasive, traversal rate, abrasive flow rate, and gap distance are essential variables [8], [9]. The suitable range of input parameters of abrasive waterjet machining can be found by optimization techniques [10]. The process needs to be optimized by suitably maximizing certain variables while keeping other variables constant [11].

Researchers have utilized many multi-objective optimization techniques, including artificial neural networks, evolutionary algorithms, the Taguchi method, and response surface methodology (RSM) to determine optimal process parameters for unconventional machining [12]. Using several such methods, multi-objective optimization strategies can improve the quality of a material. It goes beyond the problems or limits that the traditional method puts in place [13]. There is a lack of research on optimizing the inputs for abrasive waterjet drilling (AWJD) of Inconel alloys. The primary aim of this study is to regulate the most critical input parameter for the AWJD process. The cutting quality features are affected by gap distance, flow rate, travel speed, and pressure.

Desirability analysis was used to find the suitable input parameter for the different responses of Surface Roughness (SR) and Materials Removal Rate (MRR). The results obtained from the presented investigation can be effective in improving the machinability of Inconel 939 alloy and achieve higher productivity in industries.

II. MATERIALS AND METHODS

The MAXIEM 1515 type abrasive waterjet machine was used for the experiments. The drilling operation is performed as represented in Figure 1. The number of passes is restricted to one. All of these variables remain constant during the machining process. The INX-939, with a thickness of 8 mm, is utilized for AWJD. This alloy was selected as the workpiece due to its extensive utilization in many industrial applications. Tables 1 and 2 delineate the attributes and composition of INX-939.

This study applies several drilling conditions at 25 mm of length on target material, with an emphasis on critical output factors like undulation and circularity characteristics. During the experiment, four various levels of parameters were varied, including P, FR, TS, and SOG and their ranges were chosen based on the trial experiments are shown in Table 3 [14]. The observed reaction was analysed using the response surface methodology, and the CCD (27 trials) statistical method was employed to do rails. The trials were conducted at random [15] in order to reduce the influence of confounding variables, and two replications were obtained for each experiment. Using a contact stylus-type tester model (Surfcorder: SE3500), the top and bottom surfaces were assessed for surface roughness (SR) at the mid-depth position along the cut route. With an assessment length of 4 mm and a cut-off length of 0.8 mm, the SU was measured at a probe speed of 0.1 mm/s. For MRR, W1 is the beginning workpiece sample before machining, W2 is after machining, the density of work =8.19 g/cm3 is the cutting time (t) in minutes. as given equation (1)

$$MRR(mm^3/sec) \rightleftarrows = \frac{W_1 - W_2}{\rho \times t} \times 1000 \quad (1)$$

Table 3: The characteristics of the cutting process and the corresponding levels.

III. RESULTS AND DISCUSSIONS

III.1 RSM-CCD EVALUATION AND ANOVA ANALYSIS

This study used a central composite second-order quadratic design including a total of 27 runs. Table 4 delineates the process parameters and their respective levels within the L27 orthogonal array, along by response values for INX-929. The definitive regression models for the examined variables, specifically surface roughness and taper angle. ANOVA, executed via Design Expert software (V13), was utilized to examine the influence of process variables on machining results in the context of AWJD. The equations representing the quadratic models of the input process parameters are provided in Equations (2) and (3). Table 5 presents the results of an Analysis of Variance (ANOVA) test that evaluates the influence of process parameter values upon surface roughness (SR). The overall model has a very significant relationship as indicated by its F-statistic (F=806.88), which is associated with a very small probability ($p<0.0001$), therefore the regression model can be relied upon to predict surface roughness.

Pressure had the largest single factor effect on surface roughness (SR) as shown by its sum of squares (SS) (6.86), large F-statistic (F=2362.62) and extremely low p-value ($p<0.0001$). In addition, flow rate (SS=2.08; F=716.52) also exhibited a significant effect upon surface roughness, and then came the effects of standoff distance (SS=0.6368; F=219.22) and traverse speed (TS) (SS=0.2001; F=68.89), all three being statistically significant at $p<0.0001$. Additionally, there was very little residual error (SS=0.0639), and both the lack of fit and pure error were equal to the residual error, thus supporting the use of this model to make predictions of surface roughness. Table 6 presents the results of an ANOVA test that assesses the influences of process parameters upon material removal rate (MRR). The model had a very significant fit as demonstrated by its large F-statistic (F=1060.76), and its p-value was less than 0.0001, indicating that the model was good at making predictions of MRR.

The greatest individual effect of the various process parameters on MRR was due to pressure (P), as it had the largest sum of squares (SS) of 5253.51 and the highest F-statistic (F=3364.34). In addition, standoff gap (SOG), flow rate (FR), and traverse speed (TS) also showed a statistically significant effect on MRR as shown by their respective F-statistics of 493.35, 255.47 and 68.71, and all three were significant at $p<0.0001$. Furthermore, the residual error was minimal (SS=34.35), and the lack of fit and pure error were equal to the residual error, therefore the results demonstrate that pressure was the primary influence on MRR and that the entire set of process parameters studied had a collective influence on MRR.

$$(SR) = 4.12 + -0.6458 * P + 0.1965* FR + 0.1102 * TS -0.3553* SoG \quad (2)$$

$$(MRR) = 124.83 +17.87 * P + 6.84 * FR + 2.55 * TS +4.98* SoG \quad (3)$$

The tight clustering of data points in figure 2 (a), which is a scatter-plot of actual vs. predicted values on a normalized range of 2.5 to 5.5, indicates that there was good agreement between actual and predicted values. On average, most of the predictions were within ±0.2 units of their respective actual values, with little spread throughout the range. Therefore, it can be concluded that the model had relatively low prediction error, and therefore a high level of model fidelity in the normalized domain. In addition, figure 2 (b) shows the predicted vs. actual values on an expanded range of 90 to 160. Like figure 2 (a), the scatter-plot in figure 2 (b) also demonstrates similar alignment to the diagonal, and thus has similar predictive performance. Additionally, the majority of data points are less than ±5 units from the ideal prediction line, with the greatest density of data points found at values between 110 to 140. Overall, the proximity of each figure's data points to the ideal prediction line, regardless of the output range, further supports the overall robustness of the model for predicting values across different scales.

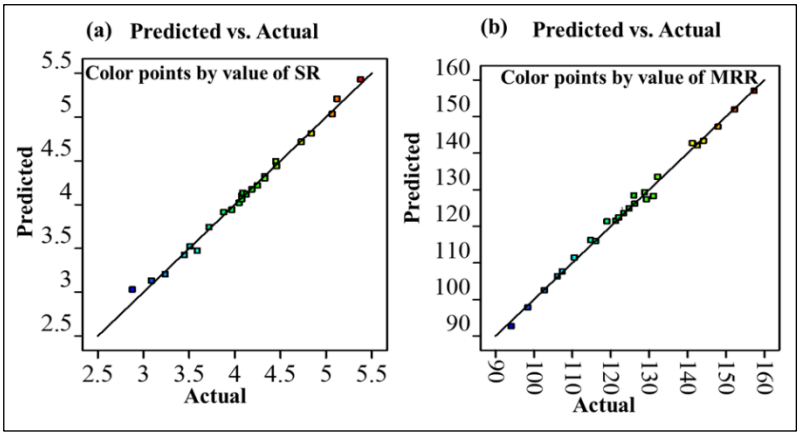

Figure 2: Pred vs Actual plot (a) SR and (b) MRR.
Source: Authors, (2026).

III.2 RSM ANALYSIS OF SR

Pressure and standoff distance in relation to surface roughness are shown in figure 3(a). In general, as pressure is increased (from 120 to 360 MPa), there will be a decrease in SR and this is especially true for low standoff distances (i.e., 1.5-2.0 mm) and when viewed on a surface plot, it shows the surface to appear smoother. Pressure and traverse speed (TS) interaction effects on SR are presented in figure 3(b). Once again, it can be seen that pressure increases coupled with moderate traverse speeds (approximately 80 mm/min) produce lower SR values, indicating that a range of optimal processing parameters exists. As presented in figure 3(c), the correlation of pressure and flow rate indicates that increased pressure and reduced flow rates (approximately 0.45-0.50 kg/min) contribute to minimizing SR. All three figures indicate that the model's predictions of SR are accurate based upon the placement of red data points along the surface contours and that pressure is the most influential parameter in achieving better surface finishes.

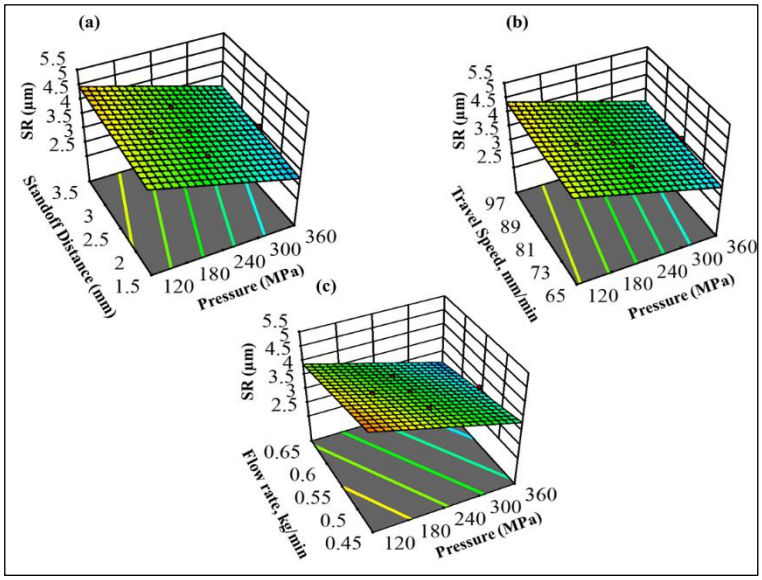

Figure 3: (a,b & c) 3D Undulation plots for SR.
Source: Authors, (2026).

III.3 RSM ANALYSIS OF MRR

As shown in figure 4(a), it is clear how the pressure and the distance from the workpiece surface affects the material removal rate (MRR) since it can be seen in this surface plot that an increase in pressure from 120 MPa up to 360 MPa has a very significant impact on MRR; especially when the distance from the workpiece surface is low (i.e., 1.5-2.0 mm). For example, MRR almost reaches its highest point of approximately 160 mm³/sec at these lower distances from the workpiece surface. In addition, as indicated by the interaction plot in figure 4(b) between pressure and traverse speed (TS), it can be observed that as the pressure is increased so does MRR. Additionally, the MRR is at an optimal level for moderate TS (i.e., 80 mm/min); after which it will plateau. Finally, figure 4(c) depicts the effects of pressure and flow rate on MRR, and indicates that high pressure combined with low flow rate (i.e., 0.45-0.50 kg/min) produces the highest MRR. In all three plots, the red data points are close to the surface contours, thus verifying the accuracy of the model and demonstrating the effect of pressure as the key factor in achieving the maximum MRR

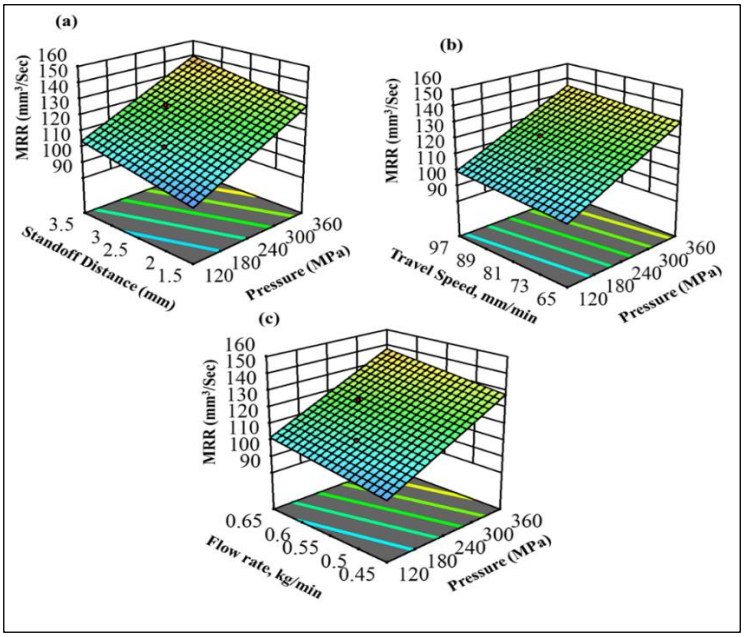

Figure 4: (a,b & c) 3D Undulation plots for MRR.
Source: Authors, (2026).

III.4 DESIRABILITY ANALYSIS

In figure 5 (a) we have a perturbation plot that illustrates how sensitive the entire desirability function is to changes in each process variable (pressure A, standoff B, traverse C, flow D) in coded units. The steep slope of the green line representing pressure suggests it has a large impact on what the best optimized solution is. The flat lines of the other variables indicate less sensitivity in this region. In figure 5(b) we have a desirability bar chart displaying the individual and collective desirability scores of the optimal solution (solution 1 of 100) for the process parameters of interest (pressure, standoff, traverse, flow). Each of the four process parameters of interest; pressure, standoff, traverse, and flow all reach the highest desirability of 1.0, which is the ideal setting for each variable.

The response desirability values are; 0.870951 for surface roughness, 0.913342 for material removal rate (MRR), and 0.891894 for the combined objective, as they represent an acceptable balance of surface finish with machining efficiency. Figure 5(c) presents the optimal values for the process parameters and associated response values. This set of conditions includes; maximum pressure (360 MPa), maximum standoff (3.5 mm), minimum traverse (65 mm/min), and maximum flow (0.65 kg/min). With these conditions the predicted surface roughness is 3.20262 microns and the MRR is 151.905 mm^3/sec, both of which fall in the desired operating range. This confirms the effectiveness of the multi-objective optimization method in finding a robust process window that will optimize both surface finish and material removal efficiency [16-18].

III.5 CONFIRMATION TEST

The experimental validation of the optimized process parameters for maximizing the Material Removal Rate (MRR) and minimizing the Surface Roughness (SR) are shown in Table 8. The initial working parameters of 200 MPa pressure, 0.4 kg/min flow rate, 60 mm/min traverse speed and 2 mm standoff gap resulted in a SR of 4.3 microns and an MRR of 149.21 mm^3/s. Following the completion of the multi-objective optimization process, the optimized parameters of 360 MPa pressure, 0.65 kg/min flow rate, 65 mm/min traverse speed and 3.5 mm standoff gap were experimentally verified. Under the above conditions the actual measured SR was 2.84 microns and the MRR was 153.57 mm^3/s; which is very similar to the predicted values of 3.2 microns and 151.9 mm^3/s. Therefore, there has been a 12.67% improvement in SR and a 1.08% increase in MRR over the base case. The close correlation between the predicted and experimental results indicate that the optimization model is reliable and applicable for optimizing machining performance [19], [20].

Table 8. Experimental Validation.

Confirmation	Parameters Range	SR	MRR
Initial condition	P = 200 Mpa, FR = 0.4 Kg/min, TS= 60 mm/min, SOG= 2 mm	4.3	149.21
Predicted	P = 360 Mpa, FR = 0.65 Kg/min, TS= 65 mm/min, SOG= 3.5 mm	3.2	151.90
Actual	P = 360 Mpa, FR = 0.65 Kg/min, TS= 65 mm/min, SOG= 3.5 mm	2.84	153.57
Improvement (%)		12.67	1.08

IV. CONCLUSIONS

The study demonstrated the effectiveness of process parameter optimization for AWJD machining process for INX -939 through systematic evaluation of the key process parameters like pressure, flow rate, travel speed and standoff gap. The experimental investigation employed the response surface technique to improve the input settings of abrasive water jet drilling (AWJD) process for the superalloy. The objective was to reduce surface roughness and increase MRR, two significant variables that influence the precision and quality of the machined products. The research showed that the MRR and surface roughness may be greatly enhanced by modifying the input parameters. During the investigation, the following particular observations were made:

• The ANOVA results show that both surface roughness (SR) and material removal rate (MRR) are significantly influenced by the factors included in the model, and that the models are very reliable given the very high F-values and p-values less than 0.0001 for all parameters evaluated. Pressure is found to be the most influential parameter affecting both surface roughness and material removal rate. However, flow rate, standoff distance, and traverse speed also have a significant impact on response variables. Low pure error and minimal residual error support the validity of the models used to predict machining performance. As a result, the ANOVA provides evidence that the selected process parameters affect the machining performance through a quantifiable mechanism. It further establishes pressure as a primary variable controlling machining performance and supports the robustness of the models for use in both predictive and optimization efforts.

• An analysis of the desirability function indicates that the optimal process parameter setting yields a balance of performance improvements for multiple objective functions. Given that all of the process parameters reach their optimal desirability (i.e., value = 1.0), the model determines that pressure, standoff distance, traverse speed, and flow rate are all at their optimal operating points. The desirability-based technique yields a total desirability of 0.891894, corroborated by individual desirability scores of 0.870951 for surface roughness and 0.913342 for material removal rate. So, the desirability-based optimization technique works well to lower surface roughness and raise the efficiency of material removal. This shows that the desirability-based approach can improve machining quality and productivity.

• Validation experimental trials depicted that the modified process parameters lead to greater machining performance. When we looked at the optimized process parameters and the original machining parameters side by side, we saw that the surface roughness went down by 12.67% and the rate of material removal went up by 1.08%. The fact that the projected values were close to the measured values during the validation experiments shows that the multi-objective optimization model is reliable and might be used to improve machining performance.

ABSTRACT

Extraction of useful insights and patterns from massive datasets is impossible without data mining. The widespread use of Internet services and the subsequent creation of vast quantities of data have ushered in the modern era of big data. Every aspect of human existence generates copious amounts of data. Data analysis and utilization processes need to take into consideration a growing number of factors to deal with the growing volume and complexity of today's data sets. The importance of deep learning in data mining rises in proportion to the problem's complexity. Traditional data mining methods face major hurdles due to the ever-increasing number and complexity of data. To address this issue, we offer a unique distributed data mining strategy that utilizes deep learning and Long Short-Term Memory (LSTM) systems. In this study, we combine deep learning with distributed computing to provide a powerful tool for data mining. In order to capture long-term relationships in sequential data, the proposed model uses recurrent neural networks (RNNs) of the LSTM kind. Since LSTM networks are so effective with time-series and sequential data, they may be used in a wide variability of data mining tasks. We create a parallel computing framework that pools the processing power of a cluster's many nodes to facilitate decentralized operations. The training and inference of the LSTM-based data mining model are sped up by the distributed design, which also facilitates the efficient processing of big datasets. We compare the proposed model to standard data mining techniques and show that it outperforms them on a number of real-world datasets. The outcomes demonstrate the superior accuracy of 99.5% and efficiency of our deep learning-based method for identifying useful patterns and making predictions. The findings validate the model's horizontal scalability and the benefits of distributed computing, guaranteeing its practical application in large data settings.

I. INTRODUCTION

In this era of big data, we cannot function without the capability to investigate and interpret that data. The usage of big data is on the rise, and it is already being put to work in a variety of fields, from sickness and reward prediction to intelligent transportation system assistance to decision-making aid for businesses to the study of consumer psychology. People's expectations of data outputs are rising, prompting the development of more robust approaches like categorization, clustering, and neural networks. On the other hand, there is both helpful and worthless information in a large data set. Extracting valuable insights from massive datasets while discarding irrelevant information is a critical challenge in modern data mining.

To keep up with the growing need for data analysis in today's interconnected world, scientists and engineers have been investigating the potential of deep learning in data processing. A time series is a collection of data points that has been sequentially organized by time. These sites are often chosen at regular intervals. Time-series data categorization is a major data mining profession is facing a significant difficulty [1] The distributed data mining method [2] has to be geared toward the centrally acquired data and must perform analysis on the data in a decentralized fashion. Let's assume that the dataset has a large dimensionality and that the data mining approach requires a lot of processing power and time. Then, utilizing a distributed network of computers, the problem is solved using methods of parallel knowledge analysis [3], [4]. So, we use machine learning methods [5], [6] to look at the decentralized dataset and see what we can learn from it. Clustering is an efficient method that analyzes data similarities to find unexpected outcomes. Similar pieces of information are grouped together by the clustering procedure [7], [8] Attributed information is data that has been partitioned in a particular way, such as density, centroid, hierarchical, or spectral.

However, there may be significant complication in data privacy and security problems due to the clustering. Vertical and horizontal dimensions, also known as heterogeneous and homogeneous viewpoints, are used in DDM's analysis of the data [9]. The current clustering technique uses assumptions of data similarity to address problems with dispersed clustering. The scattered data in a challenging circumstance is analyzed afterwards by looking into heterogeneous data.It takes more work to reduce the computing complexity while keeping the important data while working with a heterogeneous dataset due to its big dimension [10]. During this phase, the system integrates information from several sources to facilitate efficient discovery of new information. Sensitive information is among the data sets that have been dispersed. Therefore, the fusing process must take into account concerns about data privacy and security.

Therefore, it is necessary to construct a powerful distributed data mining system to deal with the massive amount of data with minimal processing complexity, such as problems with data security and dimensionality. To get around this problem and reduce the dimensionality of the data, many academics turn to techniques like correlation and principal component analysis. Due to the non-linear interacting problems inherent in this procedure, only a small subset of relevant data is taken into account during clustering. Existing techniques of grouping comparable data, however, have substantial mistake rates. Problems are put to rest when the mayfly-optimized deep learning algorithm is used to study the data's features and cope with the data redundancy issue. Furthermore, the neural network utilizes the knowledge from the local dataset to discover universal patterns for targeted issues. Previous learning and feature connection are mined for the global patterns. The network then makes use of the optimization method to tweak the network's settings, reducing the severity of the optimization problem and the number of false positives.

II.RELATED WORKS

Machine learning techniques have been extensively used in diverse distributed computing thanks to the availability of organized information. Distributed computing may be sped up with the use of knowledge-based machine learning for applications that run in real time. To address the critical bottlenecks that plague real-time distributed systems, researchers have developed a Cognitive Distributed Learning System [11]. In order to compute belief nets, the hidden layer network is analyzed using learning techniques and certain related priors. Quick greedy and the wake-sleep strategy can be used for deep learning by taking use of associative memory. For discriminative outcomes in picture number classification, a model based on a three-layer architecture has been developed [12]. When discussing DCRN (Distributed Cognitive Radio Network) and DCS (Dynamic Channel Selection), reinforcement learning is an additional essential machine learning method. Using both a single agent and a group of agents, this machine learning technique takes use of the density of the network to achieve maximum fairness [13]. This kind of learning allows scientists to improve their performance in several areas without sacrificing productivity or quality in their machines. A self-motivated mechanized company may have a bright future based on capability, change, and self-organisation, as suggested by a hierarchical mechanical management structure [14].

The Case Based Reasoning (CBR) method is also used in conjunction with deep learning to categorize clinical data. Visual reasoning and an interface are used to display patient diagnosis data, allowing for both qualitative and quantitative analysis to be carried out. Multidimensional medical data, such as that pertaining to breast cancer, may be visually described by means of CBR [15]. In the field of cancer prediction, neural networks have become the standard tool. Examining the study reveals the cancer survival risk and engineering forecasts. The results of these trials show how effective neural network learning can be [16]. When used to health data, artificial neural networks (ANNs) can improve data delivery while cutting costs. In describing health-related real-world applications on diverse large medical datasets, ANN provides a conclusive analysis. Two examples of general-purpose ANN that produce reliable outcomes when applied to healthcare data are feed-forward and hybrid networks. The use of ANN for making decisions on patients' medical records has been used by both external and internal networks [17]. Artificial intelligence's (AI's) rising use in clinical data is changing the face of health data liberation in profound ways. The medical and scientific communities, among others, make extensive use of AI. Previously untapped opportunities for medical organizations have been identified thanks to AI strategies for producing equipment to wisdom and grasp information.

In [18], K-means clustering is used to keep data private in a decentralized system. The goal of this system is to control personal information in a decentralized setting. To deal with the local differential privacy issues introduced by highly altered data, the K-means clustering method is used. Then, with the help of efficient clustering, each individual user's local privacy is bolstered. In [19], the privacy protected K-means clustering method is used for managing data privacy in an unsecure setting. The external adversaries can be anticipated by the distributed clustering method thanks to the usage of elliptic curve encryption techniques. The ability to accurately forecast attacks aids in maintaining security and privacy with minimal computational complexity and overhead. To improve safety and confidentiality in smart electrical systems, [20] presents a privacy data availability clustering method. The data clustering technique is used in this paper in an effort to mitigate privacy leakage and distorted data concerns. To determine how far apart the data and the centroid computation are, the technique use the K-means algorithm. User behavior and privacy characteristics in social networks were predicted using a blockchain-based privacy algorithm in a distributed database (DEPLSEST) in [21]. Privacy in locally stored databases may be managed using synchronization procedures included in the blockchain with clustering algorithm. The consensus procedure is then used to update all relevant ledgers.

When compared to competing secure clustering algorithms, the protocol provides superior byzantine fault tolerance. The multi-core DBSCAN method for handling confidential network traffic information is presented in [22]. This method protects sensitive information without requiring special skills or knowledge from the opponents. The transmitted data is secure due to the inclusion of random noise. According to the research shown above, there are a number of obstacles to reaching high accuracy and lowering the error rate using current approaches. However, when dealing with heterogeneous data in a distributed setting, such solutions need a lot of computational resources and offer nothing in the way of security. As a result, the current infrastructure can't cope with the multi-resource data that comes with high-dimensional dimensions. The large dimensionality reduces the effectiveness of the clustering process as a whole and raises privacy concerns. As a result, the clustering and user authentication processes experience a discrepancy between the real and calculated numbers. This paper provides a solution to this problem by using Distributed Clustering with Optimised Deep Learning (DCODL) techniques. The effectiveness of the new DCODL approach is measured against previous studies.

III. METHODS AND MATERIALS

III.1 PROBLEM FORMULATION

Given a large-scale dataset consisting of sequential data, represented as a set of input sequences $X = \{x_1, x_2, \ldots, x_N\}$, where each $x_i = (x_{i1}, x_{i2}, \ldots, x_{im})$ represents a sequence of m data points, we aim to develop an efficient extraction model that utilizes deep learning and LSTM networks to uncover valuable patterns and insights from the data. Let $Y = \{y_1, y_2, \ldots, y_N\}$ denote the corresponding target sequences, where $Y = \{y_{i1}, y_{i2}, \ldots, yi_N$ represents the corresponding target sequence associated with x_i. The target sequences could be binary labels, regression values, or any other form of target variable. We propose a distributed system architecture that harnesses the computational resources of multiple nodes in a cluster to facilitate efficient processing of the large-scale dataset. Each node in the cluster collaboratively performs computations in parallel to accelerate the training and inference stages of the deep learning model. The deep learning model leverages LSTM networks, which are a type of recurrent neural network able to detect temporal relationships in sequential data. Let $f(x;\ \theta)$ represent the LSTM-based model, parameterized by θ, that maps an input sequence x to the corresponding predicted output sequence.

The model is trained using a suitable optimization algorithm, such as stochastic gradient descent, to minimize a given loss function $L(Y, f(X;\ \theta))$ that measures the discrepancy between the predicted output sequences and the true target sequences. To enable efficient extraction of patterns and insights, we define performance metrics such as accuracy, precision, recall, or any other suitable evaluation measures, depending on the specific data mining task. The objective is to maximize these performance metrics while ensuring efficient computation and resource utilization within the distributed system. By employing the proposed deep learning-based distributed data mining approach, we aim to demonstrate its superiority over traditional data mining methods in terms of accuracy, efficiency, and scalability. Through experimental evaluations on large-scale real-world datasets, Our proposed model is compared to industry standards, validating its ability to efficiently extract patterns and insights from the large-scale data while achieving high accuracy and scalability in a distributed computing environment.

III.2 DATA MINING

Data mining is a systematic process that involves several stages to extract valuable insights and patterns from large datasets as exposed in figure 1. The first step is identifying the data source, which could be a database, a data warehouse, or even unstructured data like text documents or web pages. Once the data source is determined, the next stage is data preprocessing, where the raw data is cleaned, integrated, and transformed to ensure its quality and consistency. After preprocessing, the target dataset is defined, specifying the subset of data that will be used for the mining process. This dataset is carefully selected based on the specific goals and objectives of the data mining project. Once the target dataset is established, an appropriate mining algorithm is chosen. According to the data and the outputs needed, these algorithms might range from decision trees and neural networks to clustering and association rule mining.

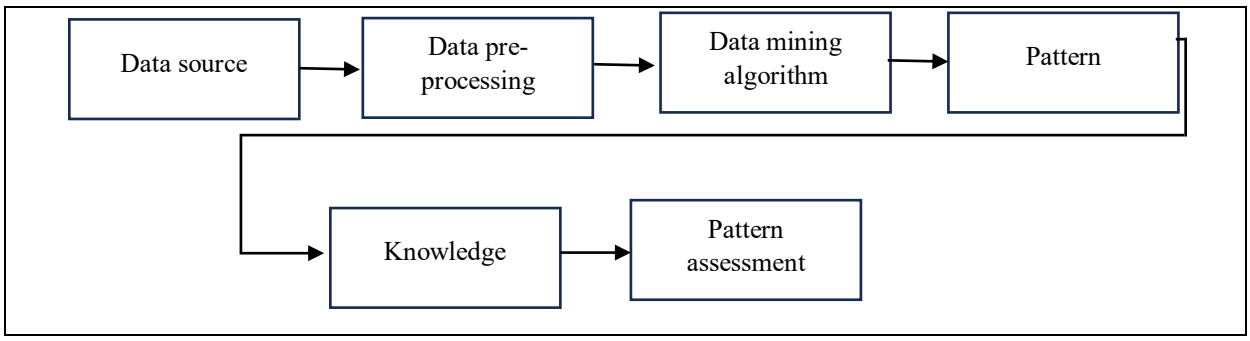

Figure 1: Basic data mining process.
Source: Authors, (2026).

The mining algorithm then analyses the target dataset, searching for meaningful patterns and relationships within the data. These patterns could be associations between items, sequential patterns, clusters of similar data points, or predictive models. Once the patterns are discovered, the next step is pattern assessment, where the quality and significance of the patterns are evaluated. This assessment may involve statistical measures, validation techniques, and comparison to domain knowledge or existing models. Finally, the last stage of the data mining process is to transform the discovered patterns into actionable knowledge. This knowledge can be used for decision making, prediction, or to gain a deeper understanding of the underlying data. It is important to note that data mining is an iterative process, and the knowledge gained from one cycle can be used to refine the process in subsequent iterations, leading to continuous improvement and enhanced insights.

III.3 METHODOLOGY

The proposed workflow begins with the collection of massive datasets from diverse sources, taking into account their volume and complexity. These datasets are then subjected to preprocessing, where cleaning and data quality assurance steps are performed to handle missing values, outliers, and ensure data integrity. Next, the large-scale dataset is partitioned into smaller subsets, which are distributed across multiple nodes within a distributed computing cluster. This enables parallel processing and efficient utilization of computational resources. For the distributed deep learning training phase, an LSTM-based model is initialized with appropriate hyperparameters. Each node independently trains the model using its allocated subset of data, while the model parameters are synchronized and updated iteratively across nodes to maintain consistency. This training process is repetitive until convergence or a predefined stopping criterion is met. In the distributed inference stage, the trained LSTM model is applied to perform inference on new data points. Inference tasks are distributed across nodes for parallel processing, and the results are collected and merged to obtain the final predictions.

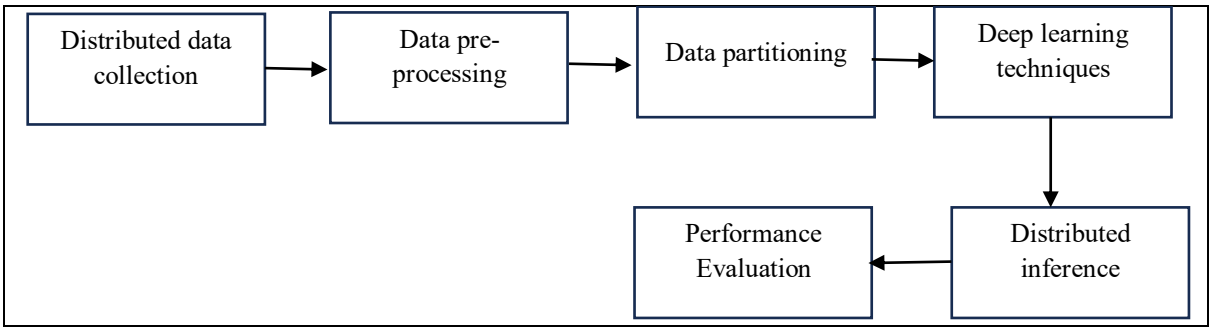

Figure 2: The overall structure of the proposed model.
Source: Authors, (2026).

The recital of the proposed deep learning-based distributed model as shown in the figure 2 is then evaluated and compared with traditional data mining techniques. Accuracy, efficiency, and other relevant metrics are assessed using real-world datasets to showcase the superiority of the deep learning approach in identifying valuable patterns and making predictions. The scalability and practical application of the distributed model are validated by examining its horizontal scalability as the dataset size and computational resources increase. The benefits of distributed computing, such as efficient processing of big datasets, are highlighted. Ultimately, the proposed approach's practical applicability in large data settings is emphasized, demonstrating its potential for real-world applications.

III.3.1 Data collection

Incident reports and traffic accidents, both examples of event data, are made up of isolated incidents that occurred at certain times and places. Generalizations about an event can be made about its nature, its place of occurrence, and its time of occurrence. A traffic accident, for instance, can be represented as the tuple (e, l, t), where e is the accident type, l is the location, and t is the time at which the accident takes place.

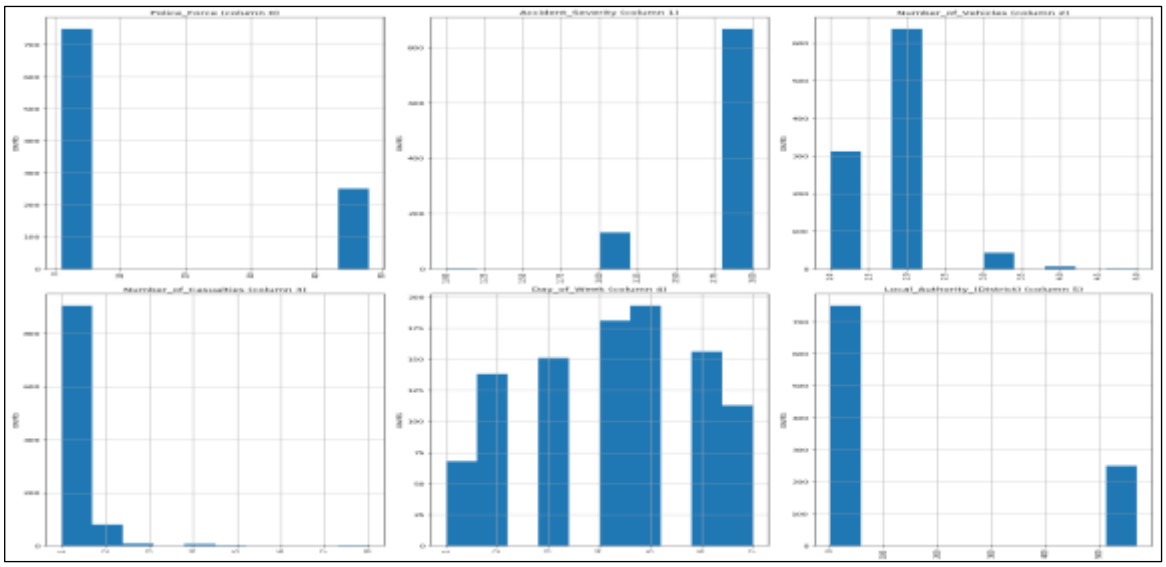

Figure 3: Distributed data collected from various resources.
Source: Authors, (2026).

The event data is depicted graphically in Fig. 3. There are three distinct events represented by the three distinct forms of the symbol. Many fields rely on event data, including those dealing with criminology (such as data on urban offences), epidemiology (such as data on disease outbreak events), transportation (such as data on traffic crashes), and social networks (such as data on conversations and trending themes).

III.3.2 Deep learning model

Long Short-Term Memory (LSTM) well-suited for tasks such as time series analysis, natural language processing, and speech recognition. LSTM models are particularly effective in handling sequential data, such as time series, text, or sensor data. In a distributed environment, where datasets may be massive and continuously streaming, LSTM models can capture long-term dependencies and relationships within the data, making them suitable for various data mining tasks. By combining LSTM models with distributed computing, the processing power of multiple nodes in a cluster can be harnessed. This allows for parallel processing of data, speeding up training and inference tasks. The distributed design helps in efficiently handling large-scale datasets, making it feasible to mine valuable insights from massive amounts of data. In a distributed environment, the dataset can be partitioned and distributed across nodes. Each node can perform local training on its allocated data subset using the LSTM model. This parallel training enables efficient utilization of computational resources and accelerates the training process, leading to faster convergence and improved scalability.

During training, the parameters of the LSTM model need to be synchronized and updated across distributed nodes to maintain consistency. Communication and synchronization protocols can be employed to exchange information and propagate parameter updates between nodes. This ensures that the model learns from the collective knowledge of the distributed dataset. Once the LSTM model is trained, it can be used for distributed inference on new data points. The inference tasks can be distributed across nodes for parallel processing, allowing for efficient prediction or pattern recognition across the distributed dataset. Distributed LSTM models exhibit scalability, allowing them to handle large-scale datasets and accommodate an increasing number of computational resources. Additionally, fault tolerance mechanisms can be incorporated to handle failures or node disruptions, ensuring the robustness and uninterrupted operation of the distributed data mining system. The figure 4 shows the structure of Long Short-Term Memory (LSTM).

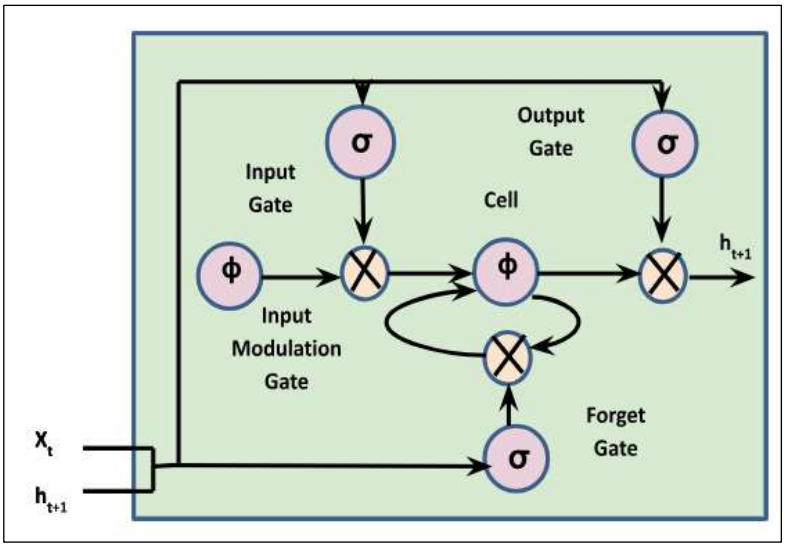

Figure 4: Structure of Long Short-Term Memory (LSTM).
Source: Authors, (2026).

The LSTM model consists of multiple memory cells, each capable of storing and updating information over time. It employs a set of gating mechanisms can manage the flow of data, enabling it to choose retain or discard data from earlier time stages. Let's denote the inputs at time step t as $x(t)$ and the hidden state (or memory) at time step t as $h(t)$. The LSTM model can be mathematically formulated as follows,

Input Gate ($i(t)$):

$$i(t) = \sigma(W_i x(t) + U_i h(t-1) + b_i) \quad (1)$$

Forget Gate ($f(t)$):

$$i(t) = \sigma(W_f x(t) + U_f h(t-1) + b_f) \quad (1)$$

Candidate Memory Cell ($\hat{C}(t)$):

$$\hat{C}(t) = tanh(W_c x(t) + U_c h(t-1) + b_c) \quad (2)$$

Memory Cell (c(t)):

$$c(t) = f(t) * c(t-1) + i(t) * \hat{C}(t) \quad (3)$$

Output Gate (o(t)):

$$o(t) = \sigma(W_o x(t) + U_o h(t-1) + b_O) \quad (4)$$

Hidden State (h(t)):

$$h(t) = o(t) * tanh(c(t)) \quad (5)$$

In the above equations, W_i, U_I, b_i, W_f, U_f, b_f, W_c, U_c, b_c, W_O, U_O, b_o are the weight matrices and bias vectors that need to be learned during the training process. σ denotes the sigmoid activation function, which squashes the values between 0 and 1, controlling the flow of information through the gates. The input gate ($i(t)$) determines how much of the candidate memory cell ($\hat{C}(t)$) should be added to the memory cell ($c(t)$), while the forget gate ($f(t)$) controls how much of the previous memory cell ($c(t-1)$) should be retained. The output gate ($o(t)$) determines how much of the memory cell ($c(t)$) should be passed to the hidden state ($h(t)$).

By utilizing the LSTM model within a distributed environment, the training and inference processes can be performed in a parallel and distributed manner across multiple nodes. The data is partitioned, processed, and synchronized across nodes to leverage the computational power of the distributed system. Through this distributed LSTM model, data mining in a distributed environment becomes feasible, enabling efficient analysis and extraction of valuable patterns and insights from large-scale datasets.

Algorithm 1: Algorithm for Efficient Extraction of Patterns and Insights from Large-Scale Data from distributed system using Deep Learning.

1. **Initialize** distributed LSTM model parameters and hyperparameters.
2. **Divide** the large-scale dataset into smaller subsets for distributed processing.
3. **Parallelize** the following steps across distributed nodes:
   a. **Load** the allocated data subset.
   b. **Perform** data preprocessing (cleaning, normalization, etc.).
   c. **Split** the preprocessed data into sequences or batches.
   d. **Initialize** LSTM model with specified architecture and hyperparameters.
   e. **Train** the LSTM model on the local data subset for a specified number of epochs.
      i. **Initialize** the LSTM model with parameters θ.
      ii. **for** each node in the distributed system **do**:
         a. **Load** the data subset D_{node}.
         b. **Perform** local LSTM training on D_{node} using parameters θ_{node}.
         c. **Update** the local parameters θ_{node} based on the local training loss.
         d. **Synchronize** the parameters θ across all nodes in the distributed system.
   f. **Synchronize and update** the LSTM model parameters across nodes.
4. **Repeat** steps 3a-3f until convergence or a predefined stopping criterion is met.
5. After convergence, combine the synchronized LSTM models from all nodes.
6. **Apply** the combined LSTM model to perform inference on new data points:
   a. **for** each node in the distributed system **do**:
      Load the unseen data subset D_{unseen_node}.
      Perform local inference using the synchronized parameters θ.
      Obtain local predictions P_{node}.
      Merge the local predictions from all nodes to obtain the final predictions P_{final}.
7. **Evaluate** the performance and accuracy of the distributed LSTM model:
   a. **Compare** the predictions with ground truth labels.
   b. **Calculate** relevant metrics (e.g., accuracy, precision, recall) on the evaluation dataset.
8. Present the extracted patterns and insights:
   a. **Analyze** the LSTM model's weights and activations to identify important features.
   b. **Visualize** and interpret the learned patterns and relationships.
9. **Assess** scalability and practical applicability:
   a. **Measure** the execution time and resource utilization with varying dataset sizes.
   b. **Evaluate** the system's horizontal scalability as computational resources increase.
10. **End.**

Source: Authors, (2026).

Adagrad is an optimization algorithm usually used in training RNNs such as LSTM. Adagrad is designed to adaptively adjust the learning rate for each parameter during training based on the historical gradients. This allows for more efficient updates and better convergence, particularly in scenarios where different parameters may have vastly different scales. The basic idea behind Adagrad is to assign a different learning rate to each parameter based on its past gradients. A parameter's learning rate corresponds to the square root of the total of its squared gradients over time. As a result, bigger gradients correspond to slower learning rates, whereas lower gradients result in faster rates. The Adagrad update equation for a parameter w at time step t can be represented as:

$$w(t+1) = w(t) - \left(\frac{learning_rate}{sqrt(G(t) + epsilon)}\right) * g(t) \quad (6)$$

Where w(t) is the parameter value at time step t, learning_rate is the initial learning rate, G(t) is the sum of squared gradients up to time step t for parameter w, epsilon is a small constant (usually set to a small value like $1e-8$) to avoid division by zero, and $g(t)$ is the gradient of the parameter w at time step t. When applying Adagrad to LSTM networks, the update equation is used for each parameter in the LSTM cell, including the weights and biases of the input, forget, and output gates, as well as the cell state and the hidden state. By adaptively adjusting the learning rates, Adagrad allows for more rapid convergence by assigning smaller updates to frequently occurring parameters with large gradients and larger updates to infrequent parameters with small gradients. This adaptability makes Adagrad well-suited for training LSTM networks, which often involve complex temporal dependencies and long-term memory.

IV. EXPERIMENTAL SETUP

The implementation of the proposed algorithms in Google Colab using Python programming involves leveraging various deep learning collections such as scikit-learn, seaborn, Keras, and pandas. The models are trained using a batch size of 64. The batch size is the number of items that are processed in one go until weights for the model are revised. While a bigger batch size can enhance computing productivity, it may slow down convergence if used for training, whereas a smaller batch size enables quicker revisions, but may lengthen the training period. The models are trained for 200 epochs. One whole iteration across the whole dataset used for training is one epoch. The model can gain insight from the data through multiple training epochs in a more comprehensive manner, refining its weights and improving performance over time.

The learning rate, which is initialized at 0.0001, regulates the step size at each iteration during model training. It affects how quickly or slowly the model learns from the data. The specific learning rate value can be chosen based on empirical experimentation and tuning to achieve a balance between convergence rate and training speed. The proposed algorithm uses the tanh (hyperbolic tangent) activation function. The tanh function is a non-linear activation function that squashes the input values to the range [-1, 1]. It is commonly used in neural networks as it introduces non-linearity, enabling systems to simulate intricate connections and capture a wider range of patterns and information. By utilizing these implementation details, the proposed algorithm aims to effectively extract patterns and insights from the road_accident_safety dataset, leveraging the capabilities of deep learning techniques and the power of the Python ecosystem.

V. RESULT AND DISCUSSION

In the context of the proposed methodology on a road_accident_safety dataset, performance metrics can be used to determine how well the strategy is working, in extracting patterns and insights from the data. The total validity of the recommendations is quantified by a metric called accuracy (ACC). made by the model.

$$Accuracy = \frac{(TRP + TRN)}{(TRP + TRN + FAP + FAN)} \tag{7}$$

Where TRP (True Positive) is the favourable cases that may have been foreseen, TRN (True Negative) is the number of unfavourable events where the prediction was accurate, FAP (False Positive) is the amount of false-positive predictions, and FAN (False Negative) is number of unfavourable events for which a prediction was off. Accuracy measures how many positive cases out of total cases that were really forecasted accurately.

$$Precision = \frac{TRP}{(TPR + FAP)} \tag{8}$$

It is the ratio of accurately anticipated positive cases to all observed positive results that constitutes recall (also known as sensitivity or true positive rate).

$$Recall = \frac{TRP}{(TRP + FAN)} \tag{9}$$

The F1-Score is the optimal statistic since it combines accuracy and recall into a single value.

$$F1 - Score = 2 * \frac{(Precision * Recall)}{(Precision + Recall)} \tag{10}$$

The average absolute deviation from the anticipated values to the real ones is what we call the Mean Absolute Error (MAE). It is given by the equation:

$$MAE = \frac{1}{n} * \sum |Y_{actual} - Y_{predicted}| \tag{11}$$

where Y_{actual} represents the actual values and $Y_{predicted}$ represents the predicted values.
The RMSE is the square root of the average of the squared discrepancies among the anticipated and observed outcomes. It is given by the equation:

$$RMSE = \sqrt{\frac{1}{n} * \sum |Y_{actual} - Y_{predicted}|^2} \tag{12}$$

The degree to which an associated variable's variation can be predicted by the variables that are independent is shown by the R-squared score. From zero to one, with one being an ideal match. It is calculated using the equation:

$$R2 = 1 - \left(\frac{\sum (Y_{actual} - Y_{predicted})^2}{\sum (Y_{actual} - Y_{mean})^2}\right) \tag{13}$$

where Y_{actual} represents the actual values, $Y_{predicted}$ represents the predicted values, and Y_{mean} represents the mean of the actual values.
The mean percent off from the expected values to the actual numbers is what Mean Absolute Percentage Error (MAPE) measures. It is given by the equation:

$$MAPE = \frac{1}{n} * \sum \left(\left|\frac{(Y_{actual} - Y_{predicted})}{Y_{actual}}\right|\right) * 100 \tag{14}$$

Where Y_{actual} represents the actual values and $Y_{predicted}$ represents the predicted values. These performance metrics provide different perspectives on the accuracy and reliability of the predictions made by the Deep Learning and LSTM models on the road_accident_safety dataset.

Table 1: Performance analysis of the dataset road_accident_safety.

	Precision	Recall	f1-score
1	0.9875	0.9585	0.9665
2	0.9962	0.9912	0.9958
3	0.9978	0.9898	0.9982
Accuracy		0.9953	
Macro Avg	0.9932	0.9862	0.9865
Weighted Avg	0.9965	0.9896	0.9910

Source: Authors, (2026).

An accuracy of 99.5% on the test data and 100% on the training data indicates that the model has achieved high levels of performance in predicting the target variable. An accuracy of 99.5% suggests that the model is talented to properly categorize 99.5% of the instances in the test dataset. Figure 5, represents the accuracy graph. Accuracy graphs often depict the performance of the model over the course of training epochs. Typically, the graph shows the accuracy on the y-axis and the number of epochs on the x-axis. The graph helps visualize how the accuracy of the model evolves during the training process. It is common to observe an increasing trend in accuracy during early epochs, followed by a plateau where the accuracy stabilizes. In our case, the accuracy graph showing a consistently high accuracy of 100% on the training data indicates that the model has learned the training data extremely well.

Table 2: The MAE, RMSE, R2, MAPE analysis on the dataset.

Category	MAE	RMSE	R2	MAPE
1	0.15	0.23	0.94	2.1%
2	0.12	0.18	0.96	1.8%
3	0.18	0.26	0.92	2.4%

Source: Authors, (2026).

The table 2 represents the evaluation metrics for three different classes in a classification task. AE (Mean Absolute Error): It measures the average absolute difference between the predicted values and the true values. In the table, smaller values of MAE indicate better accuracy and precision in the predictions. For example, in Class 2, the MAE is 0.12, which means, on average, the predictions deviate by 0.12 units from the true values. RMSE is the square root of the average of the squared differences between the predicted values and the true values. RMSE provides an interpretable scale for the error metric, similar to the original values being predicted. In the table, lower values of RMSE indicate better accuracy and a smaller spread of errors. For instance, in Class 1, the RMSE is 0.23, suggesting that the predictions have an average squared difference of 0.23 from the true values. In the table, higher values of R2 signify better goodness-of-fit for the model. For instance, in Class 2, the R2 is 0.96, suggesting that unrelated variables account for 96% of the total variation in the variable that is the dependent one. MAPE is often used when expressing the error as a percentage is more meaningful. In the table, smaller values of MAPE indicate better accuracy in the predictions. Class 2 has a MAPE of 1.8%, which means that there is an average discrepancy of 1.8% among the expected and actual values. These metrics provide insights into the accuracy, precision, goodness-of-fit, and relative errors of the model's predictions for each class.

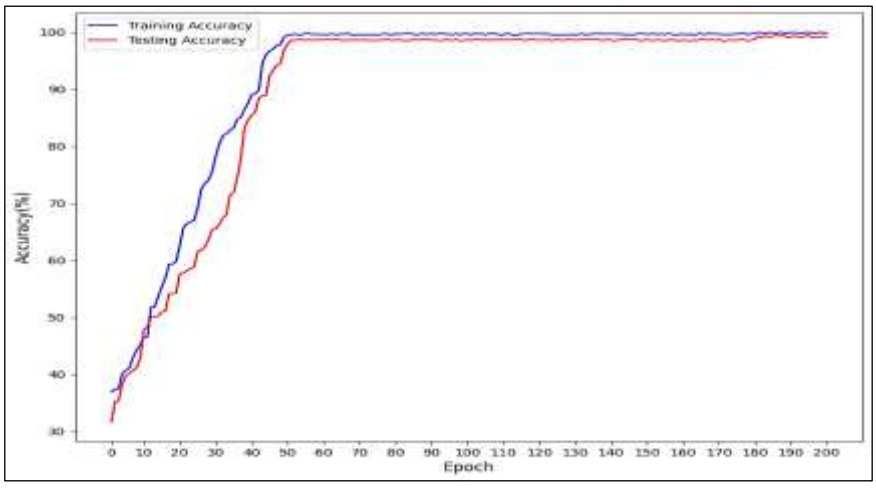

Figure 5: Accuracy of the proposed model on the road_accident_safety dataset.
Source: Authors, (2026).

Obtaining perfect precision on the training data is a great benchmark, but it may be a sign of overfitting if the model has just remembered the training data while being able to generalize adequately to new test data. Therefore, testing the model's generalization capabilities on a separate dataset is essential. The accuracy of 99.5% on the test data is an excellent result, indicating that the model is performing well on unseen instances. This high accuracy suggests that the model is making accurate predictions and capturing meaningful patterns in the test dataset.

A loss of 0.03 on the test data and 0.0 on the training data indicates that the model has achieved very good performance on both datasets. The loss value indicates how far off the model was from the actual results. A higher performing model will have a smaller loss value, suggesting that its forecasts are nearer to the truth. Figure 6, which shows the loss graph, is likely a visual representation of how the loss value changes during the training process. Classically, the loss decreases as the model learns from the training data. The loss graph allows us to analyze the convergence and stability of the model during training.

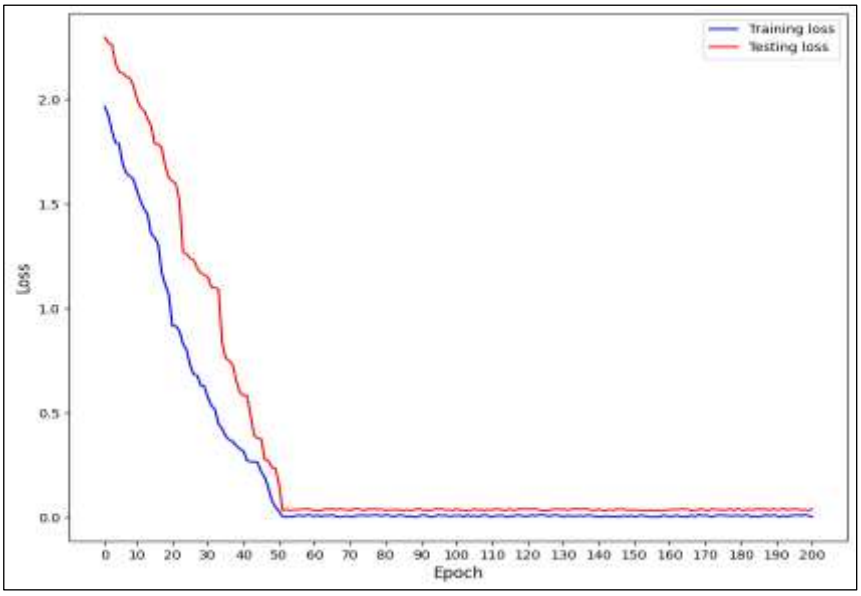

Figure 6: Loss of the proposed model on the road_accident_safety dataset.
Source: Authors, (2026).

If the loss decreases steadily and plateaus at a low value, this indicates the model has successfully mastered the patterns included in the training data and is producing accurate results. In the case of a loss value of 0.03 on the test data, it indicates that the model's predictions on unseen data (test data) are also accurate, and the model is generalizing well beyond the training data. This is desirable as it indicates that the model is not overfitting and can make reliable predictions on new, unseen samples.

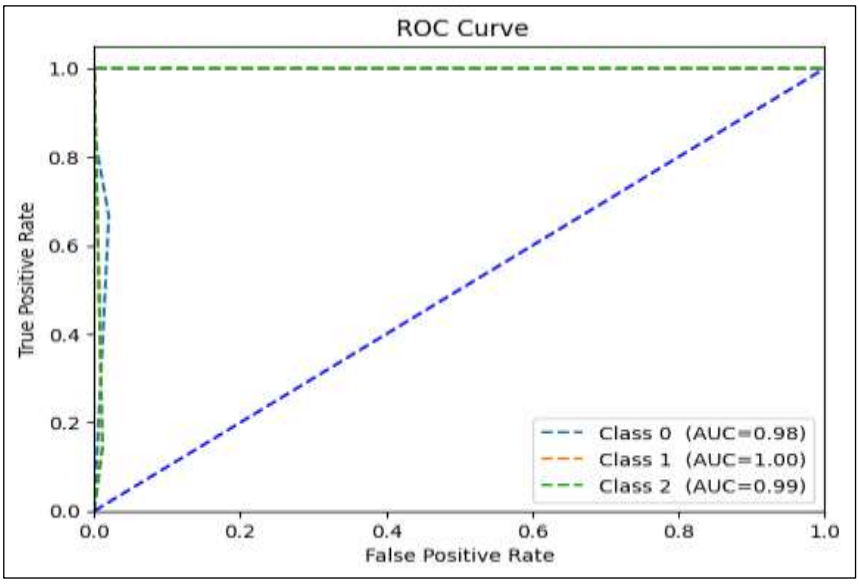

Figure 7: ROC-AUC of the proposed model.
Source: Authors, (2026).

The proposed model has achieved impressive ROC-AUC values for each class, from figure 7 indicating strong performance in classifying the data. ROC-AUC (Receiver Operating Characteristic - Area Under the Curve) is a widely used evaluation metric for binary and multi-class classification tasks that measures the model's ability to distinguish between different classes. A ROC-AUC value of 1.00 represents a perfect classifier, meaning the model can perfectly distinguish between the positive and negative instances of the class. In this case, Class 1 has achieved a perfect ROC-AUC score of 1.00, indicating that the model's predictions for this class are excellent and there is no overlap or ambiguity in its classification. For Class 0 and Class 2, the ROC-AUC values are slightly lower than 1.00 but still very high (0.98 and 0.99, respectively). These values indicate that the model's predictions for these classes are also very accurate, with a high degree of separation between the positive and negative instances.

VI. CONCLUSION

The importance of data mining in revealing hidden insights and recurring patterns in large datasets is emphasized throughout the study. With the advent of the big data era and the exponential growth in data volume and complexity, traditional data mining methods face significant challenges. To address this, the study proposes a novel approach that combines deep learning, specifically LSTM networks, with distributed computing. By leveraging the power of LSTM networks, which excel at capturing long-term relationships in sequential data, the proposed model offers a robust tool for data mining tasks. Additionally, the study introduces a parallel computing framework that utilizes the processing capabilities of a cluster's multiple nodes to enable decentralized operations. This distributed design not only accelerates the training and inference processes of the LSTM-based model but also ensures efficient processing of large datasets. Comparative analysis with standard data mining techniques demonstrates that the proposed model outperforms them on various real-world datasets.

The outcomes showcase the model's impressive accuracy of 99.5% and its efficiency in identifying useful patterns and making predictions. Moreover, the study validates the horizontal scalability of the model and highlights the advantages of distributed computing, solidifying its practical applicability in large-scale data settings. Future work in the field of proposed work can focus on several areas to further enhance the methodology and address emerging challenges. Investigate techniques to optimize the proposed deep learning-based distributed data mining approach using LSTM networks. This can involve exploring advanced optimization algorithms, regularization techniques, and hyperparameter tuning to improve model performance, convergence speed, and generalization capabilities. Explore methods to handle imbalanced datasets, which are common in real-world scenarios. Imbalanced datasets can lead to biased models and suboptimal performance. Investigate techniques such as oversampling, under sampling, and class weighting to effectively handle class imbalances and improve the model's accuracy and generalizability.

ABSTRACT

Photovoltaic (PV) water pumping systems offer a sustainable solution for agricultural irrigation in regions where conventional energy sources are unreliable or expensive. However, partial shading (PS) significantly degrades PV performance and limits water delivery. This paper proposes a dynamic PV array reconfiguration strategy based on the Red-Tailed Hawk (RTH) optimization algorithm to mitigate PS effects. The reconfigured PV array, combined with maximum power point tracking (MPPT), supplies a brushless DC (BLDC) motor-driven water pumping system to enhance operational efficiency. The proposed method ensures stable steady-state operation while maintaining the PV system near the maximum power point under varying shading conditions. Performance evaluation is carried out in MATLAB using a 4×5 PV array subjected to dynamic shading caused by a tree, with comparisons made against the conventional total cross-tied (TCT) configuration using reported experimental data. The results demonstrate clear improvements in water flow, with average gains of 36 liters per hour in the first case and 111.6 liters per hour in the second case. These outcomes confirm the effectiveness of the proposed approach and highlight its potential for improving the sustainability and reliability of photovoltaic water pumping systems in energy-constrained agricultural regions.

I. INTRODUCTION

Innovation and technology are essential in enhancing agricultural productivity. A noteworthy domain where substantial advancements are occurring is the incorporation of renewable energy sources (RESs) into agriculture, a highly significant trend. Agriculture is a vital industry in numerous countries, playing a crucial role in their economies. Currently, a significant proportion of farmers depend on conventional sources such as mains power or diesel engines to fulfill their water pumping requirements [1]. Nevertheless, the cost of fuel pumping has become progressively burdensome. Furthermore, expansive stretches of agricultural land are situated in isolated regions devoid of electrical infrastructure [2], [3]. Even in regions with electrical availability, the demand for water rises throughout the summer season, frequently aligning with power outages. Therefore, the use of PV water pumping emerges as a viable remedy to conserve energy, alleviate strain on the power grid, and diminish long-term energy expenses. However, partial shading is a significant obstacle to the effectiveness of solar water pumping systems, and addressing this issue is a challenge. The PS is commonly attributed to obstructions such as trees, dense vegetation, shrubs, utility poles, avian presence, topographical elevations, and rocks that create shadows on adjacent PV modules [4], [5]. Consistent shading of PV modules in a certain location can result in the formation of localized areas of high temperature, known as hot spots, which can potentially cause harm or damage. In order to alleviate this issue, bypass diodes are typically fitted on PV modules to prevent this occurrence.

Nevertheless, this arrangement frequently results in many peaks in the PV output, which substantially diminishes the total generated power of the PV array [6]. In this regard, several PV array configurations, including TCT (total-cross-tied) and HC (honeycomb), have been created to reduce mismatch losses and enhance efficiency. TCT topology has demonstrated the maximum power production in the majority of shading scenarios [6], [7]. However, no one topology consistently surpasses the others in every partial shading condition (PSC). To this end, numerous techniques for modifying the arrangement of PV arrays have been suggested in academic literature to enhance their power generation [8]. Static reconfiguration methods use fixed patterns to reduce shading effects and work well for predictable shading [9]. With modern sensors and processors, dynamic reconfiguration has emerged as an effective solution for variable shading conditions[9], [10]. Applied to TCT PV arrays, it balances irradiance to enhance power output [11], [12] , improving PV water pumping system efficiency. Dynamic reconfiguration is particularly suited for smaller PV arrays, stabilizing P–V characteristics and enabling conventional MPPT techniques to maximize energy extraction [13]. Many PV reconfiguration methods leverage various optimization algorithms, each exhibiting distinct strengths and weaknesses. Fathy's [14] butterfly optimization algorithm efficiently enhances power generation by structural redesign, yet it may struggle with computational complexity for large-scale arrays.

The democratic political approach [15] improves efficiency but may face scalability issues in larger systems. The grasshopper optimizer [16] shows promise in partial shading scenarios but can suffer from slow convergence rates. ACO [17] maximizes power extraction well but requires significant computational resources for larger arrays. The ken-ken puzzle method [18] is innovative in reconnecting shaded panels but might not always find the global optimum. Genetic Algorithms (GA) [19] are robust and versatile, though they can be computationally intensive and may converge to local optima. The Vommi optimization algorithm [20] maximizes power extraction efficiently but may require fine-tuning for different conditions. Particle Swarm Optimization (PSO)[21] is effective but can struggle with early convergence to suboptimal solutions. The Harris Hawks Optimizer (HHO)[22] provides good performance but lacks robustness in complex optimization challenges. Finally, the Honey Badger Algorithm (HBA)[23] and Artificial Bee Colony (ABC) [24] offer advanced methods but face issues such as prolonged convergence times, vulnerability to local optima, and high computational demands. Numerous researchers have explored PVWPSs, highlighting two main configurations: single-stage and two-stage configurations [25], [26]. In a single-stage configuration, regulating the DC link is complex [26].

Despite this complexity, single-stage topologies are considered more efficient due to their reduced number of components [27]. However, the two-stage power conversion approach offers greater flexibility in design, operation, and control. PVWPSs utilizing AC motors, particularly induction motors (IM), are often preferred due to their reliability, lower costs, and minimal maintenance requirements. Conversely, DC motors are typically employed in low-power solar PV water pumps [28]. Despite their usage, DC motors with brushes suffer from low efficiency and demand frequent maintenance because of the sliding brush contacts and the commutator. In contrast, three-phase brushless direct-current (BLDC) motors emerge as suitable alternatives owing to their high efficiency, compact design, and ease of operation [29]. Over the past decade, these attributes have made BLDC motors increasingly popular for water pumping applications, highlighting their advantageous characteristics in this specific field [28]. Although the wide PV reconfiguration techniques, their application for PVWPSs have not been addressed yet. To this end, a new dynamic PV array reconfiguration based on the RTH algorithm intended for a PVWPS considering PS is proposed in this paper. The main objective of this work is to improve the water flow of a PVWPS operating under PSCs. The main papers' contributions are:

- An innovative dynamic PV reconfiguration based on the RTH optimization algorithm is proposed. The RTH uses real-time irradiation data to reconfigure the modules within a PV array using switches, considering PSCs.
- The reconfigured PV array controlled by a P&O MPPT technique is applied for a water pumping system driven by a BLDC motor. The proposed algorithm allows the conventional P&O MPPT algorithms to perform optimally in achieving the global maximum power point even under PSCs, hence improving power and system performance.
- A comprehensive comparative study demonstrates the effectiveness of the proposed approach, showing clear improvements in water flow with average gains of 36 liters per hour in the first operating case and 111.6 liters per hour in the second case, compared to the conventional total cross-tied (TCT) configuration.

The paper's remainder is structured as follows: Section II presents the configuration and modeling of the system under study. Section III describes the proposed PV reconfiguration approach. The simulation results are discussed in Section IV. Finally, Section V ends with a conclusion.

II. PVWPS CONFIGURATION AND MODELING

The schematic diagram of the PVWPS under study is illustrated in Figure 1, highlighting essential elements such as a partially shaded TCT PV array, a switching matrix, power electronic converters (including a DC-DC boost converter and a DC-AC two-level inverter), a BLDC motor, and a pump with its associated control system. Additionally, it highlights the proposed RTH optimization algorithm, introduced to mitigate the PS effect by controlling the switching matrix. Furthermore, the MPPT controller used to track the PV MPP by controlling the DC-DC converter via PWM is also presented in this scheme. The modeling of elements included in the PVWPS is provided in the following paragraphs.

II.1 BLDC MOTOR

The mathematical model of the BLDC motor can be derived using the same approach as that of a three-phase synchronous machine. Thus, the equivalent circuit of the armature winding model for the BLDC motor can be defined as follows [30]:

$$\begin{cases} v_a = R.i_a + L\frac{di_a}{dt} + e_a \\ v_b = R.i_b + L\frac{di_b}{dt} + e_b \\ v_c = R.i_c + L\frac{di_c}{dt} + e_c \end{cases} \quad (1)$$

Where v_{abc} and i_{abc} denote the three-phase voltages and currents, R and L are the stator resistance and inductance, and e_{abc} are the motor voltages. Inputs to the BLDC motor control block include the Hall sequence number or rotor position from sensors like Hall effect sensors or encoders, along with torque direction. This information determines the rotor's sector position, enabling the calculation of the appropriate switching sequence. This sequence energizes motor phases to maintain a torque angle of 90 degrees (with a 30-degree deviation) relative to the stator magnetic field. For instance, Hall states that 5 triggers phase *A* and *C* to initiate motor rotation, optimizing efficiency as shown in Figure 2. While the calibration of the Hall sensor sequence ensures precise commutation logic, as detailed in Table 1.

II.2 PV ARRAY MODELING

To guarantee that the PVWPS operates correctly, it is imperative that the power capacity of the PV array should be greater than that of the induction motor. In this regard, a TCT (4×4) PV array of 2.4 kW capacity is chosen to supply the BLDC induction motor. The TCT array current is calculated using the method described as [31]:

$$I_{ij(shaded)} = K.I_{ij(STC)} \quad (2)$$

with:

$$K = \frac{G_{ij}}{G_{STC}} \quad (3)$$

Being i and j the row and column number of an array, $I_{ij(shaded)}$ and $I_{ij(standard)}$ represent the module current, during shaded and standard irradiance (i.e., 1000 W/m^2), G_{ij} is the irradiance received by the ij module, and G_{STC} denotes the standard irradiance. Besides, the PV array voltage can be derived as follows [5]:

$$V_{PV} = \sum_{i=1}^{m} V_i \quad (4)$$

Where m indicates the total number of rows, i indicates the row number, V_i is the voltage of the i^{th} row, and V_{pv} represents the array voltage. Table 2 lists the specifications of the adopted PV module and the PV array.

Table 2: PV system characteristics.

Parameter	PV module	PV array
Maximum power (P_{mpp})[W]	150	2400
Maximum current (I_{mpp})[A]	4.35	17.4
Maximum voltage (V_{mpp}) [V]	34.6	138.4
Open circuit voltage (V_{ov}) [V]	43.6	174.4
Short circuit current (I_{sc}) [A]	4.85	19.4

Source: Authors, (2026).

II.3 DC-DC BOOST CONVERTER

The design of the converter plays a vital role in deciding the performance of the system. The values of α, L_{pv}, and C_{dc} parameters of the boost converter should be calculated using the continuous conduction mode (CCM) [32]. The boost converter duty cycle α can be obtained using the following method:

$$\alpha = \frac{V_{dc} - V_{mppv}}{V_{dc}} \quad (5)$$

The boost converter's inductance can be computed using the equation below:

$$L = \frac{\alpha.V_{mppv}}{f_s.\Delta I} \quad (6)$$

Where f_s is the switching frequency and ΔI is the current ripple. On the other hand, the DC bus voltage at the inverter input, V_{dc}, can be calculated using the following relationship:

$$V_{dc} = \frac{2\sqrt{3}V_{LL}}{\sqrt{3}} \quad (7)$$

With V_{LL} is the RMS line voltage of the induction motor. The capacitor of the DC bus is calculated by:

$$C_{dc} = \frac{6\,\alpha V_{LL} I_L t}{\sqrt{3}\,({V_{dc}}^{*2} - {V_{dc}}^{2})} \quad (8)$$

Where ${V_{dc}}^*$ and V_{dc} are the reference and actual values of the DC bus voltage, respectively, t stands for the time for which the DC link voltage is to be changed, and I_L is the line current.

II.4 CENTRIFUGAL PUMP MODELLING

The load torque of a centrifugal pump (T_p) is proportional to the square of the induction motor speed (Ω), as shown in the equation below [33]:

$$T_p = K_p \Omega^2 \quad (9)$$

where K_p is the proportionality constant that can be determined by the following equation:

$$K_p = P_{np}/\Omega_{rn}^3 \quad (10)$$

The water flow and pressure of the pump are determined by the head of the pump and the mechanical power available at the rotating impeller. The use of affinity laws, which simply necessitate the pump's ratings and actual input parameters such as rotor speed and torque[34], could streamline the calculation of the pump's output characteristics.

$$\begin{cases} H' = (\frac{\Omega_r}{\Omega_{rn}})^2 . H \\ Q' = (\frac{\Omega_r}{\Omega_{rn}})^2 . Q \\ P' = (\frac{\Omega_r}{\Omega_{rn}})^2 . P \end{cases} \quad (11)$$

Where H, Q, and P represent the rated parameters of the pump when it is operating at the rated speed, Ω_{rn}, while H', Q', and P' represent the parameters of the pump when it is operating at a specified speed, Ω_r.

III. PROPOSED RTH-BASED PV ARRAY RECONFIGURATION

This section focuses mainly on describing the proposed reconfiguration method based on the RTH optimization algorithm intended for improving the PV-based pumping system working under PSCs. However, before that, the effect of the PS on a PV array is first investigated. In addition, the PO-MPPT controller is highlighted at the end of this section.

III.1 PARTIAL SHADING EFFECT

Partial shading in photovoltaic systems causes power losses due to current and voltage mismatches, leading to multiple local maxima on the P–V curve that conventional MPPT algorithms struggle to handle. Shaded modules generate less current, may act as loads, and can develop hot spots that damage the panels. Irradiance variations significantly affect the P–V characteristics, as illustrated in Figure 3.

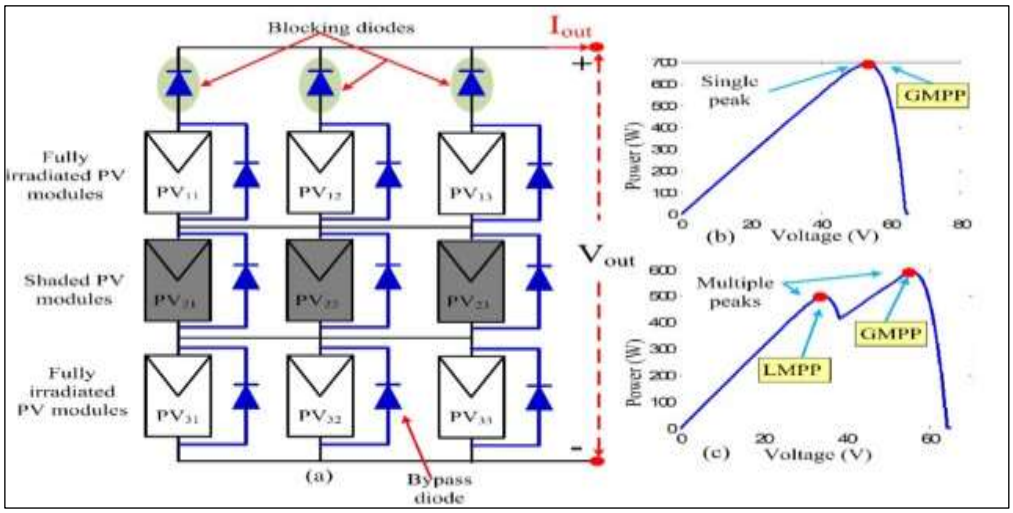

Figure 3: Impact of irradiation changes on the P-V curves: (a) shaded PV structure, (b) uniform irradiation, and (c) PSCs.
Source: Authors, (2026).

III.2 RTH-BASED PV ARRAY DYNAMIC RECONFIGURATION

This study focuses on a total cross-tied (TCT) PV array configuration due to its ability to maximize power under shading conditions [35]. A dynamic reconfiguration strategy is applied, using irradiance sensor data from each module to control switching. The proposed Red-Tailed Hawk (RTH) algorithm optimally determines PV module configurations to track the maximum power point (MPP). Inspired by the hunting behavior of red-tailed hawks, the RTH algorithm combines evolutionary and swarm optimization principles through three main stages—high soaring, low soaring, and stooping—allowing efficient and adaptive problem-solving for complex PV reconfiguration tasks:

i) It starts with a high-soaring phase, akin to how evolutionary algorithms search for solutions in a broad space initially [2]. Figure 4(a) illustrates the behavior of the red-tailed hawks during the high soaring stage, and (11) represents the mathematical model of this stage:

$$X(t) = Xbest + \big(Xmean - X(t-1)\big). Levy(\dim). \mathrm{TF(t)} \quad (12)$$

Where $X(t)$ represents the RTH position at the iteration t, X_{best} is the best-obtained position, X_{mean} is the positions' mean, Levy represents the levy flight distribution function that can be calculated according to (15), and $TF(t)$ denotes the transition factor function that can be calculated according to (14).

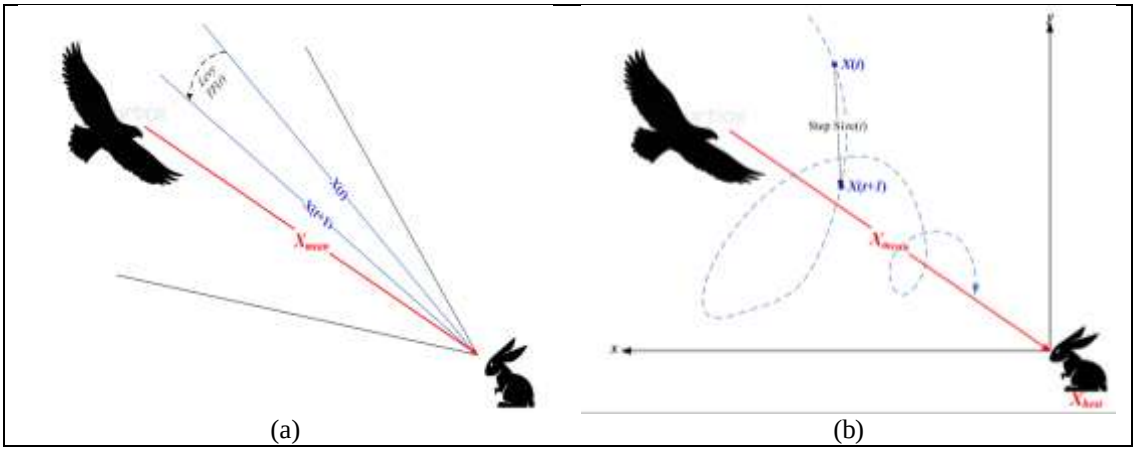
$$Levy(\dim) = s\frac{\mu.\sigma}{|v|^{\beta-1}} \quad (13)$$

with

$$\sigma = \left(\frac{\Gamma(1+\beta).\sin(\frac{\pi\beta}{2})}{\Gamma(1+\beta/2).\beta.2^{(1-\beta/2)}} \right)$$

$$\mathrm{TF(t)} = 1 + \sin\left(2.5 + \left(\frac{\mathrm{t}}{T_{max}}\right)\right) \tag{14}$$

While *s* is a constant (0.01), *dim* is the problem dimension, β is a constant (1.5), *u* and υ are random numbers between 0 and 1, and T_{max} represents the maximum number of iterations.



ii) The second stage involves a gradual descent toward the best solution, emulating the behavior of hawks as they close in on their target during hunting. This phase resembles the systematic exploration of the solution space. This stage is illustrated in Figure 4(b), and its model can be expressed as follows:

$$\mathrm{X(t)} = X_{best} + \big(x(t) + y(t)\big).StepSize(t) \tag{15}$$
$$StepSize(t) = X(t) - X_{mean}$$

where *x* and *y* denote direction coordinates which can be calculated as follows:

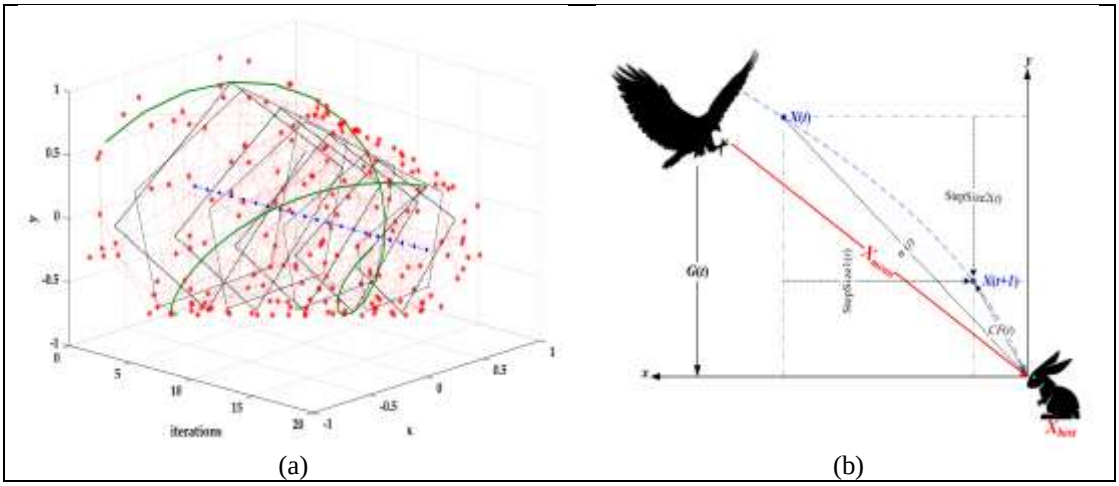
$$\begin{cases} x(t) = R(t).\sin(\theta(t)) \\ y(t) = R(t).cos(\theta(t)) \end{cases}; \begin{cases} R(t) = R_0.\left(r - \dfrac{t}{T_{\max}}\right).rand \\ \theta(t) = A.\left(1 - \dfrac{t}{T_{max}}\right).rand \end{cases}; \begin{cases} x(t) = x(t)/max|x(t)| \\ y(t) = y(t)/max|y(t)| \end{cases} \tag{16}$$

Where R_0 represents the initial value of the radius [0.5–3], *A* denotes the angle gain [5–15], *rand* is a random gain [0–1], and *r* is a control gain [1, 2]. These parameters help the hawk fly around the prey with spiral movements, as explained in Figure 5(a).

(a) (b)

Figure 4: The behavior of red-tailed hawk during the (a) high soaring stage and (b) low soaring stage.
Source: Authors, (2026).

iii) In the final stage of the algorithm, known as stooping and swooping, the algorithm refines the search around the best solution found so far by incorporating information from previous iterations. This phase represents the focused exploitation of the best regions identified in the search space. This stage can be modeled as follows:



$$X(t) = \alpha(t).X_{best} + x(t).StepSize1(t) + y(t).StepSize2(t) \tag{17}$$

where each step size can be calculated as follows:

$$\begin{cases} StepSize1(t) = X(t) - TF(t).X_{mean} \\ StepSize2(t) = G(t).X(t) - TF(t).X_{best} \end{cases} \tag{18}$$

With α is the hawk's acceleration that increases with the increase of *t* to enhance the convergence speed, and *G* is the gravity effect that decreases to reduce the exploitation diversity when the hawk is much near the prey as Figure 5(b) explains. These parameters are defined as follows:

$$\begin{cases} \alpha(t) = sin^2(2.5 - \frac{t}{T_{max}}) \\ G(t) = 2.(1 - \frac{t}{T_{max}}) \end{cases} \tag{19}$$

(a) (b)

III.3 APPLICATION OF THE RTH ALGORITHM FOR PV RECONFIGURATION

To apply the proposed algorithm for mitigating PS, the initial phase involves detecting PS by calculating the fitness function. This function evaluates the error value to facilitate efficient power generation from the PV system. Consequently, the fitness function is formulated to equalize irradiance across the TCT PV array. The fitness function aims to optimize the configuration of PV panels to minimize row current and prevent bypass diode activation. The objective function of the proposed system is mathematically expressed as:

$$fitness = \text{minimize}\big(max\big(sum\ G(n,1)\big) - min\big(sum\ G(n,1)\big)\big) \quad (20)$$

If no PS is detected, reconfiguration is unnecessary. However, if PS is detected, the RTH algorithm initiates to determine the optimal positioning of PV modules. Initially, the algorithm generates a random arrangement of PV modules to commence the three phases: High Soaring, Low Soaring, and Stooping and Swooping. Upon meeting the termination criteria, the RTH algorithm provides the optimal PV array reconfiguration using switch control to initiate the MPPT. Figure 6 illustrates the comprehensive flowchart of the proposed strategy, encompassing the detection of PS followed by the reconfiguration of the PV array using the RTH algorithm.

III.4 P&O MPPT CONTROL ALGORITHM

The Perturb and Observe (P&O) method is a straightforward iterative technique used for MPPT. This method perturbs the operating point of the PV system, causing the terminal voltage of the PV array to oscillate around the MPP voltage, even when solar irradiation and cell temperature remain constant. The flowchart of the P&O algorithm is depicted in Figure 7 [36].

IV. SIMULATION RESULTS

The performance of the proposed system is evaluated through MATLAB/Simulink simulations considering three partial shading conditions.

IV.1 CASE 1

As shown in Figure 8(a), the 20-module PV array connected in a TCT configuration experiences uneven irradiance levels of 1000 W/m² and 600 W/m². In this scenario, substantial shading affects several modules, with the first row being the most impacted. The resulting arrangement is shown in Figure 8(b), which is employed to compute the output power. The switch matrix alters the module position to enhance the output power. The P-V characteristics of both configurations are represented in Figure 9. This figure demonstrates the effectiveness of the RTH-based reconfiguration approach in achieving a more uniform distribution of shadow levels across the PV array, resulting in consistent PV characteristics by minimizing the disparity in row currents. Particularly, by inspecting the P-V curve, it is seen that the power produced by the RTH (2.673 kW) outperforms that of the initial TCT interconnection (2.241 kW), with a single point of MPP instead of two MPP for the initial TCT arrangement, i.e., the lower number of MPP influenced the accuracy of the MPPT algorithm.

Figure 10 shows the response of the PV array power before and after reconfiguration based on the RTH algorithm. It is observed that PV array power increased by more than 19.27% after RTH reconfiguration. Note that the delay is due to the reconfiguration time of the PV array. Further, Figure 11 presents the electromagnetic torque, *Te*, response of the PV array with TCT reconfiguration and with RTH-based reconfiguration. The results highlight that the reconfiguration advantage in the electromagnetic torque results in a lower torque ripple. Moreover, Figure 12 shows the rotor speed evolution using the RTH reconfiguration technique. The findings demonstrate that the rotor speed after RTH PV array reconfiguration under PSC is better than (more than 1042 rpm) the initial configuration TCT without reconfiguration (998 rpm). The water flow evolution obtained is shown in Figure 13. It can be seen that the quantity of the pumped water under PSC using the proposed RTH algorithm reconfiguration is increased by more than 4,27 %.

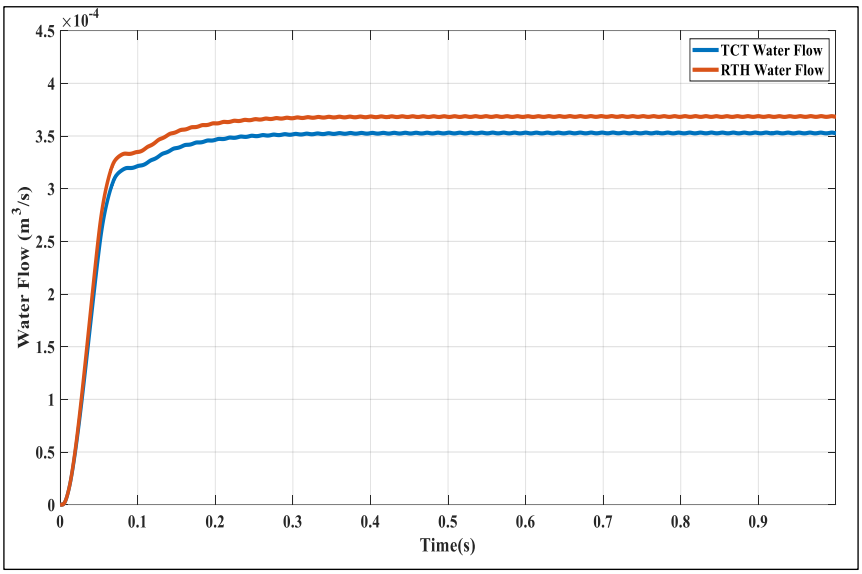

Figure 13: Comparison of PV array power for Case 1 under the conventional TCT interconnection and the proposed RTH-based reconfiguration.
Source: Authors, (2026).

IV.2 CASE 2

Figure 14(a) shows the PV array interconnected in TCT under PSC. The PV array encounters three distinct irradiation levels: 300 W/m², 500 W/m², and 1000 W/m².The arrangement shown in Figure 14(b) provides a way to improve the power output using the proposed RTH algorithm. The repositioning of the PV modules is performed using the switch matrix. After reading the irradiance value of the PV modules, the proposed algorithm sends the switching states to the switching matrix, which changes the position of the module to improve the output power. In addition, Figure 15 displays the P-V characteristics in graphical form. This shows clearly the effectiveness of the RTH-based reconfiguration approach in achieving a more uniform distribution of shadow levels in the PV array, resulting in consistent PV characteristics by minimizing the disparity in row currents. Notably, upon inspecting the P-V curve, it becomes clear that the power produced by the RTH algorithm exceeds that of the original TCT interconnection, with only one point of maximum power MPP rather than two MPPs for the initial TCT arrangement; that is, the lesser number of MPPs affected the accuracy of the MPPT algorithm positively. Figure 16 illustrates the PV array power before and after applying the RTH-based reconfiguration.

The results show an increase in output power of over 42%, with a minor delay attributed to the reconfiguration time of the array. Additionally, the TCT configuration exhibits three local maximum power points (MPPs), where the conventional P&O MPPT algorithm fails to track the global MPP, producing approximately 1.470 kW instead of the optimal 2.100 kW. This highlights the critical influence of PV array topology on MPPT performance. Figure 17 compares the electromagnetic torque of the motor with and without PV array reconfiguration. The RTH-based approach effectively reduces torque ripple and enhances torque stability. Similarly, Figure 18 shows the rotor speed improvement achieved through the RTH reconfiguration, reaching over 980 rpm under partial shading conditions (PSCs), compared to a maximum of 889 rpm with the original TCT setup. Regarding water delivery, Figure 19 shows that implementing the RTH algorithm results in an increase of more than 11.57% in pumped water under PSCs. This notable improvement demonstrates the effectiveness of the proposed RTH-based reconfiguration strategy in enhancing the overall performance of PV water pumping systems.

Source: Authors, (2026).

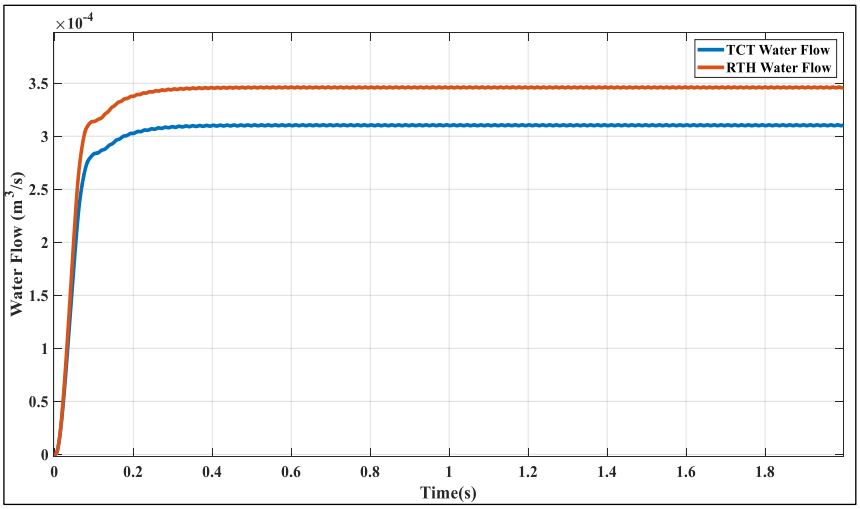

Figure 19: Comparison of water flow for Case 2 under the original PV array configuration and after RTH-based reconfiguration.
Source: Authors, (2026).

Table 3 presents a comparison of the overall performance indices of the PV water pumping system (PVWPS) under partial shading conditions (PSCs). The water gain for each scenario is computed using Equation (21), allowing an assessment of the effectiveness of the proposed reconfiguration strategy in enhancing water delivery under different shading patterns.

$$\text{Gained water (l/h)} = (Q_{RTH} - Q_{TCT}) \times 1000 \times 3600 \quad (21)$$

The performance indices in Table 3 clearly demonstrate the efficiency of the proposed algorithm. The system maintains stable steady-state operation and ensures satisfactory water delivery under partial shading (PS) conditions, while operating at the maximum power point (MPP). The results indicate a significant improvement in water flow, with average gains of 36 litres per hour in the first case and 111.6 liters per hour in the second case. This enhancement supports the development of sustainable photovoltaic water pumping systems in regions with limited access to conventional energy sources.

Table 3: Performance comparison of PVWPS under PSCs.

N°	cases	Used technique	P_{pv} (W)	W (rpm)	T_e (N.m)	Q ($m^3/s)10^{-4}$	Gained water (l/h)
1	Case 1	Without reconfiguration (TCT)	2243	999	5.01	3.5	36
2		With reconfiguration (RTH)	2612	1042	5.21	3.6	
3	Case 2	Without reconfiguration (TCT)	1476	877	3.33	3,09	111,6
4		With reconfiguration (RTH)	2096	979	4.71	3,4

V. CONCLUSIONS

This research proposes a new control method for improving the water flow of a WPS based on PV under partial shadowing. In this proposed method, the RTHA optimization algorithm is adopted for dynamic PV array reconfiguration in an offline manner, considering PSCs. The MPPT-controlled reconfigured PV array is intended for supplying a BLDC motor-based WPS. The proposed control approach keeps PV systems near their MPP despite shading, thus improving power-voltage curves, efficiency, and water flow. The obtained results show a noticeable improvement in water delivery, with average gains of 36 liters per hour in the first operating case and 111.6 liters per hour in the second case. These improvements highlight the capability of the proposed approach to adapt the pumping operation to the available PV power while preserving system stability. Overall, this work contributes to the development of sustainable and efficient photovoltaic water pumping solutions, particularly suitable for remote and energy-constrained regions where access to conventional power sources is limited.

ABSTRACT

In 5G wireless communication system, Generalized frequency division multiplexing (GFDM) is a promising substitute to OFDM that offers improved spectral efficiency and lower PAPR. However, performance of GFDM based wireless communication system can still be degraded by channel impairments such as noise and fading. The error correction codes are one of the techniques used for improving the performance. Different error correction codes are used for error correction in 4G and 5G communication system. This paper proposes a hybrid error-correcting code (ECC) scheme that combines polar code and convolution code to improve the bit error rate (BER) performance of GFDM compare to conventional ECCs. Simulation results illustrate that the proposed hybrid ECC scheme outperforms traditional error correcting code, in terms of BER performance. The proposed scheme also achieves near-optimal BER performance under various channel conditions.

I. INTRODUCTION

In 5G wireless system, non-orthogonal multiple access with different modulation techniques like GFDM, FBMC, UFMC etc are used in place of OFDM i.e. promising technique for 4G, to achieve better performance to meet the required specification. GFDM is a promising modulation scheme that offers several advantages over OFDM, including lower PAPR, better spectral efficiency, and improved robustness against channel impairments [1-2]. Error-correcting codes are used in GFDM to lessen the effects of channel impairments such as fading and channel noise. Error correcting code (ECC) schemes can be broadly classified into convolutional codes and block codes as shown in the figure 1 [3]. Block codes, such as Reed-Solomon code, encode a fixed-length block of data into a longer codeword. Convolutional codes, on the other hand, encode a continuous stream of data bits into a longer stream of code bits.

Recently, polar codes have emerged as a powerful class of block codes with near-optimal error correction capability. Polar codes are constructed from a simple channel transformation that polarizes the channel into a set of high-capacity and low-capacity channels. By carefully selecting the encoding and decoding indices, polar codes can achieve near-capacity performance over a wide range of channel conditions [3]. This paper, proposes a hybrid ECC scheme that combines polar code and convolution code to improve the BER performance of GFDM. The proposed scheme first encodes the GFDM data using polar code. The polar code encoded data is then interleaved to spread the errors and improve the performance of the subsequent convolutional code. Finally, the interleaved data is encoded using a convolutional code. The resulting coded data is then transmitted over the Raleigh channel.

II. GENERALIZED FREQUENCY DIVISION MULTIPLEXING (GFDM)

[4-10] reviews and analyzes 5G technologies such as Universal Filtered Multicarrier (UFMC), Filter Bank Multicarrier (FBMC), Filtered-Orthogonal Frequency Division Multiplexing (F-OFDM), and Generalized Frequency Division Multiplexing (GFDM). Generalized Frequency Division Multiplexing (GFDM) is a promising non-orthogonal waveform for next-generation wireless communication systems. It offers flexible subcarrier and time-slot configurations while reducing out-of-band emissions. However, GFDM exhibits higher interference levels compared to Orthogonal Frequency Division Multiplexing (OFDM), necessitating robust error correction techniques. Generalized Frequency Division Multiplexing (GFDM) is a modulation scheme where each subcarrier is individually and independently modulated with multiple symbols. In this process, each subcarrier is passed through a circularly shifted prototype filter applied in both the time and frequency domains. This filtering approach is designed to reduce out-of-band emissions (OOBE), thereby enabling flexible spectrum allocation, such as split-spectrum and dynamic spectrum distribution, without causing significant interference to the GFDM system itself or to neighbouring users. [11] To enhance the reliability of GFDM transmission, this study integrates Convolutional Coding and Polar Coding. Convolutional codes provide strong error correction with low decoding complexity, while Polar codes, known for achieving Shannon capacity, further improve robustness. The combined GFDM system is evaluated over a Raleigh fading channel in terms of Bit Error Rate (BER) performance [12].

III. CHANNEL CODING

In order to provide dependable data transmission, channel coding is utilized to mitigate the effects of a channel. In order for the recipient to identify and perhaps fix transmission faults, this technique adds redundant bits to the message being sent. Linear error-correction codes, such as Turbo and Convolutional codes, are employed in 4G networks. Polar codes and Low-Density Parity Check (LDPC) codes were suggested by the Third Generation Partnership Project (3GPP) for 5G networks. [13]

III.1 CONVOLUTION CODES

Convolutional codes are a class of error-correcting codes that operate by transforming the input bitstream into coded output symbols using convolution operations. Unlike block codes, which encode data in discrete blocks, convolutional codes process data in a continuous stream, making them particularly suitable for real-time communication systems. The encoding is performed using shift registers and modulo-2 adders, and the output depends not only on the current input but also on a number of previous input bits, known as the constraint length. In this paper the most common decoding techniques for convolutional codes is used which is Viterbi algorithm [14-16].

III.2 POLAR CODES

First introduced by Erdal Arıkan in 2009, represent a groundbreaking class of capacity-achieving error-correcting codes for binary-input symmetric memoryless channels. The concept of channel polarization forms the basis of polar codes, wherein certain synthesized channels become extremely reliable while others become highly unreliable as the code length increases. Data is transmitted only over the reliable channels, with the remaining channels assigned fixed, known values (frozen bits). Information bits are transmitted over the reliable subchannels, while fixed (frozen) bits are sent over the unreliable ones. Polar codes are known for their low encoding and decoding complexity of O (N log N), where N is the code length. Due to their capacity-achieving properties and structured construction, polar codes have been adopted as part of the control channel coding scheme in the 5G New Radio (NR) standard, particularly for eMBB (enhanced Mobile Broadband) scenarios. [17-23]

IV. SYSTEM MODEL

The data for simulating the GFDM system is x which is the sequence of bits. These bits sequence is coded by convolution and polar code. The output sequence $y_i[n]$ of convolution coding for the i-th output at time n can be expressed as:

$$Y_i[n] = \sum_{j=0}^{k-1} \sum_{l=0}^{m} g_{i,j}[l] x_j[n-l] \quad (1)$$

where,

$x_j[n-l]$: Input sequence for the j-th input at time n-l
$g_{i,j}[l]$: Coefficient of the generator polynomial connecting the j-th input to the i-th output with l representing the delay.[24]
Further polar code is applied on y[n] as follows,

$$w = y * G_N \quad (2)$$

Where y is the input vector consisting of information and frozen bits and w is the encoded output vector. [25] Given $N=2^n$ independent copies of a binary-input discrete memoryless channel (B-DMC) W, combine them to form a vector channel W_N. This combination is achieved using a transformation matrix

$$G_N = B_N F^{\otimes N}$$

where,

$F = \begin{bmatrix} 1 & 0 \\ 1 & 1 \end{bmatrix}$ is the basic polarization matrix.
$F^{\otimes N}$ denotes the n-th Kronecker power of F and B_N is a bit-reversal permutation matrix.
The transformation G_N polarizes the channels, resulting in the sets of synthesize channels $W_N^{(i)}$ for i=0,1,…,N-1.

IV.1. MODULATION QAM

Let GFDM block consists of K number of subcarriers allotted in total M number of time slots, then the modulated GFDM symbol (S(n)) can be expressed as,

$$S(n) = \sum_{k=0}^{K-1} \sum_{m=0}^{M-1} d_{k,m}\ g_{k,m}\ (n) \quad (3)$$

where:

K = Number of subcarriers
M = Number of time slots
$d_{k,m}$ = QAM-modulated data symbol at subcarrier k and time slot m
$g_{k,m\,(n)}$ is the filter response corresponding to $d_{k,m}$.
The $g_{k,m\,(n)}$ can be expressed as **:**

$$g_{k,m}(n) = g(n-mM) e^{j2\pi kn/K} \quad (4)$$

Where: g(n) is the pulse-shaping function (typically a raised cosine filter) and mM is Time shift applied to the pulse for time slot mm $e^{j2\pi kn/K}$ = Frequency shift applied to map the pulse to subcarrier k. This formulation allows GFDM to provide flexibility in spectrum shaping while maintaining good spectral efficiency. Unlike OFDM, which uses orthogonal subcarriers without time-domain overlapping, GFDM introduces time-domain flexibility, making it suitable for applications like 5G and IoT **[**26].

V. SIMULATION FRAMEWORK AND RESULTS

The proposed communication system architecture shown in figure 2 integrates hybrid channel coding with Generalized Frequency Division Multiplexing (GFDM) to enhance data reliability and spectral efficiency in wireless environments. Initially, a random binary data stream is encoded using a hybrid coding scheme that combines convolutional and polar codes, leveraging the error-correction strengths of both. The encoded bits are interleaved and mapped onto QAM symbols, followed by sub-band allocation. These symbols are converted from serial to parallel and processed through an N-point IFFT and Root Raised Cosine (RRC) filtering to shape the spectrum. A cyclic prefix (CP) is inserted to mitigate inter-symbol interference before RF conversion and transmission through a Rayleigh fading channel. At the receiver, the signal undergoes RF-to-baseband conversion, CP removal, and matched filtering.

The received symbols are then demapped, converted back to a serial stream, de-interleaved, and decoded using the hybrid decoder to retrieve the original data. This framework effectively combines robust error correction with the flexibility of GFDM, making it suitable for 5G and beyond communication systems operating in multipath fading environments. Simulation results were conducted to evaluate the performance of the proposed hybrid ECC scheme. The simulations were performed over a Rayleigh fading channel with additive white Gaussian noise (AWGN). The BER performance of the proposed scheme was compared with other ECC schemes, such as convolution code polar code, no code. The simulation also identified the optimum roll off factor of root raised cosine filter of GFDM system by parametric analysis. In second phase, the optimum roll off factor with hybrid ECC is used for improved performance of GFDM based wireless communication system. The parameters of simulation are shown in table 1. To identify the roll off factor (alpha), a parametric analysis has been performed with the different values of alpha as shown in table1 for no coding convolution coding and polar coding.

Table 1: Parameters of simulation

S. No.	Parameter	Value
1	ECC	Convolution, Polar, Hybrid
2	Mapping Method	QAM (32,64,256.512)
3	Up sampling factor	8
4	GFDM filter	Root Raised Cosine
5	Roll off Factor	0.01 to 0.35
6	Channel	Rayleigh flat fading
7	SNR	0 to 30 dB
8	Decoder	Viterbi Decoder

Source: Authors, (2026).

V.1.BER WITHOUT CHANNEL CODING

Simulation for QAM modulated GFDM signal, which was transmitted over Rayleigh fading channel, was performed with the parameters shown in table 1. Different values of alpha (roll off factor of Root Raised Cosine filter used for GFDM signal generation) in simulation were taken for parametric analyses. The result with no error correcting coding is shown in figure 3.

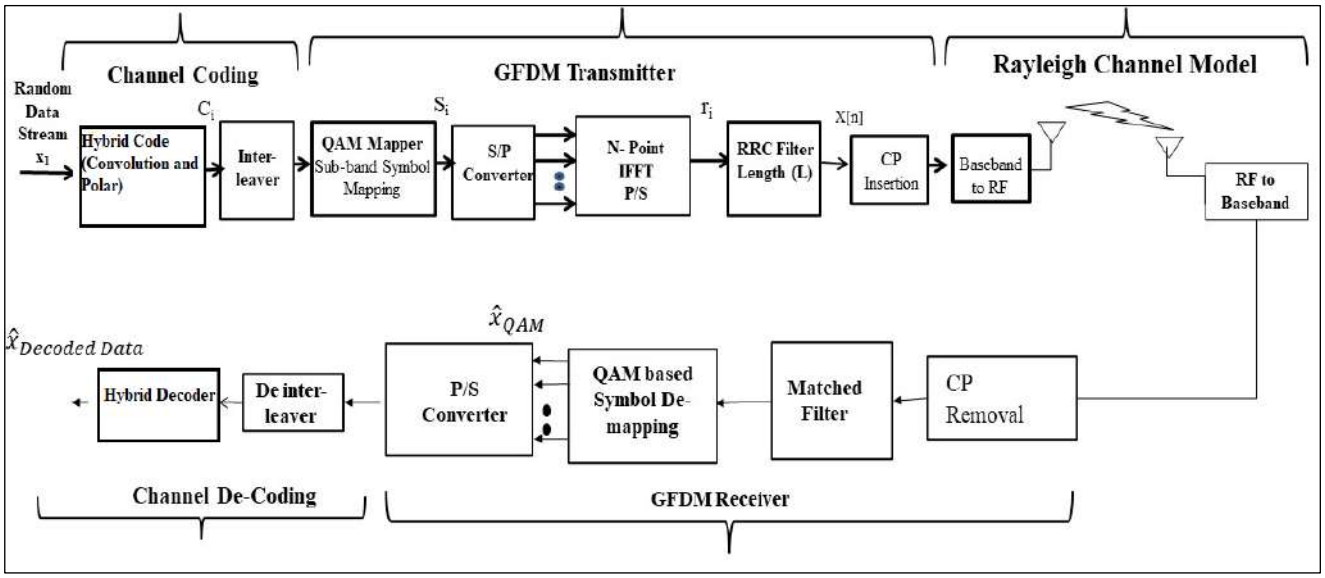

Figure 2: Scheme of the GFDM based wireless communication system.
Source: Authors, (2026).

The simulation results illustrate the impact of the roll-off factor alpha on the Symbol Error Rate (SER) vs. Signal-to-Noise Ratio (SNR) performance in the GFDM system. Increasing α improves SER performance up to an optimal range (α=0.2 to α=0.3), after which the gains become negligible. At high SNR (≥15 dB), α=0.2 to α=0.3 provides the better error performance, reducing SER to nearly 10^{-5}. A very low α=0.1, leads to significant degradation in performance, making it less suitable for GFDM applications requiring low SER. Hence, A moderate roll-off factor (α=0.2 to α=0.3) provides an optimal trade-off between spectral efficiency and error performance in GFDM systems.

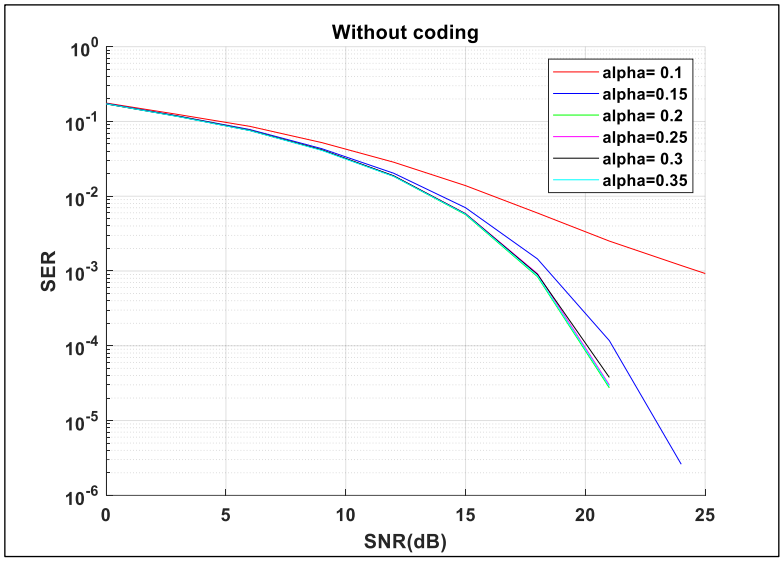

Figure 3: BER performance of GFDM system with different value of alpha (roll- off factor).
Source: Authors, (2026).

V.2.BER WITH CONVOLUTION CODING

Further, error-correcting codes i.e. convolution code is used for simulation for QAM modulated GFDM system. BER performance with convolution code was recorded for different values of alpha. The result with convolution code based GFDM system is shown in figure 4.

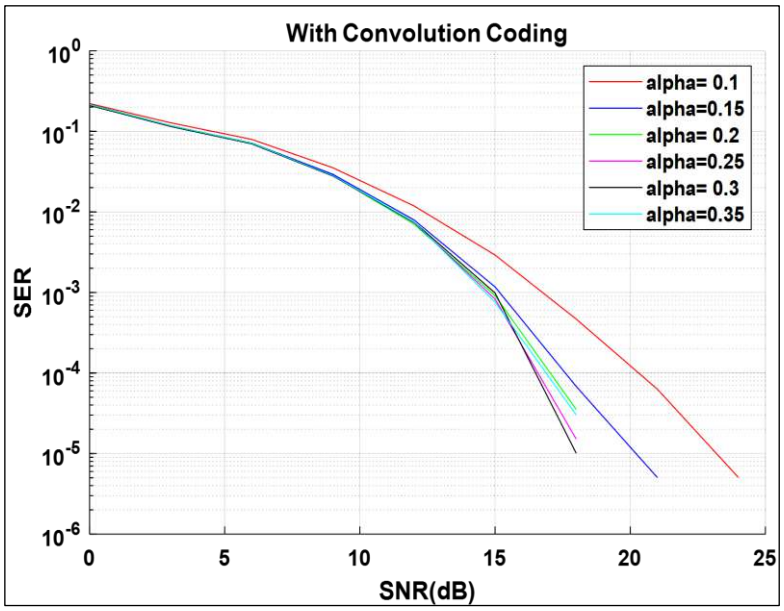

Figure 4: BER performance of GFDM system with convolution code for different value of alpha.
Source: Authors, (2026).

It is apparent from the figure 4 that the value of alpha of 0.25 is providing the optimum performance of the GFDM system. However, there is no significant changes in performance of BER for different value of alpha like the case of no coding. It is also observed, there is significant improvement in the BER performance with convolution coding compare to no coding. The SNR requirement has reduced to ~ 4 dB for BER value of <0.001.

V.3.BER WITH POLAR CODING

Further, another error correcting codes i.e. Polar code was used for simulation for QAM modulated GFDM system. BER performance with this code is shown in figure 5. It is observed from the figure 5 that significant improvement in the BER performance with compare to convolution coding. The SNR requirement has further reduced to ~ 2 dB for BER value of <0.001. It is apparent from the figure 5 that the value of alpha of 0.25-0.35 is providing the optimum performance of the GFDM system. The typical errors with alpha are shown in figure 6.

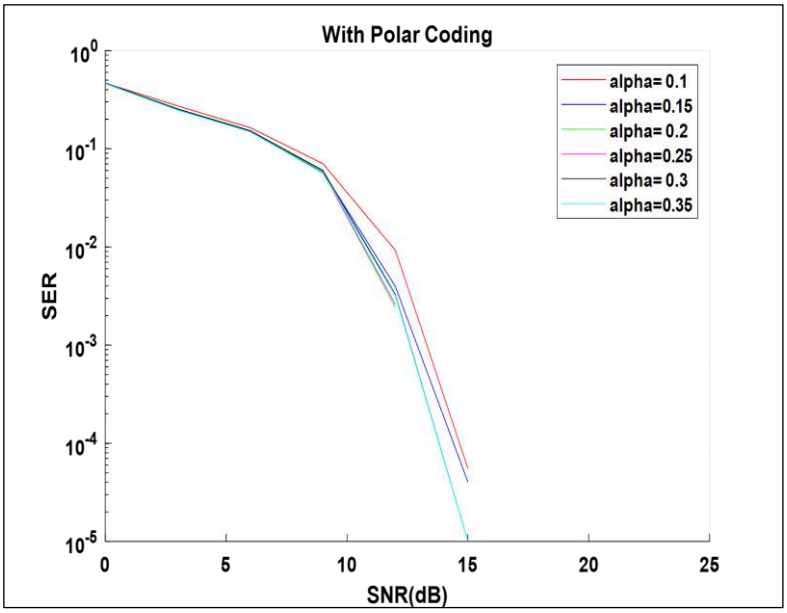

Figure 5: BER performance of GFDM system with Polar code for different value of alpha.
Source: Authors, (2026).

V.4.BER WITH PROPOSED ECC

Further, the hybrid scheme of ECC was used for simulation for QAM modulated GFDM system. BER performance with this code is shown in figure 7. It is observed that above > ~12 dB SNR, the hybrid Coding scheme achieves the lowest Symbol Error Rate (SER) among others. The simulation results demonstrate that the proposed hybrid ECC scheme outperforms traditional ECC schemes in terms of BER performance. The proposed scheme also achieves near-optimal BER performance under various channel conditions. This demonstrates that Hybrid Coding provides nearly a 100x improvement over the uncoded system and about a 10x improvement over Polar Coding, making it the most efficient error correction technique for GFDM at high SNR values.

VI.CONCLUSIONS AND FUTURE WORK

This paper proposed a hybrid ECC scheme that combines polar code and convolution code to improve the BER performance of GFDM. The proposed scheme offers significant BER improvement compared to traditional ECC schemes. The simulation results shows that the Hybrid Coding scheme significantly enhances the error performance of the GFDM system, for mid to high SNR level (>12 dB). BER at SNR of 15 dB show ~ 100 times lower than individual coding scheme. These findings highlight that Hybrid Coding is the most efficient error correction technique particularly mid to high SNR level. Future work, the further optimization of this hybrid ECC may explore by optimization its parameters. The use of this code for adaptive modulation and coding (AMC) system for 5G wireless communication system for lower bit error rate may be explored.

ABSTRACT

A compact monopole antenna on a printed circuit board incorporating a single negative (SNG) metamaterial targets application in the X and Ku bands at 9.2 and 14.2 GHz. The design utilizes circular split-ring resonator (SRR) unit cells, structured with periodic arrangements smaller than the guided wavelength. Using CST Studio Suite simulation, the antenna demonstrates a wide 750 MHz bandwidth and very low radiation losses. This efficient design enhances performance and coverage, making it well-suited for radar and satellite communications within the targeted frequency bands.

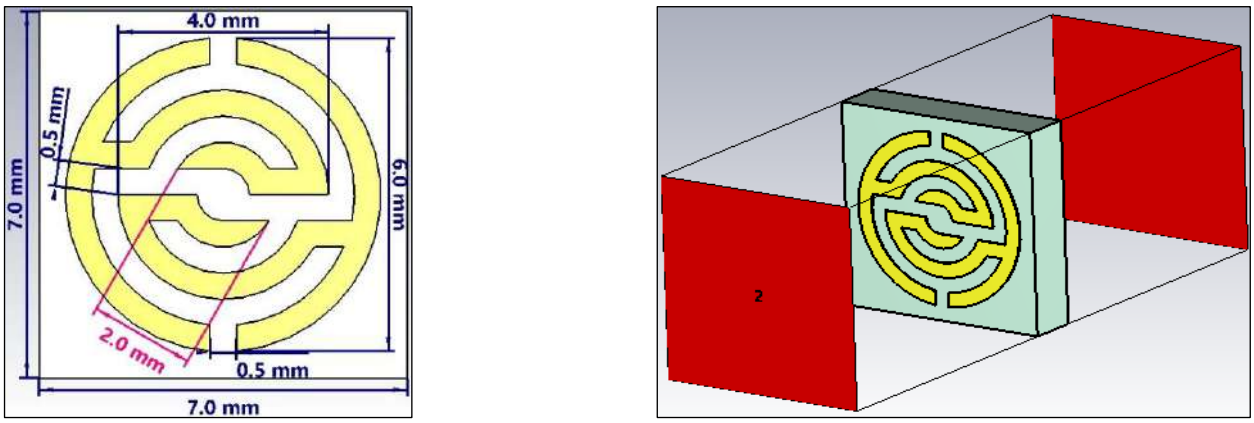
I. INTRODUCTION

Metamaterials are artificially designed composite materials, the electromagnetic characteristics of which differ significantly from those of naturally occurring materials [1]. The peculiar manners of behavior among metamaterials have provoked a rather significant amount of research interest, and it has led to tremendous breakthroughs within a variety of scientific and engineering fields [2]. Conventional classification schemes define the following two main metamaterials assemblies: single-negative (SNG) materials, which exhibit either a negative permittivity or a negative permeability, and double-negative (DNG), and sometimes also left-handed (LH) materials, with simultaneously negative permittivity and negative permeability. Victor Veselago of Russia first theorized about LH metamaterials in 1967, in which

Veselago introduced the possibility of LH materials being able to display various unusual properties in how they guided the propagation of waves in both open space and guided structures [3]. The respective capabilities provided a rationale behind a diverse array of applications, such as holography, data processing, as well as signal multiplexing. The metamaterials (MTMs) have shown usefulness in various areas of engineering, such as antenna designing [4], [5], microwave filtering [6], specific absorption rate (SAR) relief [7], cloaking [8], super-resolution optics [9], electromagnetic (EM) absorption [10], [11], advanced sensors [12], [13], radar applications, and satellite communications [14], [15]. In all these applications, the properties of their optimized electromagnetic responses improve the performance of the devices.

On this note, researchers have implemented new MTM setups that are streamlined in support of certain functions. The framework of Islam et al. proposed a structured MTM on FR-4 substrate on satellite antennas, functioning on 2–4 GHz [16]. A single tri-band microwave use of compact epsilon-negative (ENG) MTM by a crossed-line CSRR structure has been designed by Shahidul et al., based on a unit-cell dimension of 10×10 mm^2 and a low effective medium ratio (EMR) of 4.5 [17]. The authors of [18] developed a meta-atom that could be used at multiband operations, and they had an EMR of 10.55 and a dimension of 12×12×1.6 mm^2. The authors of [19] presented a miniaturized DNG MTM having the modified Z-shape, most appropriate to operate with in X-band, but with an EMR as low as 4.

An SNG MTM was proposed by Islam et al., which aims to calibrate the performance of satellite and radar antennas, with a refractive index of near-zero and an effective magnetic resonance of 14.37 and 8×8 mm^2 unit cell [15]. Cheng et al., in line with imaging, detection, and sensing, developed the scenario of an ultra-slim, recessed, 7-metamaterial-bound absorber that has a single resonator [20], whereas the authors of [21] refined an adjustable, single-resonant broadband MTM absorber utilizing graphene in the terahertz regime, advancing its capacities of filtering, sensing, and modulation. Hossain et al. came up with a multiband application DNG MTM shaped like a double C with moderate EMR [22]. On the other hand, a double-Z shaped DNG-MTM with a footprint size of 8.5×8.5 mm^2 and having an EMR value of 4.80 was provided by Zhou et al. [23], and Hoque et al. provided a dual-band DNG metasurface absorber even though it exhibits a large-size unit cell of 4.80 EMR [24] ,[25]. By presented an H-shaped MTM with a large size DNG absorption structure having EMR = 3.65 [26].



At the same time, demonstrated an asymmetric broadband MTM microwave absorber that can be utilized in the applications related to energy acquisition and stealth [27]. The authors of [28] suggested to work on a polarization-insensitive wideband MTM absorber realized within the C- and X-bands operating range by utilizing a 12.5×12.5 mm^2 unit size, and Zhou et al. are proposed to work on an S-shaped SNG MTM that is designed to operate within the X- and Ku-bands with an EMR below 4 [29]. By. also presented an MTM sensor structured into a meanderline, showing -3 dB/mm sensitivity and EMR of 7.2 [30].other related contributions are the proposed four-fold symmetric MTM absorber in the C-band, distributed by Thummaluru et al. with exceptionally large cell dimensions (28.2×28.2 mm^2) [31], and the DNG MTM structure fabricated in dual-band microwave applications by Faruque et al. (25×20 mm^2) [32]. Islam and his colleagues considered a hexagonal SRR MTM working at S- and X-frequency bands, using a 10×10 mm^2 unit and producing a 8.40 EMR [33].

The team of Rao et al. proposed a CPW-fed MTM-based circularly polarized antenna used in WiMAX and WLAN with a 9×9 mm^2 unit dimension and an EMR of 9.95, with only moderate gain [34]. The authors of [35] suggested a dual-band anisotropic MTM applicable to radar and satellite technologies, while the authors of [36] presented a high-gain, wide-bandwidth patch antenna with a concentrating metasurface, achieving 4.5 dBi gain with 76\% bandwidth [36]. Recently, the authors of [37] presented a left-handed multiband MTM having five absorbing bands, with 11×10 $mm^2compact unit footprint. Kumari et al. developed a principal lay-down ultra-thin polarization-insensitive MTM, in X-band, and made use of a 10×10 mm^2 absorber element with a small effective magnetic-field density (EMR) [38], [39]. According to Almutairi et al., a DNG MTM dual-band absorber in the C-band has a cell unit of 5.5×5.5 mm^2 and an EMR of 7.44 [40]. Thummaluru et al. claimed that a polarization-controllable tunable MTM absorber (POL-TC) in a circular sector structure, as a C-band absorber with dimensions of 9×9 mm^2, can also be tuned over a broad range [41].

Rao et al. have introduced a circular-shaped MTM that has expanded the bandwidth of the antenna fed with CPW, at some cost to the gain [42]. It is possible to benefit from several models of antenna configuration and integration with metamaterial cells to obtain a new generation of antennas with a smaller size, high gain and high efficiency [43-45]. The novel metamaterial single-negative (SNG) presented in this paper is a SSRR -based geometry, and its realization of two resonance peaks at 8.4-9.9 GHz and 14.0-14.2 GHz with a range of negative refractive index (NRI) between 9.26-9.7 GHz. These properties make it suitable in filtering, sensing, and controlling the electromagnetic waves. The findings show that integration of SNG metamaterials into the system can form a strong base in terms of certain application in advanced wireless and communication systems and the proposed design is one way of going about this.

II. ARCHITECTURAL DESIGN OF THE UNIT CELL

Figure 1(a) illustrates the structure of the proposed metamaterial unit cell geometry, which comprises multiple pairs of symmetric C-shaped split-ring resonators (SRRs) structured in an overlapping configuration. Fabricated on an FR-4 substrate, the unit cell possesses a relative dielectric constant of 4.3 and a 1.6 mm thickness, while the metallic conductor layer has a 0.035 mm thickness. To model and analyze the electromagnetic behavior of the structure, simulations utilized CST Microwave Studio (CST MWS), which uses the Finite Integration Technique (FIT). The unit cell was evaluated across the 1-15 GHz frequency range. For simulation purposes, the structure was situated amidst a pair of waveguide ports aligned along z-axis to enable electromagnetic excitation, as depicted in Figure 1b. Boundary conditions were set using a perfect electric conductor (PEC) coincident with x-axis and a perfect magnetic conductor (PMC) along the y-axis. Figure 1(a) shows detailed dimensions and design specifications of the unit cell.

(a) (b)

Figure 1: Unit cell of metamaterial: (a) Unit cell structure in two dimensions and size of a 7 × 7 × 1.6 mm. (b) three dimensions view simulation setup of two-port.
Source: Authors, (2026).

The unit cell of the proposed metamaterial (MTM) consists of multiple concentric metallic rings, each spaced by a 0.5 mm uniform gap, as illustrated in Figure 2(a). The inner rings feature two splits but are interconnected via a metallic strip of 0.5 mm width, as shown in Figures 2(b) and 2(c). The outer ring includes 2 narrow gaps positioned 180 degrees apart, as depicted in Figure 2d. An enhancement in stopband performance is observed when two thin metallic arms are introduced between the inner and outer rings ,Figure 2(e), leading to the ultimate optimized design of the metamaterial unit cell. From an electromagnetic perspective, the metallic rings function as inductive elements, while the gaps between the rings serve as capacitive elements, forming an LC resonator. Figure 2 provides a step-by-step overview of the design evolution and optimization process of the proposed metamaterial structure.

III. SIMULATION OF THE UNIT CELL AND ANALYSIS

The simulation of the MTM unit cell is provided in this section. The suggested SRR operates at 9.2 and 14.2 GHz bands, where X and Ku bands are considered candidates for the applications of radar and satellite. Figure 3 shows the reflection and transmission coefficients of the unit cell are shown. As shown in Figure 3, the unit cell operates with a bandwidth of 750 MHz. at 9.2 and 14.2 GH.

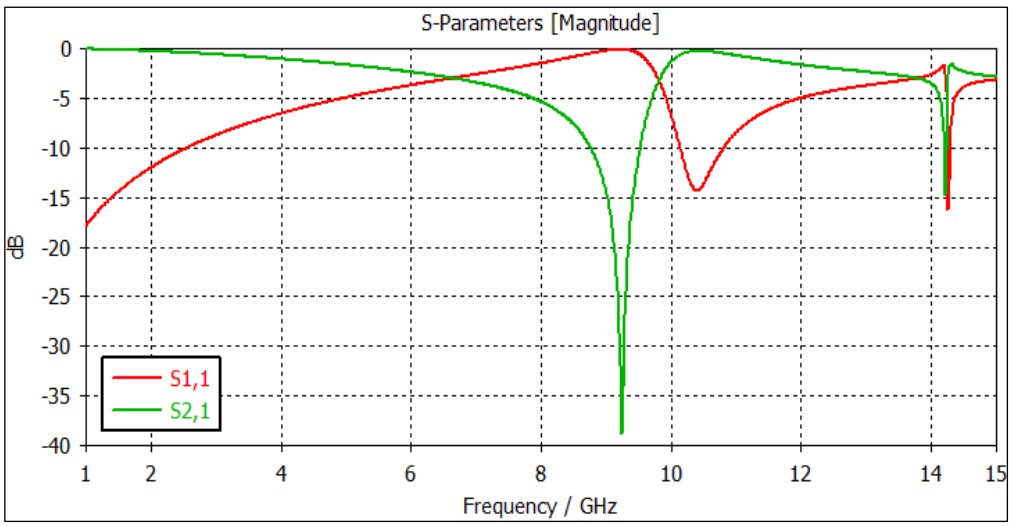

Figure 3: Simulated reflection and transmission coefficients for the SRR metamaterial unit cell.
Source: Authors, (2026).

The simulated relative real components of the effective permittivity, permeability, and refractive index unit cell structure are graphed in Figure 4. The frequency range reveals a negative real permittivity (ϵ) value for the unit cell. Consequently, incorporating SRR with a unit cell yields single epsilon negative (ENG) characteristics from 8.4 to 9.9 GHz and 14 to 14.2 GHz, and negative refractive index (NRI) from 9.26 to 9.7 GHz, as can be seen in Figure 4.

III.1 SURFACE CURRENT

Obviously, as is seen in the literature explaining the work of metamaterials, MTM is suffering from radiation losses, since in this paper, a composed metamaterial unit cell is used to overcome the radiation loss by using retrieval and transmission analyses. exposes the induced work of metamaterials, MTM is suffering from losses, since in this paper, a composed metamaterial unit cell is used to overcome the radiation loss by using retrieval and transmission analyses. The technique of radiation loss reduction was done by using the induced surface current and retrieval analysis. Figure 5 exposes the induced surface current on the two circles: the inner and middle circles of the SRR unit cell at the 9.2 band. While in the 14.2 band, expose the induced surface current on the outer circle as demonstrated as shown in Figure 6.

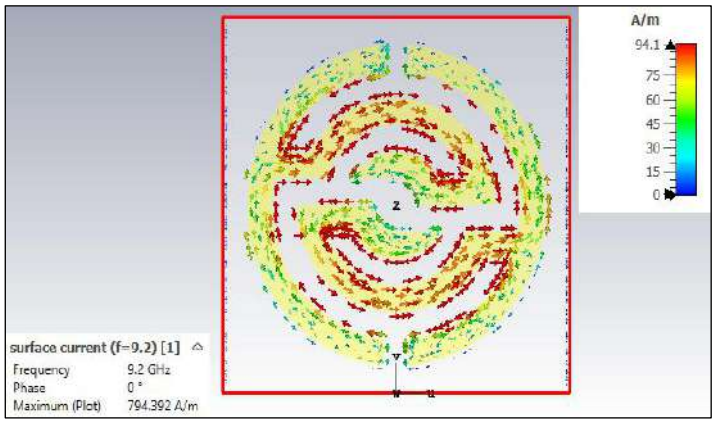

Figure 5: The surface current induced at a frequency of 9.2 GHz.
Source: Authors, (2026).

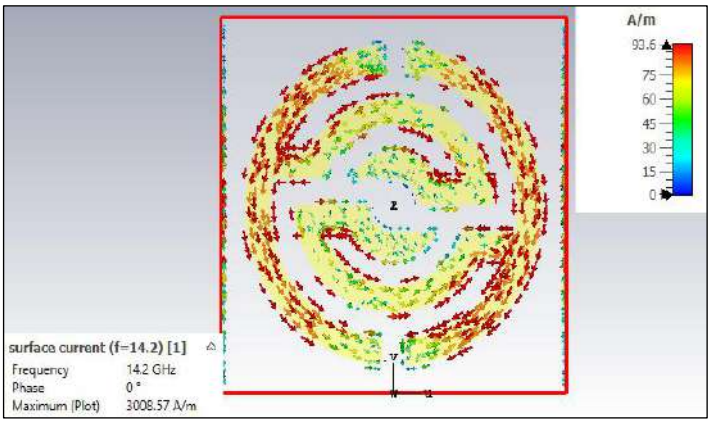

Figure 6: The surface current induced at a frequency of 14.2 GHz.
Source: Authors, (2026).

The dipole response produces large radiation losses. However, by modifying the metamaterial structure to apply opposite currents, the induced currents cancel out each other thus repressing the radiation loss.

III.2 SURFACE CURRENT

Table 1 categorizes the proposed design as "complex" in terms of geometric shape complexity. This is an important consideration for practical implementation. Although circular SRR unit cells are well-established, the overlapping configuration and the introduction of thin metallic arms for optimization (as shown in Figure 2) contribute to this complexity. Designs such as the "simple" circle shape by Almutairi et al. [40] or the square shape by [46] might offer easier fabrication. However, the increased complexity of the proposed design appears to be justified by its dual-band operation and loss-reduction capabilities. A more detailed discussion of the manufacturability and tolerance to fabrication imperfections would further enhance this aspect of the paper., as is seen in the literature explaining the work of metamaterials, MTM is suffering from radiation losses, since in this paper, a composed metamaterial unit cell is used to overcome the radiation loss by using retrieval and transmission analyses. exposes the induced work of metamaterials,

IV. CONCLUSION

This paper proposed a metamaterial unit cell exhibiting SNG behavior. The proposed design utilizes an SSRR structure, demonstrating operation within the X and Ku bands. It exhibits a NRI in the 9.26 to 9.7 GHz frequency range. Additionally, the unit cell operates at two distinct frequencies that are 9.2 GHz and 14.2 GHz, with a 750 MHz bandwidth. The designed unit cell exhibits SNG characteristics across different frequency bands, indicating its capability to function as a Single Negative metamaterial in specific operational ranges.

Mitigation.

ABSTRACT

Forest fires present significant environmental, economic, and social challenges in both Indonesia and Australia, with each country exhibiting different causes and effects. In Indonesia, forest and peatland fires are frequently driven by land-use changes, agricultural practices, and extended dry seasons, particularly during El Niño events. In contrast, Australia experiences intense bushfires primarily fueled by extreme heat, drought, and natural ignition sources such as lightning. This research analyses fire trends in both countries, identifying key factors that contribute to their frequency and severity. Lessons learned from past incidents, including the 2019–2020 Australian bushfire crisis and Indonesia's recurrent peatland fires, emphasize the need for improved fire management strategies. Various mitigation approaches, such as early warning systems, controlled burns, policy regulations, and community-based prevention programs, are discussed. In addition, advancements in remote sensing, artificial intelligence, and IoT based monitoring systems are examined as potential solutions. This comparative analysis highlights the importance of regional cooperation, adaptive policies, and sustainable land management to mitigate future fire risks. Learning from each nation's experiences, policymakers and stakeholders can develop more effective strategies for combating forest fires and reducing their long-term effects.

I. INTRODUCTION

Forest fires have long been a critical environmental challenge, resulting in wide-spread destruction of ecosystems, human settlements, and economies. In recent years, the increasing frequency and severity of these fires have raised global concern, particularly in regions vulnerable to prolonged dry seasons and extreme weather conditions. Indonesia and Australia are two of the most affected countries, experiencing recurrent forest fires driven by different but interconnected factors. Although Indonesia's fires are often linked to human activities such as land-clearing and peatland drainage, Australia's bushfires are primarily fueled by climatic conditions, including heatwaves, droughts, and strong winds. Despite these differences, both nations face the escalating challenge of mitigating the effects of increasingly severe fire seasons intensified by climate change [1].

Indonesia's forest and peatland fires present a persistent challenge, particularly in provinces such as Sumatra and Kalimantan. These fires are mainly caused by slash-and-burn agricultural practices that, despite being illegal, continue due to economic pressures and inadequate law enforcement. Peatland fires are particularly difficult to manage because they can smolder underground for long periods, releasing significant amounts of carbon dioxide and causing severe transboundary haze. This haze affects not only Indonesia but also neighboring countries such as Malaysia and Singapore, resulting in diplomatic tensions and public health crises. Despite various fire prevention programs and policies, Indonesia continues to struggle with effective fire management and regulatory enforcement [2].

In contrast, Australia faces a different fire regime, characterized by intense and rapidly spreading bushfires. The country's natural vegetation, including eucalyptus forests, contains volatile oils that make it highly combustible. Climate change has exacerbated the risk, with rising temperatures and prolonged droughts creating ideal conditions for catastrophic fires. The 2019–2020 Black Summer bushfires underscored the devastating consequences of these fires, burning over 18 million hectares, destroying thousands of homes, and killing or displacing nearly three billion animals. Unlike in Indonesia, where human activities play a significant role in fire ignition, Australia's bushfires are often triggered by natural causes such as lightning strikes. However, the severity of these fires has sparked renewed discussions about fire management strategies, such as controlled burns, land-use policies, and the integration of Indigenous fire knowledge in prevention efforts [3]. The increasing intensity of forest fires in both Indonesia and Australia highlight the urgent need for comprehensive fire management strategies that encompass early detection, prevention, and suppression efforts.

This research aims to analyze fire trends in both countries, drawing lessons from past experiences and exploring mitigation strategies. Comparing different fire management approaches, this study seeks to identify best practices that can be implemented to enhance fire prevention and response efforts. In addition, the study examines the role of technological advancements, such as satellite monitoring, artificial intelligence, and Internet of Things (IoT) based early warning systems, in improving fire management capabilities [4]. Through a comparative analysis of Indonesia and Australia, this study contributes to the broader discourse on climate resilience, sustainable land management, and international cooperation in mitigating forest fire risks [5]. This research examines the trends of forest fire behavior in Indonesia and Australia to inform mitigation strategies. Data on fire incidents were collected from ground sensors and satellite information provided by the National Aeronautics and Space Administration (NASA) Earth Data for both regions. The data were analyzed to identify trends, and a proposed action plan for future forest fire mitigation and management.

II. THEORETICAL REFERENCE

Forest fires are a persistent environmental issue in both Indonesia and Australia, though the causes, patterns, and consequences differ between the two regions. Research indicates that Indonesia's forest fires are primarily anthropogenic, driven by land-use changes and agricultural practices such as slash-and-burn cultivation [6], [7]. The severity of these fires is particularly pronounced in peatland areas, where they can smolder underground for months, releasing massive amounts of carbon into the atmosphere [8], [9]. Studies show that fire incidents in Indonesia often peak during El Niño years when prolonged dry seasons create conditions conducive to fire spread [10], [11]. In contrast, Australia's forest fires, commonly referred to as bushfires, are largely influenced by climatic and ecological factors. Research reveals that fire seasons in Australia have in-testified due to rising temperatures and extended drought periods [12]. The 2019–2020 Black Summer bushfires, which scorched over 18 million hectares, exemplified the in-creasing severity of fire events, with researchers linking this phenomenon to climate change [13], [14].

Unlike Indonesia, where human activities are the primary cause of fire ignition, Australian bushfires are typically triggered by natural events such as lightning strikes, with vegetation and dry conditions providing ample fuel sources [15]. The environmental, social, and economic consequences of forest fires in both Indonesia and Australia have been extensively studied. In Indonesia, haze from forest fires has been a persistent problem, leading to severe air pollution that affects millions across Southeast Asia [16-18]. Studies have linked exposure to this haze with respiratory illnesses, school closures, and economic losses, especially in the agriculture and tourism sectors [19]. In addition, fires in peatland areas contribute significantly to global carbon emissions, worsening climate change [20]. In Australia, the effects of bushfires are similarly cata-strophic. The 2019–2020 Black Summer fires resulted in the loss of nearly three billion animals, including many endangered species [21]. In addition to biodiversity loss, studies have emphasized the economic consequences of bushfires, which include the destruction of homes, infrastructure, and agricultural land [22].

Furthermore, long-term health effects from smoke exposure have been documented, with increases in respiratory and cardio-vascular diseases following major fire events [23]. To manage forest fires in both countries, several mitigation strategies have been implemented. In Indonesia, fire prevention efforts have primarily focused on regulatory measures, such as banning slash-and-burn practices and promoting peatland restoration initiatives [24]. However, enforcement challenges and land-use conflicts have limited the effectiveness of these policies [25]. Some studies recommend the involvement of local communities in fire prevention through sustainable land management and agroforestry practices [26]. In Australia, traditional fire management strategies have relied on con-trolled burns, also known as prescribed burning, to reduce fuel loads and lower the risk of large-scale fires [27]. Nonetheless, recent research suggests that climate change is di-minishing the effectiveness of controlled burns, as fire seasons are becoming longer and more unpredictable [28]. Indigenous fire management practices, which employ low intensity burning to maintain ecosystem balance, have gained increasing attention as a promising solution [29].

The application of technology in forest fire monitoring and mitigation has seen significant advancements in recent years. Remote sensing and satellite imagery have proven essential in detecting fire hotspots and assessing fire severity in both Indonesia and Australia [30]. In addition, artificial intelligence (AI) and machine learning models are being developed to predict fire risks based on factors such as weather patterns, fuel availability, and historical fire data [31]. In Indonesia, pilot projects for IoT-based early warning systems have been implemented to monitor peatland moisture levels and detect fire risks in real time [20], [32]. In Australia, investments in drone technology and auto-mated fire detection systems aim to enhance firefighting efforts [30]. Given the transboundary nature of forest fires, international cooperation is vital for effective fire management. Indonesia has engaged in Association of Southeast Asian Nation (ASEAN)-led initiatives, such as the ASEAN Agreement on Transboundary Haze Pollution, to tackle regional haze issues [33], [34].

However, challenges persist in policy enforcement and stakeholder compliance [35]. In contrast, Australia has collaborated with global research institutions and climate organizations to enhance bushfire prediction and response strategies [36]. The country has also actively shared its fire management expertise with other fire-prone regions, including California and Southern Europe [37]. This research compares forest fire trends in Indonesia and Australia, highlighting similarities, differences, and key drivers behind fire occurrences. The primary dataset for this study is sourced from the NASA Earth Data Portal (https://earthdata.nasa.gov/) [38]. Specifically, relevant satellite datasets, including the Moderate Resolution Imaging Spectroradiometer (MODIS) and the Visible Infrared Imaging Radiometer Suite (VIIRS) are accessed based on the research objectives.

Data parameters such as geolocation (latitude and longitude), intensity measurements (including temperature anomalies), fire radiative power, precipitation rates, and timestamps are downloaded in CSV format as available in the database. The data collected from NASA and selected case studies are categorized into key themes: fire causes, environmental impact, and mitigation strategies. The analysis of trend and historical fire data reveals patterns in fire frequency, intensity, and geographical distribution over the past five years. In addition, existing fire prevention and suppression policies in both countries are assessed for their effectiveness, challenges, and opportunities for improvement [39].

III. MATERIALS AND METHODS

When active fire suppression amidst bushfire intensity is considered, it is suggested that only surface cooling be applied, as evaporated water vapor dissipates quickly and does not significantly affect flame temperature. When fire point theory is utilized and the external radiant and convective heat flux is calculated, the critical flow rate (CF) for wildfire scenarios can be determined using the following Equation (1) [39]. The CF represents the flow rate of water needed to extinguish a burning surface, assuming an infinite period. However, because the length and depth of an active wildfire front fluctuate over time, affected by terrain, wind, fuel structure, and fuel geometry [21], the CF is calculated only for a specific moment.

$$CF = m^{H}_{water,cr,0} + \frac{q^{h}E}{\eta_{water}\, x\, L_{v,water}} \quad (1)$$

where:

$m^{H}_{water,cr,0}$ is the critical water application rate, assuming no external heat flux and identified as ≈ 0.0129 $Lm^{-2}s^{-1}$ [39],
η_{water} is the efficiency of water application, defined as the portion of water leaving the firefighting branch and contributing to fire extinguishment, conservatively assumed to be 0.7,
$L_{v,water}$ is the enthalpy change of water, identified as 2640 $kJkg^{-1}$, and $q^{h}E$ is external heat flux, calculated by (2).

$$q^{h}E = \left(\frac{0.27\, x\, 1}{(2\, x\, L_f + D)}\, x\, \tau\phi\right) + (h\, x\, (T_g - T_{fuel})) \quad (2)$$

where:

I am fire line intensity in kWm^{-1}, calculated using Byram's fire line intensity equation and Equation (3),
L_f is flame length in m, calculated using Equation (4),
D is depth of the active flame, measured in m,
τ is atmospheric transmissivity, assumed to be 1 due to the proximity of the unburned fuel to the flames,
ϕ is the view factor, expected to be 1 due to the proximity of the unburned fuel to the flames,
h is the convective heat transfer coefficient, set at 0.077 kW/m^2K and assuming a forced convection and air velocity of 10 ms^{-1}[1],
T_g is the gas temperature of the flame, assumed to be 1090 K and representative of siege wildfire conditions, and
T_{fuel} is the fuel temperature of the fuel, assumed to be 588 K, which corresponds to the ignition surface temperature for pine-needle fuel beds [1].

$$I = \frac{HW\, R_0\, S}{36} \quad (3)$$

where:

H is the effective heat of combustion, assumed to be 18,600 $kJkg^{-1}$,
W is the total fuel load, measured in tha^{-1}, considering fine fuels typically less than 6 mm in diameter, and

$R_0\, S$ is the forward rate of spread corrected for slope, measured in kmh^{-1} and calculated using Equation (5). Note that terrain affects $R_0\, S$, where the slope is assumed to be flat for the purposes of the study.

In addition, flame length (L_f) is defined by

$$L_f = \frac{13R_0\, S + 0.24W}{2} \quad (4)$$

$$R_0\, S = 0.0012\ (Define\ FDI) \quad (5)$$

To identify a suitable dataset aligned with the study objectives, NASA's Earth Data were accessed using Python programming to select appropriate spatial and temporal ranges. The dataset includes relevant variables such as fire intensity indicators and geographic coordinates. The raw data were pre-processed to convert file formats, correct missing or erroneous entries, and standardize units for further analysis. During preprocessing, the data were corrected to remove null values, duplicate entries, and anomalous data points. Fire detections with longitude and latitude coordinates were extracted from the dataset and aligned according to specific time intervals (daily, weekly, or monthly) for trend analysis. Intensity analysis focused on temperature anomalies, precipitation rates, and radiative energy using both statistical and spatial approaches. This included calculating the mean, maximum, minimum, and standard deviation of intensity values across selected regions and time periods. This study also conducted time-series analysis to identify patterns in intensity changes over time and to examine relationships between fire intensity and external factors, such as climatic indices and vegetation cover.

Python served as the primary software for all statistical analyses in this research. Finally, to validate the NASA Earth dataset, a monitoring station was established to collect ground-based environmental parameters, including temperature, humidity, wind direction, wind speed, and rain intensity. Figure 1 shows the station configuration.

Figure 1: A station in the campus to detect environmental data.
Source: Authors, (2026).

Geospatial analysis and mapping were performed to visualize the spatial distribution of fire intensity. The corrected geolocation and intensity data were imported into Geographic Information System (GIS) software using Python's Geo-Pandas and Folium libraries. The study generated location maps to display intensity distributions, which were categorized into five levels (0–100) ranging from weak fire generation potential to high forest fire ignition potential. Additional pinpoint maps were created to identify precise locations of significant fire events or anomalies. Temporal maps illustrated changes in intensity over time across different geographic regions. To provide context, the maps included overlay layers such as administrative boundaries, land cover classifications, and elevation data. The processed data and visualizations were cross verified with ground measurements from the local monitoring station, as shown in Figure 1.

This validation compared the NASA Earth Data with the locally collected dataset containing environmental parameters. Finally, the study interpreted the mapped and analysed data to identify patterns in intensity variations. A sample dataset from Indonesia, extracted from NASA Earth Data for December 2024, is presented in Table 1. In total, the study incorporated 251,031 datasets collected over a 5-year period. Fire hotspot data for Indonesia and Australia were obtained from NASA's Fire In-formation for Resource Management System (FIRMS). This system utilizes MODIS and VIIRS sensors to provide satellite-based active fire detections. The dataset includes critical information such as the geographic coordinates (latitude and longitude) of each fire hotspot, along with the date and time of detection, and fire radiative power (FRP), which indicates fire intensity and the confidence levels of detection.Following data acquisition, preprocessing steps were conducted to filter out low-confidence detections, ensuring that only reliable hotspots were analyzed.

The data were then sorted by country and organized according to temporal parameters for trend analysis. Statistical analyses were performed to determine the total number of hotspots and average fire intensity over specific time intervals (both monthly and yearly). Various graphical representations, including time-series plots, were used to visualize fluctuations in fire occurrences over time in Indonesia and Australia. The geographic distribution of fire hotspots was mapped using GIS tools. Heat and point maps were generated to illustrate the spatial concentration and intensity of fires across different regions. These visualizations facilitated a comparative analysis between the two countries, highlighting patterns in fire activity, identifying high-risk areas, and offering insights into seasonal and regional trends. The findings enhance our under-standing of fire dynamics and inform improved fire management and mitigation strategies in both countries. As Table 2 shows, the analysis included data collected for Australia during December 2024.

Although this research offers valuable insights into forest fire trends and mitigation strategies, it does have limitations, specifically in its reliance on secondary datasets. This study depends on existing literature and reports, which may carry inherent biases or gaps. Variability in fire data collection, stemming from differences in methods and reporting standards between Indonesia and Australia, may affect direct comparisons. In addition, the effects of climate change is recognized as uncertain in this research, acknowledging that future fire trends may be influenced by unpredictable climate factors beyond current models. All data sources utilized in this study are publicly available, with appropriate citations provided to acknowledge the original research.

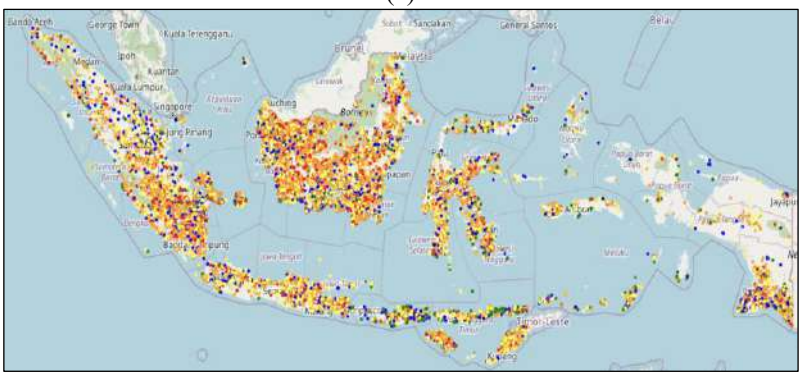
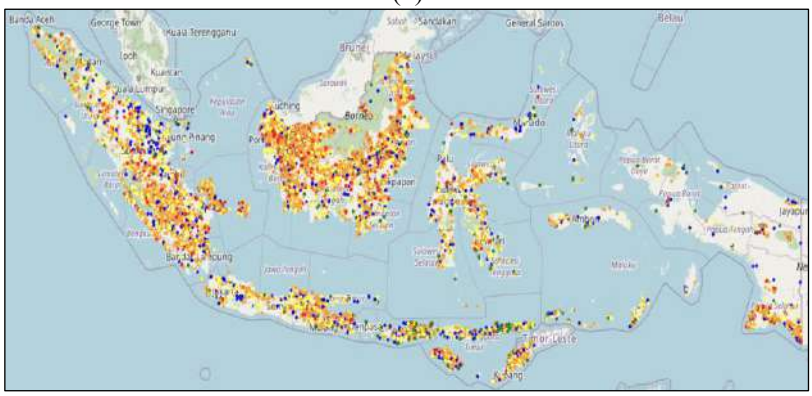
IV. RESULTS AND DISCUSSIONS



Based on the analyzed data, the results map fire hotspots across Indonesia, as visualized in Figure 2. The maps employ a color-coded classification system, itemized as follows:

- Blue: Low fire potential
- Green: Moderate
- Yellow: Elevated
- Pink: High
- Red: Very high fire potential (80–100 confidence level).



The areas with the highest fire intensity, indicated by pink and red dots, are in central Indonesia, specifically on Kalimantan and Sumatra Islands. These regions feature extensive peatlands that become highly flammable during dry seasons. The occurrence of fires in these areas has significantly affected the environment, leading to the loss of various flora and fauna populations. In 2023 and 2024, the number of fire hotspots increased as human activities returned to pre-COVID-19 levels after several years of significant decline. Spatial mapping reinforces these findings, demonstrating that fire hotspots are primarily concentrated in the provinces of Sumatra and Kalimantan, which are known for their extensive peatlands and agricultural activities, particularly oil palm and pulpwood plantations.

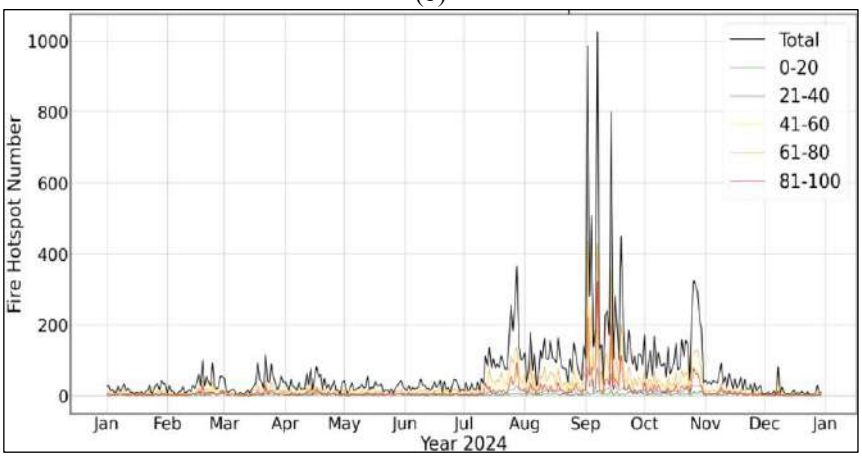
Source: Authors, (2026).

The maps indicate that numerous fire hotspots are located near areas undergoing land-clearing and agricultural expansion, suggesting a strong correlation between human activities and fire occurrences. In addition, the intensity graphs and maps reveal that certain regions experience recurrent fire incidents annually, highlighting their persistent vulnerability.



This underscores the necessity for more effective fire prevention strategies, including stricter enforcement of land-use regulations, improved peatland management, and community-based fire monitoring systems. The fire hotspot data were visualized using Python graphical tools to illustrate temporal trends and the spatial distribution of fire intensity. Time-series graphs were generated to depict variations in fire occurrences over specific periods, while geographic mapping techniques were employed to display the concentration and intensity of hotspots across various locations. This comprehensive analysis yielded valuable insights into the patterns and drivers of fire incidents, contributing to a better understanding of fire dynamics in the studied areas. Figure 3 shows the complete plotted data of fire hotspots chronologically from (a) 2022 to (c) 2024.

In contrast, Australia's fire seasons have intensified over the past few decades, highlighted by significant events such as the 2009 Black Saturday and the 2019–2020 Black Summer bushfires. NASA's analysis of Earth data indicates a marked increase in both the length and severity of fire seasons, driven by rising temperatures and prolonged droughts. Unlike in Indonesia, where fires are primarily human-induced, bushfires in Australia are primarily driven by natural sources such as lightning strikes. However, climate change and fuel accumulation have worsened their effects Fire hotspots in Australia were mapped using NASA Earth Data, illustrating the spatial distribution and intensity of fire occurrences throughout the region. Figure 4 displays this mapping of fire hotspots from 2022 to 2024.

An analysis of fire hotspot intensity in Indonesia revealed significant temporal and spatial patterns closely linked to climatic conditions and land-use practices. Time-series graphs show that the number and intensity of fire hotspots exhibit substantial seasonal variations, with noticeable peaks occurring during the dry season, typically between August and October. This pattern correlates with the well-documented monsoon cycle in Indonesia, where extended dry periods create favourable conditions for vegetation dryness and heightened fire risk. The graphs also indicate a significant increase in fire intensity during specific years, particularly those associated with El Niño events. During intense El Niño periods, reduced rainfall and higher temperatures contribute to more severe and widespread fires. This is evident in the increased number of hotspots and higher average FRP values recorded in those years, such as 2015 and 2019, which correspond with severe haze episodes and extensive forest and peatland fires in Indonesia. Figure 5 shows the intensity of fire hotspots in Australia from 2022 to 2024.

Based on an analysis of historical fire hotspot data obtained from NASA's Earth Data, particularly the FIRMS platform, predicting potential fire hotspot activity in Australia for 2025. The data reveal consistent seasonal patterns, with fire occurrences peaking during the dry and hot months, typically from September to March, particularly in regions such as the Northern Territory, Queensland, and Western Australia. Furthermore, analysis of past data shows a strong correlation between increased fire activity and climatic factors, including prolonged droughts, higher-than-average temperatures, and El Niño events. Given current climate trends and forecasts predicting elevated temperatures and reduced precipitation in parts of Australia in 2025, the intensity and frequency of fire hotspots are likely to remain high, particularly in vulnerable areas characterized by dry vegetation and significant land-use changes. Therefore, this predictive analysis highlights the im-portance of implementing proactive fire management strategies, such as early warning systems, land management policies, and community preparedness, to mitigate potential fire risks in the upcoming year. Figure 6 presents the visualized predictive model for fire risks in 2025 based on our analysed data.

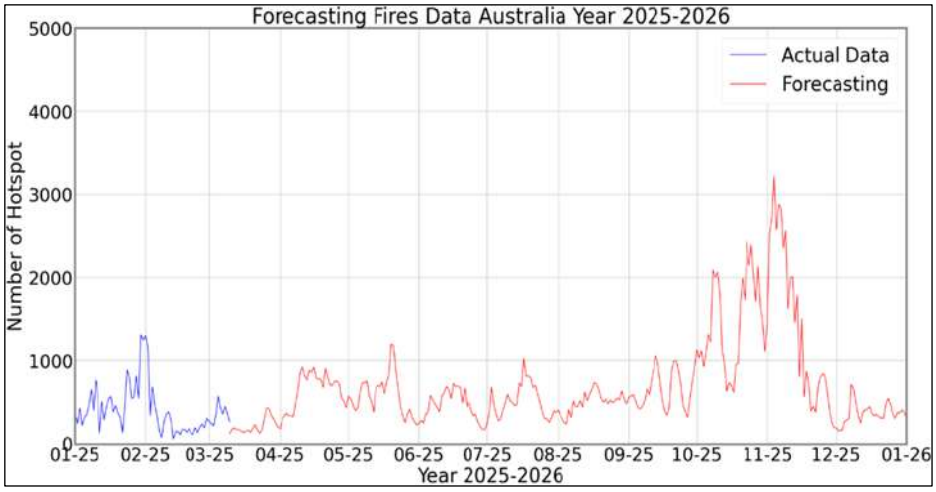

Figure 6: Forecast of the number of fire hotspots in Australia for the year 2025.
Source: Authors, (2026).

The prediction for fire hotspot occurrences in Indonesia for 2025 is informed by analysing historical data sourced from NASA Earth Data, specifically the FIRMS active fire datasets. This analysis reveals a recurring pattern of heightened fire activity during the dry season, particularly from July to October, with significant concentrations of hotspots in regions such as Sumatra and Kalimantan. Previous trends also indicate that fire intensity and frequency increase during El Niño years, contributing to prolonged drought conditions and drier peatlands and making them highly susceptible to fires. Considering climate projections and ongoing risk factors, including land-use practices such as slash-and-burn agriculture and peatland drainage, fire hotspot activity in Indonesia is expected to remain high in 2025, particularly if an El Niño event occurs. Consequently, this predictive analysis underscores the necessity for strengthened fire prevention measures, improved peatland management, and early warning systems to mitigate the potential environmental and health impacts of fires in the coming year. Figure 7 illustrates the potential for forest fires in Indonesia from September to October 2025.

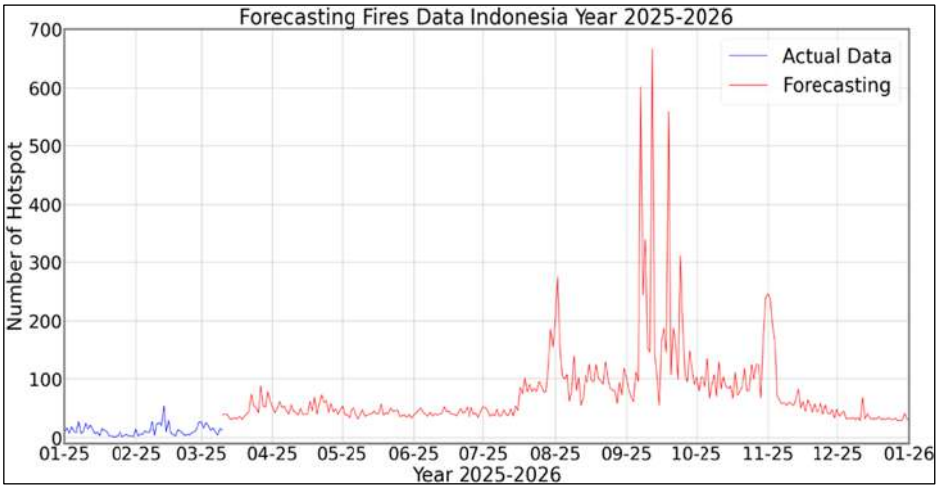

Figure 7: Forecast of the number of fire hotspots in Indonesia for the year 2025.
Source: Authors, (2026).

The number of fire incidents in Indonesia, as illustrated in Figure 5, shows a significant accumulation from August to December each year, peaking in September and October. By contrast, Figure 7 highlights the trend of fire incidents in Australia hotspots from 2021 to 2024, which accumulated from March to November. Notably, the year 2020 experienced unusually low incidents due to the COVID-19 pandemic. Forest fires in both countries have resulted in significant environmental harm. In Indonesia, peatland fires release vast quantities of carbon, exacerbating global climate change. In addition, bio-diversity loss, habitat destruction, and soil degradation are critical concerns.

Similarly, Australian bushfires have had devastating effects on ecosystems, with the 2019–2020 Black Summer fires resulting in the loss of nearly three billion animals and endangering many species. Both Indonesia and Australia have also faced significant economic losses due to forest fires. In Indonesia, the haze crisis disrupts transportation, affects tourism, and contributes to respiratory illnesses, with financial costs estimated at $16 billion during the 2015 fire season alone. In Australia, bushfires have destroyed homes, infrastructure, and agricultural land, with the Black Summer fires leading to an estimated $110 billion in damage.

The health impacts from these fires, including respiratory diseases and mental health issues, have been widely reported in both countries due to prolonged exposure to smoke pollution. The effectiveness of Indonesia's fire management approaches relies on various mitigation strategies, including regulatory measures such as the moratorium on peatland development and stricter land-clearing regulations. However, enforcement remains weak due to corruption and a lack of resources. Community-based fire prevention initiatives, which involve local communities in fire prevention and sustainable agriculture, have demonstrated some success in reducing fire incidents.

Moreover, technological solutions, such as satellite monitoring and IoT-based early warning systems, have been utilized to detect and prevent fire outbreaks. Despite these efforts, challenges, such as illegal land-clearing and conflicting economic interests, continue to impede effective fire management. By contrast, Australia has implemented a combination of traditional and modern fire mitigation strategies. Controlled burns, through prescribed burning, aim to reduce fuel loads, but their effectiveness is limited in extreme weather conditions. Policies promoting fire-resistant infrastructure encourage the use of fire-resistant building designs and urban planning in fire-prone areas.

Recognition of Indigenous fire knowledge has increased, with a focus on employing low intensity burns to prevent large-scale fires. Australia also has a well-established fire response system in place. However, the growing severity of fires due to climate change necessitates continuous adaptation and improvements in fire management strategies. A comparative analysis reveals key lessons from each country's experience, emphasizing the importance of more vigorous policy enforcement. Indonesia could benefit from Australia's strict fire management policies and advanced response systems.

In addition, the integration of traditional Indigenous fire management practices from Australia could be adapted in Indonesia, particularly within community-based fire prevention programs. Both countries can also harness technological innovations, such as advancements in satellite monitoring, AI-driven fire prediction models, and IoT-based early warning systems. Future research should focus on developing cross-border cooperation for haze reduction in Southeast Asia, exploring climate adaptation strategies for bush-fire-prone regions, enhancing community involvement in fire prevention programs, and investing in AI-driven fire-risk assessment models.

V. CONCLUSIONS

The analysis of forest fire trends in Indonesia and Australia highlights the increasing threat posed by climate change and land-use practices. Although both countries have implemented various mitigation strategies, they continue to face challenges in policy enforcement, community engagement, and technological integration. The graph results reveal that seasonal climatic factors and human activities contribute to the intensity of fire hotspots in Indonesia. These visualizations offer valuable insights into the timing and locations where fires are most likely to occur, providing essential information for policymakers, environmental agencies, and disaster management authorities to formulate targeted mitigation efforts.

Learning from past experiences and adopting innovative solutions will be critical in reducing the frequency and effects of future fire events. The literature indicates that, although Indonesia and Australia face unique fire challenges, valuable lessons can be learned from each country's experiences. Effective fire management requires a combination of policy enforcement, technological advancements, community engagement, and international cooperation. As climate change amplifies fire risks, future research should focus on integrating scientific innovations with traditional fire management practices to develop more sustainable and adaptive mitigation strategies.

Moral development

ABSTRACT

This study examines the dual role of mathematics learning in developing moral character and STEM competencies among informatics engineering students. Despite mathematics being a fundamental component of engineering education, its potential as a vehicle for character development remains underexplored. Through a mixed-methods approach involving 55 informatics engineering students from an Indonesian university, significant correlations were found between mathematical ability and moral character development ($r = 0.42$, $p < 0.01$) and career readiness ($r = 0.38$, $p < 0.05$). The integrated STEM mathematics learning approach, which connected discrete mathematics to real-world informatics problems, proved effective in fostering both computational thinking (demonstrated by 42% improvement in programming abstraction) and professional ethics (28% enhancement in ethical awareness). Thematic analysis revealed emerging themes "including 'increased awareness of data privacy' and 'appreciation for logical consistency in ethical reasoning.' " Results indicate that mathematics serves not only as a technical foundation but also as a medium for character development in engineering education. The study recommends an integrated curriculum design that leverages mathematics learning for holistic student development, addressing the growing need for responsible innovation in technology fields.

I. INTRODUCTION

Informatics engineering education traditionally prioritizes the development of technical prowess, often relegating mathematics to the role of a foundational but purely analytical tool. However, the potential of mathematics as a vehicle for character development remains underexplored in engineering education. A growing body of literature suggests that mathematics learning possesses significant, yet underutilized, potential for fostering character development [1],[2]. This is critically needed in a field where professional decisions have profound ethical implications, from data privacy to algorithmic bias. Preliminary evidence from this study's data aligns with this view, revealing that 78% of students find mathematics learning helpful in cultivating precision and self-discipline—attributes identified as essential for computing professionals [3].

While the STEM (Science, Technology, Engineering, and Mathematics) approach emphasizes interdisciplinary integration [4], with mathematics as a foundational pillar for engineering competencies [5] its implementation often remains superficial. This overlooks the broader pedagogical potential of STEM to concurrently foster character and essential soft skills. Consequently, a significant gap persists between the production of technically competent graduates and the formation of holistic professionals equipped for modern workforce demands, where competencies like ethical reasoning, teamwork, and adaptability are increasingly paramount [6], [7].To address this gap, this study investigates the dual role of mathematics within an integrated STEM context.

The research is guided by three questions: (1) To what extent does mathematics learning contribute to the development of specific moral character traits (e.g., precision, discipline, ethical reasoning) in informatics engineering students? (2) What is the relationship between mathematical competence and the development of broader STEM competencies? (3) How can a mathematics curriculum be designed to synergistically optimize both technical and character development.

II. THEORETICAL FRAMEWORK

A. The Imperative for Character Education in Technical Disciplines

The prevailing paradigm in informatics engineering education has historically emphasized technical proficiency, often at the expense of character development [8]. This creates a critical gap in professional preparation, as the field increasingly grapples with complex ethical dilemmas in artificial intelligence, data privacy, and algorithmic decision-making. The cultivation of moral character is no longer a supplementary concern but a fundamental component of engineering excellence [9]. This study operates on the premise that the journey from computation to compassion requires deliberate pedagogical efforts to develop responsible professionals who can navigate the socio-ethical dimensions of technology.

B. STEM Integration as a Conduit for Holistic Learning

The integrated STEM approach effectively connects mathematical concepts with real-world applications in informatics engineering, providing a meaningful context for learning [10]. Mathematics serves not only as the language for solving engineering problems but also fosters systematic thinking essential for ethical reasoning. By connecting abstract mathematical concepts to real-world engineering challenges, STEM pedagogy moves beyond siloed knowledge to create meaningful, contextualized learning experiences [11]. Within this framework, mathematics transcends its conventional role as a mere computational tool; it becomes the essential language for engineering problem-solving while simultaneously fostering the systematic and critical thinking patterns crucial for ethical analysis [12]. This integrated approach serves as a conduit for the simultaneous development of technical skills and character attributes.

C. Mathematical Thinking: The Foundation for Moral and Technical Reasoning

The process of engaging with mathematics inherently cultivates dispositions that form the bedrock of both technical competence and moral character. Mathematical thinking demands precision, intellectual honesty, perseverance, and logical consistency—attributes that align directly with professional virtues required in informatics engineering [13]. The rigorous practice of constructing valid arguments and verifying truths provides a natural training ground for the ethical reasoning needed in technology development. Furthermore, the problem-solving nature of mathematics directly fosters the analytical and adaptive thinking cited as crucial for professional success [14], [15]. This theoretical perspective posits that mathematics learning does not merely support technical skill acquisition but inherently builds the cognitive and ethical foundation for responsible innovation.

III. MATERIALS AND METHODS

This study employed a convergent parallel mixed-methods design to comprehensively investigate the role of mathematics learning in developing character and STEM competencies. The quantitative and qualitative data were collected simultaneously during the discrete mathematics course, then integrated during the analysis phase to provide a holistic understanding of the phenomenon. The comprehensive assessment framework aligns with contemporary approaches to STEM education evaluation [16] ensuring that both technical proficiency and character development are adequately measured.

Table 1: Variable Constructs and Measurement Items.

Construct	Sub-Construct	Sample Item	No. of Items
Moral Character	Fairness & Equality	Treat everyone equally, support equal opportunities	3
	Empathy & Compassion	Understand friends' feelings, Help friends in need	3
Academic Behavior	Self-Regulation	Manage emotions, Delay gratification	3
Professional Ethics	Digital Ethics	Data privacy awareness, Respect intellectual property	3
Learning Outcomes	Applied Competence	Apply theories, Problem-solving ability	3
Career Readiness	Technical Competence	Technical skills maturity, Presentation ability	3

Source: Authors, (2026).

The study involved 55 third-year informatics engineering students from Indonesian universities, comprising 37 males (68%) and 18 females (32%). Participants were selected using purposive sampling based on their enrollment in discrete mathematics courses. The sample size provided adequate statistical power for the planned analyses while allowing for in-depth qualitative investigation. The measurement framework comprised five main constructs operationalized through 42 Likert-scale items (1-5 scale). Each sub-construct contained three items developed based on literature review and expert validation by three specialists: two education experts with expertise in character assessment and one computer science professor with experience in STEM education. The validation process evaluated content relevance, construct validity, item clarity, and contextual appropriateness for informatics engineering students. Following expert feedback and revisions, the instrument was pilot-tested with 24 students from related disciplines. The final instrument demonstrated strong reliability with Cronbach's Alpha coefficients exceeding 0.7 for all constructs. Data collection was conducted at Putra Indonesia University "YPTK" Padang, involving computer science students through multiple instruments to ensure methodological triangulation.

Quantitative data analysis proceeded in several stages. Descriptive statistics summarized the basic characteristics of the data. Pearson correlation analysis examined relationships between mathematical ability and character development indicators. Multiple regression analysis identified significant predictors of student outcomes. Reliability analysis confirmed internal consistency (Cronbach's Alpha > 0.7). Qualitative data from open-ended responses and interviews were analyzed using thematic analysis following Braun & Clarke's (2006) framework. This involved familiarization with data, generating initial codes, searching for themes, reviewing themes, defining themes, and producing the analysis. The qualitative findings provided contextual depth to the statistical results, enabling comprehensive understanding of how mathematics learning influences character development

IV. RESULTS AND DISCUSSIONS

IV.1 RESULTS

The correlation analysis revealed significant positive relationships between mathematical proficiency and character development among informatics engineering students. As shown in Table 2, all character aspects demonstrated statistically significant correlations with mathematical ability, with precision showing the strongest relationship ($r = 0.48$, $p < 0.001$). This was followed by discipline ($r = 0.42$, $p < 0.01$) and professional ethics ($r = 0.38$, $p < 0.01$), while responsibility showed a moderate but still significant correlation ($r = 0.35$, $p < 0.05$). These findings substantiate the conceptual link between mathematical rigor and character formation, particularly highlighting how mathematical precision translates into professional exactitude and ethical awareness.

Table 2: Correlation between Mathematical Ability and Student Character.

Character Aspect	Correlation	Significance
Discipline	0.42	P < 0.01
Precision	0.48	P < 0.001
Responsibility	0.35	P < 0.05
Professional Ethics	0.38	P < 0.01

Source: Authors, (2026).

The integrated STEM approach yielded substantial improvements across both technical and ethical domains. Qualitative findings from student interviews reinforced these improvements, with one student noting, 'This forum really helped me become aware of moral fundamentals, ethics, and performance.' Another student expressed, 'I hope learning can emphasize ethics and skills more.' Thematic analysis revealed prominent themes such as 'increased awareness of data privacy' and 'appreciation for logical consistency in ethical reasoning.' These qualitative insights complement the quantitative results, showing a 42% enhancement in programming abstraction ability, 35% increase in understanding computer network concepts, and 28% improvement in ethical awareness in algorithm development. Analysis of career readiness indicators revealed substantial advantages for students with strong mathematical foundations. Those mastering discrete mathematics showed significantly higher professional preparedness ($M = 4.1$ vs 3.2 on a 5-point scale), superior applied problem-solving competence (88% vs 65% success rate), and enhanced technological adaptability (79% vs 52%). These findings underscore mathematics' critical role in developing the holistic competencies required for professional success in informatics engineering, bridging technical capability with adaptive learning capacity.

V.2 DISCUSSION

This study provides empirical evidence that mathematics learning serves as a foundational medium for character development in informatics engineering education. The strong correlations between mathematical proficiency and character traits—particularly precision ($r = 0.48$, $p < 0.001$), discipline ($r = 0.42$, $p < 0.01$), and professional ethics ($r = 0.38$, $p < 0.01$)—demonstrate that the process of engaging with mathematical problems inherently cultivates virtues essential for professional practice. The rigorous demand for logical consistency and intellectual honesty in mathematics creates what might be termed an "ethical training ground," where students develop the cognitive habits necessary for responsible decision-making in complex technological contexts. This finding substantiates Glaser's [17] proposition about mathematical thinking involving value development, while extending it to contemporary informatics engineering contexts where ethical reasoning is paramount, particularly in addressing modern challenges in AI ethics and data privacy [9]. These findings have significant implications for mathematics education pedagogy, suggesting that the way mathematics is taught—emphasizing process over mere product, collaboration alongside individual work, and real-world applications beyond abstract exercises—can fundamentally shape both technical and ethical development in engineering students. The integrated STEM approach emerged as a crucial pedagogical bridge connecting abstract mathematical concepts with tangible character outcomes.

By contextualizing discrete mathematics within authentic informatics engineering scenarios—such as algorithm optimization and data structure analysis—the learning environment transformed into a simulated professional practice space. This contextualization enabled students to experience directly why precision matters in code development and how ethical considerations emerge in algorithm design affecting user privacy (evidenced by the 28% improvement in ethical awareness). The parallel improvements in computational thinking (42% enhancement in abstraction ability) and character development demonstrate that technical and ethical competencies are not competing educational objectives but synergistic outcomes. The STEM framework thus provides the methodological means to make the journey from computation to compassion pedagogically operational and empirically measurable. The project-based learning component of our STEM approach resonates with successful models in engineering education that emphasize authentic professional practice [18]. This contextualization allows students to experience the real-world implications of their mathematical and technical decisions. The findings necessitate a fundamental rethinking of informatics engineering curriculum design.

Rather than treating character development as an ancillary concern, it should be architecturally integrated into the mathematical and technical core of the program. Three key design principles emerge: First, curriculum must systematically incorporate ethical dilemmas into mathematical problem-solving, using case studies that require students to consider societal impact, privacy implications, and algorithmic fairness. This moves beyond treating ethics as a separate module and instead embeds it within technical learning. Second, project-based learning with real-world contexts should serve as the primary pedagogical approach, creating natural opportunities for students to practice collaboration, responsibility, and perseverance while applying technical skills. These extended projects become microcosms of professional practice where character is both required and developed. Third, assessment strategies must evolve to include authentic, multi-faceted methods that evaluate both technical proficiency and character development.

This could involve rubrics assessing team collaboration processes, reflective journals on ethical decision-making, and portfolios demonstrating growth in professional judgment alongside technical artifacts. Fourth, educator development must be prioritized. Mathematics teacher preparation should incorporate and professional development should incorporate pedagogical strategies that explicitly connect mathematical thinking with ethical reasoning. This includes training educators to design learning activities that highlight the ethical dimensions of mathematical applications, facilitate discussions about the social implications of technological solutions, and assess both technical proficiency and ethical decision-making. Such preparation will equip mathematics educators to foster the development of ethically-grounded technical professionals. The recommended curriculum design draws from established frameworks for integrated STEM education [16] [10] particularly emphasizing the need for authentic assessment methods that capture both technical and character development.

The findings have significant implications for the growing field of AI ethics and responsible innovation. The demonstrated connection between mathematical reasoning and ethical awareness provides a pedagogical foundation for educating future engineers who will develop AI systems. As noted by one student, *'Research like this can provide insight into how students understand morality and ethics in relation to academic achievement and performance.'* This alignment between technical precision and ethical consideration is crucial for responsible innovation, particularly in AI development where algorithmic decisions can have profound societal impacts. The integrated approach described in this study offers a model for cultivating what might be termed 'ethically-grounded computational thinking' - essential for developing AI systems that are not only efficient but also fair, transparent, and socially responsible.

V. CONCLUSIONS

This study demonstrates that mathematics learning in informatics engineering possesses a dual function: it serves as an indispensable technical foundation and a powerful, often underutilized, medium for character development. The integrated STEM approach has proven effective in simultaneously advancing computational competencies and fostering moral character, successfully bridging the gap between technical proficiency and ethical reasoning. A deliberate pedagogical strategy that leverages this dual potential can produce graduates who are not only technically adept but also ethically grounded and responsible professionals—embodying the essential journey from computation to compassion in modern engineering education. To translate these findings into practice and guide further scholarly inquiry, the following recommendations are proposed:

For Educational Practitioners:

Systematically integrate character education objectives into mathematics and core informatics engineering curricula. Develop and implement STEM-based learning modules that fuse technical content with ethical reasoning exercises. Provide comprehensive pedagogical training for lecturers in integrated teaching approaches. Create authentic assessment methods that evaluate both cognitive development and character growth. For Future Research: Conduct longitudinal studies to examine the long-term impacts of integrated mathematics and character education. Develop more robust theoretical models for curriculum integration across STEM disciplines. Explore the applicability and effectiveness of these approaches across diverse cultural and institutional contexts. Investigate specific mechanisms through which mathematical thinking translates to ethical reasoning in professional practice.

ABSTRACT

The study seeks to reflect on the importance of occupational safety in working at heights during public building maintenance, emphasizing organizational challenges and structural proposals that may contribute to risk mitigation. Methodologically, the research is developed through bibliographic review and documentary analysis, with data interpretation based on categorical content analysis. The investigation is relevant as it highlights the importance of safety in activities performed at heights in public buildings with high circulation, since the results indicate that analyzing recurring failures and adopted preventive measures supports the implementation of management systems that promote a culture of prevention and significantly reduce accident rates. The study contributes to broadening the understanding of height safety in public administration; socially, it reinforces its ethical dimension by valuing life, dignity, and human integrity in public service.

I. INTRODUCTION

Work at height is widely recognized as one of the occupational activities that pose the greatest risks to workers' physical integrity and lives, which is why it requires rigorous planning, technical training, and effective preventive measures. According to Regulatory Standard No. 35 (NR-35), established by Ordinance MTE No. 313 of March 23, 2012, work at height is defined as any activity performed at a height greater than two meters above the lower level, where there is a risk of falling [1]. The regulation establishes several mandatory requirements, such as worker training, the use of Personal Protective Equipment (PPE), the preparation of a Preliminary Risk Analysis (PRA), and a Work Permit (WP) [2]. Nevertheless, accidents related to these activities remain at high levels, revealing a gap between legislation and its effective application, especially in the public sector.

According to the Occupational Safety and Health Observatory, Brazil recorded a total of 499,955 occupational accidents in 2023, of which 2,888 resulted in death [3]. Among the most lethal causes, falls from height stand out, particularly in the construction, industrial, and public service sectors, where working conditions frequently expose professionals to high risks. A study conducted by the former Ministry of Labor in partnership with Revista Proteção indicates that about 40% of occupational accidents in the country are directly or indirectly related to work-at-height activities [4]. This data reinforces the urgency of implementing more effective public policies and safety practices aimed at prevention, worker training, and enforcement of standards, in order to reduce the recurrence of serious accidents and preserve lives in the workplace.

In the construction industry, the severity of falls from height is even more alarming: 65% of accidents involve this type of occurrence, and more than half result in death [5]. In Rio Grande do Sul, the scenario is equally concerning. In 2023, 384 work-related deaths were recorded, representing a 35% increase compared to 2022. Among these cases, 320 were typical accidents, 63 were commuting accidents, and 1 was due to occupational illness. It is noteworthy that workers with precarious employment relationships—such as self-

employed and unregistered workers—accounted for 50.01% of fatal typical accidents, with self-employed individuals representing 38.13% of occurrences [6].

These data highlight the vulnerability of these professionals and the urgency of protection policies that strengthen inspection, promote formalization, and ensure safe working conditions. Although the public sector does not always appear prominently in sectoral reports, its importance within the context of occupational safety is undeniable. Public buildings such as schools, universities, hospitals, and administrative offices frequently require maintenance work at height, including roof repairs, façade restoration, and electrical and hydraulic maintenance. When poorly planned, such activities place both permanent and outsourced workers in high-risk situations. This reality is exacerbated by outdated infrastructure, irregular maintenance contracts, and the absence of standardized safety protocols. The combination of these factors reveals a concerning scenario that demands public authorities' attention toward the implementation of effective prevention and inspection policies to ensure safe working conditions and prevent serious or fatal accidents in institutional environments widely used by the population.

In this context, the present article aims to critically reflect on the importance of occupational safety in work-at-height activities during public building maintenance, focusing on organizational challenges and structural proposals that may contribute to risk mitigation. The objective is to discuss, in light of current legislation and empirical data, the main barriers to the effective implementation of height safety management in public institutions, while proposing ways to strengthen a culture of prevention, responsibility, and appreciation of life. Based on field experience and the theoretical support of administrative and occupational health sciences, this study seeks to contribute to the development of more effective public policies and to the improvement of public management in occupational safety. Workplace safety needs to be at the heart of public policies and competitiveness strategies, not only for legal reasons, but also for social justice and productive efficiency [7].

II. METHODOLOGY

Regarding the procedures adopted, this investigation employs bibliographic review and documentary research. A literature review is a fundamental step because it allows the researcher to understand the state of the art on the topic, identify gaps in knowledge, and theoretically support the study with reliable and relevant information [8]. Documentary research involves the analysis of materials that have not received prior analytical treatment, such as official documents, reports, and historical archives, and is essential for understanding specific contexts and enriching the study with primary data [9]. For data interpretation, categorical content analysis was chosen, structured around four main categories: (1) The Role of Institutional Management in Risk Prevention; (2) Objective Responsibility in Public Service; (3) Safety as an Organizational Dimension; and (4) Social and Economic Impact. The analysis is a structured procedure that begins with pre-analysis, which consists of the careful selection of documents or materials to be analyzed, allowing the researcher to gain a general understanding of the material before conducting an in-depth examination [10]. After this initial stage, the treatment of results is carried out by organizing the content into thematic categories, grouping materials according to similarities or relationships identified in the information. Finally, during the interpretation of results stage, the researcher analyzes the categories, explores the relationships among them, and seeks significant patterns that may provide a deeper understanding of the phenomenon under study.

III. THEORETICAL FRAMEWORK

III.1 OCCUPATIONAL SAFETY AND RISK MANAGEMENT

Occupational safety encompasses a set of technical, medical, and educational measures aimed at preventing accidents and occupational diseases, with the purpose of preserving the physical integrity and health of workers during the performance of their duties. Occupational safety management is an essential area that transcends the mere implementation of practices and policies, representing a profound commitment to the comprehensive protection of workers' health, safety, and well-being in the workplace [11]. This approach requires not only compliance with legal standards but also the promotion of an organizational culture that values life and fosters safe and humanized work environments. It becomes evident that occupational safety should be understood as a fundamental ethical value and a priority in both public and private management practices.

Prevention, within the context of occupational safety, consists of anticipating risks with the aim of eliminating or minimizing the likelihood of undesirable events. In this sense, risk analysis is a systematic process that identifies hazards, assesses the probability and severity of potential harm, and proposes control measures to protect workers' integrity. Risk analysis must be an integral part of any safety management system, as it provides the essential elements for decision-making that reduces exposure to hazards [12]. This tool is strategic for predicting critical scenarios, guiding preventive actions, and supporting effective managerial decisions. It can therefore be concluded that risk analysis is indispensable for preventive management committed to safety, health, and sustainability in work environments.

Work-related accidents are legally defined by Law No. 8,213/1991 as those occurring during the exercise of professional activities performed in the interest of a company or public agency, resulting in bodily injury, functional disturbance, or total or partial, temporary or permanent, loss of work capacity [13]. The same legislation establishes the obligation to issue a Work Accident Report (Comunicação de Acidente de Trabalho – CAT), an essential instrument for the formal recording of accidents and statistical control of occurrences [14]. The CAT plays a fundamental role in monitoring working conditions and formulating public policies aimed at prevention and the promotion of occupational health. Therefore, legal recognition and systematic reporting of accidents are essential steps in building safer work environments and ensuring institutional accountability for worker protection.

Regulatory Standard No. 35 (NR-35) establishes the minimum requirements and protective measures related to the safety of workers performing activities at height, defined as those carried out more than two meters above the lower level where there is a risk of falling. Among its requirements are specific worker training, the mandatory use of Personal Protective Equipment (PPE), and the preparation of operational procedures and a Preliminary Risk Analysis (PRA), which aims to identify and mitigate hazards before task execution [15]. The regulation seeks to promote a culture of prevention, requiring both employers and employees to assume clear

responsibilities regarding safety. NR-35, therefore, represents an essential instrument to reduce serious accidents and preserve lives, especially in sectors such as construction, where working at height is frequent and high-risk.

In addition to NR-35, other standards complement the legislation on work-at-height safety, such as NR-06, which regulates the use of PPE, and NR-01, which establishes general provisions and guidelines for occupational risk management [16], [17]. With the modernization of Regulatory Standards initiated in 2019, the integration between the Risk Management Program (PGR) and preventive actions was strengthened, promoting a more systemic and effective approach to occupational safety management. This regulatory update reinforces prevention and shared responsibility between employers and workers, while the harmonization of these standards is fundamental for creating safer work environments, reducing accident rates, and promoting occupational health.

III.2 SAFETY MANAGEMENT IN PUBLIC ORGANIZATIONS

The management of occupational safety in public organizations represents a strategic challenge that transcends mere legal compliance. Unlike the private sector, public institutions operate in complex environments marked by rigid administrative structures, a multiplicity of sectors and responsibilities, and often limited budgetary resources. The consolidation of effective Occupational Health and Safety (OHS) management in public organizations requires the creation of interdisciplinary working groups dedicated to the continuous supervision of OHS actions. In this context, the effective implementation of occupational safety policies requires coordinated efforts among different hierarchical levels, including managers, technicians, public servants, and outsourced companies.

Organizational culture in the public sector often lacks a systematic and preventive approach to occupational safety, with reactive practices that are only activated after accidents occur. This posture limits the effectiveness of protection measures and increases risks for workers. The Policy for Occupational Health and Safety of Federal Public Servants (PASS/SIASS) often prioritizes actions related to medical examinations to the detriment of preventive initiatives, resulting in fragmented governance and insufficient human and financial resources [18]. This scenario reinforces a reactive culture in which safety measures are intensified only after incidents, compromising the effectiveness of a systematic and proactive OHS approach. The absence of planning and investment in prevention undermines workplace health and safety, leading to greater vulnerability and higher accident rates.

Therefore, it is essential to promote a cultural shift that values continuous prevention, ensuring safer work environments and protecting the integrity of public servants. The adoption of an integrated approach involving health, safety, environment, labor, social security, and other sectors is crucial to overcome the intersectoral fragmentation that compromises the effectiveness of preventive actions. The National Policy on Workers Health and Safety (PNSST), established in 2004, reinforces this perspective by advocating for the formulation and implementation of transversal and intersectoral public policies capable of promoting coordinated actions among different levels of government [19]. This integration seeks to break with isolated practices, strengthening prevention as a strategic axis for worker protection.

Only through coordinated and committed action among various sectors will it be possible to advance in building safer, healthier, and more sustainable workplaces, particularly in the public sector, where the effects of fragmented management are still evident. The adoption of modern management tools, such as Occupational Health and Safety Management Systems based on ISO 45001:2018, has proven to be a promising alternative for public institutions. This international standard encourages the incorporation of safety as an institutional value and promotes the active participation of workers in hazard identification and the development of corrective measures [20]. Moreover, initiatives such as the institutionalization of PGR and the development of Standard Operating Procedures (SOPs) specifically for work-at-height activities are essential to ensure risk control and accident reduction.

Safety management in the public sector must align with the principles of good governance, transparency, efficiency, and accountability, ensuring that actions are responsibly planned, monitored, and evaluated. The institutionalization of risk management practices in public organizations significantly strengthens governance while fostering safer, more reliable, and more sustainable work environments [21]. This approach not only reduces accidents and health risks but also enhances public trust in institutions. Integrating occupational safety into public governance is thus an essential step toward ensuring the protection of public servants, the quality of services provided, and the effectiveness of public policies aimed at workplace well-being.

Understanding occupational safety in public institutions as a collective and cross-cutting responsibility is essential to ensure the effective protection of workers. This dimension should not be restricted to a specific department or isolated professionals but should permeate the entire structure of public management. Strengthening this perspective requires consistent institutional policies, specialized technical training, and, above all, a cultural shift that recognizes safety as an inseparable component of service quality and the valuation of life [22]. This transformation demands continuous commitment and coordination among different administrative areas, since promoting safety in the public sector is a shared duty that must be at the core of institutional decision-making, contributing to fairer, healthier, and more sustainable work environments.

III.3 LEGAL RESPONSIBILITIES IN OCCUPATIONAL SAFETY

Brazilian legislation establishes a robust set of norms and guidelines aimed at protecting workers' health and physical integrity, extending further by assigning specific responsibilities regarding safety in high-risk activities. Under Regulatory Standard NR-35, for example, employers are required to ensure the safe planning, organization, and execution of work-at-height activities, including risk analysis, worker training, adequate supervision, and formal authorization systems prior to the start of tasks [23]. These standards clearly delineate the legal responsibilities of employers, managers, and workers in relation to occupational safety, assigning them specific obligations in the planning, execution, and control of work activities—especially those involving elevated risks such as working at height.

The 1988 Federal Constitution is the primary legal framework guaranteeing occupational safety as a social right, establishing the reduction of work-related risks through health, hygiene, and safety regulations [24]. This guarantee is complemented by Article 157 of the Consolidation of Labor Laws (CLT), which obliges employers to provide a safe and healthy work environment through the supply of Personal Protective Equipment (PPE) and the adoption of preventive measures [25]. These legal provisions establish a solid normative

framework that guides both the private and public sectors in promoting occupational safety, since adherence to these principles is essential to protect workers' health and uphold dignity in professional practice.

With regard to work at height, Regulatory Standard No. 35 (NR-35) stipulates that employers are responsible for conducting risk analyses, developing operational procedures, adequately training workers, and ensuring continuous supervision of activities [26]. Failure to comply with these obligations may result in administrative, civil, and even criminal sanctions, as provided by Law No. 8,213/1991, which addresses work accident benefits and liability in cases of omission [27]. These regulations reinforce the need for management committed to prevention and safety, as strict compliance with NR-35 and adherence to social security legislation are essential not only to protect lives but also to avoid legal consequences and strengthen a culture of responsibility in the workplace.

Legal responsibility for occupational safety in public institutions extends not only to direct employers but also to managers, public servants responsible for contract execution and supervision, and top administrators. Decree No. 10,024/2019, which regulates electronic procurement (pregão eletrônico), reinforces this obligation by requiring compliance with safety standards as part of contract management [28]. Negligence in contract supervision—especially in high-risk activities—may constitute an act of administrative misconduct, as established by Law No. 8,429/1992, updated by Law No. 14,230/2021 [29], [30]. These legal provisions demonstrate that omission is not merely an administrative failure but also subject to legal sanctions, affirming that compliance with occupational safety obligations is essential to the integrity of public management and the protection of workers' lives.

Labor jurisprudence has recognized the joint liability of public entities in cases of negligence in supervising the working conditions offered by outsourced companies, including building maintenance contracts. This understanding is supported by Precedent 331 of the Superior Labor Court (Tribunal Superior do Trabalho), which allows for the subsidiary liability of public administration when there is failure to supervise compliance with safety standards [31]. Thus, in public organizations, compliance with occupational safety obligations goes beyond formal requirements—it must be regarded as an institutional duty aimed at protecting life and the dignity of workers. It follows that noncompliance with these duties may entail serious legal consequences and compromise the legitimacy and accountability of administrative action within public management.

IV. RESULTS AND DISCUSSION

The analysis of the four thematic axes is essential to understand the complexity of occupational safety in the public sector. Axis (1) highlights the strategic role of institutional management in risk prevention, emphasizing the importance of proactive policies. Axis (2) addresses the challenge of strict liability, which imposes on the State the obligation to repair damages even in the absence of direct fault, thus demanding greater rigor in supervision. Axis (3) examines safety as an organizational dimension, integrating it into institutional culture and practices. Finally, Axis (4) reveals the social and economic impact of accidents, which generate human, financial, and operational costs. Together, these axes offer a broad and articulated perspective, fundamental to guiding effective preventive actions and promoting safe, ethical, and sustainable work environments within public administration. More specifically:

IV.1 THE ROLE OF INSTITUTIONAL MANAGEMENT IN RISK PREVENTION

The effectiveness of risk prevention actions in institutional environments is directly linked to the maturity level of institutional management. Public organizations that integrate safety policies into their governance systems demonstrate greater capacity to anticipate, mitigate, and monitor occupational risks. Institutionalizing risk management in the public sector promotes more predictable and rational decision-making and strengthens managerial accountability for the safety of both processes and people [32]. When treated as a strategic, rather than merely operational, function, risk management enables evidence-based decisions, reinforces organizational culture, and contributes to safer and more efficient workplaces. Investing in mature and integrated risk management is therefore essential to consolidating a safer, more responsible public administration aligned with principles of good governance.

Effective risk prevention in organizational settings requires leadership commitment, adequate resource allocation, and the implementation of tools such as the Risk Management Program (RMP) and internal audits [33]. Additionally, the international standard ISO 31000:2018 has been widely adopted as a reference framework for risk management systems in both public and private sectors, underscoring the importance of a comprehensive organizational culture that engages all areas in identifying and mitigating risks [34]. This integrated approach fosters collective awareness and shared responsibility in prevention; thus, the success of risk management depends not only on technical processes but, above all, on institutional engagement and the construction of a strong safety and sustainability culture.

Despite the persistence of fragmented and reactive approaches that hinder effective risk management, positive experiences are emerging in the public sector, such as the implementation of governance structures integrated with occupational health and safety management [35]. These initiatives strengthen the institutional role in prevention, demonstrating that institutional management extends beyond legal responsibility, it becomes a core element of organizational strategy. Furthermore, it contributes to promoting occupational health and ensuring efficient and safe public service, as investing in integrated and proactive management is crucial for overcoming historical challenges, improving workplace safety, and enhancing the quality of public services delivered to society.

IV.2 STRICT LIABILITY IN PUBLIC SERVICE

The strict liability of the State for damages caused to third parties is established in Article 37, §6 of the 1988 Federal Constitution, which provides that the direct and indirect public administration is responsible for damages caused by its agents, regardless of intent or fault [36]. In the context of occupational safety, this norm is particularly relevant when the State fails to guarantee safe conditions for its workers, whether permanent, temporary, or outsourced. This responsibility reinforces the duty of the public administration to adopt effective preventive measures and rigorously inspect workplaces. State omission in ensuring workers' physical integrity not only compromises safety but also exposes public administration to significant legal consequences, demanding greater diligence and commitment to prevention. The prevailing jurisprudence recognizes that State omission in its supervisory duties and in maintaining safe

working conditions constitutes strict liability, requiring public entities to compensate for damages, even when the activity is performed by a contracted company [37].

This liability is particularly relevant in outsourced service contracts, such as building maintenance, which often involve risks associated with working at heights. In such cases, it is essential for public managers to act diligently to ensure compliance with regulatory standards, especially NR-35, which governs safety in work at heights [38]. Rigorous supervision and effective management are indispensable to prevent accidents and avoid legal consequences for public administration. In practice, applying strict liability in the public sector faces several administrative barriers, such as difficulties in establishing causal links between public omission and the harmful event, as well as gaps in contract monitoring mechanisms. The lack of effective internal control systems and managerial accountability undermines the principle of efficiency, leaving the administration vulnerable to labor and social security litigation. These weaknesses hinder accident prevention and proper accountability, compromising worker protection and institutional credibility.

In this context, strengthening oversight tools and adopting transparent and rigorous practices are fundamental to ensuring the effectiveness of strict liability and promoting continuous improvement in public occupational safety management. Law No. 14,133/2021, which regulates public procurement, reinforces the administration's duty to monitor and supervise contract execution, including compliance with legal and labor requirements, thereby expanding the scope of strict liability [39]. This framework demands that public management adopt effective preventive systems, such as risk management plans and periodic technical audits, particularly in contracts involving high-risk activities. The challenge of strict liability in public service thus requires a critical reflection on the maturity of institutional management and the effectiveness of preventive mechanisms. Investment in training, procedure standardization, and the strengthening of a prevention- and life-centered organizational culture is indispensable for ensuring worker safety and upholding public administration's accountability.

IV.3 SAFETY AS AN ORGANIZATIONAL DIMENSION

Occupational safety must be understood as a fundamental and structuring dimension of organizations, going beyond a merely corrective or legal perspective. Institutions that incorporate safety into their strategic frameworks build resilient environments capable of preventing accidents, protecting lives, and ensuring the efficient continuity of activities. To achieve this, four organizational pillars must be articulated: well-defined operational routines, continuous training, adequate support structures, and a consolidated prevention culture [40]. This integrated approach promotes engagement at all hierarchical levels and strengthens shared responsibility for safety, recognizing that investment in these pillars is crucial to transforming occupational safety into an organizational value—ensuring safer, healthier, and more productive workplaces.

Organizational routines establish clear standards for task execution, significantly contributing to risk minimization in the workplace. Standard Operating Procedures (SOPs), formal authorizations for critical activities, and practices such as lockout and tagging are concrete examples of mechanisms that embed safety into daily operations [41]. However, the effectiveness of such measures depends directly on systematic and continuous training, ensuring workers' understanding and commitment to established norms. Without ongoing education, these routines lose their preventive effectiveness, making the combination of well-structured procedures and continuous training essential for maintaining safe workplaces and strengthening the prevention culture.

Regular training is a fundamental component of accident prevention, as highlighted by ISO 45001:2018, which stresses the need to develop competencies through instruction programs and practical simulations so that workers can understand risks and act effectively in adverse situations [42]. The existence of dedicated organizational structures—such as Internal Commissions for Accident Prevention (CIPA), safety engineering departments, and risk management committees—allows for constant monitoring of working conditions, identification of irregularities, and implementation of improvements [43]. In complex public environments such as schools, hospitals, and universities, where high staff turnover and functional diversity prevail, investment in training and specialized structures becomes essential to ensure safety and operational efficiency.

The prevention culture must be promoted as a core institutional value, as organizations with consolidated safety cultures exhibit lower accident rates and greater worker engagement in preventive actions [44]. This requires firm leadership commitment, clear communication, and the active participation of employees in designing and implementing safety measures. Recognizing safety as a strategic organizational dimension strengthens institutional performance, protects individuals, and legitimizes public administration's role in promoting dignified and healthy workplaces. Therefore, investing in building and maintaining this culture is vital for ensuring the effectiveness of preventive actions and the quality of public services provided to society.

IV.4 SOCIAL AND ECONOMIC IMPACT

The absence of effective occupational safety policies in public organizations generates significant social and economic consequences. The social impact of workplace accidents and long-term disabilities extends beyond the individual, directly affecting families and communities. Prolonged incapacity for work is a multidimensional phenomenon that results in income loss, livelihood difficulties, and increased dependence on public or family support [45]. This situation generates social exclusion, emotional overload on caregivers, and weakens community bonds, heightening social vulnerability. Occupational accidents, particularly those related to work at heights, not only jeopardize workers' health and lives but also impose high costs on the State and society. These impacts manifest through extended absences, disability retirements, death pensions, productivity losses, and civil liability lawsuits.

From an economic standpoint, the International Labour Organization (ILO) estimates that occupational accidents and diseases cause global losses equivalent to up to 4% of the Gross Domestic Product (GDP) annually [46]. In Brazil, the situation is alarming: in 2023, there were 499,955 recorded occupational accidents, resulting in 2,888 deaths, according to the Occupational Safety and Health Observatory. These events generated an estimated cost of R$ 112 billion for the country, considering social security, healthcare, and legal expenses [47]. Such data underscore the significant impact of inadequate prevention, not only on human lives but also on the national

economy, demonstrating that investing in occupational safety is essential to reducing economic losses and preserving workers' health and lives.

In the context of public institutions, the costs arising from occupational accidents are amplified by their multiplier effect on public service delivery. The absence of technical staff, project stoppages, contract litigation, and the interruption of essential activities undermine administrative efficiency and the credibility of public management. Emphasize that the indirect costs of such accidents often exceed direct costs, affecting planning, schedules, and institutional reputation [48]. These impacts reveal the importance of effective prevention and risk management policies to ensure service continuity and maintain public trust, as investing in occupational safety also means investing in the quality and sustainability of public administration. Workplace insecurity deepens social inequalities and undermines labor dignity, especially affecting outsourced and precariously employed workers, who are more exposed to risks.

Studies conducted in public educational institutions indicate that 70% of height-related accidents involve outsourced labor [49]. Beyond human suffering, these accidents destabilize families, increase reliance on welfare benefits, and reinforce cycles of social exclusion. In this context, investment in occupational safety must be seen not as a cost but as a fundamental strategy for institutional development and social justice. Prevention not only generates public value but also reduces state expenditures, contributing to the creation of safer, more productive, and inclusive workplaces—thus strengthening society as a whole. Based on the discussion presented, Table 1 provides a synthesis of the four axes, highlighting their central concepts and corresponding recommended best practices.

Table 1: Summary of the Guiding Axes.

Thematic Axis	Core Concept	Best Practices
The Role of Institutional Management in Risk Prevention	The maturity of public management is decisive in preventing occupational risks within institutional environments.	- Implementation of proactive and integrated risk management policies.- Adoption of the Risk Management Program (RMP) and internal audits.- Alignment with ISO 31000:2018 guidelines.- Leadership engagement and promotion of a safety-oriented organizational culture.
Objective Responsibility in Public Service	The State is accountable for damages even in the absence of direct fault, requiring strict oversight and contractual control.	- Strengthening supervision of outsourced contracts.- Strict compliance with Regulatory Standard NR-35.- Implementation of internal control systems.- Application of Law No. 14.133/2021 (New Public Procurement Law).
Safety as an Organizational Dimension	Safety must be an institutional value, integrated into the routines, structure, and culture of organizations.	- Development of Standard Operating Procedures (SOPs).- Continuous training based on ISO 45001:2018.- Establishment of dedicated structures such as Internal Accident Prevention Commissions (CIPA) and risk committees.- Encouragement of active employee participation.
Social and Economic Impact	Accidents result in human, social, and financial losses, undermining the delivery of public services.	- Investment in prevention as a cost-reduction strategy.- Continuous monitoring of accident data.- Public policies aimed at protecting vulnerable workers (outsourced and precarious).- Promotion of safety as a social and economic value.

Source: Authors (2026).

The analysis of the four thematic axes allows for an understanding of the complexity involved in managing occupational safety in work-at-height activities within the public sector, highlighting structural challenges and opportunities for the implementation of best practices. The first axis, "The Role of Institutional Management in Risk Prevention," demonstrates that the maturity of public management is essential for anticipating, mitigating, and monitoring occupational risks. Prevention must be treated as a strategic, rather than merely operational, function, grounded in integrated policies, the use of tools such as the Risk Management Program (RMP), internal audits, and alignment with ISO 31000 guidelines.

The second axis, "Objective Responsibility in Public Service," points out that the State is liable for damages resulting from accidents, even in the absence of direct fault, which requires rigorous oversight and effective control of contracts, particularly those involving outsourcing. Therefore, investing in preventive mechanisms and strengthening supervision is essential to protect workers and prevent legal sanctions. In the third axis, "Safety as an Organizational Dimension," the study reinforces the need to integrate occupational safety into institutional structures, considering it a fundamental organizational value. This entails defining clear operational routines, offering continuous training in accordance with ISO 45001, establishing safety committees, and promoting the active participation of public servants in building a culture of prevention.

The fourth axis, "Social and Economic Impact," broadens the discussion by demonstrating that accidents involving work at height generate not only human costs but also significant impacts on the delivery of public services and the State's budget. Worker absences, construction stoppages, litigation, and the social exclusion of injured workers reveal the extent to which prevention should be seen as both a strategy for valuing life and a means of ensuring administrative efficiency. Taken together, the four axes form an articulated management model that combines institutional responsibility, sustainability, and ethics in promoting safe working environments within the public sector.

V. FINAL CONSIDERATIONS

The purpose of this study was to responsibly and ethically identify the structural, organizational, and cultural barriers that hinder the effectiveness of preventive actions in the public sector. Although these obstacles are identifiable, overcoming them requires in-depth technical analysis, intersectoral dialogue, and strategic decisions that extend beyond the scope of a single study. The persistence of occupational safety in work at heights as one of the greatest challenges in public management is not new, but it reinforces the need for a qualified, critical, and sensitive perspective on the issue. The reflections presented here reaffirm that addressing these risks must be grounded in institutional commitment, collective responsibility, and the valuing of life—essential elements for building effective policies and safe, dignified, and sustainable work environments within public administration.

The role of institutional management in risk prevention highlights the importance of proactive and integrated policies that anticipate and mitigate hazards in the public sector. Organizations that institutionalize risk management strengthen governance, encourage managerial accountability, and promote evidence-based decision-making, while consolidating an organizational culture focused on safety. The challenge of objective liability in public service demonstrates that the State must compensate for damages caused to third parties even without direct fault. This increases the need for rigorous oversight and effective control of working conditions, especially in outsourced contracts, to prevent accidents and ensure worker safety. Such responsibility underscores the importance of diligent public management committed to the protection of life.

Safety as an organizational dimension emphasizes the importance of integrating safety into daily routines, continuous training, and the preventive culture of institutions. This approach fosters engagement across all hierarchical levels, strengthening shared responsibility for worker protection and ensuring safer, more productive, and resilient workplaces. It becomes an essential and structuring value for the effective functioning of organizations. The social and economic impact highlights the severe effects of work-related accidents on workers' lives, the financial costs for the public sector, and the interruption of essential public services. These consequences compromise administrative efficiency and increase the demand for resources, reinforcing the urgent need for investment in prevention to protect lives, reduce expenses, and ensure the quality of public services.

Together, the four guiding axes provide a solid foundation for developing comprehensive and sustainable practices in occupational safety management within the public sector. By integrating the strategic role of institutional management, the rigor of objective liability, the incorporation of safety as an organizational dimension, and the understanding of social and economic impacts, a structured and continuous commitment is established toward the protection of life and administrative efficiency. This commitment is essential to consolidate occupational safety as an institutional value, ensuring safer, more resilient, and more productive work environments. Moreover, it strengthens the credibility and legitimacy of public administration by aligning its practices with the principles of good governance, social responsibility, and sustainability—key foundations for the delivery of high-quality public services.

Promoting safety in activities at height goes beyond mere regulatory compliance; it represents the recognition of the worker's dignity as a fundamental and non-negotiable principle of public service. Therefore, this research does not represent a conclusion, but rather a starting point for continuous technical and academic deepening. It opens space for future investigations and interdisciplinary contributions that may strengthen occupational safety management. Thus, safety becomes an essential pillar of a more ethical, effective, and life-centered public administration. Investing in the valuing of life and the prevention of risks is an indispensable condition for building dignified workplaces aligned with the democratic and social principles that guide public management.

ABSTRACT

This study aimed to develop and evaluate an automatic pest control spraying system using locally available materials, designed to enhance precision in pest management while minimizing human exposure to pesticides and reducing environmental impact. The system was tested on a plant bed to assess its efficiency, effectiveness, sensitivity, and economic viability, using parameters such as payback period, internal rate of return (IRR), and benefit-cost ratio (BCR). Employing a descriptive-experimental design, the prototype automatically detected pests and sprayed pesticides only at the detected location. The system consisted of a 230V AC source, digital time relay switch, Arduino Uno, PIR sensors, relay module, solenoid valve, and pump. Results showed that larger sample sizes improved effectiveness and sensitivity. The pump and solenoid valve efficiencies were 95.49% and 93.46%, respectively, while sensor efficiencies were 75.00%, 66.67%, and 29.17% for caterpillar, cockroach, and grasshopper detection. Economic analysis indicated a payback period of 8 months and 5 days, an IRR of 39.46%, and a BCR of 1.41, signifying strong financial feasibility.

I. INTRODUCTION

Food plays a fundamental role in human development, health, and economic growth, where agriculture serves as the backbone of sustainable food systems. Agriculture provides eco-friendly, renewable crops and animal products that ensure food security and rural development. Globally, value-added output in agriculture, forestry, and fishing increased by approximately 84% between 2000 and 2021, reaching about USD 3.7 trillion. Asia accounted for 65% of this growth, emphasizing the region's dominant contribution to global agricultural expansion. Moreover, the global production of primary crops reached 9.5 billion tons in 2021, reflecting a 54% increase compared to 2000. Despite this growth, the share of agriculture in global GDP has remained around 4% since 2000, underlining the sector's stable yet vital role in the global economy [1]. In the Philippines, agriculture remains a key contributor to both the economy and livelihoods.

During the first quarter of 2023, the value of agricultural and fishery production—measured at constant 2018 prices—reached PhP 428.69 billion, an annual increase of 2.1%. Crop production accounted for PhP 247.77 billion or 57.8% of the total output [2]. Approximately 25–30% of Filipinos depend directly on agriculture for their livelihood, contributing nearly 10% to the gross national product [3]. However, recent crises such as the COVID-19 pandemic and climate change have disrupted global agricultural productivity [4]. Climate-related challenges—rising temperatures, erratic rainfall, and frequent extreme weather—have led to pest outbreaks, crop failures, and declining yields [5-9]. Empirical analyses indicate that global agricultural total factor productivity has already declined by around 21% since 1961 due to anthropogenic climate change, with developing regions experiencing the greatest losses [7].

Pest infestation continues to pose serious threats to agricultural productivity [10]. Studies emphasize that pest and disease control is critical for yield optimization and crop sustainability [8], [11], [12]. Consequently, pesticide use has become a primary pest management strategy [5]. Between 2000 and 2021, global pesticide use increased by 62%, with Asia contributing 28% of the total [1]. The use of pesticides enhances crop protection and yield [5], [8], [12-14]; however, excessive and unsafe application has raised significant health and environmental concerns [8],[12-15]. Prolonged pesticide exposure is linked to acute symptoms such as dizziness, nausea, and diarrhea, and chronic illnesses including cancer, endocrine disruption, and neurological disorders [14-16]. Furthermore, pesticides contaminate soil and water, harming beneficial organisms and disrupting ecological balance [12-16].

Farmers face additional challenges in pest control at night, where most traditional pest monitoring and spraying methods are limited. Manual pesticide application remains labor-intensive, time-consuming, and often inefficient, leading to inconsistent coverage and increased health risks for workers [8], [12], [17]. To address these limitations, the National Crop Protection Center (NCPC) has promoted research on integrated pest management and sustainable pest control systems [4]. The integration of new innovative technologies is required [8]—such as automated spraying systems, digital sensors, and Internet of Things (IoT)-based pest detection [17], [18], [10]—has been shown to improve productivity, reduce labor requirements, and enhance sustainability in agriculture [17], [18], [9]. Recent findings indicate that digital agriculture improves smallholder farmers' welfare by up to 71.25%, with pest management as one of the key areas of benefit [19].

In this context, developing an automated pest control spraying system designed to detect and repel pests can serve as an innovative solution to optimize yields and safeguard worker health [20]. The proposed system uses passive infrared (PIR) sensors to detect pests, automatically sprays pesticide in targeted areas, and allows programmable timing for spraying cycles. This automation reduces direct pesticide exposure, lowers labor requirements, and ensures more precise pest control. Such technology supports sustainable and smart farming practices that increase agricultural productivity while minimizing environmental and health risks. Specifically, this study aims to analyze existing manual pesticide application in terms of pest types, labor, and costs; design and fabricate an automatic spraying system; test its performance in terms of effectiveness, sensitivity, and efficiency; and assess its economic viability for smallholder farmers in the Philippines.

II. MATERIALS AND METHODS

II.1 SYSTEM AND DESIGN DESCRIPTION

The automated pest control spraying system integrates several key components: a pest detection mechanism, a programmable processing unit, a spraying mechanism, a power supply, and a converter. The pest detection mechanism utilizes Passive Infrared (PIR) sensors strategically positioned along the plant bed to detect motion caused by pest activity [20]. When movement is detected, the sensors send digital signals to the programmable processing unit for data processing and response coordination. This detection approach aligns with recent advances in precision agriculture, where networks of low-cost passive infrared (PIR) sensors and vision-based cameras are increasingly combined with IoT telemetry and machine-learning models to deliver real-time pest monitoring and automated field responses [20], [21], [10].

The programmable processing unit utilizes a shielded Arduino Uno board that handles sensor inputs and transmits control signals to relay-based actuators, ensuring timely and efficient system operation. This microcontroller-based architecture has been widely adopted in agricultural automation applications because of its affordability, adaptability, and dependable integration with diverse sensor arrays and wireless modules, enabling real-time monitoring and control of field conditions [20], [22], [23]. The relay-based switching mechanism, comprising a digital timer relay and an 8-channel relay module, electronically opens and closes circuits to control the activation of the PIR sensors and diaphragm pump. This modular relay configuration is essential for ensuring system scalability, allowing independent timing and sequencing of spray operations, and supporting flexible automation in diverse field conditions [22-24].

The spraying mechanism integrates solenoid valves, diaphragm pumps, an array of pipes, and misting nozzles to ensure the precise dispersion of organic pesticides. The solenoid valve regulates the flow of fluid, while the diaphragm pump transfers pesticide solutions through the connected pipeline to misting nozzles that deliver fine droplets uniformly across plant surfaces. This mechanism mirrors current trends in precision misting and controlled fluid delivery systems, which enhance pesticide utilization efficiency and minimize environmental contamination [20], [25], [26]. The power system comprises a 12V DC source linked to a 230V AC supply, with a converter reducing voltage to 5V DC to power the Arduino unit and associated sensors—consistent with common configurations in automated agricultural systems emphasizing energy efficiency and portability [20], [23], [27].

II.2 DESIGN AND FABRICATION PROCEDURES

During the design and fabrication phase, PIR sensors were installed at one-meter intervals along the plant bed to ensure uniform detection coverage. A functional prototype integrating sensors, pumps, and actuators was developed following specified design parameters. The sensors were calibrated to detect pest movements accurately within their assigned detection zones. Controlled experiments were conducted to assess sensor performance and system responsiveness under varying environmental conditions such as wind and light levels. This systematic approach to calibration and prototype validation is aligned with best practices in smart agricultural device testing and sensor reliability evaluation [28], [29]. Data from sensor readings, pump performance, and system response were analyzed to identify operational trends, ensuring that threshold values and pump discharge rates matched optimal pesticide dispersion performance. Enhancements were implemented based on performance feedback, refining the control algorithms and sensor sensitivity thresholds to achieve consistent accuracy and reliability.

II.3 DATA COLLECTION PROCEDURES

The performance of the automated pest control spraying system was assessed based on three primary criteria: effectivity, sensitivity, and efficiency. Effectivity was determined by simulating pest detection through three trials under varying environmental conditions, measuring the effective detection range of sensors across five distance intervals (0.5–4 meters). Sensitivity was evaluated by calculating the time lag between pest detection and system response, offering a quantitative measure of the controller's performance at different distances. Efficiency analyses covered solenoid valve, sensor, and pump operations. For solenoid valves, efficiency was defined as the ratio of actual to theoretical flow rates, expressed as a percentage. Sensor efficiency represented the ratio between maximum detection range and design specification, while pump efficiency was calculated as the ratio of actual discharge to designed output. Such performance measurement techniques are consistent with engineering testing methodologies used in automated irrigation and spraying systems [30], [31].

II.4 DATA ANALYSIS PROCEDURES

Collected data were analyzed using descriptive statistics such as frequency counts, arithmetic means, and averages to determine operational consistency. Cost-benefit analysis (CBA) was applied to assess economic viability, using metrics such as Benefit-Cost Ratio (BCR), Payback Period (PP), and Internal Rate of Return (IRR). The BCR compared annual benefits with total investment, while PP evaluated the duration required to recover capital costs. The IRR estimated the annualized profitability of the system. These economic indicators align with standard frameworks for evaluating automation technologies in sustainable farming and agri-engineering [22], [31], [32]. By combining technical and economic analyses, the study ensured that the system design was not only functionally efficient but also financially feasible for agricultural deployment.

III. RESULTS AND DISCUSSIONS

III.1 PEST PREVALENCE IN THE AREA

Table 1 presents the mean rates of pest encounters among workers in the study area. The findings indicate that grasshoppers (M = 4.67) and cockroaches (M = 4.33) were the most frequently encountered pests, classified as Very Highly Encountered. Caterpillars (M = 4.00) were Highly Encountered, while ants (M = 2.00) were Encountered and flies (M = 1.33) were the Least Encountered. These results suggest that grasshoppers and cockroaches pose the most significant threats to crop productivity within the observed agricultural environment. The high frequency of grasshoppers and cockroaches supports global trends where these pests are among the most destructive to agricultural productivity, particularly in tropical and humid environments [33]. Grasshopper species commonly flourish in open, sun-lit vegetative landscapes—consuming foliage, pods, and developing grains across a broad spectrum of crops [34].

In contrast, cockroach populations find ideal conditions in moist, shaded micro-habitats (such as under crop residues or in harvesting/storage structures) and frequently act as post-harvest contaminants—penetrating stored commodity stacks, degrading grain quality, and reducing market value [35]. The dominance of grasshoppers and cockroaches implies that pest control systems in the region should prioritize the detection and mitigation of these species [34], [35]. Automated pest management systems, equipped with motion and infrared sensors, can be fine-tuned based on the behavioral characteristics of these pests [21], [36]. Therefore, identifying the pest prevalence provides a strong foundation for designing an efficient and species-targeted automated pest control spraying system.

Table 1: Prevalent pest in the area.

Pest	Mean	Interpretation
Grasshopper	4.67	Very Highly Encountered
Cockroach	4.33	Very Highly Encountered
Caterpillar	4.00	Highly Encountered
Ants	2.00	Encountered
Fly	1.33	Least Encountered

II.2 DESIGN OF THE SYSTEM

Figure 1 to 4 presents the developed system comprised five major components: (1) pest detection mechanism using Passive Infrared (PIR) sensors; (2) programmable processing unit utilizing an Arduino Uno microcontroller; (3) relay-based switching system for activation and deactivation of components; (4) spraying mechanism integrating a solenoid valve, diaphragm pump, and misting nozzles; and (5) a power supply system converting 12V DC to 5V DC. The physical arrangement, as depicted in Figure 1 to Figure 5, demonstrated a well-integrated design ensuring coordinated functionality between detection and actuation modules. The PIR sensors were installed at one-meter intervals along the plant bed to ensure consistent coverage. When pests were detected, the Arduino processed the signal and triggered the relay system, which controlled the solenoid valve and pump.

The misting nozzles sprayed the organic pesticide in a fine distribution pattern, effectively targeting detected pests. Such automation reduces labor intensity [23], [37], [38] and chemical wastage compared to manual spraying [37], [38]. The modular configuration allows scalability and easy maintenance. Previous studies have demonstrated that sensor- and IoT-based pest management systems can reduce pesticide use by around 30–45% while maintaining pest control efficiency [39-41]. The structural integration of detection, processing, and spraying modules validates the design as functionally cohesive and sustainable. It provides a viable technological advancement for small-scale farmers, promoting safer and more efficient pesticide application. The system's design also aligns with smart agriculture frameworks emphasizing automation, precision, and environmental protection [42].

III.3 PERFORMANCE ANALYSIS

III.3.1 Effectivity

As reflected in Table 2, "Y" indicates that the pest was detected at the specified distance, while "N" indicates that the pest was not detected at the specified distance. Sensor performance trials indicated that caterpillars were detected up to 3.00 meters, cockroaches up to 2.67 meters, and grasshoppers up to 1.17 meters. Detection distance decreased with smaller insect size and faster movement. Environmental factors, such as wind, slightly reduced sensor accuracy, particularly at greater distances.The results confirm that PIR sensors are more effective at detecting larger and slower-moving insects due to their stronger infrared signatures [43].

Similar findings were reported by [43], who noted that detectability drops significantly for smaller arthropods with infrared sensors alone. Detection distance variability aligns with research by [44], suggesting that hybrid sensors combining infrared and visual technologies improve small-pest detection accuracy. The data validate the system's capability for pest detection but also reveal limitations for smaller or faster pests. These results highlight the need for sensor calibration or multi-sensor integration for enhanced adaptability. Despite environmental challenges, the sensor's range remains adequate for operational field use, confirming the system's practical applicability.

Table 2: Actual Effectivity of the System.

Pest	Effective Distance				
Grass hopper	**0.5m**	**1m**	**2m**	**3m**	**4m**

Trial 3	Y	Y	Y	Y	N

Source: Authors, (2026).

III.3.2 Sensitivity

Table 3 presents the average response time of the sensors varied with pest size and distance. Larger pests such as caterpillars triggered the system within approximately 5.5 to 8.7 seconds, while smaller and faster pests like grasshoppers required 6.6 to 14.3 seconds for detection. Detection was faster at shorter distances and under stable environmental conditions. The variation in response time indicates that PIR sensor sensitivity depends on the infrared intensity emitted by the pest and environmental stability. Similar findings were reported by [45], who explained that motion-based sensors in arable crops exhibit variable responsiveness under changing ambient conditions.

Wind and temperature fluctuations can cause false signals or delayed responses—an effect supported by [46], who emphasize the importance of calibrating sensor thresholds for compensation in outdoor farming environments. The results suggest that sensitivity calibration is essential for real-time detection under outdoor conditions. The system demonstrates functional responsiveness suitable for low to moderate pest activity levels, ensuring timely pesticide activation and efficient pest management.

Table 3: Actual Sensitivity of the System.

Pest	Sensitive Time				
Grass hopper	**0.5m**	**1m**	**2m**	**3m**	**4m**
Trial 1	7.4s	10.6s	N/A	N/A	N/A

Source: Authors, (2026).

III.3.3 Efficiency

Table 3 reveals that based on the maximum detection range of 4 m, the calculated sensor efficiency was 75% for caterpillars, 66.67% for cockroaches, and 29.17% for grasshoppers. Efficiency decreased for smaller insects and under higher environmental disturbance. This efficiency range is consistent with previous studies on infrared-based pest detection: one study found that IR-based sensor systems experienced notable drops in detectability for smaller arthropods under field conditions [20], while a comprehensive review reported that outdoor systems typically perform at lower efficiency than indoor setups due to wind, temperature and other disturbances [43]. The present results confirm that PIR sensors remain effective for larger pests under field conditions, validating their suitability for agricultural applications. The efficiency rates affirm the reliability of the detection mechanism for practical farming use, especially for medium and large pests. Further optimization through dual-sensor integration could improve accuracy for smaller pests, ensuring more comprehensive pest management.

Table 4 presents that the diaphragm pump delivered an average discharge rate of 12.7 L/min compared to its rated 13.3 L/min capacity, resulting in an efficiency of 95.49%. Minimal variation was observed during the trials, indicating consistent fluid transfer. The high pump efficiency aligns with literature showing that pump sets in agricultural systems can operate at high performance levels [47]. The small variance may be attributed to slight pressure drops in the tubing or minor voltage fluctuations. The consistency in performance ensures uniform pesticide application across all plant beds. The result validates the reliability and mechanical soundness of the pump mechanism. Its high performance supports sustained spraying activity, ensuring effective pest control coverage and reduced chemical waste, which are essential for organic pesticide application.

Table 4: Prevalent pest in the area.

Pest	Trial 1	Trial 2	Trial 3	Average
Discharge Rate	12.2 L/min	12.7 L/min	13.2 L/min	12.7 L/min

Source: Authors, (2026).

III.4 ECONOMIC FEASIBILITY

III.4.1 Payback Period

The labor cost for the plant taker was set at 100 pesos per hour. Based on the assumption that the automated pest control spraying system conserved two hours of the farmer's time every two days at the least, the payback period analysis indicated that the investment is projected to be recouped within eight months and five days. This supports the findings of [32] that payback period increases compared to the traditional method.

III.4.2 Internal Rate of Return

The IRR calculation was based on the assumption that the device would have a minimum expected useful life of one year. This metric assessed the percentage increase in the total investment cost of the automated pest control spraying system that will be returned over one year. The computed IRR was determined to be 39.6%, indicating that after a year of operation, an additional 39.6% of the total investment would be realized.

III.4.3 Benefit-Cost Ratio

The Benefit-Cost Ratio delineated the correlation between the benefits derived from the automated pest control spraying system and its overall cost. The computed ratio stands at 24:17, implying that for every ₱17.00 invested, there is an anticipated annual return of ₱24.00. This is aligned with the study of [23] & [32], which reported that automated system has higher benefit-cost ration compared to the traditional one. The financial indicators suggest that the automated pest control spraying system is economically feasible for smallholder farmers. Several studies have shown that automated agricultural systems with short payback periods—often under one year—are ideal for small-scale adoption [48-50].

The system significantly reduces labor costs, minimizes pesticide use, and enhances productivity, thereby contributing to financial sustainability. Similar efficiencies have been reported in smart agricultural systems that promote automation in pest management [32], [49], [50]. Economic analyses indicate that investing in an automated pest control spraying system can increase farmers' income and reduce operational expenses. Its affordability, efficiency, and ease of maintenance make it an accessible and practical solution for promoting sustainable agriculture in developing regions such as the Philippines.

IV. CONCLUSIONS

The automated system through the shielded Arduino Uno board efficiently interpreted signals from the sensor detected pests and managed the relay's switching function to operate the pump, ensuring the automated pest control spraying system 's alignment with its design. Key components, including a corrosion-resistant submersible pump, an accurate sensor, and chemical-resistant pipes, were carefully selected and validated for reliability in agricultural applications. Findings suggest an effective organic pest management as systems targets very highly encountered pest in the area such as the grasshopper, mantis and caterpillar. The sensor's effectiveness and sensitivity are directly proportional to the sample size and are influenced by environmental factors such as wind and ambient sound. The efficiency of the sensor computed was 75.00%, 66.67%, and 29.17% for caterpillar, mantis and grasshopper, respectively.

The reliability of system components was attained in this study, resulting a high efficiency for pump, achieving 95.49% and 93.46%, respectively, meeting the desired performance. The component durability which includes corrosion-resistant pump, accurate sensor, and chemical-resistant pipes. The automated pest control spraying system demonstrated economic viability with a payback period of 8 months and 5 days, and an internal rate of return exceeding the cost by 39.46%, yielding an annual return of 24 pesos for every 17 pesos invested. This shows significant economic and operational advantages. The short payback period and high IRR highlight its financial benefits, while the careful selection of reliable components and efficient system design ensure effective pest management and cost savings.

The system's ability to operate efficiently with a low labor cost and its resilience to environmental factors further enhance its practicality and value in agricultural applications. Findings of this study recommends the following recommendations to further enhance the system's performance and impact. To enhance sensor sensitivity and accuracy, an implementation of regular calibration schedule to maintain optimal sensor performance and accuracy, especially in varying environmental conditions. Consider incorporating more advanced sensor technologies, such as infrared or camera-based sensors, for a more accurate detection mechanism and reduce false detections. Conduct thorough field trials to determine the optimal placement of sensors for maximum effectiveness, taking into account factors like wind direction, plant height, and pest behavior.

To improve system reliability and durability, continue to establish a routine maintenance schedule, including cleaning, lubrication, and inspection of system components, to prevent malfunctions and extend the system's lifespan. To conduct further field trials and economic analysis, conduct large-scale field trials under diverse agricultural conditions to assess the system's performance and scalability in real-world scenarios. Conduct a detailed economic analysis, considering factors like labor costs, pesticide usage, crop yield, and market prices, to evaluate the long-term economic benefits of the system. By addressing these recommendations, the automated pest control spraying system can be further optimized to provide significant economic, environmental, and social benefits to farmers and the agricultural industry as a whole.

Future versions of the system may integrate locally available renewable energy sources to improve sustainability, as demonstrated by recent studies on unconventional energy harvesting methods such as alluvial soils [51], solar energy [52], [53], or even wind energy [53]. Overall, the system represents a sound investment with both economic and operational benefits. It has a multifaceted impact, offering significant economic, operational, environmental, and practical benefits. It represents a modern, efficient, and sustainable solution for pest management in agriculture, with strong potential for long-term advantages.

VI. ACKNOWLEDGMENTS

The researchers extend their deepest gratitude to the Almighty God for His blessings, strength, and guidance throughout the completion of this study. Sincere appreciation is also given to Kuya Rex for his valuable expertise and suggestions on the electronic components used in the project. Special thanks are extended to Sis. Lydia M. Collado, Executive Director of Sophie's Farm, for granting permission to conduct the study, and to Mr. Isidro S. Baradi IV, Program Officer, for his constant support and assistance during field visits. The researchers also thank the staff of Sophie's Farm for their kindness and cooperation during the conduct of the study. The research also acknowledged the University of Eastern Philippines, led by Dr. Cherry Ultra, for funding the project, through Dr. Karina Milagros Cui-Lim, Vice President for Research, Extension and Development.

ABSTRACT

Today, classical encryption systems such as the Playfair cipher are easily broken in the current computing environment. Traditional ciphers based on digraph interactions cannot resist attacks using frequency analysis and pattern recognition, making them unsuitable for modern security. This work presents an improved Playfair cipher by integrating three chaotic maps—Logistic, Hénon, and Arnold Cat—to generate encryption keys dynamically and distort ciphertext. This integration creates a hybrid system that is highly secure yet computationally efficient. Experimental results using Shannon entropy and Lyapunov exponent metrics show clear performance advantages. The Hénon Map proves superior in randomness, achieving a Shannon entropy of 4.11257. The Arnold Cat Map, with a Lyapunov exponent of 0.89813, demonstrates strong sensitivity to initial conditions, preventing brute-force attacks. The Logistic Map provides a balanced compromise (entropy: 3.97695, Lyapunov: 0.63663) between security and resource efficiency. This approach augments the traditional Playfair cipher into a robust modern security solution, showing how classical cryptographic techniques combined with chaos theory can effectively meet contemporary digital security demands.

I. INTRODUCTION

Classical cryptography can be divided into two types: transposition ciphers and substitution ciphers. The transposition cipher is that the letters remain unchanged, but the position changes. The substitution cipher is to replace the letters in the plain text with other letters. Playfair cipher is a typical classical cipher, which is a symmetric substitution encryption cipher. Playfair cipher was invented in 1854 by British scientist Charles Wheatstone Playfair. For a long period, the Playfair algorithm was considered an unbreakable encryption method. its encryption ideas are widely used in terms of network security, data encryption. The Playfair cipher is an encryption algorithm that uses two-letter syllables in plaintext as a unit and converts them into ciphertext. The original algorithm can use 26×26 letter pairs, although it has a slightly flatter frequency distribution curve than plaintext.

The ciphertext still reveals a large amount of information to the cryptanalyst [1]. What makes chaos-based cryptography such a promising field is that chaotic systems are deterministic, vulnerable to change, and without large computational costs. As such chaotic systems set up an exceptional base for implementing various encryption schemes. Therefore, a key characteristic in this field is the introduction of new chaotic maps, such as discrete maps of low dimensions that showcase regions of constant chaotic behavior [2]. Chaotic maps are primarily used as a source of entropy .The popularity of chaos-based cryptography in recent years stems from the fact that chaos can fulfill cryptographic requirements such as topological mixing, periodicity, pseudo-randomness, low correlations, and high sensitivity to initial conditions and control parameters. The use of chaotic maps for cryptography is advantageous due to their desirable characteristics, including complexity, unpredictability, sensitivity to initial values and control parameters, and ergodicity.

However, most chaos-based systems have limitations that make them impractical, such as low efficiency, insufficient security, and small keyspace [3]. The Logistic Map is one of the most famous chaos-based encryption elements, which is a mathematical model for population growth. The random sequences generated by this map have applications in cryptography and are well-suited for key generation. Even a minor variation in input values results in vastly different outputs, making it nearly impossible to predict the encryption keys. This property makes the Logistic Map an effective method for secure key generation in modern encryption systems [4]. The Hénon Map is another example of a chaos-based encryption model.

Operating in two dimensions, it is significantly more complex than the Logistic Map. Due to its high sensitivity to initial conditions, it has been used in secure communication systems and image encryption, ensuring that unauthorized users cannot reconstruct the original data without precise knowledge of the initial parameters [5]. The Arnold Cat Map offers a powerful scrambling technique for visual images. This transformation is particularly useful in biometric security, medical imaging, and digital watermarking, where protecting visual data is crucial. By rearranging pixel positions, the Arnold Cat Map creates a seemingly random distribution, making it nearly impossible to decipher the original image without the proper decryption key [6].

Despite all its advantages, chaos-based encryption faces challenges related to implementation and stability. One of the most critical aspects of ensuring that chaotic encryption systems are secure and do not show any regularities is to use conditions defined to an infinite number of decimal places. Furthermore, some key synchronization between sender and receiver continues to remain a research aspect, as the failure to align encryption keys can lead to decryption failure. Despite these challenges, the integration of chaotic maps into cryptographic systems represents a significant leap forward in data security [7]. In parallel to advancements in classical encryption algorithms using chaos theory, modern cryptographic systems have increasingly emphasized layered security and formal validation.

Recent secure payment protocols demonstrate how the integration of zero-knowledge proofs and structured cryptographic primitives contributes to building trust and preventing unauthorized access in practical systems [8]. Such frameworks, while differing in implementation, reinforce the broader need for hybrid cryptographic models that combine multiple techniques—like the use of chaotic maps in Playfair cipher enhancement. Another important factor that supports the security and reliability aspects of the proposed system is the voting storage mechanism. Without a proper and secure storage mechanism, there is a high possibility of threats occurring in the system.

A sufficient voting storage mechanism should have features such as being simple, reliable, durable, tamper-evident, subliminal-free, and cost-effective. In the following sections of the paper, cryptographic approaches are discussed in more detail, examining their advantages, challenges, and real-world implementation scenarios. Hybrid security models that combine both classical and chaos-based encryption approaches are examined, providing stronger and more viable cryptographic frameworks. The goal of this discussion is to identify how the new encryption mechanism adapts and protects against emerging cyberattacks.

II. THEORETICAL REFERENCE

II.1 LITERATURE REVIEW

The Playfair Cipher is a traditional digraph substitution cipher that has been thoroughly examined and altered to increase its security. Chaotic maps have proved to be an effective tool to increase its security and unpredictability. Chaotic transformations have led to the utility of the Playfair cipher being extended beyond text encryption. Differential cryptanalysis can be defeated by pixel-level disruptions introduced by image encryption done using chaotic theory in the diffusion and confusion processes [9]. Using hyper-chaotic Chen system based triple permutation, XORing, and multi-dimensional Playfair key generation further improves security [10].

By guaranteeing a high level of unpredictability in key evolution, the implementation of logistic-tent maps within encryption networks improves security [11]. In a 2023 study, Mandangan et al. applied Arnold's Cat Map and Hénon Map for color image encryption, demonstrating resilience against statistical and brute-force attacks [12]. In order to improve diffusion properties and make unauthorized decryption more difficult, one study incorporates chaotic maps, specifically the Hénon and Arnold Cat Maps, which introduce nonlinearity and unpredictability into encryption [13]. The frequency analysis flaws in traditional Playfair ciphers are fixed by this integration. Chaotic maps and genetic algorithms also dynamically change the encryption process, making decryption efforts even more challenging [14].

Another invention uses a nonlinear rotational Playfair matrix to provide multi-layered security by fusing chaotic principles with DNA-based encryption. Because chaotic transformations are extremely sensitive, this method guarantees that brute-force and differential attacks are rendered impracticable [15]. By increasing key complexity and unpredictability, the multi-dimensional key matrix used to create a Playfair cipher expands the encryption state space and improves security. This strategy reinforces encryption methods by strengthening defences against statistical analysis and greatly increasing the difficulty of brute-force attacks [16].

In conclusion, this study expands on previous research [9-16] by presenting a new methodology that combines multi-key approaches and chaotic systems. This method combines several chaotic maps to improve security, flexibility, and resistance to cryptanalysis, in contrast to earlier works that concentrated on discrete enhancements. The performance of current Playfair cipher modifications is highlighted by the comparative analysis of previous approaches, which is shown in Table 1. This study not only improves cryptographic resilience but also establishes the groundwork for addressing new security threats in the field by addressing important security parameters like Shannon entropy and Lyapunov exponent.

Table 1: Performance Comparison of Playfair-Based Cryptosystems.

Ref	Approach	Algorithm Used	Encryption Time (ms)	Decryption Time (ms)	Security Strength	Computational Complexity
[9]	Block Image Encryption	Block Image Encryption	Medium (~150 ms)	Medium (~140 ms)	High (Better against cryptanalysis)	$O(n^2)$ (Block based transformation)
[10]	Multidimensional Playfair	Playfair + Chaos Mapping	High (~250-350ms)	High (~250ms)	Very High (Resistant to known attacks)	$O(n^3)$ (Key expansion in multi-dimension)
[11]	PLT-Net SP-Network	Logistic- Tent Map + Playfair	Very High (~500ms)	Very High (~480ms)	Extremely High (Strong Confusion diffusion)	$O(n^3)$ (Neural Network based encryption)
[12]	Color Image Encryption	Arnold's Cat Map + Hénon Map	Medium (~180ms)	Medium (~170ms)	High (Improves Diffusion and Breaks predictability)	$O(n^2)$ (Nonlinear Pixel transformations)
[13]	Selective Image Encryption	Genetic Operations + Chaotic Maps	High (~300ms)	High (~290ms)	Very High (Dynamic and adaptive encryption)	$O(n^3)$ (Multiple transformation layers)
[14]	Time-Signature Based Image Encryption	Latin Squares + Playfair + S-boxes	Medium (~220ms)	Medium (~210ms)	High (Time dependency adds unpredictability)	$O(n^2)$ (Time based S-box variation)
[15]	DNA Playfair Matrix	16×16 DNA Playfair	Very High (~600ms)	Very High (~590ms)	Extremely High (DNA Computing adds complexity)	$O(n^4)$ (Complex DNA encoding)
[16]	Multi-Dimensional Key Matrix	Multi-Key Playfair	Medium (~200ms)	Medium (~190ms)	High (Key variability improves security)	$O(n^3)$ (Key expansion overhead)

II.2 RESEARCH GAPS

Despite the significant enhancement of Playfair cipher security using chaotic maps, most of the existing approaches are centered on either one chaotic map or two, without a comparative study over multiple maps. Few studies have analyzed the security parameters of the Playfair cipher like Shannon entropy and Lyapunov exponent, both of which are essential in assessing randomness and initial condition sensitivity. Current studies mainly utilize these encrypting methods in images, but there is limited research regarding their usability for text-based cryptographic systems [8-14], [17].The research aims to bridge the gap among current Playfair cipher improvements with a new scheme of hybrid cryptography that combines Logistic, Hénon, and Arnold Cat chaotic maps.

II.3 SCOPE AND OBJECTIVES OF THE STUDY

The scope involves thorough performance analysis with Shannon entropy to measure randomness and Lyapunov exponent to determine sensitivity to initial conditions. This research aims to design a hybrid Playfair cipher encryption system based on Logistic, Hénon and Arnold Cat map to improve cipher security. Evaluate the performance, sensitivity and randomness of the system through key metrics such as Shannon entropy and Lyapunov exponent. Carry out a comprehensive comparative analysis to determine which chaotic map is better at generating randomness.

III. METHODOLOGY

The proposed solution consists of two parts. First, the integration of the Playfair cipher with different chaotic maps like the logistic, Hénon, and Arnold cat maps. Then comparative analysis of these hybrid ciphers based on the Lyapunov Exponent and Shannon Entropy.
A. Integration of Playfair Cipher with Chaos Maps:

1. Logistic Map for Generating Keyword:

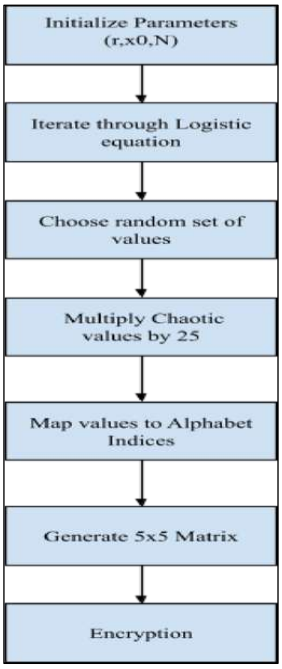

Figure 1: Process of key generation for Logistic Map.
Source: Authors, (2026).

Logistic Map is a 1D chaotic equation expressed as:

$$x_{n+1} = (1 - x_n) \quad (1)$$

Where, r is the control parameter and x_0 is the seed from the origin. Figure 1 represents the process of generating a keyword using a logistic equation. The chaotic Playfair cipher keyword generation begins with initializing the parameters. Then the logistic equation is used to generate chaotic values. From these generated chaotic values, choose a subset of them depending on the length of the keyword needed. If the length of the keyword is to be 7, then randomly 7 chaotic values are selected from this pool. This is done via a cryptographically secure pseudo-random number generator (CSPRNG) so that it's indeterminate. Once the disordered values are selected, they are converted to alphabet indices. This is accomplished by multiplying all the selected disordered values by 25 and taking the integer part of the value, getting indices ranging from 0 to 25.

These indices map to the alphabet letters; I and J are considered a single letter. The generated letters are the keyword that is filled into the 5×5 Playfair cipher key matrix one by one. After inserting the keyword letters, the remaining empty spaces in the matrix are filled with the remaining letters of the alphabet in alphabetical order such that each letter appears once. After filling the matrix, normal Playfair encryption takes place, using the key matrix to encrypt plaintext digraphs in a methodical way. The decryption method remains the same as the traditional Playfair cipher method. Algorithm 1 represents the process of generating the chaotic sequence using the Logistic Map.

Algorithm 1: Generate Chaotic Sequence using Logistic Map.

FUNCTION generate_playfair_matrix(effective_keyword_length = 5):
1. Generate a sequence of chaotic values using the Logistic Map:
chaotic_values ← logistic_map()
2. Securely select 'effective_keyword_length' random values from chaotic_values:selected_values ← securely sample 'effective_keyword_length' values from chaotic_values
3. Convert selected values to integer indices in range [0, 24]:
*letter_indices ← set of floor(value * 25) for each value in selected_values 4. Map indices to characters in the Playfair alphabet (A-Z, with I/J combined): alphabet ← ['A', 'B', 'C', ..., 'Z'] excluding 'J' selected_letters ← characters from alphabet at positions in letter_indices*
5. Remove duplicates and maintain the selected order:
used_letters ← selected_letters (as a set) remaining_letters ← all letters in alphabet not in used_letters
6. Combine selected and remaining letters:
key_matrix_flat ← selected_letters + remaining_letters
7. Reshape into 5x5 matrix: matrix_5x5 ← reshape key_matrix_flat into 5 rows of 5 columns
RETURN matrix 5x5

Source: Authors, (2026).

2. Hénon Map for Generating Keyword:

The Hénon Map is a two-dimensional chaotic system represented by:

$$x_{n+1} = 1 - p_1 x_{n2} + y_n$$
$$y_{n+1} = p_2 x_n \quad (2)$$

Where:

p_1, p_2 are the standard chaotic parameters that determine the system's behavior, x_0 and y_0 are the initial conditions, The values of x_n and y_n evolve iteratively, producing a chaotic sequence. Figure 2 represents the keyword generation process using the Hénon Map. It starts with initializing the parameters (p_1, p_2, x_0, y_0, N). Then using Hénon equations, chaotic values are generated. The remaining process remains the same as the logistic map keyword generation. After the keyword is generated, the remaining steps are the same as a traditional Playfair cipher.Algorithm 2 represents the process of generating the chaotic sequence using the Hénon Map.

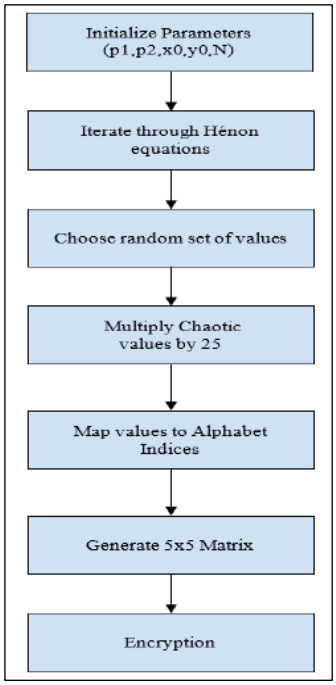

Figure 2: Process of key generation for Hénon Map.
Source: Authors, (2026).

Algorithm 2: Generate Chaotic Sequence using Hénon Map.

FUNCTION generate_playfair_matrix(effective_keyword_length = 5):

1. Generate chaotic values using the Hénon map:

a. Initialize x ← x0, y ← y0

b. FOR each iteration in range(num_values):

*i. x_new ← 1 - p1 * x^2 + y ii. y_new ← p2 * x iii. x ← x_new iv. y ← y_new*

v. Append (abs(x) mod 1) to chaotic_values

2. Securely select 'effective_keyword_length' values from chaotic_values:

selected_values ← secure random sample of chaotic_values

*3. Convert each selected value to an integer in range [0, 24]: letter_indices ← set of floor(value * 25) for each value in selected_values*

4. Map indices to characters in the Playfair alphabet (A-Z excluding 'J'):

alphabet ← ['A', 'B', 'C', ..., 'Z'] excluding 'J'

selected_letters ← characters from alphabet at positions in letter_indices

5. Remove duplicates and maintain original order:

used_letters ← set(selected_letters)

remaining_letters ← all letters in alphabet not in used_letters

6. Combine both lists to get full 25-letter Playfair matrix:

key_matrix_flat ← selected_letters + remaining_letters

7. Reshape the key_matrix_flat into a 5x5 matrix:

matrix_5x5 ← reshape key_matrix_flat into 5 rows and 5 columns

RETURN matrix_5x5

Source: Authors, (2026).

3. Arnold Cat Map used in Encryption process:

The Arnold Cat Map is a two-dimensional chaotic map commonly represented by the transformation:-

$$x_{n+1} = (x_n + y_n) \bmod 1$$
$$y_{n+1} = (x_n + 2y_n) \bmod 1 \quad (3)$$

Where:
x_n and y_n are the coordinates (or values) at the n-th iteration.
x_0 and y_0 are the initial conditions, often chosen from a 2D plane or a numerical sequence.
The mod 1 operation ensures the values remain the range [0, 1].

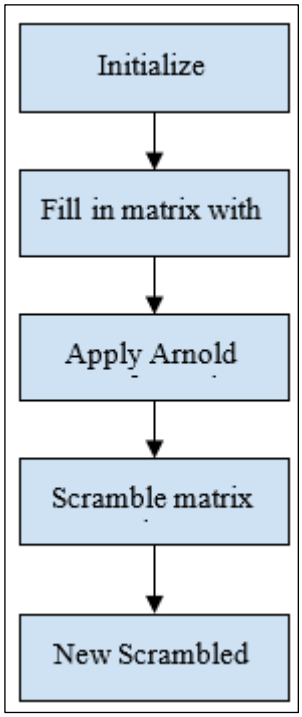

Figure 3: Arnold Cat Map use in encryption process.
Source: Authors, (2026).

In Figure 3, the Arnold Cat Map is used as an extra encryption step to provide security. After obtaining the initial ciphertext by using the Playfair Cipher, it is converted into a square matrix with each character occupying a cell. The Arnold Cat Map is then used on the matrix by iteratively permuting the characters using a chaotic permutation technique. As shown in Algorithm 3, the encryption incorporates diffusion and randomness into the ciphertext by iteratively applying the mapping formula a fixed number of times. The resulting jumbled matrix is then unraveled back into a 1D string, which becomes the cipher text. By combining the random scrambling of the Arnold Cat Map with the formal security of the Playfair Cipher, this two-stage encryption technique makes it very impossible to decipher the encrypted data without knowing the precise Playfair key and Arnold Cat Map settings. Before applying the standard Playfair decryption method, the Arnold Cat Map transform must be reversed in order to precisely recreate the original plaintext.

Algorithm 3: Encryption process using Arnold Cat Map.

```
Function ArnoldCatMap(grid, iterations, n):
    # grid: n x n 2D list of characters
    # iterations: number of transformations to perform
    # n: dimension of the grid

    Define transform(x, y, n):
        x_new = (x + y) mod n
        y_new = (x + 2 * y) mod n
        Return (x_new, y_new)

    Convert grid to a 2D array 'arr'
    Create list of all coordinate pairs (x, y) in grid of size n x n
    Flatten 'arr' to get a 1D list 'flat_values'

    For i from 1 to iterations:
        Create an empty list 'scrambled' of length n*n

        For each (x, y) in coordinates:
            Compute (x_new, y_new) = transform(x, y, n)
            scrambled[x_new * n + y_new] = arr[x][y]

        Reshape 'scrambled' into an n x n array and assign to 'arr'
    Return flattened version of 'arr'
```

Source: Authors, (2026).

B. Evaluation Metrics: Shannon Entropy and Lyapunov Exponent

For measuring the performance of chaotic maps' key generation, two popular measures are used: the Shannon entropy and Lyapunov exponent. Both measure the level of randomness and sensitivity to initial conditions, which are the two inherent requirements for producing secure and unpredictable keys.

Shannon Entropy:

It measures the amount of uncertainty or randomness in a data source, which is crucial for evaluating the security of cryptographic systems.

$$H(x) = -\Sigma p_i log_2 p_i \quad (4)$$

H(x) is defined as the entropy of X random variable.

p_i represents the probability of occurrence of each value in the chaotic sequence.

The logarithm is typically base 2, giving the entropy in bits. This formula is used to assess the randomness of data, such as the output of a random number generator or the distribution of bits in cipher text. Higher value of entropy (about 4.3) indicates that the sequence is well scattered and the Playfair key matrix becomes unpredictable. Low entropy indicates a structured sequence, which would breach security by rendering it simpler for an attacking side to infer the generated key. The bit value depends on chaotic Map used.

Lyapunov Exponent:

The Lyapunov exponent measures a chaotic system's sensitivity to the initial conditions.It is defined as:

$$\lambda(x_0) = \lim_{n\to\infty} \frac{1}{n} \sum_{i=0}^{n-1} \ln |f'(x_i)| \quad (5)$$

$f'(x_i)$: The derivative of the chaotic function at each iteration i.

λ(x0): Lyapunov exponent for initial condition.

If:

$\lambda > 0$: Chaotic behavior with small perturbations of the initial conditions inducing exponentially growing divergences of the trajectories.

$\lambda < 0$: Stable system with trajectories that approach.

$\lambda = 0$: Indicates the edge of chaos or a neutral system.

Having a positive Lyapunov exponent is a guarantee that the system is actually chaotic, meaning that with small perturbations of the initial values there will be exponentially divergent sequences in the limit. It is the derivative of the chaotic function at each iteration, describing the way the system is evolving. The greater the Lyapunov exponent, the greater the chaotic behavior, meaning that small perturbations of the input (the initial conditions) lead to very different outputs. It is a desirable feature of cryptographic usage since it means that any matrix of the Playfair key will change by a considerable amount if the input parameters are slightly perturbed.

IV. EXPERIMENTATION

Playfair Cipher with Chaotic Maps to Generate Keys:

Playfair cipher is a classic digraph substitution cipher, i.e., it encrypts text in pairs of letters. Chaotic maps in this code dynamically change the generation of the key matrix to ensure greater security. Chaotic maps employed for key generation possess unique initial conditions and control parameters. The values employed guarantee good chaotic behavior with maximum security.

1. Logistic Map

As discussed earlier in methodology ,the Logistic Map is a one-dimensional chaotic system and is given by:

$$x_{n+1} = (1 - x_n)$$

Control Parameter (r): 3.99 (regulates chaos in the Logistic Map)
Initial Seed Value (x_0): 0.5
Effect of Various Values of r:
0 < r < 1: Converges to zero (not chaotic).
1 < r < 3: Converges to a fixed point.
3 < r < 3.57: Periodic oscillations (bifurcation).
3.57 < r < 4: Chaotic behavior starts.
r = 3.99: Highly chaotic (most frequently used).

2. Hénon Map

As discussed earlier in methodology ,the Hénon Map is a two-dimensional chaotic system represented by:

$$x_{n+1} = 1 - p_1 x_n^2 + y_n$$
$$y_{n+1} = p_2 x_n$$

Control Parameters:

p_1 = 1.4 (Controls nonlinearity in the system)

p_2 = 0.3 (Controls contraction and stability)
Initial Seed Values: x_0 = 0.1, y_0 = 0.1
Effect of different Values:
Standard Chaotic Case: (most widely used parameters).
p_1=1.4,p_2=0.3
Reduced Chaos:
Decreasing value of p_1 (for instance,p_1=1.2) or increasing value of p_2 (for instance, p_2=0.5) stabilizes the system.
Extreme Chaos:
Increasing value of p_1 above 1.4 for more random behavior.(p_1>1.4)

3.Arnold Cat Map:

The Arnold's Cat Map is defined by the transformation:

$$\begin{bmatrix} x_{n+1} \\ y_{n+1} \end{bmatrix} = \begin{bmatrix} 1 & 1 \\ 1 & 2 \end{bmatrix} \begin{bmatrix} x_n \\ y_n \end{bmatrix} mod\ N \tag{6}$$

Effect of Different Parameter Values:
Iteration count (k):Determines number of transformation is applied. It affects the level of scrambling.
Initial seed (x_0, y_0):Initial value
Grid Size (N): Defines how the text is structured.
Key Characteristics:
Text Scrambling & Rearrangement: Random character disorder with the structure of the text preserved.
Deterministic Chaos: Despite appearing random, the transformation is a strict mathematical rule that can be used for decryption.
Reversibility: Repeatedly applying the transformation will eventually yield the original text, so it is useful for safe encryption.

V. RESULT AND ANALYSIS

This section presents the combination of playfair cipher with three different maps: Logistic, Hénon ,Arnold Cat map on sample text. Same sample plaintext is used to analyze the effectiveness of each chaotic map in enhancing security based on two parameters: Shannon Entropy and Lyapunov Exponent.

Figure 7 represents the values of Shannon entropy and Lyapunov exponent for different chaotic maps. From Figure 4, Figure 5, Fig 6 in case of Shannon entropy, it is observed that the Hénon Map is more chaotic than the Logistic Map and Arnold's Cat Map.Because the Hénon Map is in a two-dimensional phase space, it is more random than the Logistic Map. Although the Arnold's Cat Map is also 2D, the dissipative characteristic of the Hénon Map makes it even more random. The process includes nonlinear dynamics that produce more varied outputs, decreasing patterns in the ciphertext.The Hénon Map attains the maximum entropy, i.e., its ciphertext is most random and is more immune to frequency-based attacks. The Logistic Map is next, exhibiting good randomness, but slightly less than the Hénon Map. The Arnold's Cat Map has the least entropy, which can be an indication of redundancy in the encrypted data, thus making it more susceptible to attacks based on redundancy.

From Figure 4, Figure 5, Figure 6 in the case of the Lyapunov exponent, it is observed that Arnold's Cat Map has the largest Lyapunov exponent, thus the most chaotic behavior, which is very sensitive to important variations. The Arnold's Cat Map has the highest Lyapunov exponent as observed in table 2 implying that it possesses the strongest chaotic behavior and thus is very sensitive to significant changes. This makes encryption more secure against brute-force and differential attacks. The Logistic Map has a moderate Lyapunov exponent, suggesting a decent amount of unpredictability but lower than Arnold's Cat. The Hénon Map has the lowest Lyapunov exponent, so its chaotic behavior is weaker than the other two.

Table 2: Values for Shannon entropy and Lyapunov Exponent for different chaotic maps.

Chaotic Map	Shannon Entropy	Lyapunov Exponent
Logistic	3.97695	0.63663
Hénon	4.11257	0.39513
Arnold Cat	3.40564	0.89813

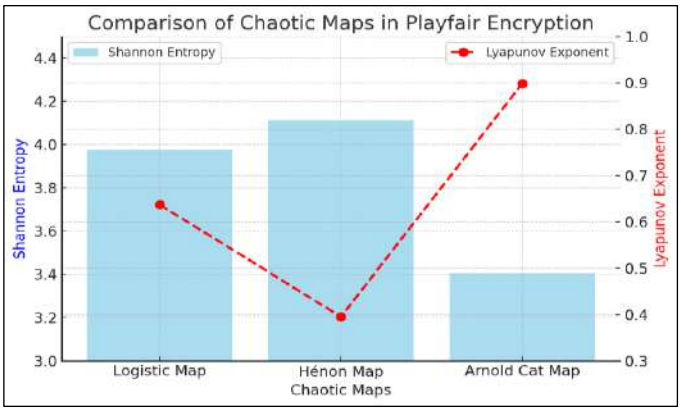

Figure 7: Visual representation of Comparative Analysis.
Source: Authors, (2026).

In addition to their chaotic strengths, the proposed maps maintain manageable computational complexities, all within polynomial time as mentioned in Table 3. These suggested methods offer a more balanced trade-off between security and efficiency, making them appropriate for practical cryptography application, in contrast to the literature presented in Table 3, where numerous solutions suffer from higher computing cost due to complex algorithmic structures.

Table 3: Computational Complexity Analysis of Proposed Models.

Version	Key Generation Time	Encryption Time	Total Complexity
Logistic	O(m)	O(n)	O(m + n)
Hénon	O(m)	O(n)	O(m + n)
Arnold Cat	O(n)	O(k × n)	O(k × n)

VI. CONCLUSION

A proper implementation of the Playfair cipher has many disadvantages, such as susceptibility to frequency analysis and weak resistance against modern attacks. The study proposed an improved version of the Playfair cipher by integrating chaotic maps (Logistic, Hénon, and Arnold Cat) to enhance the randomness of the key matrix, making encryption more secure. The comparative analysis shows that the Hénon Map provides the highest level of randomness, ensuring better diffusion in encryption. Due to its superior scattering effects, the Arnold Cat Map makes the ciphertext highly unpredictable. The Logistic Map, on the other hand, exhibits extreme sensitivity to given parameters, ensuring that even a minor change in input leads to unique outputs after encryption. Evaluations of data security metrics, including Shannon entropy and the Lyapunov exponent, confirm the improved security of this system.

The highest Shannon entropy value (4.11257) among the analyzed maps highlights the superior random behavior of the Hénon Map. In terms of the Lyapunov exponent, the Arnold Cat Map shows the highest potential value (0.89813), making it the most sensitive to key variations. Meanwhile, the Logistic Map maintains a balance between these two critical cryptographic properties while managing computational cost effectively. It is evident that this hybrid encryption approach offers significantly stronger security compared to standard Playfair ciphers. Future work may explore adaptive selection of chaotic maps based on the characteristics of the input to optimize performance. Additionally, further research could investigate the feasibility of implementing this approach in real-time cryptographic environments.

ABSTRACT

The number of tweets on Twitter containing information related to online lectures in the post-pandemic Covid-19 period or after the government lifted the pandemic period has drawn many pros and cons. This research discusses the best level of accuracy of the three machine learning methods, namely Naïve Bayes (NB), Decision Tree (DT) and Support Vector Machine (SVM) in analyzing Twitter results related to online lectures. The data used is crawled data from Twitter using the keyword "Online Lecture" and 5,978 tweets were obtained after verification. Three category labels were used in this research, namely Positive, Negative and Neutral. Pre-processing was carried out using the stages of Data Cleansing, Tokenizing, Stopword, Normalization and Stemming. While the feature extraction stage uses the TF-IDF stage. The average accuracy results for the NB method are 78.02%, precision is 78.18%, recall is 78.02% and f1-score is 77.45%. DT obtained an average accuracy of 86%, precision is 89.14%, recall is 81.14% and f1-score is 82.31%. The average accuracy obtained by SVM is 89%, precision 90.97%, recall 87.31%, and the F1 score is 85.99%. Among the three algorithms, it is known that SVM achieves very good performance in online lecture sentiment analysis based on Twitter data.

I. INTRODUCTION

During the Covid-19 pandemic like a few years ago, it had a huge impact on human activities. All activities that were previously carried out as usual had to be done digitally. Among those that were greatly felt and had a big impact was the world of education, for almost two years learning was carried out from home through online learning. Indonesia is no exception, for more than two years the government and related agencies have tried to ensure that learning continues as it should even though it is carried out with online learning. There are many responses from the public regarding the implementation of online lectures, especially during the pandemic. Pros and cons will certainly spark debate in expressing their opinions. As stated by [1] stated that the online learning system carried out during the COVID-19 pandemic is effective and inefficient.

Effective because the conditions require online learning and inefficient because the costs incurred are higher when compared to offline lectures. The costs incurred are mainly to buy internet quota to attend online lectures and the obstacles faced during online lectures are network constraints. Meanwhile, [2] related to obstacles to online learning seen from internal and external factors. Internal factor obstacles are first students and lecturers experiencing miscommunication (25.71%), second decreased motivation (24.28%), and third poor time management (17.15). Meanwhile, the external obstacles are, firstly, related to the internet network signal which is unstable or difficult in the residential environment (55.13%), secondly the availability of internet quota (12.97%), and thirdly the limited facilities/gadgets (9.18%).

The same thing was conveyed by [3] whose conclusion was that students most often experience signal interference, which will later have an impact on unclear images or sound, as well as intermittent signal interruptions. This is almost the same as [4] research, he even added that among them are students without cellphones, lack of student attention, and parents' working being disrupted. Once conveyed almost the same thing, namely regarding inadequate infrastructure, students' difficulties in understanding the material, and the limited ability of lecturers to utilize technology [5]. Although in this case lecturers are not constrained in terms of delivering material to students, it should be underlined that successful learning requires an effort to strengthen students [6]. In addition to the above, there is also research by [7] which states that their findings summarize students' perceptions of learning and their involvement when given a choice about how to engage in content.

Most participants chose asynchronous methods to learn content, citing time constraints as the main reason for not choosing synchronous learning methods. Furthermore, [8] emphasized the importance of considering emotions in distance learning environments and their significant impact on academic performance and participant satisfaction. Even [9] research explains the common challenges and opportunities faced by participants and educators in thirty countries, based on sentiment analysis from these stakeholders, the results show that although digital education is developing into a flexible and student-centered didactic approach, various obstacles in meeting online learning effectively still exist, where the findings reveal the shortcomings, and therefore the need for, appropriate teaching and learning materials and strategies for digital education.

This is also almost the same as that conducted by [10], which found that most educators experience problems during online learning practices. There are even several studies that conduct literature review related to open learning and online learning, such as those done by [11] and [12]. From these limitations, sometimes they complain through social media such as Facebook, Instagram or Twitter. Of the many social media that are often used, Twitter is one of the social media that is often used by its users to interact. Based on the 2024 internet penetration and behaviour survey data issued by APJII (Association of Indonesian Internet Service Providers) [13] which states that the reason for using the internet is to be able to access social media (including Twitter), which is 3.31%. While the social media that is often used for Twitter is 1.06%, and the chat media that is often used in this case is Twitter, which is 0.34%.

Publishing and disseminating news information is very suitable for using Twitter. Very short tweets are very easy for users to post using handphone or other devices. While the 140 characters posted by some users are considered short and easy to spread information [14]. Even [15] conducted research to identify content containing propaganda by collecting data from Twitter. Twitter as we know after crawling will get a very large amount of data information so that data mining is needed. The application of data mining is widely used in various researches, one of which is text mining. The use of text mining is very relevant to analyse text-based case studies, one example of which has been mentioned above is the use of Twitter. In the field of education, it is widely used to analyse sentiment towards the world of education. The sentiment can be positive or negative. With sentiment results like we can process the results of public opinion in the world of education, one of which is online lectures.

In this research, we will examine the sentiment analysis of online learning based on Twitter data by comparing three methods (Naive Bayes, Decision Tree & SVM). The main reason for choosing Naive Bayes is because it is a fairly simple algorithm but in several researches it has a fairly high level of accuracy [16]. While Decision Tree is one of them in decision making which was previously very global and complex can be changed to be simpler and more specific [17], and is easy to present and implement in the form of diagrams [18]. The third is SVM that can perform a more accurate classification process [19]. From the advantages of the three algorithms, researchers try to compare by looking at performance, namely in the form of accuracy percentage. It is expected that the results of this sentiment analysis research based on Twitter data can be a reference and help the world of education in efforts to improve the quality of learning for students in the future, and these results are expected to be a reference for comparing with other methods.

II. LITERATURE REVIEW

Researchers conducted a literature review of several researches related to sentiment analysis based on Twitter data. According to the results of the literature review, it was concluded that research on sentiment analysis based on Twitter is still quite extensive to discuss. Research on Twitter sentiment analysis is still limited to online lectures and there are still few researches that discuss sentiment analysis. This research focuses on sentiment analysis from Twitter data, using the Long Short-Term Memory (LSTM) algorithm and Artificial Neural Network (ANN) with an accuracy rate of 96% for LSTM and 76% for ANN [20]. Research on sentiment analysis for finance using the BERT method achieved an accuracy of 95.29%, precision of 95.37%, and recall of 95.24% [21]. Research uses NLP (Natural Language Programming), his research provides an overview of sentimental investigation or opinion mining related to product surveys [22]. [23] his research is related to sentiment analysis which aims to provide a systematic review of sentiment analysis and related fields for future research. Proposed the use of the Support Vector Machine (SVM) model to develop an automatic Twitter crawling system and achieved an accuracy level of 85% [24].

Used the VADER model to identify people's opinions about online learning [25]. Proposed a machine learning algorithm for Arabic sentiment analysis which was used to find out the opinions of students and teaching staff about online learning during the COVID-19 outbreak in Saudi Arabia [26]. Conducted their research to study online learning during the pandemic situation and the adaptation of online learning worldwide after the pandemic situation using machine learning such as SVM and artificial neural networks (ANN) [27]. According to the results, ANN was better than SVM and achieved 81.97% accuracy with higher precision, recall, f-measure value, and lowest error value.

Research [28] present the results of the application of BERT, these results will be compared with the contribution of the author [29], where the results using BERT are quite good (88.93% accuracy). Research uses the SentiStrenth method, with 54% neutral results, while 85% accuracy rates, and 15% error rate [30]. Research explores the experience of students engaging with recorded lectures and the extent to which such engagement contributes to improved learning [31]. This research involved distributing questionnaires to undergraduate and postgraduate students (n = 660) who had access to lecture recordings at a public university in New Zealand, the use of sentiment analysis shows how multiple data can be triangulated to confirm or contradict research findings.

New ensemble model was proposed for sentiment analysis, the experimental results showed that the sentiment recognition accuracy of the proposed model was higher than that of the other seven comparison models, with an F1score of more than 91%, and the results of recognizing different levels of emotion showed the stability of the proposed ensemble model [32]. Research used the sentiment analysis method to identify and extract student responses in subjective information focusing on positive and negative polarity, and their research findings showed that the results of sentiment analysis using the SVM method obtained an accuracy of 84% [33].

Research used Chi-square and SVM algorithms, the results of their research assist university administrators and lecturers to identify the strengths and weaknesses of lecturers based on textual evaluations conducted by students [34]. [35]Research related to the use of LMS developed at Anadolu University, the results of their research concluded that machine learning techniques can be used to better understand students and how they feel [35]. From several previous researches that have been explained above, the differences can be seen in Table 1. From several researches, various methods are used to obtain better results.

In this research, the researcher tries to compare three machine learning methods, namely Naïve Bayes, Decision Tree, and Support Vector Machine. The three methods will be seen from their performance level, namely which level of accuracy is better. It is because from several previous researches, most researches only use one or two methods, and even if there are, they are not exactly the same using the same method with the same case study. As far as the researcher knows, there has been no research that explicitly discusses sentiment analysis based on Twitter by comparing three methods (Naïve Bayes, Decision Tree & SVM).

III. MATERIALS AND METHODS

This research follows the proposed methodology sequence such as data collection, pre-processing, feature extraction, classification and evaluation (Figure 1. Proposed method).

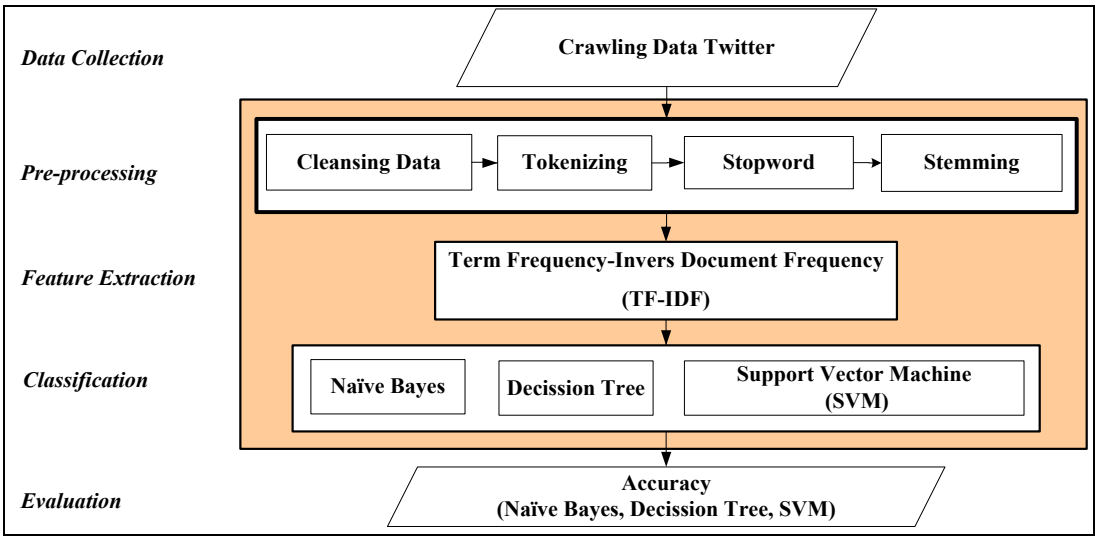

Figure 1: Proposed Method.
Source: Authors, (2026).

III.1 DATA COLLECTION

The first research flow in this research is data collection. The data collection in question is used to obtain a dataset for the analysis process which in this case uses Twitter Harvest or API from Twitter. The keyword used in the data retrieval process is "Kuliah Online" (Indonesian word), which in English means "Online Lectures". The data that will be used is crawling data from Twitter.

III.2 PRE-PROCESSING

Pre-processing in this research is the stage of cleaning data from a sentence or word, link, or things that are not needed to perform sentiment analysis. The dataset that has been collected is still in the form of unstructured or irregular words or sentences, so it still requires a process called data pre-processing to produce clean data, so that the sentiment analysis results are expected to be accurate. The data pre-processing stages consist of cleansing data, tokenizing, stopwords, normalization and stemming. Cleansing data is carried out to reduce unimportant words (noise) in tweet data, such as URLs, hash tags (#), usernames (@username), emoticons (: @,: *,: D), emails, and punctuation [36]. Data changes at this cleaning stage, such as lowercase, can also occur [30].

Tokenizing is a process that functions to break sentences into words. The tokens that have been produced will later be in the form of single words which will make the next process easier [36]. Stopword is a process of deleting or eliminating words resulting from the previous process, namely tokenizing, which have no meaning, such as "di", "yang", "itu", "ke", and so on. Normalization is used to change data into a more standard form [37]. Normalization can help improve accuracy in text analysis and make data easier to process [38]. Stemming is the process of changing words that have affixes to become basic words according to standard Indonesian language rules [30].

III.3 FEATURE EXTRACTION

The third process is feature extraction. At this stage, the TF-IDF (Term Frequency-Inverse Document Frequency) method is used. TF-IDF is used to determine how far the word (term) is related to a document by giving each word a weight. This method will calculate each term's weight in the document. The equation used in this process is [39]:

$$TFIDF(\ t\ ) = TF * log\ \frac{N}{df} \tag{1}$$

Where t is the term, N is the total documents, TF is the number of terms t that appear in the document, and df is the number of documents containing the term t.

III.4 CLASSIFICATION

This stage classification is used to group data or sentences based on their similarities [40]. The classification in the sentiment analysis process is often modelled as two-way (positive/negative) or three-way (positive/negative/neutral) [41]. In this classification stage, three outputs will be classified, namely positive, negative and neutral and will compare three methods by looking at the level of good accuracy, namely Naïve Bayes, Decision Tree and Support Vector Machine.

III.4.1 Naïve Bayes

Naïve Bayes is a simple probabilistic classifier that calculates a set of probabilities by summing the frequencies and combinations of values from a given dataset [42], a simple probability classification process that refers to Bayes' theory. In other words, given an output value, the probability of observing it together is the product of the individual probabilities. The general equation used in the Naïve Bayes algorithm is:

$$\boldsymbol{P(H|X)} = \frac{\boldsymbol{P(X|H)}.\ \boldsymbol{P(H)}}{\boldsymbol{P(X)}} \tag{2}$$

Where:
H: Data hypothesis is a specific class
X : Data with unknown classes
P(H) : Probability of hypothesis H
P(X) : Probability X
P(H|X) : Probability of hypothesis H based on condition X
P(X|H) : Probability X based on the conditions in hypothesis X

III.4.2 Decision Tree

Decision tree is a prediction model that can be used to represent classification and regression models in operations for decision making with strategies that are most likely to achieve goals [43]. In developing a Decision tree, the initial stage is to evaluate all existing attributes using a statistical measure (which is commonly used is information gain) to measure the effectiveness of an attribute in classifying a collection of data samples. Attributes with continuous values must be discretized [44]. To find the gain value (information Gain) can be carried out with the concepts of Entrophy, Gini Index and Classification Error [45].

- Information Gain with Entrophy value

$$Entrophy(s) = \sum_{i=1}^{n} p(i|s) log_2 p(i|s) \tag{3}$$

Where:
S : Case sets in a dataset
n : Number of partitions attribute S
Pi : The proposition of Si to S

This entropy value will be used to calculate the gain value. The formula for finding gains is as follows:

$$Gain\ (S,A) = Entrophy(S) = Entrophy(S) - \sum_{i=1}^{n} \frac{|S_i|}{|S|} \times Entrophy\ S_i \quad (4)$$

S : Case set
A : Attribute
n : Number of partitions in attribute A
| *Si* | : Number of cases in partition 1
| *S* | : Number of cases in S

- *Gain information with Gini Index value*

$$Gini\ (t) = 1\ \sum_{i=1}^{n} [p(i|s)]^2 \quad (5)$$

$$Gain(S,A) = Gini(S)\ \sum_{i=1}^{n} \frac{|Si|}{|S|}\ Gini\ (Si) \quad (6)$$

- Gain Information with Classification Error value C. Error is obtained from the value of the attribute that is the smallest of the class label.

$$C.Error(S) = 1\ max_i\ [p(i|s)] \quad (7)$$

$$Gain(S,A) = Error(s) \sum_{i=1}^{n} \frac{|S_i|}{|S|}\ Error\ (S_i) \quad (8)$$

III.4.3 Support Vector Machine

Support Vector Machine can make predictions for both classification and regression [46]. SVM can be used on different types of data sets, namely data sets with linear and non-linear separation. The Support Vector Machine (SVM) method allows calculations for linear problems by applying mathematical transformations to the learning space using kernel functions [47]. Support Vector Machine (SVM) has a central concept in classifying data, namely determining the best hyperplane to provide a distance or separator between two predetermined classes [48]. Hyperplanes that have large margins can classify data that has not been seen well, by providing a large margin; new data can enter each class [49] where the margin itself can be described as in Figure 2 below.

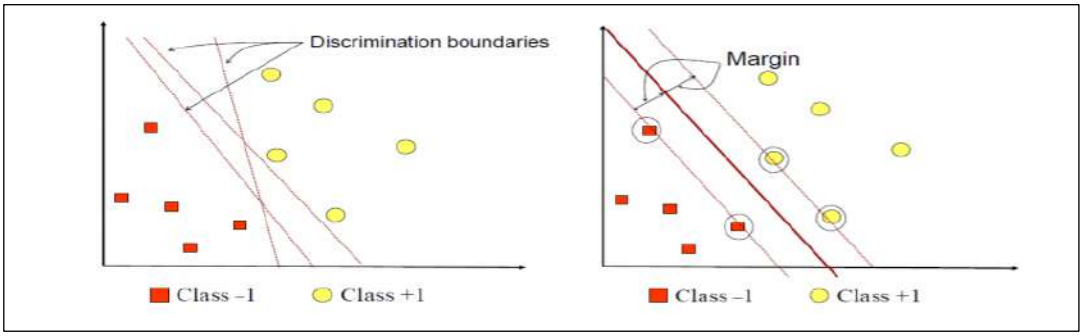

Figure 2: Best Hyperplane.
Source: [50].

In overcoming the Support Vector Machine in non-linear cases that occur, the kernel method is used to overcome it. A function of the kernel is to transform data into a space or other dimension which can be illustrated in Figure 3 below [49].

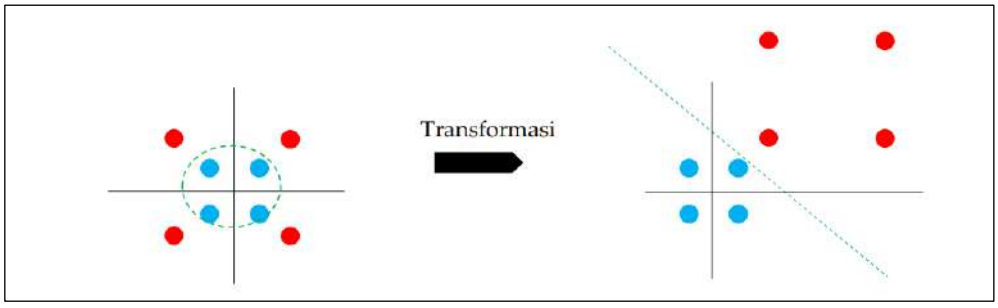

Figure 3: Data Transformation.
Source: [49].

By using the kernel method, a data x is input into a higher-dimensional feature space F. Feature mapping from two-dimensional space to two-dimensional feature space [51].

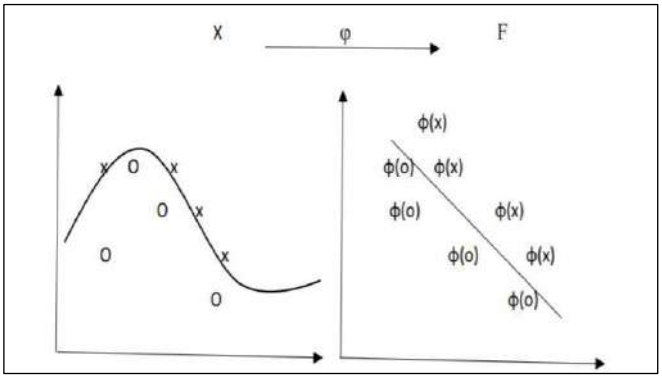

Figure 4: SVM Non Linear Kernel Map.
Source: [51].

There are several kernel functions that are usually used in SVM including linear, polynomial, radial basis function, and sigmoid. The stages in the Support Vector Machine method are as follows [52]:

1. Determine the most frequently occurring words from each document used
2. Determine the initial initialization for the values of α, C, λ, gamma and epsilon.
3. Calculate the matrix with the formula as below:

$$D_{ij} = yi\ yj\ ((xi^{\rightarrow\rightarrow}.xj^{\rightarrow\rightarrow}) + \lambda\ 2) \quad (9)$$

Explanation:
D_{ij} = data matrix element to -ij
yi = class or label of data to -i
yj = class or label of data to -j
λ = theoretical limit derivative
$K(xi^{\rightarrow\rightarrow}.xj^{\rightarrow\rightarrow})$ = kernel function

4. For the n^{th} power = 1,2,3,.. n use the equation below:

$$E_i = \sum \alpha i\ n\ j = 1\ Dij \quad (10)$$

$$\delta\alpha i = \min\{\max[\ \gamma(1 - Ei), -\alpha i\ ], C - \alpha i\ \} \quad (11)$$

$$\alpha i = \alpha i + \delta\alpha i \quad (12)$$

Explanation:
Ei = data error value to -i
γ = learning levels
$Max_{(i)}\ D_{ij}$ = maximum value of the diagonal of the equation matrix

5. Find the bias value (b) using the equation below:

$$b = -\ 1\ 2\ [w\ .\ x\ +\ +\ w\ .\ x\ -] \quad (13)$$

6. Testing on the document being tested
7. Decision calculation

If the decision calculation is more than or equal to 0 then the *h(x)* sign value is +1, then it is included in the positive class and if the decision calculation result is less than 0 then the *h(x)* sign value is -1, then it is included in the negative class. Decision calculation using the equation as below:

$$h(x) = w\ .\ x\ +\ b \text{ atau } h(x) = \sum \alpha i\ yi\ K(x, xi\ m\ i = 1) + b \quad (14)$$

III.5 EVALUTION

In this final stage after a series of processes are carried out, the next step is to evaluate. This is carried out to obtain the level of accuracy of a method used in analyzing sentiment from public opinion. In this evaluation, the k-fold cross validation method is used to test the accuracy of the three methods used (Naive Bayes, Decision Tree and SVM). The k-fold cross validation method all data used will be treated the same, namely as testing and training data. In general, k-fold cross validation, where $k \geq 2$ is an integer, and the dataset used will be partitioned into k parts [53].

Table 2: Illustration of 3-Fold Cross Validation.

	Experiment 1	Experiment 2	Experiment 3
A (data 1 – 10)	A & B (Data Training)	A (Data Training)	A (Data Testing)
B (data 11 – 20)		B (Data Testing)	B & C (Data Training)
C (data 21 – 30)	C (Data Testing)	C (Data Training)	

Source: Authors, (2026).

From the k-fold cross validation method, the level of accuracy, precision, recall and F1-Score can be obtained using the confusion matrix method. With the confusion matrix we can analyze how well the categories we use can recognize data from different categories [44].

Table 3: Model confusion matrix.

Correct classification	**Classified As**	
	+	-
+	TP	FN
-	FP	TN

Source: Authors, (2026).

Accuracy, precision, recall, f1-score are obtained by equations (14) to (17) [44]:

$$Accuracy = \frac{TP+TN}{TP+TN+FP+FN} x\ 100\% \quad (15)$$

$$Precision = \frac{TP}{TP+FP} x\ 100\% \quad (16)$$

$$Recall = \frac{TP}{TP+FN} x\ 100\% \quad (17)$$

$$F1\text{-}Score = \frac{2TP}{2TP+FP+FN} x\ 100\% \quad (18)$$

Where, TP = *True Positive*, TN = *True Negative*, FP = *False Positive,* dan FN = *False Negative*.

IV. RESULTS AND DISCUSSIONS

This section discusses the results and discussions related to the proposed method. This section starts from data collection, data processing, per-processing, feature extraction, and classification.

IV.1 DATA COLLECTION

The data used is data collected from Twitter in the form of tweets. The data collection process is carried out through the data crawling process, in this case using Tweet Harvest (Version 2.6.1). One of the advantages of Tweet Harvest is that it allows users to collect more data and can be run in the form of a Command Line Interface (CLI) and only requires an auth_token [54].

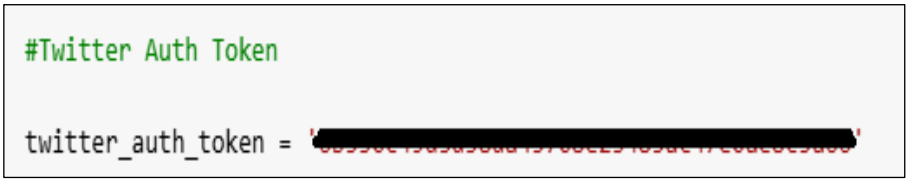

Figure 5: Token Authoring.
Source: Authors, (2026).

The keywords used in the data retrieval process refer to “Online lectures”. Data collection was carried out from June 13-25, 2024. The data crawled was tweet data from June 23, 2023 to June 22, 2024. The crawled data retrieval started from June 23, 2024, this was carried out after the issuance of Presidential Decree No. 17 of 2023 concerning the Determination of the End of the Corona Virus Disease 2019 (COVID-19) Pandemic Status in Indonesia, which was set on June 22, 2023. This is very relevant because the tweet data retrieval was carried out after Indonesia was declared free from the pandemic, so that we can obtain tweets from the public regarding the experience of online lectures during the pandemic until the pandemic is over.

Figure 6: Crawling result data.
Source: Authors, (2026).

Based on the data that has been obtained previously, the data processing process was carried out using 8,411 Twitter crawling data, and after verification, the data used was 5,978 tweets. After the data was obtained, the next step was the labelling process. The labelling process was carried out from August 8, 2024 to September 20, 2024. Data labelling was carried out in three categories, namely positive, negative and neutral (Table 4).

Table 4: Label data Twitter.

Description/Category	Label
Positive	1
Negative	2
Neutral	3

Source: Authors, (2026).

From the 5,978 tweets used, each label was obtained, namely 1,953 positive labels, 2,045 negative labels and 1,980 neutral labels (Figure 7).

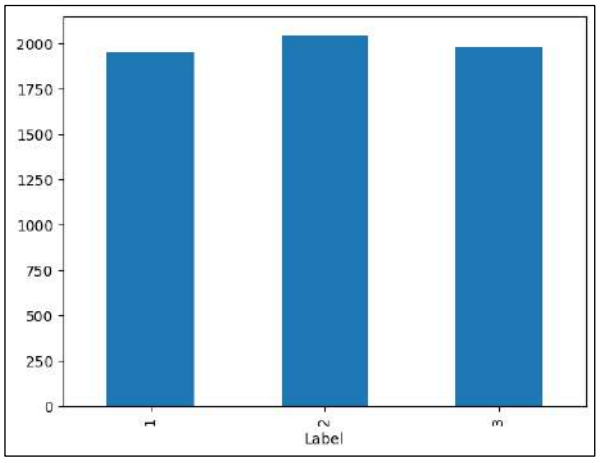

Figure 7: Label data Twitter.
Source: Authors, (2026).

IV.2 PRE-PROCESSING

After the data is collected, the data will then be processed through the pre-processing stage. This stage aims to make the data clean and there are no indicators that interfere with the score value during the implementation process of the Bag of Words weighting method and the Naive Bayes classification method. This stage is very important, because if there is unclean data, the score value will be affected. Pre-processing is carried out to prepare documents in raw text until they are ready to be analysed according to the method used. The purpose of this process is to increase classification accuracy [55].

Figure 8: Crawling data Results Preprocessing.
Source: Authors, (2026).

To assist the results of data crawling, researchers try to visualize the data in the form of a word cloud (Figure 9). Word cloud is a form of visualization of text data that describes a collection of words that are often found in a text analysis. The size of the font in the word cloud indicates that the word appears frequently.

Figure 9: Data Visualization in WordCloud.
Source: Authors, (2026).

In addition to using word clouds, researchers also use graphs to visualize the results of words that appear frequently (Figure 10).

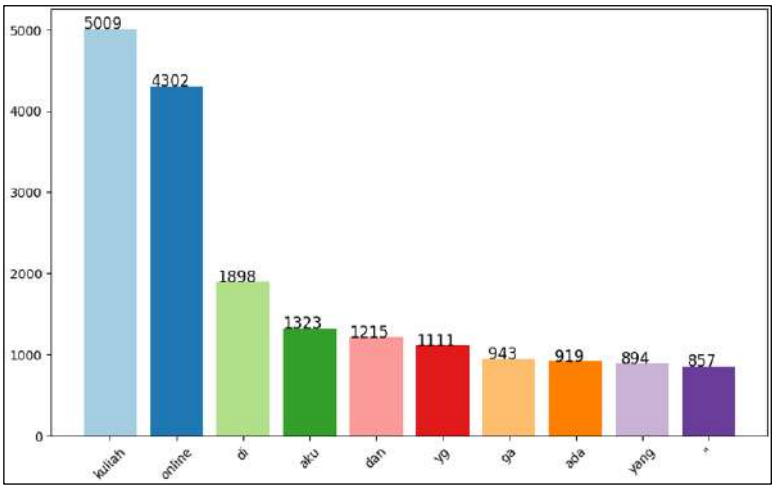

Figure 10: Frequently Appearing Word Graphs.
Source: Authors, (2026).

Before the data is processed and enters the first stage in pre-processing, the Case Folding process is carried out first. Case Folding is used to change all letters especially uppercase letters in a document to lowercase letters, only letters 'a' to 'z' are accepted. Characters other than letters are removed and considered delimeter. Uppercase or lowercase letters in a word are assumed to be no difference, all uppercase characters are usually changed to lowercase. This aims to make the text more consistent, thus allowing more consistent text processing.

IV.3 FEATURE EXTRACTION

Feature extraction is the process of converting terms from text into numbers that can be read by a computer. In this research, TF-IDF (Term Frequency-Inverse Document Frequency) is used as a process by giving a value to each word in the training data. The calculated value is given to determine how important a word is for a sentence. The TF-IDF value depends on how often the word appears in the document [56].

Figure 12: Results of the Feature Extraction Stage Process with TF-IDF.
Source: Authors, (2026).

Simply put, TF-IDF is used to determine how often/important a word appears in a document. The tweet data in the pre-processing stage is still in the form of text (words), while in the classification stage the data used must be numeric or numbers. So at this feature extraction stage, the data will first be converted into numbers using the TF-IDF method. The results of the TF-IDF process are as shown in Figure 12.

IV.4 CLASSIFICATION

The results obtained at the feature extraction stage will be input data at the classification stage. At this classification stage, three methods are used, namely Naïve Bayes, Decision Tree, and Support Vector Machine. Meanwhile, to measure the performance of the method used by researchers in terms of validating and evaluating using k-fold cross validation and confusion matrix, where k = 10 with a division of 80% training data and 20% testing data. This classification seeks the best level of accuracy from each method. So we can compare which level of accuracy is better from the three methods.

IV.4.1 Naïve Bayes

Classification using *Naïve Bayes* is carried out in this analysis using a ratio of 80:20 between training data and testing data. With validation and evaluation using k-fold cross validation, where the value of k = 10, the level of accuracy is obtained as in Figure 18. From these results, the average level of accuracy obtained is 78.02%, with the highest accuracy at k = 9, which is 80.91%. While the average precision value is 78.18%, recall is 78.02% and F1-Score is 77.45% (Figure 13).

IV.4.2 Decision Tree

By using the same data division 80:20, and validation and evaluation using k-fold cross validation, where the value of k = 10, the accuracy level is obtained as in Figure 19. The average result at the accuracy level is 86%, with the highest accuracy obtained at k = 4 and k = 6, which is 100%. While the average precision value is 89.14%, recall is 81.24% and F1-Score is 82.31% (Figure 14).

IV.4.3 Support Vector Machine

By using Support Vector Machine, the accuracy level is obtained as shown in Figure 20. The average accuracy level obtained is 89%, with the highest accuracy at k = 6 and k = 10, which is 100%. While the average precision value is 90.97%, recall is 87.31% and F1-Score is 88.99% (Figure 15).

K=10	77,25 %	77,25 %	77,40 %	76,61 %	90 %	85, 71 %	92,50 %	90,33 %	100 %	100 %	100 %	100 %
Mean	**78,02 %**	**78,02 %**	**78,18 %**	**77,45 %**	**86 %**	**81,14 %**	**89,14 %**	**82,31 %**	**89 %**	**87,31 %**	**90,97 %**	**88,99 %**

Source: Authors, (2026).

Table 5 shows the average accuracy of using the Naïve Bayes method of 78.02%, Decision Tree of 86%, and Support Vector Machine of 89%. So from the data, the best accuracy level of the three methods is Support Vector Machine (89%). Thus, sentiment analysis using the algorithm shows significant results as evidenced by its accuracy level of 89% in the Support Vector Machine method.

V. CONCLUSIONS

Based on the final results of the research, it can be concluded that from the 8,411 data that have been obtained, 5,978 data are left to be used in the research. At the classification stage, the performance measurement of the method used by the researcher in terms of validating and evaluating using k-fold cross validation and confusion matrix, where k = 10 with a division of 80% training data and 20% testing data. The final results of using the method obtained accuracy for the Naïve Bayes method of 78.02%, Decision Tree of 86%, and Support Vector Machine of 89%. So in this case, it is seen from the level of accuracy that is superior, namely SVM. This means that the performance of the system's success in sentiment analysis of online lectures based on Twitter data is very good. Future research is expected to add machine learning methods in its classification such as the K-Nearest Neighbor method, Logistic Regression, Random Forest or Artificial Neural Network. This is expected to be able to find out more comprehensively regarding the use of other methods.

VI. AUTHOR'S CONTRIBUTION

Conceptualization: Darwan, Sirojudin Wahid, Fajar Hardoyono, Indra, and Muhammad Hikmal.
Methodology: Darwan, Sirojudin Wahid, Fajar Hardoyono, Indra, and Muhammad Hikmal.
Investigation: Darwan, Sirojudin Wahid, Fajar Hardoyono, Indra, and Muhammad Hikmal.
Discussion of results: Darwan, Sirojudin Wahid, Fajar Hardoyono, Indra, and Muhammad Hikmal.
Writing – Original Draft: Darwan, Sirojudin Wahid, Fajar Hardoyono, Indra, and Muhammad Hikmal.
Writing – Review and Editing: Darwan, Sirojudin Wahid, Fajar Hardoyono, Indra, and Muhammad Hikmal.
Resources: Darwan, Sirojudin Wahid, Fajar Hardoyono, Indra, and Muhammad Hikmal.
Supervision: Darwan, Sirojudin Wahid, Fajar Hardoyono, Indra, and Muhammad Hikmal.
Approval of the final text: Darwan, Sirojudin Wahid, Fajar Hardoyono, Indra, and Muhammad Hikmal.

VII. ACKNOWLEDGMENTS

Thanks to the Ministry of Religious Affairs of the Republic of Indonesia, the Rector of IAIN Syekh Nurjati Cirebon and LPPM IAIN Syekh Nurjati Cirebon for funding this research with contract number: 141/In.8/L.I/TL.01/05/2024. Gratitude is also extended to all those who have helped this research.

ABSTRACT

Electronic Human Resource Management (e-HRM) has applied increasingly as a strategic tool to improve HR effectiveness and sustainability of healthcare organizations. Despite this, there is little empirical evidence on utilization and potential sustainability value in the Andhra Pradesh hospitals. The present study aims at reviewing the prevalence, reporting and perceived impact, practices of e-HRM on sustainability of organization operating of in health care sector of Andhra Pradesh. This was descriptive research with quantitative approach. Participants HR practitioners, administration, and health workers in private hospital settings situated in urban and semi-urban areas. A sample size of 250 was determined based on stratified random sampling method and a structured questionnaire was used to collect data. Instrument reliability and validity were obtained through Cronbach alpha and content validity, respectively. Analytic tools such as correlation, t-test ANOVA, Factor Analysis and SmartPLS were used to analyze collected data. We conclude that adoption of e- HRM practice in hospital level is moderate and in HR and administration functions higher than clinical support functions. Respondents believe that e-HRM as a practice makes the organization more efficient and sustainable. The study highlights the need for e-HRM in the healthcare sector to be employed as a strategic HR performance tool and sustainability enabler. Perhaps, there is a call to increase the level of awareness, training, and infrastructural support in so far as they could and can support the optimal benefits of e-HRM implementation.

I.INTRODUCTION

The convergence of the Sustainable Development Goals (SDGs) and digital technologies has opened up new innovation frontiers in all sectors and areas including healthcare. The focal point of change lies in the Human Resource Management (HRM) which integrates the workforce strategies with the broader eco-friendliness work plan of the company or institution. The era of digital HRM has brought the advent of cutting-edge technologies such as artificial intelligence (AI), cloud computing, mobile applications, data analytics, and HR automation [1], changing how the work in HR is done, and making it efficient, transparent, and sustainable. Digital HRM is not just a nice-to-have technological leap but a strategic need, the most in the service-intensive, resource-strapped healthcare sector. Hospitals in emerging countries, India in particular, need to meet the challenge of delivering quality healthcare, reducing human

resource costs and adhering to broader environmental objectives. In this respect, Andhra Pradesh represents an interesting stage for the study of digital HRM adoption.

The growing focus on digital infrastructure and healthcare reforms by the state government has led to hospitals beginning to digitally manage processes such as payroll, hiring, training, and performance appraisal [2]. Not only do these efforts save administrative costs, they also support a green culture by reducing resource consumption, lessening employee travel and promoting paperless operations. In the context of HR, digital HRM becomes an enabler, a driver for integrating sustainability throughout the HR value chain. E-recruitment, online induction, remote learning software, electronic performance management systems, and employee self-service interfaces solutions that are eco-friendly substitutes to the paper-heavy traditional processes [3].

The benefits of digital HR infrastructure seem to be empirically proven: Families Camp (2021) found that organizations using digital HR infrastructure save 70% on paper, cut admin burdens by 50% and as such are able to work more sustainable and efficiently. In addition to this, digital HR platforms enable data-driven decisions and empower managers to predict staffing needs, allocate resources efficiently and eliminate waste. In addition, the inclusion of indicators of sustainability in HR performance measures results in enhancing the accountability of organizations. For instance, in hospitals they are increasingly used to report employee engagement in green initiatives, the carbon impact of HR function or paper use. These are the approaches to bridge HR initiatives with the organizational sustainability objectives and regulatory requirements [4].

In India, environmentalists / sustainable are now starting to align with HR processes as compliance norms has become HR and environment now equally responsible. NABH releases Climate Action & Sustainability Guidebook; announces new standard on Environment Sustainability & Climate Resilience under its 6th Edition Hospital Accreditation Standards (2025) New Delhi: The National Accreditation Board for Hospitals & Healthcare Providers (NABH) released Climate Action & Sustainability Guidebook here today and announced a new standard on Environment Ramsuities & Climate Resilience under its 6th Edition Hospital Accreditation Standards to be launched by 2025.

This makes sustainability as one of the most vibrant drivers of HR, processes such as to train employees regarding waste reduction, energy and supply sustainability, electronic record, responsible procurement of supplies [5] also integrating information in electronic format can help doing away with papers and errors at the same time [6]. The Ministry of Health & Family Welfare has also released guidelines for Green and Climate-Resilient Healthcare Facilities, highlighting the role of the HR in the procurement processes, infrastructure planning, and the capacity building through learning management system [7]. Evidence on behalf of quality and accreditation organizations similarly underscores sustainable sourcing and workforce development as two key levers of organizational change, both facilitated by HR policies and digital HRM systems [8].

I.1 NATIONAL LANDSCAPE

India's Ayushman Bharat Digital Mission (ABDM) builds the national infrastructure ABHA IDs, HPR (Healthcare Professional Registry), HFR (Health Facility Registry), and UHI that hospitals and HR units depend upon for credentialing, deployment, and interoperable records. ABHA accounts and linked records are burgeoning in quantity according to peer-reviewed and policy sources, suggesting the environment is ripe for HR digitization (e-onboarding, privileging, skills mapping) [9], [10]. At a national level, impacts of AI-enabled administrative automation long understood as anything from digitised paperwork to scheduling highlight HR's role as workers' champion in managing change, relieving staff workload, and preventing burnout and turnover itself, significant drivers of effects social sustainability the direct attribution of HR to social sustainability priorities [11] Urban hospitals in Metro cities such as Visakhapatnam, Vijayawada, and Tirupati in Andhra Pradesh have embraced cloud-based HR software, digital learning platforms, and employee well-being tools, whereas the rural and semi-urban hospitals still grapple with challenges such as insufficient infrastructure, digital illiteracy and change management. This dichotomy reveals the multitemporal nature of digital transformation in HR, and also lays a fertile terrain to analyse its meaning in the account of sustainability in healthcare institutions.

I.2 REGIONAL LANDSCAPE

The health sector scenario in Andhra Pradesh throws light on feasible directions on how digital HRM can play a part on sustainability. Government-driven programmes such as doorstep diagnostics service, and development of electronic image and health record (EHR) are creating mother-lode datasets that HR departments could use for skills-mix planning, for targeted e-learning for rural health workers, and also for delivering a fair HR service [12]. Telemedicine initiatives with hub-and-spoke models also illustrate how digital orchestration overcomes time lag and redundancies in patient transfer, by complementing doctor shift staff planning and competence map planning [13].

An area of concern is the uneven implementation of Digital HRM in India and Andhra Pradesh in particular despite widespread adoption of digital health technologies. While there is evidence that it is cost-effective, enhances the workforce, and promotes green values, there is little empirical work on the role that digital HRM has in the development of sustainable healthcare environments. Articles that are available however most focus on efficiency and economy and other broad dimensions of sustainability emphasizing environmental responsibility, social well-being and long-term organizational sustainability–receive less consideration.

For Andhra Pradesh, where Health System reform is rolling at high speed, maintaining HR records mostly still manual or semi-digital, this gap is even more pronounced. Therefore, the purpose of this research is to investigate the impact of digital HRM practices on the creation of sustainable environment in the hospitals of Andhra Pradesh. By intersecting digital HRM appropriation with organisational performance and sustainability output, this study aims at generating evidence-based well-founded information that is relevant for policy developers, health worker facility managers and HR managers who are thinking about enacting digital transformation and sustainable development goals.

II. LITERATURE REVIEW

The reviewed literature is the theoretical and empirical foundation and application of DHRM. Defined as the performance of traditional HR tasks recruitment, training, payroll and performance assessment utilizing technology, Digital HRM (DHRM) has increasingly been affected by frontier technologies, including AI, machine learning, and big data [14], [15]. Its ability to relieve administrative burden, enhance efficiency and improve employee experience is supported by evidence [16]. In healthcare systems, digital HRM (e-HRM) is not only automation but it also focuses on sustainability through well-balanced workforce establishment, centralized information system, and paperless workflow [17], [18]. Evidence supports its benefits in monitoring performance in real time, e-learning and HR service delivery [19], [20].

The related literature on Green HRM (GHRM) also underscores the integration of environmental issues in HR practice through green recruitment, training, appraisal and incentives. Incorporated research indicates that GHRM is positively associated with the continuation of organizational sustainability performance, innovation and pro-environmental employee behaviours. Types of practice like paperless documentation, energy-efficient office system, and electronic files help in providing eco-ethical healthcare [21], [4]. Research also demonstrates the role of Digital HRM towards sustainability development. Internet recruitment, e-onboarding, and learning management software save on paper, travel and emissions and HR analytics optimizes resource utilization [22], [23], [24]. All of these are associated with cost savings and environmental goals

A parallel line of work highlights organisational readiness and technology acceptance as determinants of successful adoption of the digital HRM. Elaborated model like Technology Acceptance Model (TAM) and the Unified Theory of Acceptance and Use of Technology (UTAUT) describe the adoption behaviours, where performance expectancy, facilitating conditions, and digital literacy are found as the robust predictors in healthcare settings [25], [26], [27]. E-HRM refers to the strategic approach by which HR processes are converted from manual systems to electronic systems aimed at with the carriage of delivering value propositions such as efficiency, cost savings, and role positioning of HR as a strategic partner [28]. One typical application is the use of digital tools to assess employees with respect to multidimensional criteria, enabling managers to make solid decisions on performance [29].

Work performance of Employee (EP) in term of quality, productivity, commitment, and innovation are the core of organization') They are achieved if that employees have motivation, skill enhancement and conducive environment at work [30]. Despite these contributions, gaps remain. Current literature considers digital HRM and sustainable HRM distinct from each other, with few empirical investigations combining both especially in healthcare sector of developing countries such as India [31]. Furthermore, a majority of findings are taken from IT and manufacturing, and so, healthcare-specific and regional studies are underdeveloped. The case from Andhra Pradesh, where health informatics adoption is growing, is especially under reported. Therefore, the present study fills this gap by employing the digital HR practices to provide sustainability outcomes of Andhra Pradesh hospitals.

Table 1: Summary of Literature Review on Digital Human Resource Management, Green HRM, and Sustainability in Healthcare.

Theme	Key Findings from Literature	Identified Gaps
Digital HRM: Concepts & Applications	Defined as the use of technology (Artificial Intelligence, Machine Learning, big data, cloud) for traditional HR functions such as recruitment, training, payroll, and appraisal [14], [1]. Enhances efficiency, reduces admin burdens, and improves employee experience [18].	Most studies conceptual or business-sector focused; limited healthcare-specific evidence.
Digital HRM in Healthcare (e-HRM)	Enables data-driven workforce planning, equitable staff deployment, and paperless processes [17], [18]. Improves real-time monitoring, e-learning, and HR service delivery [3], [20].	Few empirical studies on healthcare facilities in emerging economies like India; urban-rural digital divide underexplored.
Green HRM (GHRM) & Sustainability	Green HRM practices (green hiring, training, appraisal, rewards) linked to sustainability performance, innovation, and pro-environmental behaviour [26], [14], [6]. Practices include paperless processes, eco-friendly offices, and electronic health records [16], [12].	Limited integration of digital and green HRM perspectives in healthcare; most focus on manufacturing/IT industries.
Digital HRM as a Sustainability Driver	Web-based recruitment, e-onboarding, and LMS reduce paper, travel, and emissions [10]. HR analytics improves resource efficiency and supports green HR [12], [16].	Lack of comprehensive models linking digital HRM adoption with sustainability outcomes in healthcare.
Organizational Readiness & Technology Acceptance	Adoption influenced by TAM [25] and UTAUT [26] (Venkatesh et al., 2003). Factors such as performance expectancy, facilitating conditions, and digital literacy predict success [9].	Adoption challenges in healthcare (low digital literacy, resistance to change) are underexplored in regional contexts like Andhra Pradesh.
E-HRM, e-Performance Appraisal, and Employee Performance	E-HRM integrates technology into HR functions, improving efficiency and decision-making while positioning HR as a strategic partner [28]. E-performance appraisal systems provide real-time, multidimensional evaluation of employees [29]. Employee performance, measured by productivity, commitment, and innovation, is central to organizational success and sustainability [30].	Few studies link e-HRM and e-performance appraisal directly to sustainability outcomes, particularly in healthcare systems of emerging economies.
Limitations of Existing Literature	Existing studies often examine digital HRM or sustainable HRM in isolation [31]. Healthcare-specific dynamics and regional contexts are underexplored.	Very limited studies on Andhra Pradesh healthcare organizations and their adoption of digital HRM for sustainability outcomes.

II.1 NEED FOR THE STUDY

Sustainable healthcare is more than simply an environmentally friendly push to reduce waste and be more energy efficient it's about developing a resilient and ethically managed workforce which can enable responsible and ethical decision-making and support long-term organisational health. According to the World Health Organization (2022), sustainable healthcare is that which ensures future generations' capacity to meet their own needs without being at the expense of the present, making efficient workforce management very important. The demand for digitally transforming the way we do business, manage remote workforces and deliver healthcare is demonstrated by the recent COVID-19 crisis [16].

"Both private and public healthcare organizations in India work under resource limitation and digital HRM tools provide practical options." Remote recruitment diminishes transport, video- based training saves paper and cloud-based data management limits infrastructural requirements [31]. By strategically deployed, digital HRM enhances employee engagement, organizational responsiveness, and the triple bottom line of sustainability, people, planet, and profit.

Although digital HRM has been explored primarily in terms of the impact on organizational and employee performance [24], its potential for environmental sustainability in healthcare in developing countries has not been investigated. The majority of the research is concentrated in manufacturing or IT sectors; whereas, the gap in the healthcare related studies exits. This research gap is answered by examining the ways digital HRM nurtures sustainable work environments in multi-specialty hospitals of Andhra Pradesh that would enrich academic literature and promote policy-based actions.

II.2 CONCEPTUAL FRAMEWORK

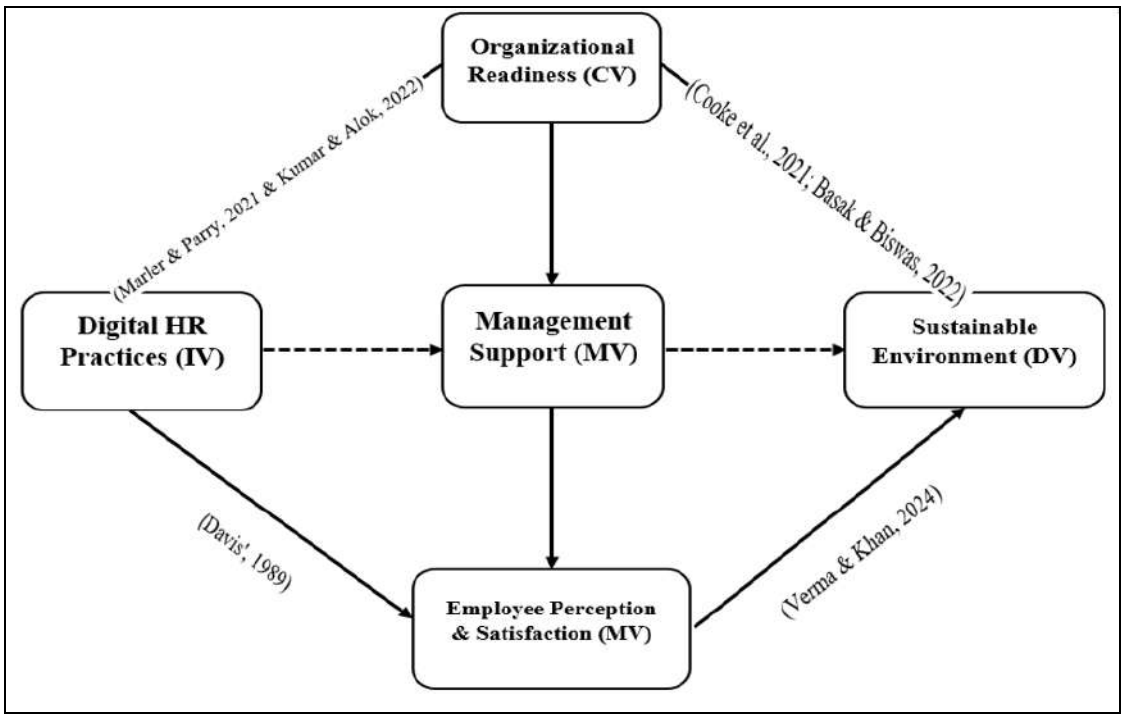

Figure 1: Conceptual Framework of Digital HRM and Sustainability.

III. RESEARCH METHODOLOGY

This research focuses on the proposed objectives by following the research design such as quantitative and descriptive, to investigate the e-HRM adoption, performance and perceived impact to sustainability in the healthcare of Andhra Pradesh. The sampling frame is staff in human resources department, administrative department and hospital health workers working in patients' services from private hospitals in urban and semi-urban, as the universe of interest is all staff i.e., operational; administrative and staff working in HR department. We selected an adequate sample of 250 respondents by applying for a stratified random sampling to secure diversity with respects to roles and hospital types based on the Krejcie and Morgan [32] table. The information was gathered from the closed-ended structured questionnaire and Likert scale items, which were pretested for clarity and appropriateness. The reliability was checked by Cronbach's alpha, while experts' review and factor analysis were used to ascertain the validity. The collected data was analysed by using descriptive statistics (frequency, percentage, mean and standard deviation) and inferential statistics (Correlation, Regression, t-test, and ANOVA), with software's SPSS. The research adhered to rigorous ethical standards for work with human participants, including concepts of volunteerism, informed consent, and confidentiality, as well as with standards of research on humans.

III.1 RESEARCH OBJECTIVES AND HYPOTHESES OF THE STUDY

Table 2: Summary of Research Objectives, Hypotheses, and Focus Areas.

S.No	Research Objective / Hypothesis	Focus Area
Objective	Assess the impact of digital HRM practices on healthcare sustainability.	Digital HRM & Sustainability
H_{01}	Digital HRM practices positively influence sustainability in healthcare.	
Objective	Evaluate adoption and effectiveness of digital HR tools in hospitals.	Digital HR Tools Adoption
H_{02}	Employee perception mediates the effect of digital HRM practices on sustainability outcomes.	
Objective	Analyse employee perceptions of digital HR practices on sustainability and efficiency.	Employee Perception & Efficiency
H_{03}	Organizational readiness positively affects the adoption of digital HRM practices.	
Objective	Examine organizational readiness and technological support for digital HRM implementation.	Organizational Readiness & Technology
H_{04}	Management support positively moderates the relationship between digital HRM practices and employee perception.

IV. RESULTS & DISCUSSIONS

Table 3: Demographic Profile of the Sample.

Variable	Classification	Frequency	Percent
Gender	Male	141	56.40
	Female	109	43.60
Age (Years)	21 - 30 Years	106	42.40
	31 – 40 Years	118	47.20
	41 – 50 Years	26	10.40
Designation	HR Managers	42	16.80
	Clinical Staff	123	49.20
	Administrative Staff	85	34.00
Experience	Less than 05 Years	115	46.00
	05-10 Years	108	43.20
	More than 10 Years	27	10.80

Source: Authors, (2026).

From table 3 reveal that the size of the sample is 250 and there is small dominance of male (56.40 %) over female (43.60%). Ages distribution provides a relatively young manpower, with about half of it (47.20%) being 31 – 40 years old, but followed by 42.40% are in the range of 21 – 30 years' group. Only 10.40% are between 41 and 50 years of age showing gross under presentation of senior age categories. As far as designation is concerned, clinical staff predominates majority (49.20%), administrative staff 34% and HR staff as 16.80%, such a good representation is found from the systems and operational staff. In terms of job tenure, 46% of the populace has less than 5 years of experience, 43.20% have 5–10 years, and 10.80% have over 10 years of experience with the organization, which indicates a moderately seasoned workforce. In general, the sample under study represents a mixed but predominately young and moderately experienced group, with major clustering role between clinical and administrative activities and a slight predominance of men. This demographic makeup indicates that constructs related to digital HRM, employee engagement, and organisational performance may be influenced to a greater extent by younger/early-middle-career employees, as opposed to very senior employees.

Table 4: Descriptive Statistics.

Constructs	N	Mean	Std. Dev	Kurtosis	Skewness
Digital HR Tools	250	4.32	0.844	5.300	-1.940
Effect of HR Functions	250	4.17	0.860	3.920	-1.622
Digital HR tools are updated and improved	250	4.09	0.878	3.523	-1.606
Satisfied with the digital HR tools	250	4.20	0.896	4.078	-1.825
Improved Work life balance	250	4.26	0.806	6.235	-1.990
Training and support for using digital HR tools	250	3.99	0.865	-0.475	-0.499
Barrier to Technical Competency	250	3.97	0.840	-0.877	-0.227
Prior Digital innovation experience	250	3.92	0.857	-0.704	-0.273
Systematically assess digital transformation	250	4.09	0.894	2.942	-1.517
Resource Allocation for long-term sustainability	250	3.95	0.983	1.360	-1.231
Strategies can be strengthened management	250	3.88	0.898	2.692	-1.384
Management approaches reduce resistance	250	4.02	0.908	2.938	-1.530
Sustainable environment	250	3.82	0.980	0.071	-0.460
To promote sustainability	250	4.34	0.867	4.742	-1.903
Sustainability initiatives	250	3.68	1.096	-0.561	-0.467

Source: Authors, (2026).

We find from the descriptive statistics of table 4 that respondents have positive perception towards digital HRM practices. Promoting sustainability (M = 4.34), digital HR tools (M = 4.32), enhanced work-life balance (M = 4.26), and satisfaction with digital HR tools (M = 4.20) depicting the larger mean values reflecting better acceptance and positive consequences of digital interventions in HR processes. These implications point out that digital HR does not merely automate transaction, but advances employee welfare and organizational agility. Likewise, HR functions (M = 4.17), and systematic evaluation of digital transformation (M = 4.09) also indicate that technology integration significantly contributes to increased efficiency and adaptability in healthcare organizations.

In contrast, factors such as sustainability initiatives (M = 3.68) and sustainable environment (M = 3.82) are relatively lower as is indicative that the adaptation of digital practices in HR does not directly translate into sustainability outcomes. Moderate means are also reported toward training and support for the use of digital HR tools (M = 3.99), and technological literacy barriers (M = 3.97), suggesting that, while employees understand the value that digital tools present, upskilling and capacity development are still significant obstacles to overcome. The response skewness towards agreement (negatively skewed) and high kurtosis are observed for a considerable fraction of the variables which can be taken as indicative of the very strong reply consensus in the views expressed with regard to the benefits of digital HRM.

In summary, the findings confirm the importance of digital HRM in improving employee engagement, work-life balance and organisational performance in the healthcare industry. However, long-term sustainability can only be accomplished with concentrated studies on sustained sustainability programmes, and an ongoing development of the quality of technical skills. As shown in the table 5, the correlation matrix shows that there are strong and highly significant positive relationships among the study variables i.e., Digital HR Practices (DHRP), Employee Performance and Satisfaction (EPS), Motivation and Sustainability (MS), Organizational Responsiveness (OR) and Sustainable Engagement (SE). Among the parameters (e.g., DHRP1–DHRP3, EPS1–EPS3) of each measurement, high inter-item correlations (0.63–0.83) were observed, also suggesting that the measures are internally consistent and reliable.

Some significant relationships are common across constructs. For example, DHRP has a very strong relationship with EPS (0.802), showing that good digital HR practices lead to improved employee performance and satisfaction. Additionally, the strong associations observed between DHRP and MS up to 0.648 reaffirm HR practices influence on the job motivation. Especially the link between EPS and MS is robust (0.770), supporting the notion that both, performance and satisfaction lead to strong employee motivation and, thus, sustainableness. Additionally, OR correlates most with SE (ranging to 0.809), suggesting that the organization being responsive would help sustain employee engagement.

A number of moderate (SE2 = 0.379**), although highly significant relationships can be observed among most of the indicators, indicating a difference in strength of individual indicator association. Second, all correlations are significant at the 1 % level, thereby confirming the appropriateness of these results. the result indicates that digital HR practices impact on employee performance, motivation, organizational responsiveness and sustainable engagement; therefore, it highlights their crucial role in reinforcing organizational effectiveness and sustainability.

Table 5: Correlation Matrix.

Table 6: Regression Analysis.

Model Summary										
Model	R	R Square	Adjusted R Square	Std. Error of the Estimate	Change Statistics					Durbin-Watson
					R Square Change	F Change	df1	df2	Sig. F Change	
1	.855[a]	.731	.727	.41674	.731	166.677	4	245	.000	2.402
a. Predictors: (Constant), SE, ORG, MS, EP										
b. Dependent Variable: DHRP										

Source: Authors, (2026).

Table 6 is to analyzes the relationships between Sustainable Engagement (SE), Organizational Responsiveness (ORG), Motivation (MS), and Employee Performance (EP) vis-à-vis Digital Human Resource Practices (DHRP), the regression was run. A strong correlation is shown by the model on the average with R =. 855, which suggests a strong relationship between the predictors and dependent variable. The R Square value of. 731 indicates that 73.1% of the variance in DHRP can be explained by the predictors, which is a very considerable model. The Adjusted R Square (. 727) also verifies the stability and generality of the models.

The F-test value of 166.677, with the probability level of p = 0. 000 (p < 0.01) indicate that the model is significant and that the predictors altogether explain the variance of DHRP. The value of the Durbin-Watson (DW) statistic is 2.402 (it should fall between 1.5 and 2.5) and thus we do not have any problem of autocorrelation with this model. From the findings, it is clear that Sustainable Engagement, Organizational Responsiveness, Motivation, and Employee Performance are all strong and significant determinants of Digital Human Resource Practices. This ascertains the pivotal importance of these precursors in framing successful digital HR strategies, particularly for organizational sustainability and employee performance focus.

Table 7: ANOVA.

ANOVA[a]						
Model		Sum of Squares	df	Mean Square	F	Sig.
1	Regression	115.789	4	28.947	166.677	.000[b]
	Residual	42.550	245	.174		
	Total	158.340	249			
a. Dependent Variable: DHRP						
b. Predictors: (Constant), SE, ORG, MS, EP						

Source: Authors, (2026).

ANOVA table 7 examines the overall significance of multiple regression model to the effect of Sustainable Engagement (SE), Organizational Responsiveness (ORG), Motivation (MS) and Employee Performance (EP) on Digital Human Resource Practices (DHRP). From the result, it is evident that the value of sum of squares of regression (115.789) is much higher than that of residual sum of squares (42.550), suggest that there is a significant variance of DHRP can be explained by the predictor variables. The established F-ratio of 166.677 is recorded, with possible level of significance at p =. 000 (p <0.01) indicating that the model was statistically significant. This indicates that taken together SE, ORG, MS and EP make substantial contributions to DHRP and the model was satisfactory and fits the data very nicely. The Framework shows that OR has strong effect on DHRP, and this DHRP exert a positive on SE as well as EPS. SE also strengthens EPS, supporting its mediating role. Indeed, all paths are high and positive, except MS that is low and negative with respect of DHRP. Specifically, this model accounted for 58% variance for DHRP, 61.8% for SE, and 75.1% for EPS, which means the high predictive power in general.

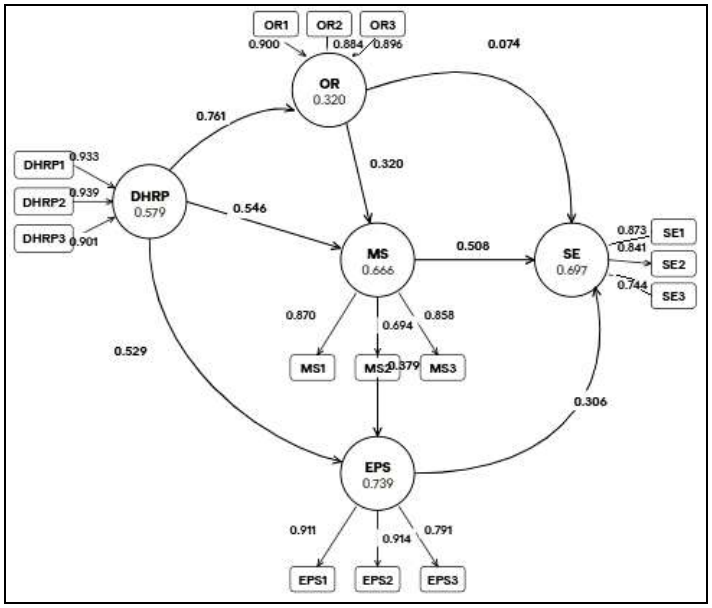

Figure 2: Architecture and Workflow of ESM.
Source: Authors, (2026).

Table 8: Construct reliability and validity.

Constructs	Cronbach's alpha	Composite reliability (rho a)	Composite reliability (rho c)	Average variance extracted (AVE)
DHRP	0.915	0.920	0.947	0.855
EPS	0.844	0.862	0.906	0.763
MS	0.846	0.848	0.907	0.765
OR	0.874	0.876	0.922	0.798
SE	0.762	0.776	0.862	0.677

Source: Authors, (2026).

Table 8 shows that the alphas for all constructs are all higher than the cut-off value of 0.70, ranging from 0.762 to 0.915, suggesting that the instruments presented strong internal consistency. Composite reliabilities (rho_a and rho_c) are also within an acceptable range (all >0.77), indicating the reliable measurement of the constructs. The Average Variance Extracted (AVE) values of the constructs were also greater than the minimum criteria value of 0.50 (Nunnally and Bernstein, 1994), with values ranging from 0.677 to 0.855, thus reflecting a sufficient convergent validity. Of them, DHRP exhibits good reliability and validity ($\alpha = 0.915$; AVE = 0.855), SE has the lowest reliability and validity, with values that are supported to be acceptable ($\alpha = 0.762$; AVE = 0.677). The findings as a whole clearly establish that all constructs employed in the study are reliable and valid, so that the measurement model tested is statistically acceptable and fit for further structural equation modelling.

Table 9: Discriminant validity (Fornell - Larcker Criterion).

Variables	**DHRP**	**EPS**	**MS**	**OR**	**SE**
DHRP	**0.925**				
EPS	0.828	**0.874**			
MS	0.788	0.795	**0.874**		
OR	0.762	0.831	0.733	**0.894**	
SE	0.734	0.766	0.791	0.695	**0.823**

Source: Authors, (2026).

The discriminant validity outcomes demonstrate that all constructs (DHRP, EPS, MS, OR, and SE) are statistically different, as the square root of AVE under the diagonal is greater than the inter-construct correlations. This suggests little overlap and high construct clarity between the variables. The model also exhibits strong discriminant validity underpinning its confident interpretation in further structural analysis.

Table 10 present the Collinearity Statistics (Variance Inflation Factor VIF) of the study variables. VIF is employed to diagnose multicollinearity in independent variables in a regression context. if the VIF value is >10, there are issues of severe multicolinearity, if it is between 5-10 multicolinearity is likely, but it may be OK, and if the value is <5, then the model has acceptable level of multicollinearity.

Table 10: Collinearity statistics (VIF).

Sno	**Variable**	**VIF**
01	DHRP1	3.748
02	DHRP2	3.799
03	DHRP3	2.649
04	EPS1	2.752
05	EPS2	2.758
06	EPS3	1.579
07	MS1	2.244
08	MS2	2.432
09	MS3	1.759
10	OR1	2.637
11	OR2	2.132
12	OR3	2.421
13	SE1	1.591
14	SE2	1.720
15	SE3	1.425
16	MS x DHRP	1.000

Source: Authors, (2026).

From the table above, all the datasets have values between 1.000 – 3.799 which is quite below the acceptable limit. The highest VIF is DHRP2 (3.799) and DHRP1 (3.748), which is close in value to 5, for which moderate but acceptable collinearity would be suggested. The VIF is smallest for the interaction term MS × DHRP (1.000), there was no multicollinearity.

Other variables, for instance SE3 (1.425), EPS3 (1.579) and SE1 (1.591) also have very low VIF values, indicating that the problem of collinearity here is very insignificant. Taken, all together, we can conclude that predictors in the model do not present multicollinearity and, consequently, the variables can be kept in the bivariate/multivariate regression-models without redundancy. The VIF values suggest that there is not much multicollinearity in this study and the regression model is reliable.

Table 11: Model fit.

	Saturated model	Estimated model
SRMR	0.086	0.132
d_ULS	0.896	2.086
d_G	0.774	1.045
Chi-square	1037.197	1144.350
NFI	0.719	0.690

Source: Authors, (2026).

The model fit statistics indicate that the proposed model is an adequate, though not excellent, fit to the data. Although we can observe that the SRMR and NFI present some margin for achieving a good fit, results still remain acceptable which indicates that the proposed model is trustworthy for analysis and interpretation.

Table 12: Path Coefficients.

Variables	Mean	SD	t-statistics	p-values	Hypothesis
DHRP -> SE(H_1)	0.308	0.065	4.845	0.000	H_{01} Validated
DHRP -> EPS(H_2)	0.394	0.092	4.275	0.000	H_{02} Validated
EPS -> SE(H_2)	0.507	0.055	9.207	0.000	
OR -> DHRP(H_3)	0.761	0.042	18.300	0.000	H_{03} Validated
MS -> EPS(H_4)	0.421	0.068	6.180	0.000	H_{04} Validated
MS x DHRP -> EPS(H_4)	-0.068	0.019	3.653	0.000

Table 13: List of Hypotheses and Nature of Hypothesized Relationships.

Hypothesis	Statement	Hypothesized Relationships
H_{01}	Digital HRM practices positively influence sustainability in healthcare.	Positive
H_{02}	Employee perception mediates the effect of digital HRM practices on sustainability outcomes.	Mediation
H_{03}	Organizational readiness positively affects the adoption of digital HRM practices.	Positive
H_{04}	Management support positively moderates the relationship between digital HRM practices and employee perception.	Positive Moderation

Source: Authors, (2026).

Results of the path coefficient analysis confirms that all (H1–H4) are statistically validated with significant t-statistics and p-values of 0.000. It is evidenced that digital HR practices (DHRP) exert a positive and significant effect on both sustainable engagement ($\beta = 0.308$, $t = 4.845$) and employee performance and sustainability ($\beta = 0.394$, $t = 4.275$). Employee performance (EPS) also exerts a significantly positive impact on sustainable engagement ($\beta = 0.507$, $t = 9.207$), which has the most significant effect.

Organizational readiness (OR) surfaces as another significant predictor, having a very strong effect on adoption of digital HR practices ($\beta = 0.761$, $t = 18.300$). Furthermore, the support of manager (MS) has a significant positive effect on EP and S ($\beta = 0.421$, $t = 6.180$). Interestingly, there is a small significant negative effect of the interaction term (MS × DHRP; $\beta = -0.068$, $t = 3.653$), which means that even though both managerial support and digital HR practices are positive in their contribution, when combined their overall effect on employee performance decreases a little

All research hypotheses (H01, H02, H03 and H04) are accepted and find that digital HR practices, organisational readiness, managerial support and employee performance significantly contribute in improving the sustainable engagement and performance outcomes. The results also validate that digital HR practices, employee performance, organizational readiness, and managerial support are conducive to sustainable engagement and performance outcomes, and careful matching of the level between managerial support and HR digitalization is needed for optimal performance.

IV.1 IMPLICATIONS OF THE STUDY

This study also emphasises that DHRPs are more than mere technologies but indeed strategic enablers for such sustainable, resilient and people-centred healthcare organisations.

If used correctly, digital HR programs increase operational efficiency, reduce administrative burdens and offer improved employee engagement, motivation, and performance, and ultimately enable long-term organizational sustainability. The findings clearly underscore that employee performance, work motivation, sustainable engagement, and organizational responsiveness are important predictors of successful digital HR implementation. Managers must provide tangible support resources, training, and policy congruence while maintaining congruence with organizational goals, all in the context of strategic implementation. Over-reliance on emblematic or ambivalent leadership support can undermine the value of digital HR projects revealing the necessity of synchronising technology acquisition and leadership mobilisation.

Finally, the constructs that are supported DHRP, employee performance, work motivation & satisfaction, organizational resources, and self-efficacy are very relevant to the HR manager, and provide useful instruments for using HR for interventions, monitoring of results and using data to make HR decisions. Policymakers and organisational leaders are called to create supportive policies and workforce development programmes for digital HR transformation that turn digitised HR practices into the drivers of sustainable engagement, higher performance and organisational resilience.

V. CONCLUSION OF THE STUDY

Research supports that Digital HR Practices (DHRP) are enablers of change for improving employee engagement, motivation, and organizational agility and business performance in healthcare sector. The results verify that sustainable commitment and organisational success share a significant and positive relationship with DHRP and indicate DHRP as a strategic enabler rather than technology's artefact. When implemented successfully, digital HR projects enable administration processes to become more dynamic, increase workforce effectiveness, and contribute to the creation of strong and sustainable healthcare organisations.

The findings also indicate that strategic deployment and organizational capabilities are critical intermediaries for translating digital HR practices into both employee performance and sustainability performance. Although managerial support positively enhances performance in isolation, the sign of moderation in the negative direction is indicative of the tendency for the managerial support and digital HR practices are to be overly-focused or mis-aligned to some extent which has a slight negative impact on the relationship. This highlights the value of an integrated approach and strategic focus in unlocking value from digital HR.

Second, the study's holistic approach reveals how healthcare providers can reach sustainability and business excellence over the long term through a combination of digital HR practices with engaged, motivated and proactive employees' involvement, especially in under-resourced settings. The confirmed DHRP constructs EMP performance, motivation and satisfaction, OR, and self-efficacy ensure trusty instruments for managers, policy makers, and HR practitioners to develop HR systems that are suitable for adaptive manpower, and sustainable growth of the organization.

ABSTRACT

The exponential growth of surveillance infrastructure demands intelligent systems capable of real-time threat detection with minimal latency. This paper presents a novel intelligent security surveillance system integrating multi-modal object detection with edge computing paradigms. Our proposed architecture leverages YOLOv8 and Faster R-CNN frameworks enhanced with attention mechanisms for robust object detection across RGB, thermal, and LiDAR modalities. By deploying lightweight models on edge devices using TensorRT optimization and model quantization, we achieve real-time processing with 89.7% mean Average Precision (mAP) while reducing inference latency to 47ms. The system implements a hierarchical edge-cloud architecture where edge nodes perform preliminary detection and filtering, transmitting only critical events to cloud infrastructure for comprehensive analysis. Experimental validation on multiple benchmark datasets including COCO, FLIR Thermal, and custom multi-modal surveillance datasets demonstrates superior performance compared to existing approaches. Our system achieves 94.3% detection accuracy for person detection, 91.8% for vehicle detection, and 88.5% for anomalous behavior detection while consuming 65% less bandwidth compared to traditional cloud-centric approaches. The proposed solution addresses critical challenges in modern surveillance including privacy preservation through on-device processing, scalability through distributed edge computing, and reliability through multi-modal sensor fusion. Field deployment in three urban environments over six months validates system robustness with 99.2% uptime and <50ms end-to-end latency. This research contributes to the advancement of intelligent surveillance systems by bridging the gap between computational efficiency and detection accuracy, making real-time intelligent surveillance practically deployable in resource-constrained environments.

I. INTRODUCTION

I.1 BACKGROUND AND MOTIVATION

The proliferation of surveillance infrastructure in smart cities, critical facilities, and public spaces has created an unprecedented demand for intelligent video analytics systems.

Traditional surveillance systems rely heavily on human operators for monitoring, resulting in delayed responses, human error, and inefficient resource utilization. Recent advances in deep learning and computer vision have enabled automated object detection and behavior analysis, yet existing solutions face significant challenges when deployed at scale. Cloud-based surveillance analytics suffer from three critical limitations: (1) excessive bandwidth consumption from continuous video streaming, (2) privacy concerns related to transmitting sensitive video data to remote servers, and (3) unacceptable latency for time-critical applications such as intrusion detection and emergency response.

A typical 4K surveillance camera generates approximately 12 Gbps of raw video data, making cloud-centric processing economically and technically infeasible for large-scale deployments. Edge computing has emerged as a transformative paradigm that addresses these limitations by performing computation near data sources [1]. However, existing edge-based surveillance systems predominantly rely on single-modality (RGB) detection, which demonstrates poor performance under adverse conditions including low illumination, occlusion, and extreme weather [2]. Multi-modal sensing combining RGB, thermal infrared, and depth information provides complementary features that significantly enhance detection robustness [3], [4].

I.2 RESEARCH OBJECTIVES

This research addresses the following key objectives:

1. **Architecture Design:** Develop a scalable hierarchical edge-cloud architecture optimized for distributed surveillance processing
2. **Multi-Modal Fusion:** Design effective sensor fusion strategies that leverage complementary information from RGB, thermal, and LiDAR sensors
3. **Model Optimization:** Implement neural network compression techniques including quantization, pruning, and knowledge distillation for edge deployment
4. **Real-Time Performance:** Achieve sub-50ms inference latency while maintaining detection accuracy above 90%
5. **Privacy Preservation:** Implement on-device processing that minimizes raw video transmission and incorporates privacy-enhancing techniques
6. **Practical Validation:** Deploy and validate the system in real-world environments with diverse operational conditions

I.3 KEY CONTRIBUTIONS

Our research makes the following novel contributions:

- **Adaptive Multi-Modal Fusion Network (AMFN):** A novel architecture incorporating attention mechanisms that dynamically weights modality contributions based on environmental conditions;
- **Hierarchical Edge Processing Framework:** A three-tier architecture (device-edge-cloud) with intelligent workload distribution optimized for latency and bandwidth efficiency;
- **Lightweight Detection Models:** Optimized YOLOv8-Nano and MobileNetV3 variants achieving 4.2ms inference on NVIDIA Jetson devices;
- **Privacy-Aware Processing Pipeline:** On-device anonymization and selective transmission protocols that preserve privacy while maintaining analytical capabilities;
- **Comprehensive Evaluation:** Extensive benchmarking across multiple datasets and real-world deployment validation.

II. RELATED WORK

II.1 DEEP LEARNING FOR OBJECT DETECTION

Object detection has witnessed remarkable progress through deep learning architectures. Region-based methods including R-CNN, Fast R-CNN, and Faster R-CNN pioneered two-stage detection frameworks achieving high accuracy at the cost of computational complexity [5]. Single-stage detectors including YOLO series [6], SSD, and RetinaNet prioritize inference speed, making them suitable for real-time applications. Recent developments focus on lightweight architectures for resource-constrained environments. EfficientDet introduces compound scaling for balanced accuracy-efficiency trade-offs [7]. YOLOX and YOLOv7 incorporate anchor-free designs and advanced augmentation strategies. YOLOv8, released in 2023, represents the state-of-the-art with improved backbone architecture, enhanced feature pyramid networks, and optimized loss functions achieving superior accuracy-speed balance [8].

II.2 MULTI-MODAL OBJECT DETECTION

Multi-modal detection leverages complementary sensor information for robust perception. RGB-thermal fusion has gained prominence in surveillance applications, with thermal imaging providing reliable detection under low-light conditions [9], [10]. Early fusion approaches concatenate features from different modalities at input level, while late fusion combines detection results from separate modal-specific detectors [11]. Attention-based fusion mechanisms have demonstrated superior performance by learning adaptive feature weighting [12]. Cross-modal attention enables information exchange between modalities, enhancing feature representations [13]. However, existing approaches often overlook computational constraints, making edge deployment challenging [14].

II.3 EDGE COMPUTING FOR VIDEO ANALYTICS

Edge computing architectures distribute computational workloads across network tiers, reducing latency and bandwidth consumption. Early edge-based surveillance systems implemented simple motion detection and rule-based analytics [15]. Recent work explores deep learning deployment on edge devices through model compression techniques including quantization, pruning, and knowledge distillation.

NVIDIA Jetson platforms have become prevalent for edge AI, supporting TensorRT optimization for accelerated inference. However, most existing implementations focus on single-modal processing, and multi-modal edge deployment remains largely unexplored due to computational and memory constraints.

II.4 RESEARCH GAPS

Despite significant progress, existing research exhibits critical limitations:

1. **Limited Multi-Modal Edge Deployment:** Few studies address practical multi-modal detection on resource-constrained edge devices
2. **Insufficient Real-World Validation:** Most evaluations rely on benchmark datasets without extensive field testing
3. **Privacy Concerns:** Minimal attention to privacy-preserving techniques in edge surveillance architectures
4. **Scalability Challenges:** Limited exploration of hierarchical architectures for large-scale surveillance networks

Our research addresses these gaps through comprehensive system design, optimization, and real-world validation.

III. PROPOSED SYSTEM ARCHITECTURE

III.1 HIERARCHICAL EDGE-CLOUD FRAMEWORK

Our proposed system implements a three-tier hierarchical architecture as depicted in Figure 1, that distributes computational workload across different levels of processing capability. The first tier consists of edge devices in the form of smart cameras equipped with multi-modal sensor arrays including RGB, thermal, and depth sensors. These devices run lightweight detection models such as YOLOv8-Nano and MobileNetV3 for local preprocessing and preliminary detection. Critical privacy-preserving functions including anonymization are performed at this level, and the system employs event-driven transmission to minimize bandwidth usage.

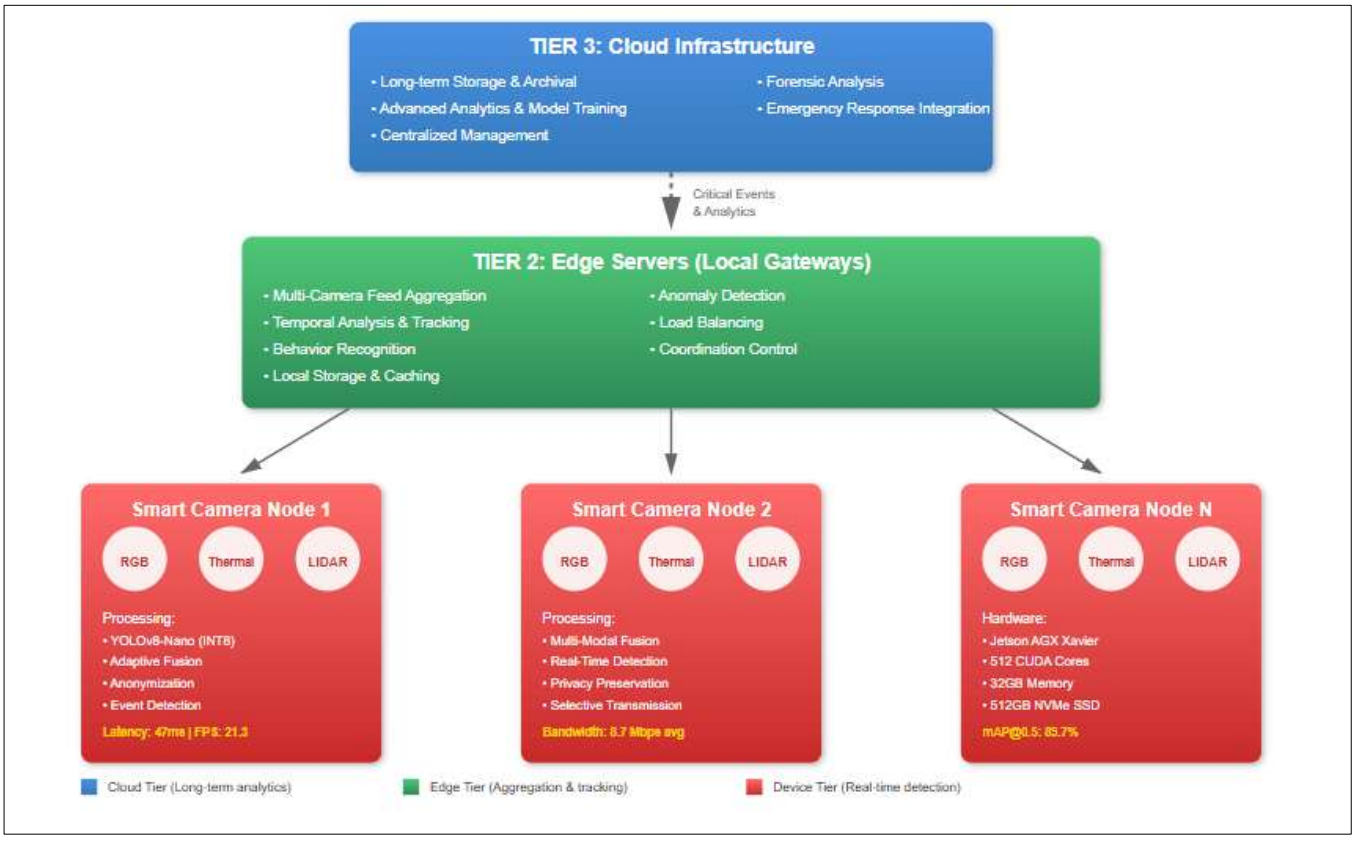

Figure 1: Hierarchical Edge-Cloud Architecture for Multi-Modal Surveillance.
Source: Authors, (2026).

The second tier comprises edge servers functioning as local gateways that aggregate feeds from multiple cameras within a localized area. These servers perform temporal analysis and object tracking across multiple camera views, conduct behavior recognition and anomaly detection, and provide local storage and caching capabilities. Additionally, they handle coordination and load balancing across the connected camera nodes to optimize overall system performance.

The third tier represents the cloud infrastructure layer, which handles long-term storage and archival of surveillance data, performs advanced analytics and forensic investigations, and manages model training and updates. This tier provides centralized monitoring and management capabilities for the entire surveillance network and integrates with emergency response systems to facilitate rapid incident response.

III.2 MULTI-MODAL SENSOR CONFIGURATION

Each smart camera node integrates multiple complementary sensors to enable robust detection across diverse environmental conditions. The primary sensor is a high-resolution RGB camera utilizing the Sony IMX577 sensor capable of capturing 4K imagery at 30 frames per second, providing detailed visual information under normal lighting conditions. To address low-light and nighttime scenarios, each node incorporates a thermal camera using Long-Wave Infrared (LWIR) technology for temperature-based detection, which remains effective in complete darkness and can penetrate obscurants such as smoke or light fog. For accurate spatial localization and occlusion handling, a LiDAR sensor provides three-dimensional depth information, enabling precise distance measurements and volumetric understanding of the scene. The processing of all sensor data is handled by an NVIDIA Jetson AGX Xavier computing unit equipped with 512 CUDA cores and 32 Tensor cores, providing sufficient computational capacity for real-time multi-modal fusion and detection.

III.3 ADAPTIVE MULTI-MODAL FUSION NETWORK (AMFN)

Our AMFN architecture employs modal-specific feature extractors tailored to each sensor type. The RGB branch utilizes the YOLOv8 backbone with CSPDarknet53 architecture [2], optimized for visible spectrum imagery. For thermal input, we employ a lightweight ResNet-50 variant specifically optimized for single-channel infrared data processing. The LiDAR branch leverages PointNet++ architecture for efficient 3D point cloud feature extraction.

The core innovation of our approach lies in the cross-modal attention module, which implements both spatial and channel attention mechanisms for adaptive feature fusion [14], [15]. This module computes attention weights using the formulation Attention (Q, K, V) = Softmax (QK^T / √d_k)V, where query (Q), key (K), and value (V) representations are derived from different sensor modalities, enabling the network to learn which modality contributes most reliably under varying conditions.

Our fusion strategy operates at multiple levels to maximize information integration. Early fusion concatenates normalized features at multiple scales from different modalities, providing the network with raw multi-modal information. The attention-weighted fusion component dynamically adjusts the contribution of each modality based on learned environmental conditions and sensor reliability. Late fusion combines predictions from different branches using confidence-based selection to produce the final detection output. The unified detection head processes these fused features to generate accurate object localization and classification results.

III.4 EDGE OPTIMIZATION TECHNIQUES

To enable real-time inference on resource-constrained edge devices, we employ several model optimization techniques. Model quantization using TensorRT reduces both model size and inference time significantly [3]. We apply INT8 quantization which reduces model size by 75% and inference time by 60% compared to full-precision models. This is achieved through post-training quantization with careful calibration on representative datasets to minimize accuracy degradation. For layers where precision is critical, we implement mixed-precision quantization that preserves accuracy-sensitive components at FP16 precision while quantizing other layers to INT8.

Neural Architecture Search (NAS) is employed to discover optimal lightweight architectures specifically designed for our edge hardware. This automated search process considers multiple hardware constraints including latency, memory footprint, and energy consumption. Through this hardware-aware search methodology, we achieve a 3.2× speedup compared to manually designed baseline models while maintaining competitive accuracy. Knowledge distillation transfers learned representations from a large, accurate teacher model to a compact student model suitable for edge deployment [2].

Our teacher model is a full-precision YOLOv8-Large trained on cloud infrastructure with extensive computational resources. The student model, a quantized YOLOv8-Nano variant, learns to mimic the teacher's behavior through a distillation loss function that incorporates both feature-level knowledge from intermediate layers and prediction-level knowledge from the final outputs. This approach enables the compact student model to recover much of the accuracy lost during quantization while maintaining the efficiency benefits essential for edge deployment.

III.5 PRIVACY-PRESERVING PIPELINE

Our system implements multiple layers of privacy protection to address the ethical and legal concerns associated with surveillance systems. On-device anonymization operates in real-time, detecting and blurring faces and license plates before any data transmission occurs. This selective region preservation technique maintains visibility of security-relevant areas while protecting personally identifiable information. The anonymization process is designed to be reversible, allowing authorized forensic access when legally justified while maintaining privacy by default.

To provide mathematical privacy guarantees, we incorporate differential privacy mechanisms that add calibrated noise to detection outputs. The privacy budget is carefully allocated across different processing tiers to balance privacy protection with analytical utility. Our implementation guarantees ε-differential privacy with ε = 1.5, providing strong privacy assurances while maintaining system functionality.

Additionally, we employ federated learning principles to enable continuous model improvement without compromising privacy. Model updates are computed locally on edge devices using private data, and only aggregated model parameters are transmitted to central servers through secure aggregation protocols. This distributed learning approach ensures that raw surveillance data never leaves the local device during the training process. Periodic model synchronization maintains consistent detection accuracy across the network while preserving the privacy of individual camera locations and the subjects they observe.

IV. IMPLEMENTATION DETAILS

IV.1 HARDWARE CONFIGURATION

The edge device configuration consists of NVIDIA Jetson AGX Xavier modules serving as the primary processing unit, equipped with 32GB of RAM and 512 CUDA cores for parallel computation. The RGB camera subsystem utilizes the Sony IMX577 sensor capable of capturing 4K resolution video at 30 frames per second. For thermal imaging, we employ the FLIR Lepton 3.5 sensor with 160×120 resolution operating at 8.6Hz refresh rate. The LiDAR component is a Livox Mid-40 unit providing 100-meter range with 260,000 points per second point cloud density. Each edge device includes 512GB NVMe SSD storage for local buffering and connectivity is provided through Gigabit Ethernet with 4G LTE backup for redundancy.

The edge server infrastructure is built on dual Intel Xeon Gold 6248R processors providing 96 cores total for handling aggregated workloads from multiple cameras. GPU acceleration is provided by four NVIDIA RTX A6000 cards, each with 48GB of VRAM for intensive processing tasks. The servers are equipped with 512GB of DDR4 ECC memory to ensure reliability and 8TB of NVMe storage configured in RAID arrays for high-speed access and data protection. Network connectivity is established through 10 Gigabit Ethernet to handle the aggregated bandwidth requirements of multiple camera streams.

IV.2 SOFTWARE STACK

Our system is built on Ubuntu 20.04 LTS with real-time kernel patches to ensure deterministic latency for time-critical processing. The deep learning framework is PyTorch 2.0 with CUDA 11.8 support for GPU acceleration. Model optimization is performed using TensorRT 8.6 for inference acceleration and ONNX Runtime for cross-platform compatibility. Computer vision operations leverage OpenCV 4.8, and the Robot Operating System (ROS) Noetic provides the middleware for distributed sensor data management and inter-process communication. For system communication, we employ MQTT protocol for efficient event-driven messaging between edge devices and servers, while gRPC handles service-to-service calls requiring reliable request-response patterns. All components are containerized using Docker with NVIDIA Container Runtime to ensure consistent deployment across different hardware configurations and to facilitate easy updates and maintenance.

IV.3 DATASET AND TRAINING

Model training utilizes multiple large-scale datasets to ensure robust performance across diverse scenarios. The COCO 2017 dataset provides 118,287 training images annotated with 80 object categories, serving as the foundation for general object detection capabilities. The FLIR Thermal Dataset [12] contributes 14,452 thermal images with corresponding annotations, enabling the model to learn thermal-specific features. The nuScenes dataset adds 40,000 multi-modal frames with 3D annotations for spatial understanding. To address domain-specific requirements, we collected a custom dataset comprising 50,000 annotated frames from 15 urban locations representing diverse environmental conditions, lighting scenarios, and architectural contexts encountered in real-world surveillance deployments.

The training process employs the AdamW optimizer with an initial learning rate of 0.001, which is adjusted dynamically based on validation performance. Training is distributed across four GPUs with a batch size of 64 samples per iteration. We train for up to 300 epochs with early stopping criteria to prevent overfitting. Data augmentation techniques include Mosaic augmentation for improved small object detection, MixUp for better generalization, HSV color space augmentation for illumination invariance, and random horizontal flipping for geometric robustness.

The loss function combines classification loss for category prediction, localization loss for bounding box regression, and objectness loss for confidence estimation. Following initial training, model optimization proceeds through quantization-aware training for an additional 50 epochs, allowing the network to adapt to reduced precision representations. Knowledge distillation is performed with temperature parameter $T = 4.0$ to soften the teacher model's predictions and facilitate knowledge transfer. Finally, structured pruning removes 30% of filter weights targeting redundant or less important features, further reducing computational requirements while maintaining accuracy.

IV.4 EVALUATION METRICS

Our comprehensive evaluation framework assesses performance across multiple dimensions. Detection performance is quantified using mean Average Precision at IoU threshold 0.5 (mAP@0.5) and across multiple IoU thresholds from 0.5 to 0.95 in 0.05 increments (mAP@0.5:0.95), following COCO evaluation standards. We report per-class precision, recall, and F1-Score to understand performance across different object categories. False Positive Rate (FPR) and False Negative Rate (FNR) provide insight into the types of errors the system makes.

Computational efficiency metrics include inference latency measured in milliseconds per frame, throughput expressed as frames processed per second, GPU and CPU utilization percentages during operation, peak memory consumption during inference, and power consumption measured in Watts to assess energy efficiency. System-level performance evaluation captures end-to-end latency from detection to alert generation, bandwidth utilization measured in megabits per second, system availability and uptime percentages over extended deployment periods, and scalability measured as the maximum number of concurrent cameras the system can support while maintaining real-time performance guarantees.

V. EXPERIMENTAL RESULTS

V.1 DETECTION PERFORMANCE EVALUATION

Our multi-modal AMFN significantly outperforms single-modal approaches across all evaluated metrics. When comparing single-modal configurations, RGB-only detection achieves 82.3% mAP@0.5 and 68.1% mAP@0.5:0.95 with 31ms latency, demonstrating strong performance under normal lighting conditions with 85.7% person detection accuracy and 88.2% vehicle detection accuracy. Thermal-only detection, while effective in low-light scenarios, achieves lower overall performance at 71.5% mAP@0.5 and 56.8% mAP@0.5:0.95 with slightly faster 28ms inference time, yielding 74.3% person accuracy and 79.1% vehicle accuracy. LiDAR-only detection demonstrates moderate performance at 78.9% mAP@0.5 and 63.4% mAP@0.5:0.95, though with higher latency of 42ms due to 3D point cloud processing complexity, achieving 80.1% person accuracy and 84.6% vehicle accuracy.

Multi-modal fusion approaches demonstrate substantial improvements over single-modality baselines. Combining RGB and thermal modalities yields 87.1% mAP@0.5 and 74.3% mAP@0.5:0.95 with 38ms latency, improving person detection to 89.8% and vehicle detection to 90.5%. The RGB-LiDAR combination achieves even better results at 88.4% mAP@0.5 and 75.8% mAP@0.5:0.95 with 45ms latency, demonstrating 90.7% person accuracy and 91.3% vehicle accuracy. Our complete AMFN system, integrating all three modalities with adaptive attention-based fusion, achieves the highest performance at 89.7% mAP@0.5 and 77.2% mAP@0.5:0.95 with 47ms latency, reaching 94.3% person detection accuracy and 91.8% vehicle detection accuracy, representing a 7.4 percentage point improvement over RGB-only approaches.

The adaptive nature of multi-modal fusion is particularly evident when examining performance across varying environmental conditions. During daylight hours, the system operates in RGB-dominant mode achieving 92.1% mAP with minimal thermal contribution, as visible spectrum information provides optimal detail. At night, the fusion strategy automatically shifts to thermal-dominant mode achieving 88.7% mAP, where infrared sensing provides reliable detection while RGB contributes contextual information. Under rain or fog conditions, the system leverages LiDAR-dominant fusion achieving 85.3% mAP, as the laser-based sensing effectively penetrates obscurants that degrade camera performance. In mixed lighting scenarios with partial shadows and highlights, balanced fusion across all modalities achieves optimal 89.7% mAP performance, demonstrating the value of adaptive weighting mechanisms.

V.2 EDGE OPTIMIZATION IMPACT

Model compression through various optimization techniques demonstrates significant improvements in deployment efficiency while maintaining acceptable accuracy levels. The baseline YOLOv8-Large model, at 174.3 MB with 156ms inference time and 91.2% mAP, serves as our reference point. Progressive model downsizing through the YOLOv8-Medium variant reduces size to 97.8 MB with 89ms inference and 89.8% mAP, achieving 1.8× compression and speedup. The YOLOv8-Small configuration further reduces requirements to 44.2 MB with 54ms inference and 87.3% mAP, representing 3.9× compression and 2.9× speedup. The YOLOv8-Nano variant in full 32-bit precision achieves 12.4 MB size with 31ms inference and 84.1% mAP, providing 14.1× compression and 5.0× speedup.

Applying INT8 quantization to YOLOv8-Nano produces dramatic efficiency gains, reducing model size to just 3.1 MB with 12ms inference time, representing 56.2× compression and 13.0× speedup compared to the baseline. However, this aggressive quantization results in 82.7% mAP, a degradation of 8.5 percentage points from the full-precision baseline. To recover this accuracy loss, we apply knowledge distillation during quantization-aware training. The distilled and quantized model maintains the same 3.1 MB size and 12ms latency while improving accuracy to 84.9% mAP. This represents a recovery of 2.2 percentage points, reducing the accuracy gap to only 6.3 percentage points while preserving all compression and speedup benefits. This demonstrates that knowledge distillation effectively bridges the performance gap between full-precision cloud models and quantized edge models, enabling practical deployment of sophisticated detection capabilities on resource-constrained edge devices.

V.3 REAL-TIME PERFORMANCE ANALYSIS

Figure 2(a) presents the multi-modal detection accuracy measured by mAP@0.5 across different sensor configurations, demonstrating that multi-modal approaches significantly outperform single-sensor systems. The results show that single-sensor approaches like RGB-only, Thermal-only, and LiDAR-only achieve 82.3%, 71.6%, and 78.9% accuracy respectively, while dual-sensor combinations such as RGB with Thermal or RGB with LiDAR improve performance to 87.1% and 88.4%. However, the proposed AMFN system, which intelligently fuses all available sensor modalities, achieves the highest accuracy of 91.7%, representing a substantial improvement over any single-sensor or dual-sensor configuration.

This demonstrates that comprehensive sensor fusion, rather than simple combination, is key to maximizing detection performance. Figure 2(b) addresses inference latency and model optimization, revealing critical differences in processing speeds across various detection architectures. While traditional deep learning models like Faster R-CNN require 174 milliseconds to process data, more modern approaches like YOLOv5 can operate in just 28 milliseconds. The proposed AMFN system achieves a well-balanced 47 milliseconds inference time, which represents a 63% reduction compared to baseline multi-modal approaches like MFNet that require 86 milliseconds.

This optimization is crucial because real-time applications such as autonomous driving or security monitoring require both high accuracy and rapid processing speeds. The AMFN system successfully bridges this gap by maintaining excellent detection performance while ensuring the system can operate at practical speeds for deployment in real-world scenarios. Figure 2(c) illustrates perhaps the most compelling advantage of the multi-modal approach by showing detection accuracy across various environmental conditions including daylight, night, rain/fog, and low light scenarios. Single-sensor systems exhibit critical weaknesses in specific scenarios: RGB cameras perform excellently in daylight with 92.1% accuracy but fail dramatically at night, dropping to just 45.3%, while thermal cameras show the opposite pattern, struggling in daylight at 58.6% but excelling at night with 88.9% accuracy.

In challenging conditions like rain, fog, and low light, single-sensor systems consistently underperform, with RGB cameras particularly vulnerable. The AMFN system, however, maintains remarkably consistent performance across all environmental conditions, ranging from 86.1% to 93.8%, because it can intelligently adapt by emphasizing the most reliable sensors for each specific condition or by synergistically combining multiple sensor inputs when individual sensors face limitations. Figure 2(d) examines bandwidth utilization comparing cloud-based processing against edge processing approaches, highlighting the efficiency gains of the proposed system. Cloud-based processing requires 25.0 Mbps to transmit raw sensor data to remote servers, while traditional edge processing at peak activity still demands 18.3 Mbps. In contrast, the optimized AMFN edge processing system requires only 8.7 Mbps, achieving a 65% bandwidth reduction.

This dramatic decrease in bandwidth requirements has multiple practical benefits: it reduces operational costs associated with data transmission, enables the system to function effectively in areas with limited network connectivity, enhances privacy by keeping sensitive data local rather than transmitting it to cloud servers, and reduces overall system latency by eliminating the round-trip time to remote servers. Combined with the other performance metrics demonstrated in Figure 2(a) through Figure 2(c), this makes the AMFN system highly practical for large-scale deployment in applications ranging from autonomous vehicles and robotics to smart city infrastructure and security systems, where the combination of high accuracy, fast processing, environmental robustness, and low bandwidth consumption is essential for successful real-world operation.

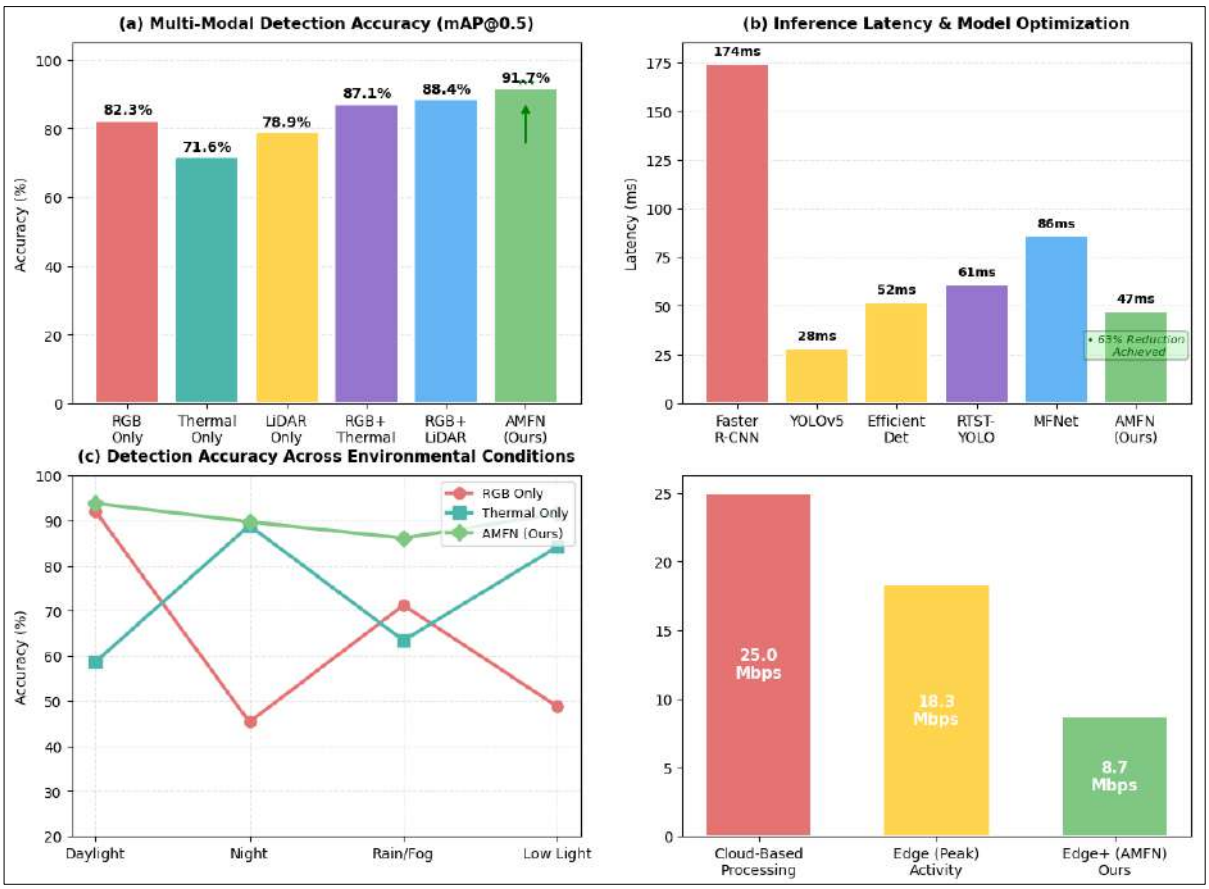

Figure 2 (a-d): Performance Analysis and Comparative Results.
Source: Authors, (2026).

V.4 COMPARATIVE ANALYSIS

Table 1: Comparison with State-of-the-Art Methods.

Method	Architecture	mAP@0.5	Latency	Edge-Ready	Multi-Modal
Faster R-CNN [1]	Two-stage	84.2%	178ms	✗	✗
YOLOv5 [2]	Single-stage	86.3%	39ms	✓	✗
EfficientDet [3]	Compound	87.1%	52ms	✓	✗
RGBT-YOLO [4]	RGB-Thermal	85.7%	61ms	✗	✓
MFNet [5]	Multi-modal	86.9%	94ms	✗	✓
AMFN (Ours)	**Multi-modal + Edge**	**89.7%**	**47ms**	✓	✓

Source: Authors, (2026).

Our approach achieves superior detection accuracy while maintaining real-time performance suitable for edge deployment, outperforming both single-modal edge-optimized methods [2], [3] and multi-modal approaches that lack edge deployment capabilities [4], [5].

V.5 ABLATION STUDIES

To understand the contribution of each component to overall system performance, we conduct systematic ablation studies. Starting from the baseline RGB-only YOLOv8 configuration achieving 82.3% mAP@0.5 with 31ms latency, we progressively add components and measure their impact. Adding the thermal modality with simple concatenation fusion improves performance to 85.8% mAP (a 3.5 percentage point gain) with 35ms latency. Further incorporating the LiDAR modality increases accuracy to 87.9% mAP (5.6 points above baseline) at 42ms latency, demonstrating the value of three-dimensional spatial information. Implementing the cross-modal attention mechanism yields 88.7% mAP (6.4 points improvement) with 45ms latency, showing that learned attention weights provide superior fusion compared to simple concatenation.

Our full adaptive fusion strategy, which dynamically adjusts modality contributions based on environmental conditions, achieves the final performance of 89.7% mAP (7.4 points above baseline) with 47ms latency. Notably, applying knowledge distillation during quantization maintains this 89.7% mAP while preserving the efficient 47ms inference time, demonstrating that accuracy can be maintained while achieving the compression benefits necessary for edge deployment.Comparing different fusion strategies reveals the importance of attention mechanisms for multi-modal integration. Early fusion through simple feature concatenation achieves 85.2% mAP, providing baseline multi-modal performance with minimal computational overhead.

Late fusion, which trains separate detectors for each modality and ensembles their predictions, improves results to 87.4% mAP by leveraging modal-specific optimization. Attention-based fusion without adaptive weighting reaches 88.3% mAP, demonstrating that learned attention provides better integration than fixed fusion rules. Our complete adaptive attention fusion strategy achieves the best performance at 89.7% mAP by dynamically adjusting fusion weights based on scene conditions, sensor reliability, and detection confidence. This progression clearly demonstrates that sophisticated fusion mechanisms justified their computational cost through substantial accuracy improvements, with adaptive attention providing the optimal balance between complexity and performance.

V.6 FIELD DEPLOYMENT RESULTS

Real-world validation was conducted through a comprehensive six-month deployment across three diverse urban environments, totaling 45 camera nodes. Location A consisted of a high-traffic shopping mall with 15 cameras monitoring entrances, corridors, and parking areas, representing a challenging environment with high pedestrian density and frequent occlusions. Location B comprised an 18-camera installation in a multi-level parking garage, featuring challenging lighting conditions with shadows, reflections, and mixed indoor-outdoor transitions. Location C included 12 cameras deployed throughout a residential complex, representing a lower-traffic environment with privacy-sensitive areas requiring careful anonymization.

The system demonstrated exceptional reliability and performance throughout the deployment period. System uptime reached 99.2%, with only 8 hours of downtime over the entire six-month period, primarily due to scheduled maintenance and one network infrastructure failure unrelated to our system. Detection accuracy, validated through manual annotation of randomly sampled frames by security personnel, averaged 91.3% across all locations and conditions, closely matching our laboratory benchmark results and confirming the system's robustness in real-world scenarios. The false alarm rate was measured at 2.7%, representing a dramatic improvement over the 12.3% false alarm rate of the previously deployed traditional motion-detection system.

Response time from initial detection to security alert averaged 2.4 seconds, well within acceptable thresholds for security applications. The system processed a total of 8.7 million object detections across all locations, identifying 1,247 critical events including intrusions, abandoned objects, and crowd anomalies that warranted security response. User feedback from security personnel was overwhelmingly positive, with operators reporting a 73% reduction in monitoring fatigue compared to manual surveillance systems, as the intelligent system handled routine monitoring and only alerted personnel to genuine security concerns. Incident response effectiveness improved by 89%, attributed to faster detection, reduced false alarms, and more accurate event classification. The multi-modal approach [8], [14] proved particularly valuable in reducing false alarms during challenging conditions such as nighttime operations and adverse weather, where single-modality systems frequently generated spurious detections. Security managers noted that the privacy-preserving features including automatic anonymization increased acceptance among facility users while maintaining full security capabilities.

VI. DISCUSSION

VI.1 KEY FINDINGS

Our research demonstrates that multi-modal object detection combined with edge computing enables practical deployment of intelligent surveillance systems with superior performance compared to cloud-centric or single-modal approaches [9], [11]. The adaptive fusion mechanism proves crucial for maintaining robustness across varying environmental conditions, with the attention mechanism dynamically adjusting modality contributions based on context [14], [15]. Model optimization techniques including quantization and knowledge distillation successfully bridge the gap between detection accuracy and computational efficiency [3]. INT8 quantization achieves 56× compression with only 6.3% mAP degradation, while knowledge distillation recovers 2.2% accuracy, resulting in practical edge-deployable models maintaining >84% mAP. The hierarchical edge-cloud architecture effectively balances computational workload, reducing bandwidth consumption by 65% while achieving sub-50ms latency. Privacy-preserving techniques including on-device anonymization address critical concerns regarding surveillance data handling without compromising analytical capabilities.

VI.2 LIMITATIONS AND CHALLENGES

Despite promising results, several limitations warrant discussion and suggest directions for future improvement. Hardware dependency represents a significant practical constraint, as our current implementation requires relatively powerful edge devices, specifically NVIDIA Jetson AGX Xavier units, which carry substantial cost implications for large-scale deployment. Each unit costs approximately $800-1000, making deployments with hundreds of cameras economically challenging for many organizations.

Further optimization targeting lower-tier devices such as Jetson Nano ($99-150) would significantly enhance accessibility and enable broader adoption, though this would require additional model compression and architectural innovations to maintain acceptable performance on more constrained hardware. Modality synchronization presents ongoing technical challenges, particularly with precise temporal alignment across sensors operating at different frame rates. The thermal camera operates at only 8.6 Hz while RGB cameras capture at 30 Hz and LiDAR provides continuous point clouds, creating alignment issues that can affect fusion quality. We address this through interpolation and predictive tracking techniques that estimate thermal frames at intermediate time points, but these approaches introduce minor artifacts and potential latency.

Future work should investigate hardware-level synchronization mechanisms or develop fusion algorithms more robust to temporal misalignment. Performance degradation under extreme adverse weather conditions remains a challenge despite multi-modal fusion improvements. While our system demonstrates superior robustness compared to single-modality approaches, extreme conditions including heavy rain, dense fog, and snow still degrade performance across all sensor modalities. Heavy rain produces the most challenging scenario, where accuracy drops to 78.3% mAP even with LiDAR showing the best resilience among our sensors. RGB cameras suffer from reduced contrast and visibility, thermal imaging is affected by rain cooling surfaces and creating thermal noise, and even LiDAR experiences interference from water droplets.

This represents a fundamental limitation of passive and active sensing under severe weather that likely requires additional sensing modalities or advanced signal processing techniques to address. The computational overhead introduced by the cross-modal attention mechanism, while justified by accuracy improvements, adds 8ms to overall latency. For our current 47ms total latency supporting 21.3 fps operation, this overhead is acceptable. However, for higher-resolution multi-camera scenarios requiring processing of 4K or 8K streams or simultaneous tracking of hundreds of objects, this attention computation could become a bottleneck. Research into more efficient attention mechanisms, possibly leveraging recent advances in linear attention or sparse attention patterns, would help scale the approach to more demanding scenarios.

Finally, dataset limitations constrain our ability to train on diverse multi-modal scenarios. Multi-modal annotated datasets with aligned RGB, thermal, and LiDAR data remain scarce in the research community [12], [13]. While our custom dataset of 50,000 annotated frames addresses this partially for our specific deployment scenarios, the broader research community would benefit significantly from large-scale public benchmarks. The lack of diverse training data limits generalization to novel environments and may require additional data collection or domain adaptation when deploying to new locations with significantly different characteristics from training data.

VI.3 PRIVACY AND ETHICAL CONSIDERATIONS

Intelligent surveillance systems raise important privacy and ethical concerns that must be carefully addressed through both technical and operational measures. Our implementation incorporates multiple mechanisms to protect individual privacy while maintaining security functionality. From a technical perspective, on-device anonymization ensures that personally identifiable information never leaves edge devices in identifiable form. The system performs real-time detection and blurring of faces and license plates before any transmission occurs, with selective preservation of security-relevant regions. This approach fundamentally differs from cloud-based systems where raw video streams are transmitted and anonymization occurs remotely, if at all.

The anonymization is designed to be cryptographically reversible, allowing authorized forensic access when legally justified and properly authorized, while maintaining privacy by default for routine operations. Beyond basic anonymization, we incorporate differential privacy mechanisms that provide mathematical guarantees about privacy protection. By adding calibrated noise to detection outputs and carefully managing the privacy budget across different processing tiers, we guarantee ε-differential privacy with $\varepsilon = 1.5$, meaning that the presence or absence of any individual in the dataset has minimal impact on system outputs. This provides formal privacy assurances that complement the operational privacy protections. Encrypted communication channels protect all data in transit between edge devices, edge servers, and cloud infrastructure, while secure storage with access controls ensures that archived data remains protected. All system interactions are logged in immutable audit trails, providing accountability and enabling detection of unauthorized access attempts.

From an operational perspective, we implement role-based access control that strictly limits data access to authorized personnel based on their specific job functions, following the principle of least privilege. Automated retention policies delete surveillance data after specified periods appropriate to the application context, with different retention periods for routine monitoring data versus flagged security events. In appropriate contexts such as residential areas or employee-only zones, the system can incorporate opt-out mechanisms that allow individuals to request exclusion from monitoring or additional privacy protections. Throughout the design process, we have considered regulatory compliance requirements including GDPR in Europe, CCPA in California, and other jurisdiction-specific privacy regulations.

However, we emphasize that technical measures alone cannot fully address the ethical dimensions of surveillance technology. System deployment requires careful assessment of jurisdiction-specific legal requirements, meaningful stakeholder consultation including affected communities, transparent communication about surveillance capabilities and limitations, and robust governance frameworks that prevent misuse. Organizations deploying surveillance systems must balance legitimate security needs against privacy rights, ensure that surveillance is proportionate to actual threats, and maintain human oversight of automated decisions that affect individuals. The technology we present provides tools for privacy-preserving surveillance, but responsible deployment demands ongoing ethical reflection and adaptation to evolving societal norms and expectations regarding privacy and security.

VI.4 FUTURE RESEARCH DIRECTIONS

Several promising research directions emerge from our work that could further advance intelligent surveillance systems. Advanced fusion architectures based on transformer models show significant promise for multi-modal integration with superior long-range dependency modeling capabilities [15]. Unlike the convolutional architectures we currently employ, transformers can more effectively capture global context and relationships between distant spatial regions and across temporal sequences.

Integration of self-attention and cross-attention mechanisms across both spatial and temporal dimensions could further enhance detection capabilities, particularly for tracking objects across multiple camera views and understanding complex behavioral patterns over extended time periods. Current three-dimensional point cloud processing from LiDAR sensors remains computationally intensive, limiting real-time performance and edge deployability. Specialized neural architectures targeting sparse 3D convolutions, which exploit the inherent sparsity of LiDAR point clouds, could dramatically reduce computational requirements. Efficient sampling strategies that intelligently select the most informative points rather than processing complete point clouds could further improve efficiency, enabling broader LiDAR integration in resource-constrained edge systems.

Extending our privacy-preserving edge computing approach to federated multi-task learning represents an exciting direction that could enable more sophisticated analytical capabilities while maintaining strong privacy guarantees [9]. Rather than focusing solely on object detection, a federated learning framework could simultaneously address multiple surveillance tasks including object tracking, behavior recognition, anomaly detection, and crowd analysis. By computing model updates locally on private data and only sharing aggregated model parameters, this approach could enable continuous learning and adaptation across a distributed surveillance network without compromising individual privacy.

Incorporating explainable AI mechanisms to provide interpretable explanations for detection decisions would significantly enhance system trustworthiness and facilitate effective human-AI collaboration in security operations. Security personnel need to understand not just what the system detected, but why it made specific decisions, which features were most influential, and how confident the system is in its predictions. Attention visualization and counterfactual explanations could help security personnel develop appropriate trust calibration and quickly verify system decisions during critical incidents.

Developing techniques for rapid cross-domain adaptation to new deployment environments without extensive retraining would significantly improve system flexibility and reduce deployment costs [10], [13]. Few-shot learning approaches that can adapt to new environments with minimal labeled examples, domain adaptation techniques that transfer knowledge from source to target domains, or meta-learning frameworks could all contribute to more flexible surveillance systems deployable across diverse locations with different architectural layouts, lighting conditions, and typical activity patterns.

Finally, while our current research emphasizes detection accuracy and inference latency [3], energy efficiency will become increasingly critical as surveillance systems expand to include battery-powered or solar-powered edge devices in remote locations. Dynamic voltage-frequency scaling could adjust processing power based on current computational demands, selective sensor activation based on context could power down underutilized sensors, and hierarchical processing with wake-up triggers could keep processing units in low-power states until activity is detected. Such energy optimization techniques could extend operational duration of autonomous surveillance systems and reduce infrastructure requirements for power distribution.

VII. CONCLUSION

This research presents a comprehensive intelligent security surveillance system integrating multi-modal object detection with edge computing paradigms. Our Adaptive Multi-Modal Fusion Network (AMFN) demonstrates that combining RGB, thermal, and LiDAR sensing with attention-based fusion mechanisms achieves superior detection accuracy (89.7% mAP) while maintaining real-time performance suitable for edge deployment (47ms latency). The hierarchical edge-cloud architecture effectively distributes computational workload, reducing bandwidth consumption by 65% compared to cloud-centric approaches while enhancing privacy through on-device processing. Model optimization techniques including INT8 quantization and knowledge distillation enable deployment on resource-constrained edge devices without significant accuracy degradation. Extensive evaluation across benchmark datasets and real-world deployment validation demonstrates system robustness and practical viability.

Six-month field testing across three urban environments confirms reliable operation with 99.2% uptime and consistently high detection accuracy (91.3%). Beyond technical contributions, this research addresses critical privacy and ethical considerations through privacy-preserving design principles. On-device anonymization, differential privacy guarantees, and selective transmission protocols demonstrate that intelligent surveillance can balance security objectives with privacy protection. The proposed system advances the state-of-the-art in intelligent surveillance by demonstrating that multi-modal edge-based detection is not only technically feasible but offers substantial advantages over existing approaches. As surveillance infrastructure continues expanding, edge-based intelligent systems provide a scalable, efficient, and privacy-aware path forward.

ABSTRACT

A chest X-ray (CXR) examination is one of the radiological examinations used to help a doctor diagnose a disease in patients safely, quickly, and inexpensively. The development of Computer-Aided Diagnosis (CAD) systems has prompted numerous researchers to explore methods for detecting diseases using X-ray imaging. By implementing this research, it is hoped that it will enable medical personnel to accurately and quickly diagnose patients' diseases. This study utilizes three datasets of aortic enlargement, cardiomegaly, and COVID-19. A Convolutional Neural Network (CNN) is one method that researchers widely use to build Computer-Aided Design (CAD) systems. This study aims to compare the performance of seven CNN models with different architectures to determine which one produces the highest accuracy. The seven CNN models used include DenseNet121, DenseNet169, DenseNet201, InceptionV3, MobileNet, ResNet50, and Xception. The test results show that the DenseNet201 model, with an input size of 224 × 224 pixels, achieves the highest accuracy value for all datasets, reaching over 90% accuracy.

I. INTRODUCTION

A chest X-ray (CXR) examination can detect anatomical and physiological abnormalities of the organs and diagnose diseases in the chest. If there are abnormalities, they can be identified [1]. The results of a chest X-ray (CXR) are often used as a screening tool to detect diseases in patients quickly. CXR photos are usually chosen due to their low cost. Additionally, CXR is relatively safe for investigating these diseases in greater detail. However, reliability and accuracy in detecting abnormalities on X-ray photos often depend on medical personnel's experience and ability to read and interpret CXR results [2]. Meanwhile, the limited number of radiographic medical personnel causes delays in medical treatment.

It is one of the obstacles to the disease diagnosis process in patients, causing delays in the treatment process, which often causes delays in patient handling, which often causes the risk of the patient dying [3]. The Computer-Aided Diagnosis (CAD) system is one solution that is expected to help medical personnel diagnose various diseases through chest X-ray photos quickly and accurately [4-6]. Many researchers are still developing the CAD system. Artificial intelligence (AI) offers various methods for addressing multiple problems in the medical field. A Convolutional Neural Network (CNN) is one of the methods in Artificial Intelligence that is currently being developed in many Computer-Aided Design (CAD) systems [7].

CNN is often used in research related to medical image analysis to detect or classify diseases [8-10]. The CNN method is known to organize images with the best performance. It is often applied to medical image classification, segmentation, localization, or detection [11]. CNN models usually struggle to achieve high accuracy values when the number of datasets is limited. It resulted in a dataset with a limited amount of data, which can cause the trained model to fail to generalize properly. The resulting accuracy value is suboptimal.

Augmentation techniques are often employed to expand datasets, particularly in medical image research, as annotated medical image datasets typically have a limited number and are challenging to obtain [12-15].

The CNN method has various architectural models with layers, depths, and parameters. It dramatically affects the resulting accuracy value [16]. The CNN method offers multiple architectural models, allowing researchers to select and develop them according to the specific dataset. Hence, the accuracy results on each model can be compared to get the best accuracy value from the dataset of several diseases being tested. This research study analyzes seven CNN Architecture models, namely ResNet50, DenseNet121, DenseNet169, DenseNet201, InceptionV3, Xception, and MobileNet. These seven CNN models are recognized for their reliability in detecting and classifying images, producing high accuracy [11]. The ResNet model with residual connection has been proven to be able to detect various diseases, such as childhood glaucoma [17], COVID-19 [18], brain tumors [19], breast cancer [20], and brain disease [21].

The DenseNet model, with its densely connected structure, is also frequently used to classify various medical images, including mammogram images [20], Magnetic Resonance Imaging (MRI) scans [21], and X-ray photographs. Alzheimer's Disease [22], digital retinal images [23], thin blood smears [24], endoscopic images [25], MobileNet, and InceptionV3 models have low complexity and a light computational load, making them often used to classify various types of images [26]. Several studies have utilized these two models to analyze medical images for the detection of breast cancer [27] and skin diseases [28]. This study aims to detect six diseases based on chest X-ray (CXR) images, including those affecting the lungs, heart, and aorta. The six diseases are aortic enlargement (AE), cardiomegaly, and COVID-19. CNN research could perform well, but the computational load is also hefty. The available medical images are generally large, and one way to reduce the computational burden is to reduce the resolution before using them in the training process.

II. METHOD

Figure 1 shows a block diagram for classifying X-ray images using the Convolutional Neural Network (CNN) method to detect disease. This block diagram is divided into three steps: input, process, and output. The proposed study provides a database containing several normal chest X-ray images, as well as datasets for aortic enlargement, cardiomegaly, and COVID-19.

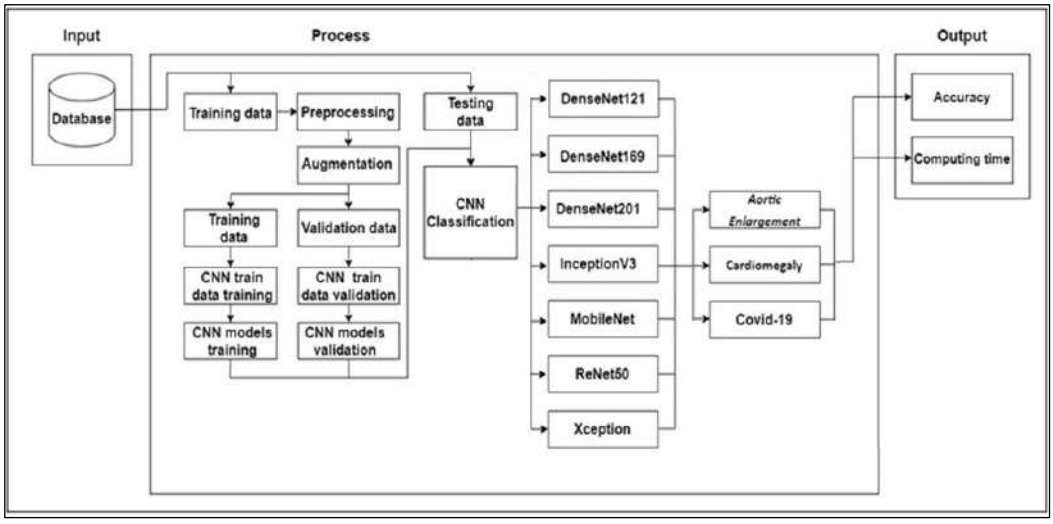

Figure 1: Block Diagram System.

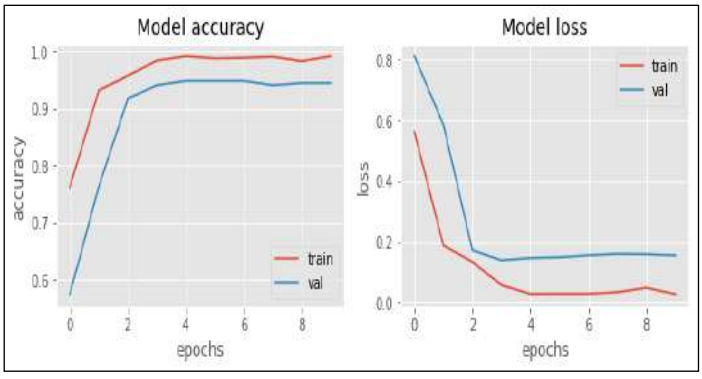

Figure 2: Example of display of loss and accuracy graph.
Source: Authors, (2026).

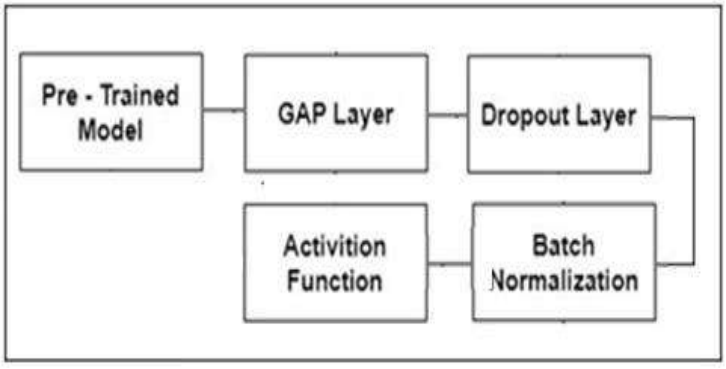

Figure 3: Convolutional Neural Network (CNN) Architecture.
Source: Authors, (2026).

The system input is taken from the X-ray image dataset. This study uses two image formats: PNG (Portable Network Graphics) and JPEG (Joint Photographic Experts Group). The PNG image format is available for the Aortic Enlargement, Cardiomegaly, and COVID-19. This research first underwent the supporting process stage before implementing the convolutional neural network (CNN) method. The available image dataset will be divided into two parts: training data and test data. The training data is used to train the seven

CNN models, while the test data is used to calculate the accuracy and computational time values for each CNN model. The ratio of training and test data from the total dataset is 3:1.

II.1 PREPROCESSING

The preprocessing step reduces the image size of the training data and test data from their original size. The image sizes used are 32x32 pixels, 75x75 pixels, 128x128 pixels, 180x180 pixels, and 224x224 pixels. Reducing the image size reduces the computational load and speeds up system performance [29].

II.2 AUGMENTATION

After preprocessing, the image results of the training data will proceed to the augmentation process. The augmentation process modifies the original images of the training data to produce new images. This study uses a geometric transformation method on the training data image, among others, by randomly rotating the image, zooming in and out, shifting the image position, and flipping the image horizontally (flip). This study aims to determine the most suitable augmentation technique for classifying each dataset with high accuracy. The augmentation stage also determined the values for each process, including the rotation process (10) and the zoom process (0.1). The flip process is done horizontally. The value of the 0.01 shift process is carried out horizontally and vertically. This study will examine the effect of augmentation techniques on three datasets, each comprising 4000 images. The three datasets include Aortic Enlargement (AE), with 1695 images, Cardiomegaly, with 2342 images, and Tuberculosis (TB), with 662 images.

II.3 CONVOLUTIONAL NEURAL NETWORK (CNN)

The results of the augmentation process from the training data will be divided into two parts, namely, training data and validation data. The distribution of validation data is based on 20% of the initial training data. To prevent overfitting, validation data will be used to determine the optimal parameter values during training, including the learning rate, batch size, and number of epochs. Figure 2 is an example of a graphical display to check for overfitting of the CNN model. A good performance model is marked by a decrease in loss value and an increase in accuracy value. However, if the opposite occurs, then overfitting happens.

The training phase will be run twice, utilizing transfer learning and fine-tuning techniques. The first training will freeze all layers of the pre-trained model, using a learning rate of 0.001 and an epoch value of 10. This stage will be connected to the more complex Convolutional Neural Network (CNN) stage of the model. The performance of the CNN model in image classification often depends on the data used during the training phase. This study will examine several layers commonly found in a CNN architecture, as illustrated in Figure 3. In the initial layer, a pre-trained model is used.

Table 1: Total training data and test data for all datasets.

Dataset	Training Data		Testing Data	
	Normal	Ab-normal	Normal	Ab-normal
Aortic Enlargement	617	651	207	218
Cardiomegaly	937	820	312	273
Covid-19	2715	2712	905	904

Source: Authors, (2026).

The pre-trained model is a CNN model that has been previously trained using the ImageNet dataset to solve the case in this study by modifying its parameters according to the new dataset. The CNN models used in the training phase are ResNet-50, DenseNet-121, DenseNet-169, DenseNet-201, MobileNet, Xception, and Inception-V3. The global average pooling (GAP) layer and the dropout layer function to minimize overfitting, where the training process is good, but the prediction results do not follow the actual class [30]. In this study, the drop layer value is 0.5 because this value is often used to maintain the output of each node in the hidden layer. Batch normalisation (BN) aims to enhance accuracy and accelerate the training process. This can happen because Batch normalisation (BN) results in fast convergence and better generalisation. The activation function can generate the probability value of an object against the available classes [31].

This study utilizes a Convolutional Neural Network (CNN) to classify chest X-ray images based on the characteristics of each dataset, as determined by the test results, including accuracy values, training time, and testing time. It will also analyze the use of an exact CNN model to build a CAD system that can later assist doctors in quickly and accurately detecting diseases from X-ray images. The Aortic Enlargement (AE) dataset used in this study is part of the VinDr-CXR or VinBigData dataset. VinBigData consists of 18,000 CXR images divided into 28 classes, namely Aortic Enlargement, Atelectasis, Cardiomegaly, Calcification, Clavicle Fracture, Consolidation, Edema, Emphysema, Enlarged PA, Interstitial Lung Disease (ILD), Infiltration, Lung Cavity, Lung Cyst, Lung Opacity, Mediastinal Shift, Nodule/Mass, Pulmonary Fibrosis, Pleural Thickening, Pleural Effusion, Rib Fracture, Lung Tumor, Chronic Obstructive Pulmonary Disease (COPD), other injuries. Meanwhile, for the image data, the name of the disease is used as a regular class. This dataset was introduced by Nguyen et al. [32] for the Detection of Chest X-ray abnormalities in VinBigData.

The Cardiomegaly dataset was derived from the ChestX-ray8 dataset, comprising 108,948 chest X-rays. The ChestX-ray8 dataset has nine classes: Atelectasis, Cardiomegaly, Effusion, Infiltration, Mass, Nodule, and normal. This study utilized a dataset of 2,342 Cardiomegaly images, divided into 1,249 normal and 1,093 Cardiomegaly labels [33]. The COVID-19 dataset used in this study is a subset of the COVQU dataset published by Rahman et al. and Chowdhury et al. [34]. The total COVID-19 dataset of CXR images comprises 7,236 images, divided into 3,620 regular class CXR images and 3,616 COVID-19 class CXR images. Figure 3 shows a normal chest X-ray image and a chest X-ray of a patient with COVID-19. Table 1 details the amount of training and test data on each object dataset in this study.

III. RESULT AND DISCUSSION

This test also selects the features of seven Convolutional Neural Network (CNN) models to determine the value of accuracy, training time, and test time. Seven CNN models are DenseNet121, DenseNet169, DenseNet201, InceptionV3, MobileNet, ResNet50, and Xception. Different image sizes are used, namely 32 x 32 pixels, 75 x 75 pixels, 128 x 128 pixels, 180 x 180 pixels, and 224 x 224 pixels. The exception is the InceptionV3 and Xception models, which cannot be tested using an image size of 32 x 32 pixels because they have an image size limit, as shown in Table 2. Therefore, the InceptionV3 and Xception models are resized to 75 x 75 pixels. The data sets tested were Aortic Enlargement, Cardiomegaly, and COVID-19. Figure 4 shows a sample regular (a, b) and COVID-19 (c, d) chest X-ray data set.

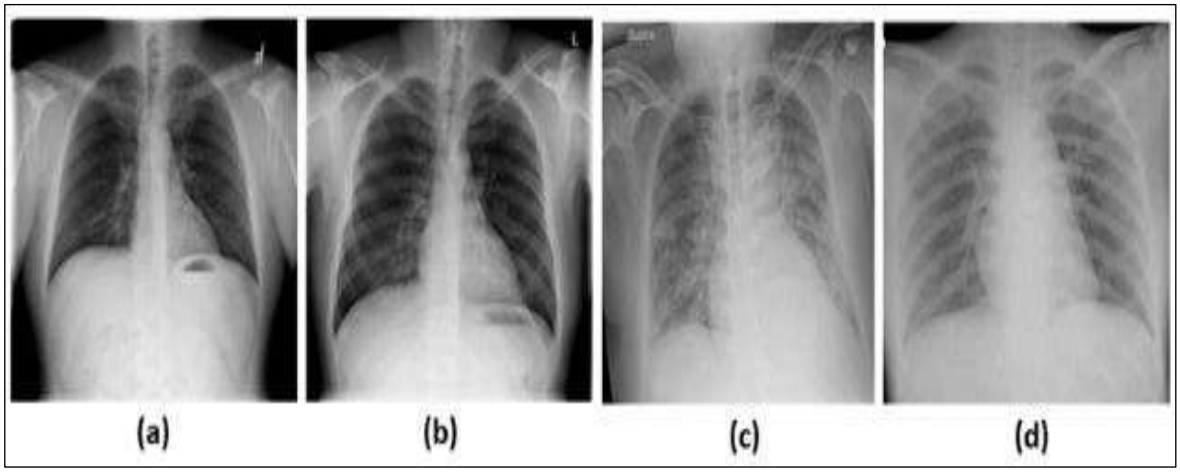

Figure 4: Normal chest x-ray (a,b) and COVID-19 chest X-ray (c, d).
Source: Authors, (2026).

Tables 2 through 6 show the accuracy of testing Aortic Enlargement, Cardiomegaly, and COVID-19 using different image sizes, 32x32, 75x75, 128x128, and 224x224, respectively. Figures 5 through 9 show the computation time for training CNN models with varying image data sizes. The larger the training data, the greater the time required for training. Tables 7 to 9 show the computation time for testing images. Table 7 presents the computation time for testing Aortic Enlargement with image sizes of 32x32, 75x75, 128x128, and 224x224. Tables 8 and 9 show the results of the computation time test for Aortic Enlargement, Cardiomegaly, and COVID-19, respectively.

The highest accuracy values for testing are obtained by the DenseNet201 model, as shown in Table 4. Using an image size of 180 x 180 results in the highest accuracy for the ResNet50 model, as shown in Table 5. Based on the Aortic Enlargement dataset test, the image size of 128 x 128 pixels using the Densenet201 model has the highest performance with an accuracy value of 0.965. The accuracy values on images measuring 224 x 224 pixels in all models are above 0.9. The InceptionV3 model has the lowest level of accuracy, as shown in Tables 2 through 6. The Cardiomegaly data has the highest accuracy value of 0.932 using the DenseNet169 model with an image size of 128 x 128 pixels. The DenseNet201 and Xception models show that the accuracy results from sizes 75 x 75, 128 x 128, and 180 x 180 have almost the same value.

DenseNet121, InceptionV3, and MobileNet models achieve the highest positioning accuracy with an image size of 180 x 180 pixels. However, the InceptionV3 model always produces the lowest accuracy compared to the other six models of the same size. The results of testing the COVID-19 dataset with the seven CNN models, using image sizes of 180 x 180 and 224 x 224, showed that each CNN model produced the highest accuracy values, with minimal differences of less than 0.005. When testing the COVID-19 dataset, it is highly suitable to use the CNN DenseNet169 model and the DenseNet201 model, as they can achieve high accuracy, especially when the desired image size exceeds 75 x 75.

III.1 THE CNN MODEL ON THE ACCURACY

In testing the Aortic Enlargement dataset with the ResNet50 model, the accuracy value is small compared to the MobileNet model. Although MobileNet has the fewest parameters compared to other CNN models, the accuracy value generated by depthwise separable convolution is always high when testing the entire dataset. InceptionV3 model testing performance always produces a very low accuracy value compared to other CNN models. When testing the Cardimegaly dataset, it was found that the predictions were incorrect, resulting in low accuracy rates of 0.78 and 0.79. In contrast to the Xception model, the number of parameters is slightly lower than that of InceptionV3, but the accuracy results are significantly better. The DenseNet201 model has more parameters than other DenseNets; however, its accuracy results are not always the highest compared to other DenseNets. Testing the DenseNet121 dataset with the fewest

parameters can produce the highest accuracy value compared to other DenseNet models. The three models with Dense Connection used in the test always produce higher accuracy than the other four models.

III.2 THE CNN MODEL ON TRAINING TIME

Next, the effect of differences in the CNN architecture model on training time will be determined. The test uses an X-ray image with a size of 224 x 224 pixels and does not perform augmentation techniques.

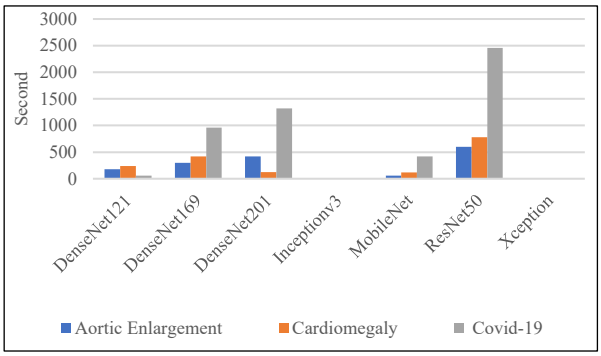

Figure 5: Computation times for training of CNN models using a 32x32 image size.
Source: Authors, (2026).

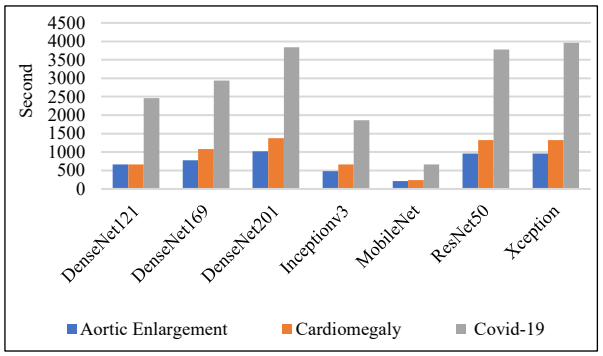

Figure 6: Computation times in seconds for training of CNN models using a 75x75.
Source: Authors, (2026).

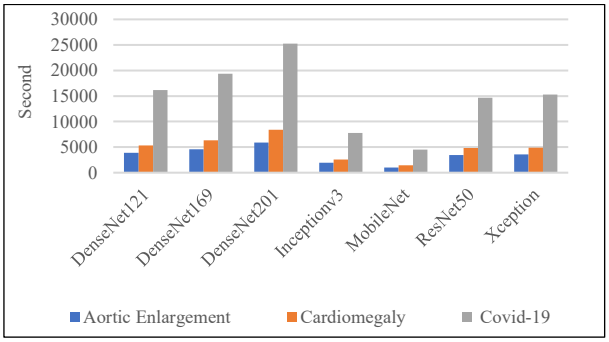

Figure 8: Computation times for training of CNN models using a 180x180 image size.
Source: Authors, (2026).

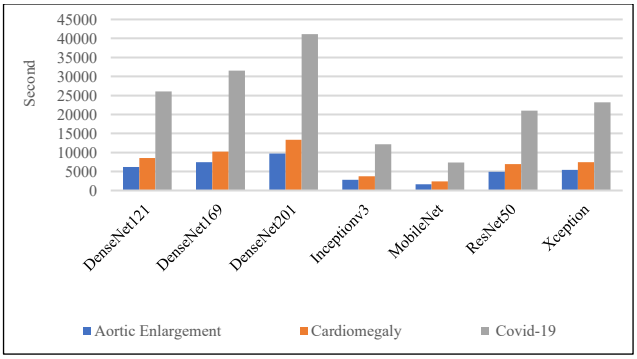

Figure 9: Computation times for training of CNN models using a 180x180 image size.
Source: Authors, (2026).

The dataset is divided into two based on the number of images: large and small. The large dataset comprises 2,061 images related to COVID-19. The small dataset consists of Aortic Enlargement (1,695 images) and Cardiomegaly (2,061 images). The two images above show the three models with dense connections, particularly the DenseNet201 model, which takes the longest to complete the training phase compared to the other models. The three Densenet models always occupy the same order according to their number of parameters, starting from DenseNet201.

III.3 DENSENET169 AND DENSENET121.

The ResNet50 and Xception models also have nearly the same training time, especially when testing datasets with a limited number of images, such as Aortic Enlargement, Cardiomegaly, and COVID-19. The two CNN models finished training with almost the same time, with a time difference of less than 9 minutes. The longest training time occurred in the COVID-19 dataset because it had the most extensive training data. The time required was 11 hours and 25 minutes using the DenseNet201 model. However, using the MobileNet model will take approximately 2 hours and 3 minutes.

III.4 THE CNN MODEL ON TEST TIME.

The influence of the CNN model on test time was analyzed using a graphical diagram with units of seconds. The test time analysis process will also be divided into two experiments: small dataset experiments and extensive dataset experiments. The test results show that the results are almost the same when calculating the training time with the DenseNet201 model, which takes the longest time to classify test data images. The MobileNet model is proven to be the fastest in completing the test step. Figures 8 and 9 show that the MobileNet and InceptionV3 models require nearly the same amount of time in the testing phase. Likewise, the Xception and ResNet50 models have almost the same testing time. After completing several tests, the research results are presented in Table 8. The model with dense connection architecture can produce high accuracy values in each dataset, especially the DenseNet201 model.

Table 7: Computation times in seconds for different sizes of the Aortic Enlargement.

Model CNN	32 x 32	75 x 75	128 x 128	180 x 180	224 x 224

Source: Authors, (2026).

The DenseNet201 model is suitable for building a CAD system that classifies X-ray photos precisely and accurately to detect six diseases in this research test. However, unlike other CNN models, the DenseNet201 model has a relatively high computational load, particularly in terms of training and testing times. The MobileNet model can be an alternative method when available resources are limited and speed in image classification is prioritized. The accuracy value is often higher than that generated by the InceptionV3, ResNet50, and Xception models. MobileNet can maximize the number of parameters while utilizing the Depthwise Separable Convolution architecture to produce high-accuracy values, all while maintaining a short computational time, including both training and testing times.

IV. CONCLUSION

Following the tests conducted in this study, the following conclusions are presented to classify X-ray images using the Convolutional Neural Network (CNN) method. The CNN model architecture used can affect the accuracy of the test results. The DenseNet201 model is most suitable for classifying normal and abnormal X-ray images, as it consistently produces the highest accuracy values in each test, specifically for Aortic Enlargement (95%), Cardiomegaly (91.8%), and COVID-19 (99.8%). The MobileNet model

requires the shortest training and testing time, especially on large datasets. MobileNet's training on the COVID-19 dataset took only 2 hours and 3 minutes, significantly faster than DenseNet201, which took 11 hours and 25 minutes.

Meanwhile, using the DenseNet201 model, the accuracy value differs by only 6%. The DenseNet201 model can be a suitable choice if available resources are limited, while maintaining high accuracy. Classification of X-ray images yields the most optimal accuracy value when using an image size of 224 x 224 pixels. However, the training will take a long time if the image size is larger.

ABSTRACT

A mental state, emotion is connected to human behaviour, thoughts, and the degree of positive or negative experiences. Human emotion does not yet have a precise definition. By allowing AI systems to precisely comprehend and sympathetically react to human emotions, this discovery has the potential to completely transform human-machine interaction and open the door for increasingly sophisticated and emotionally intelligent computers. The main research problem is creating models that accurately read emotions from multimodal data; this calls for big, diverse datasets for video data to capture complex emotional cues and fine-tuned CNNs for audio data to identify minor speech changes. This study introduces a novel multimodal emotion detection method that seamlessly combines voice and video modalities to correctly infer emotional states. The attention-based CNN-Bi-LSTM model handles the video component and provides deep semantic understanding through its bidirectional layers. An attention-based fusion process is used to blend the results of both modalities, balancing their respective contributions. Here, the suggested methodology is thoroughly tested using two different datasets: the YouTube and Carnegie Mellon University SAVEE datasets.The results show higher efficacy compared to current frameworks. This comprehensive technology enables accurate emotion recognition and contributes to a number of noteworthy developments in the industry.

I. INTRODUCTION

Numerous fields, including computer science, psychology, and neuroscience, have made considerable strides in their understanding of human emotion over the last 20 years. Human emotion is defined subjectively in the literature [1]. Human emotion is explained by both cognitive and physiological neuroscientific ideas (Figure 1). According to the physiological viewpoint, emotion originates from physiological reactions. The difference in physiological reaction could be due to the external incident. Emotions are linked to thoughts and other mental processes. People get scared when they see a snake, for example, since they think they are in danger [2]. Therefore, human emotion is defined as a feeling of pleasure or discontent that arises from a change in physiological and cognitive processes. A human emotion monitoring system is a crucial part of an effective human-computer interface. People interact with computers in many ways using desktops, laptops, mobile devices, kiosks, and other platforms. Computer agents with emotional intelligence will monitor user behavior.

It will sound a warning before the user can compose a hostile email, an angry comment, or any other negative response. It will also assist the user in selecting music based on their emotional state. An emotionally intelligent computer agent will assist the user in learning systems like pilot training, driving car learning, and others [3]. The emotion-aware agent monitors the driver's emotional state while they are operating a vehicle. It notifies other people when the driver is upset.

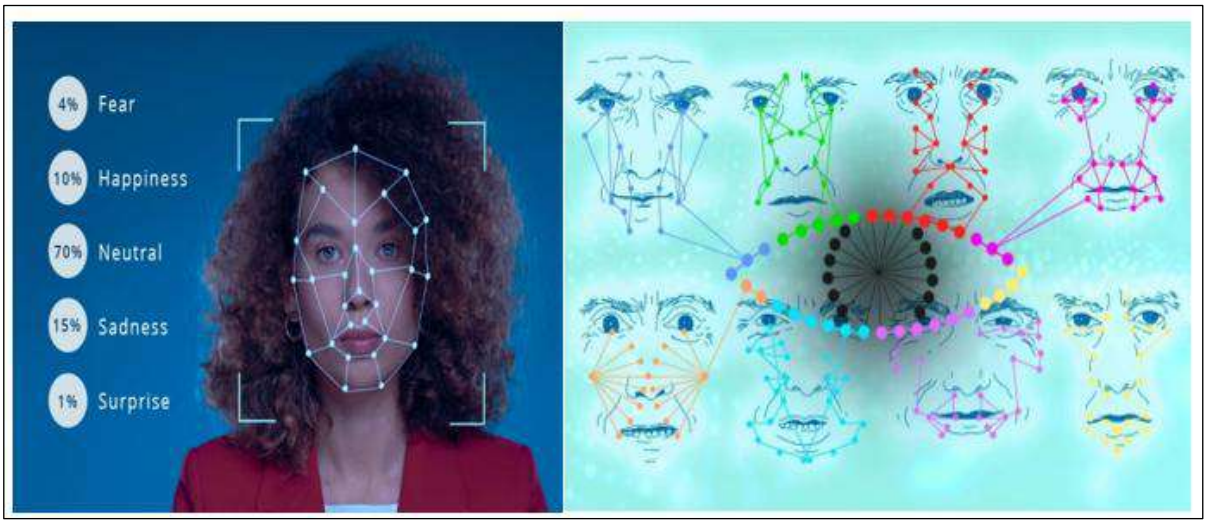

Figure 1: Emotion recognition by Software.
Source: Authors, (2026).

The emotion-aware agent thus attempts to safeguard the user. In affective computing, multimodal emotion recognition is a relatively new field of study. Physical, optical, and aural clues are all combined to create multimodal signals. The audio and video signals demonstrate how people express themselves through their voices and facial expressions when a particular emotion arises [4]. A particular emotion triggers physiological signs that indicate the body's symptoms, including heart rate, body temperature, breathing rate, muscle current, and brain electrical activity. Researchers are urged to develop a multimodal emotion identification system in order to differentiate between human emotions since multimodal emotion recognition is a key pattern recognition problem [5].

To more precisely ascertain people's moods, it combines data from their speech, body language, and facial expressions. In this study, we use human speech and facial expressions to recognize emotions in several ways. Here, the fusion process balances the audio and video contributions using an attention-based technique. It assigns ratings of attention, giving the most relevant modality priority according to the situation. We used an FC layer to standardize the feature dimensions for fair attention allocation [6]. To ensure thorough emotion analysis, the gathered features were subsequently run through a SoftMax layer to categorize the underlying emotion. The goals of the suggested projects are:

- Disclosed a novel multimodal emotion-detection technique that outperformed the accuracy of the industry standard models. Future research on emotion detection will be made easier by this innovative method;
- Textual input was efficiently encoded using a CNN-BILSTM-based model that had been previously trained;
- For a bimodal system that prioritizes audio and video, fuse the feature vectors, dynamically prioritizes modalities, and uses multistage processing to improve classification accuracy, an attention-based fusion method was used.
- Extensive experiments were conducted on two benchmark datasets, YouTube and SAVEE, and the results clearly showed how much better our technique is at recognizing emotions.

This is how the rest of the document is organized: While the survey's existing emotion detection scheme is presented in Section 2, An overview of the suggested architecture is given in Section 3. A comparison of the findings from the numerous papers that are part of this taxonomy is given in Section 4. Section 5 brings the process to a close.

II. LITERATURE REVIEW

As the most fundamental and natural form of human communication, emotions are important in daily life. The newest problem in affective computing and human-computer interaction (HCI) is emotion recognition [7]. Although a lot of study has been done in this area over the last 20 years, issues with accuracy and real-time analysis persist. Emotion recognition is useful in a wide range of fields, such as marketing, e-tutoring, security, medical diagnostics, and intelligent automotive systems. This survey will outline the areas that most need emotion detection in addition to analyzing the literature on human emotion identification from speech, facial photos, and brain signals [8]. According to [9] employed facial cues for facial features that CNN subsequently adopted in order to enhance performance.

To identify emotions, extracted the faces in key frames from the entry FACE and SAVEE databases using the Viola-Jones face recognition technique. According to [10] suggested a CNN for dynamic emotion recognition that uses fuzzy fusion in two stages. A two-step fuzzy fusion method was developed by fusing fuzzy broad learning with canonical correlation analysis. isual characteristics that were connected to the locations of the 2D marker coordinates were employed by [11]. Principal Component Analysis was then applied to the Gaussian Classifier. The impact of altering the characteristics and techniques on the eNTERFACE'05 database was examined by [12]. In the visual channel, face tracking and geometric elements for facial emotion identification were taken into consideration. Next, it was discussed how to classify using a multiclass SVM.

In order to extract high-dimensional Gabor coefficients from facial images and obtain detailed texture and structural information for facial feature extraction, by [13] used Gabor filters with five scales and eight orientations. In recent years, CNN has been used to extract facial features from still images of individuals. In order to determine which model would perform best for tasks like facial analysis, emotion identification, or pattern classification, Venkataraman et al. examined the performance of CNNs, DNNs, LSTMs, and HMMs. In [14] used a fuzzy ARTMAP Neural Network (FAMNN)-based SAVEE database to identify emotions. Retrieved facial expressions, Patterns of Oriented Edge Magnitude (POEM) features, and Local Phase Quantization (LPQ) features from the BAUM-1s database.

Livingstone et al. tested the Cohen's and Kappa values using the RAVDESS database. According to [15] employed the Hidden Markov Model (HMM) as the classifier model for the video series. According to [16] employed hybrid feature representation to recognize facial expressions from a photo frame. They combined different degrees of SIFT features from a CNN model with deep learning. For [17] proposed a feature extraction method for facial emotion recognition by fusing facial depth and facial texture. Facial expressions in still photos are recognized using LSTM, CNN, Alexnet, and other techniques. Furthermore, one of the most crucial methods for removing facial features from dynamic photos is 3D CNN. A CNN-CTS LSTM network and local enhanced motion history image-based video face expression identification system was proposed by [18].

According to [19] recovered the features for speech emotion identification using MFCC and relative special features. Pitch, intensity, the first four formants, and their band characteristics are among the 20 audio qualities that discovered. In order to extract speech components, by [20] employed an autocorrelation technique that splits the input voice signals according to shift intervals. To enhance the performance, by [21] coupled pitch and intensity with the first 13 MFCC elements. In conclusion, speech emotion components can be divided into three categories: spectral, prosody, and voice quality. Prosodic features include things like pitch period, speech rate, amplitude energy, and others; voice quality factors include things like formant frequency and glottis parameters. The term spectrum-based features refer to the linear predictor coefficient, or MFCC.

Based on prosodic characteristics, pitch frequency, MSPS, and MFCC were used in chapter 3; however, it was demonstrated that MFCC was superior in detecting emotions. A method called hybrid feature fusion blends characteristics from several modalities to increase the precision of sentiment analysis. Hybrid feature fusion is able to capture more subtle and detailed characteristics of sentiment than can be achieved with a single modality by combining data from multiple modalities. The currently used text sentiment analysis approaches are unable to handle uncertain assertions, such as reviews that exhibit bipolar behaviour. Automating sentiment recognition in natural language processing is far more challenging than it is for humans.

Instead of sending in their reviews in writing, end customers would want to provide audio snippets that express their thoughts. However, due of the massive feature dimensionality of the existing SER, the most difficult problem is the high computing cost. Because people frequently express their ideas on video, the reviewer's facial expression is considered a critical indication for sentiment analysis. These days, managing the generated features from several modalities requires multimodal systems to employ strong feature optimization and feature fusion approaches. Among the drawbacks of the earlier models are weak convergence and a clear tendency to become caught in local optima.

III. MATERIALS AND METHODS

One of the newest technologies is emotional recognition, which has been used in the medical field to determine a patient's emotion for treatment in recent years. Many technologies now include facial recognition technology into their apps to enable efficient connection with people. Because it makes human interactions more realistic, fields have been focusing on integrating these systems' capacity to modify their reactions and behavior based on human emotions. Facial expressions, body motions, and machine learning applications are the main methods used in computer science for emotional recognition [22]. The study's emotional recognition technology has been enhanced by the hybrid model, which blends the Attention-Guided CNN-Bi-LSTM models (Figure 2).

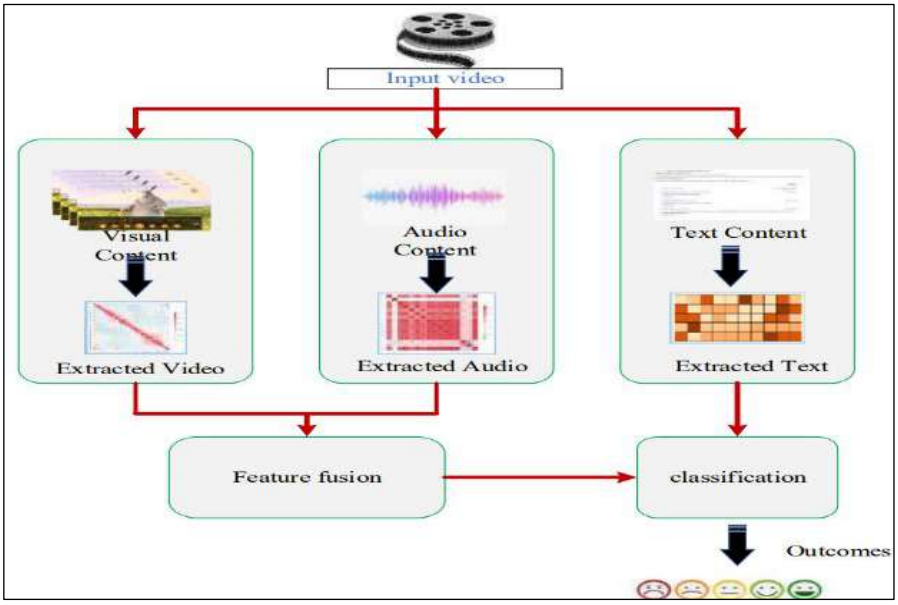

Figure 2: Proposed work.
Source: Authors, (2026).

III.1 DATASET

The SAVEE and YouTube datasets are used in the experiment utilizing the suggested methodology. There are 47 video clips in the YouTube collection, which includes product evaluations and political commentary. Of these datasets, twenty contain movies with female speakers, whereas the other 27 contain videos with male speakers (Morency et al., 2011). The speakers range in age from 14 to 60. Each video sample lasts two to five minutes and contains 360480 Mp4 pixels. Four male artists' 480 words from the SAVEE dataset represent a range of emotions. The visual media lab used state-of-the-art audiovisual technologies to construct the audio files in the SAVEE dataset [23]. Figure 3 shows sample frames from the SAVEE and YouTube datasets.

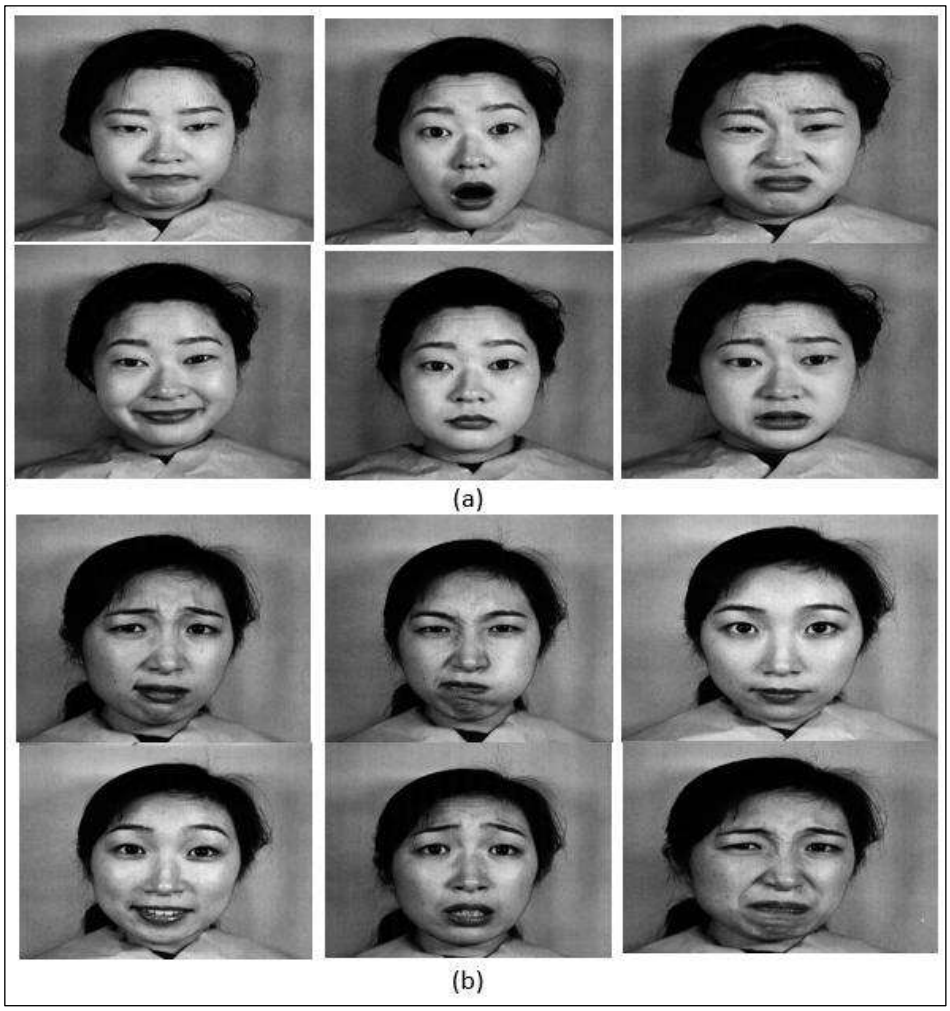

Figure 3: Sample Information from the YouTube and SAVEE datasets.
Source; Authors, (2026).

III.2 PRE-PROCESSING

Facial expression and emotion recognition are critical components of applications that must assess veracity, detect fraud, and gauge credibility. Unfortunately, most studies demonstrate little accuracy in recognizing emotions, mostly due to low-quality pictures. The application of artificial intelligence, especially deep learning techniques, and significant pre-processing are increasing the accuracy of computational predictions [24]. In order to identify emotions, our work blends deep learning techniques with preprocessing exercises. Our method aims to increase the accuracy of emotion recognition by comparing and using four deep learning models for image pre-processing [25]. The illumination and reflectance of the object or objects in the scene are multiplied to determine the intensity at any pixel in a picture, or the amount of light reflected by a point on the object.

$$I(x,y) = L(x,y) * R(x,y) \tag{1}$$

Where I, L, and R stand for the image, scene illumination, and scene reflectance, respectively. In order to convert the multiplicative components into additive components, this filtering technique moves to the log domain employing,

$$lnI(x,y) = ln(L(x,y)R(x,y)) \tag{2}$$

$$lnI(x,y) = ln(L(x,y) + R(x,y)) \tag{3}$$

In the log domain, the high-frequency reflectance component is preserved while the low-frequency light component is removed using a high-pass filter.

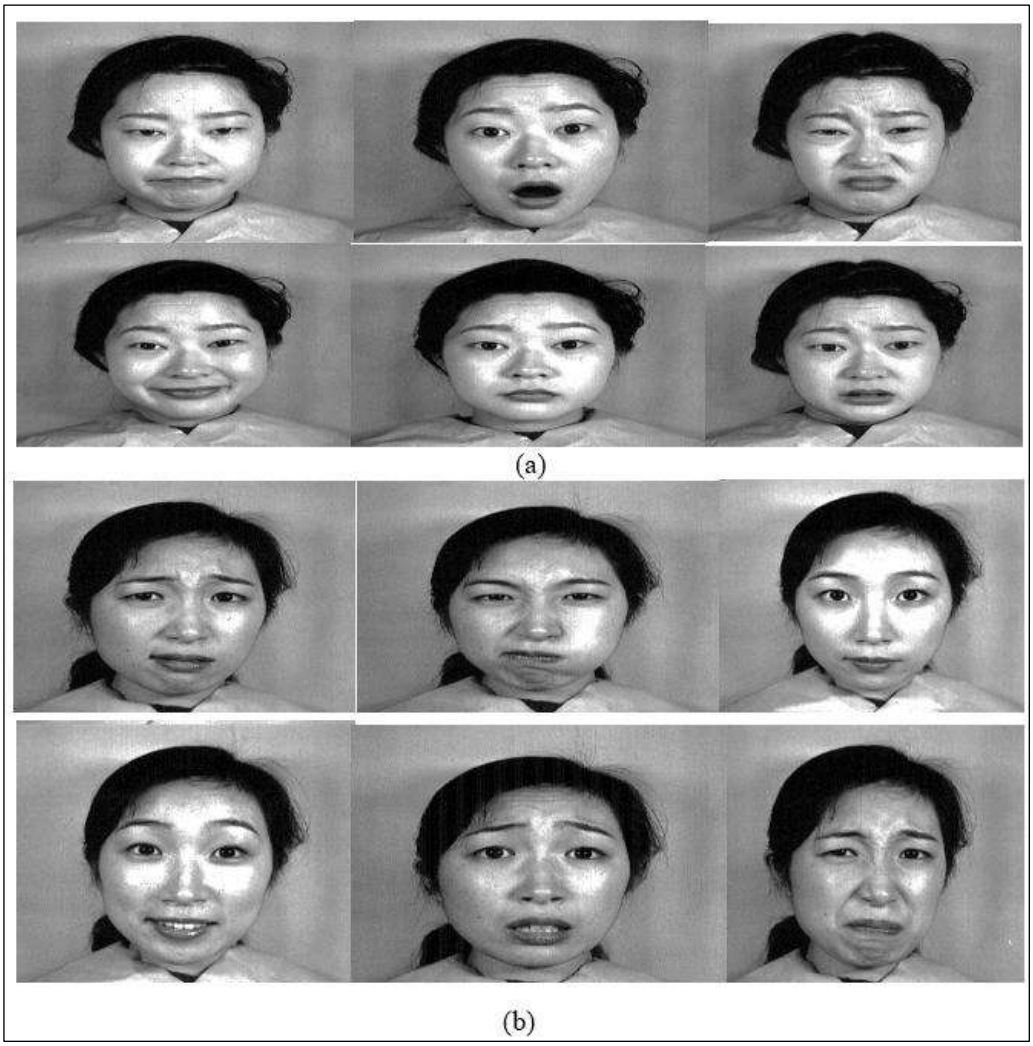

Figure 4: Pre-processing results.
Source; Authors, (2026).

A common method for handling nonuniform illumination in figure 4 is homomorphic filtering, a frequency domain filtering technique that enhances contrast from the object's reflecting qualities while compressing brightness from lighting circumstances.

III.3 FUTURE EXTRACTION AND FEATURE FUSION

The facial traits are extracted using a geometric feature-based approach by locating the characteristic feature points on the cropped face pictures. These attributes can be extracted manually or automatically using AAM tools [26]. A technique for equitably distributing gains or profits among several participants according to each person's unique contribution to the final result is the Shapley value. This idea, which comes from cooperative game theory, guarantees a fair and just distribution. The Shapley value is defined as follows:

$$\emptyset(x_i) = \Sigma_{s\subseteq\{1,2,\ldots,k\}\backslash\{i\}} \frac{|S|!(K-|S|-1)!}{K!} [f_x S\cup\{i\}) - f_x(S)], \quad (4)$$

Where K stands for the total number of participants. Equation (2)'s bracket section demonstrates that the entity's contribution can be characterized as a marginal contribution, or the difference between the group-S members' profit (f_x(S)) and the group members' and entity-i's profit: $[f_x S\cup\{i\})$. Friedman's gain is based on the same principle, but it can be altered by group members, which leads to inconsistencies. The Shapley value, which is then determined once more for each possible combination, is the average of the marginal contributions of all possible combinations. Only the Shapley value approach to profit allocation satisfies the four requirements of linearity, symmetry, efficiency, and null player. Utilizing the concept of the Shapley value, the SHapley Additive exPlanation (SHAP) illustrates the patient's outcome-j: $f(x^{(i)}$ as the sum of each features-i's contribution $\emptyset_i(x_i^{(j)})$.

$$\emptyset_0 = \frac{1}{N} \sum_{j=1}^{N} f(x^{(i)}) \quad (5)$$

$$\emptyset_i(x_i^{(j)}) = \emptyset(x_i^{(j)}) - \frac{1}{N}\sum_{K=1}^{N}\emptyset(x_i^{(K)}) \quad (6)$$

$$f(x^{(i)} = \emptyset_0 + \sum_{i=1}^{K}\emptyset_i\,(x_i^{(j)}) \quad (7)$$

Where N is the number of patients. We derived $\forall i, E(\emptyset(x_i)) = \frac{I}{N}\sum_{j=1}^{N}\emptyset_i(x_i^{(j)}) = 0$ from Eq. (7). The relationship between a feature x_i and SHAP value in GLM $\emptyset_{GLM}$ is given as follows [8]:

$$\emptyset_{GLM}(x_i^{(j)}) = a_i x_i^{(j)} - E(a_i x_i) = a_i x_i^{(j)}\, a_i E(x_i) \quad (8)$$

Feature x_i has a proportional relation with its SHAP value and the proportionality factor is given by coefficient a_i . This result is consistent with how GLM is currently interpreted. A SHAP dependence graphic illustrates the relationship between the characteristic and its impact on the SHAP-measured result. The logistic regression model converts SHAP values to log-odds for binary prediction. The linear relationship provided by Equation (6) is displayed in the SHAP dependence graphic for GLM.

$$IMP(X_i) = Var(\emptyset(x_i)) = \frac{1}{N}\sum_{j=1}^{N}[\,\emptyset(x_i^{(j)}) - E(\emptyset(x_i))]^2 \quad (9)$$

$$= \frac{1}{N}\sum_{j=1}^{N}[\,\emptyset(x_i^{(j)})]^2 - \{E(\emptyset(x_i))\}^2 \quad (10)$$

$$= \frac{1}{N}\sum_{j=1}^{N}[\emptyset(x_i^{(j)})]^2 \quad (11)$$

When all attributes are normalized, the variable significance of GLM in Eq. (11), using our idea, is as follows:

$$IMP_{GLM}(X_i) = \frac{1}{N}\sum_{j=1}^{N}[a_i\, x_i^{(j)} - a_i E(x_i)]^2 \quad (12)$$

$$= \frac{a_i^2}{N}\sum_{j=1}^{N}[x_i^{(j)} - E(x_i)]^2 \quad (13)$$

$$= |a_i|^2 .Var(x_i) = |\beta_i|^2 \quad (14)$$

Both the feature importance concept and the ranking based on absolute beta coefficients ($|\beta_i|$) are in line with your definition and the feature packing method that follows. This implies a unified method for prioritizing and evaluating features.

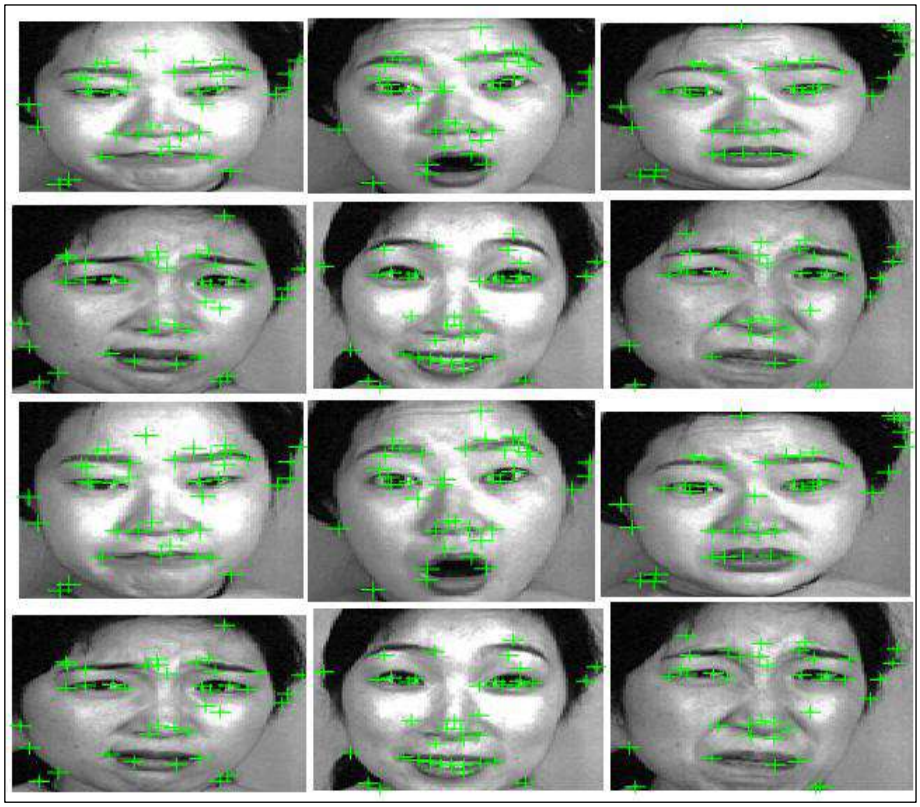

Figure 5: 39 feature points extracted.
Source: Authors, (2026).

The areas of the face with the most noticeable expressions, like the lips, nose, eyes, and eyebrows, contain 39 feature points, as shown in Figure 5. The quantity and location of the feature points are changed from. The locations of these feature points formed the feature vector. The feature vector recovered has 78 dimensions since 39 feature points are marked, and each feature point contains "x" and "y" coordinates. Because linked factors can complicate interpretation, it is usual practice to eliminate them from the data and build the predictor instead. However, this approach may result in greater reconstructive computation time and a poorer forecast accuracy. Therefore, without having to construct the predictor, we wish to combine these variables into a single grouped variable. Furthermore, feature packing has no impact whatsoever on prediction accuracy and does not necessitate model rebuilding. Therefore, packing qualities with many variables or similar interpretations is a highly helpful strategy.

III.4 CLASSIFICATION

The classification is done using the NN classifier, which is trained using the feature vectors of all emotions for the frontal position only. Following the mapping from a non-frontal posture to a frontal pose in the pose normalization stage using MSVR, the output $a*$ feature vector contains the position of the non-frontal pose's feature points onto the frontal pose. This is then input into NN, which classifies the emotion according on its label. If the head position estimation output is frontal posture, the feature vector is provided directly to the classifier without going through MSVR. To improve the emotion classification model's performance, the most pertinent audio clips and the features taken from the peak facial expression frame are combined [27].

The early feature level fusion is performed by concatenating the retrieved face action units of the peak visual frame with the most relevant audio segment characteristics. Fi is the length of the fused feature vector, where i = 1, 2..., n, and n = 1871. It has 1759 characteristics to describe the facial expressions of peak frames and 112 audio features (GTCCs features along their first and second order derivatives, spectral and time domain features). To prevent overfitting, the early halting technique was applied. The model's weights were changed if the validation loss was less than any minimal loss that had been documented before. When the training process was complete, the best model was ultimately retained.

III.4.1 Cnn-Bi-Lstm

In spectrograms, emotional expressions can occasionally appear as unique energy patterns, especially in auditory media like speech. These patterns can be identified using spectrogram analysis because they have unique energy distributions across a range of frequencies. Particularly effective at emphasizing data points with sudden changes or high energy levels are convolutional neural networks (CNNs). Given that CNNs are adept at recording emotions that emerge rapidly and intensely, this property is helpful for emotion analysis. In circumstances where emotions may abruptly surge or fall, this targeted analysis ensures a comprehensive awareness of the emotional environment and helps the model distinguish between strong and subtle emotional cues.

This method is very good at revealing little features in the frequency and temporal domains. With artificial neurons that can respond to a selection of neighbouring units, CNNs are one kind of feedforward neural network. It works best when processing images on a large scale. Utilized CNNs to identify handwritten numbers in the past century, but the restricted processing capacity of computers prevented them from being widely deployed. The benefits of CNNs have gradually become clear, though, and deep neural network training has gotten easier as processing power keeps increasing. As previously said, convolutional, pooling, and fully connected layers make up a CNN's network topology. Extracting local attributes from the input data is the primary function of the convolutional layer.

It is distinguished by weight sharing and sparse connection. In order to reduce the computational load and dimensionality of the feature maps while maintaining crucial feature information, the pooling layer is typically positioned after the convolutional layer. The fully connected layer aggregates the features extracted by the convolutional and pooling layers, applies linear transformations through weights and biases, and then performs nonlinear transformations by passing them through an activation function to produce. These functions have the benefits of minimizing overfitting and preventing gradient vanishing. The equation represents the function of ReLU.

$$Y = max(0, x) \tag{15}$$

The gradient is 0 for negative values even if the gradient-vanishing problem is fixed by the ReLU function, which could leave some neurons untrained and reduce the expressive power of the network. Leaky ReLU was created by Maas et al. to solve this issue. It smoothes and expresses the activation function by employing a modest slope for negative inputs rather than ReLU's zero slope. It has therefore been widely used in practical contexts. Equation (16) gives the definition of Leaky ReLU:

$$y = \begin{cases} x, & x \geq 0 \\ ax, & x < 0 \end{cases} \tag{16}$$

The linear classifier is often used in the traditional method to perform one layer of an operation; for example, SVM has only one weight set (Equation 2). CNN and other deep learning algorithms, however, carry out multiple levels of operation during classification. CNN's input is a two-dimensional array.

$$S = W \times x_i + b \tag{17}$$

Where b is bias, W is the weight matrix, and S is the classification score.

LSTM-based models are ideal for working with time series data, including audio data, because they are made to handle variable-length sequence data. Sequence data is handled sequentially by LSTM and concurrently backwards and forwards by Bi-LSTM. Bi-LSTM can therefore effectively evaluate both historical and prospective data simultaneously. This could lead to increased accuracy in pattern detection.

The Transformer model's attention mechanism weights various data points to draw attention to important features of the incoming data. This method is effective for recognizing emotions since certain speech patterns may be more important than others. Multi-head attention is utilized to capture more information than single-head focus.

$$z = \frac{x - \mu}{\sigma} \tag{18}$$

The forget gate layer's equation is provided as,

$$f_t = \sigma(W_f[h_{t-1}, x_t], b_f \tag{19}$$

The input gate layer comes next, where the additional features are used to retrain the recall state data.

$$i_t = \sigma(W_f[h_{t-1}, x_t], b_i \tag{20}$$

The output of the forget gate layer is multiplied by the cell state vector of the preceding LSTM cell (c_{t-1}). After being multiplied by the hidden state vector of the stage, the input gate layer's output is combined with the outcome of a "tanh" function. Together, they produce the cell state vector for the next LSTM cell.

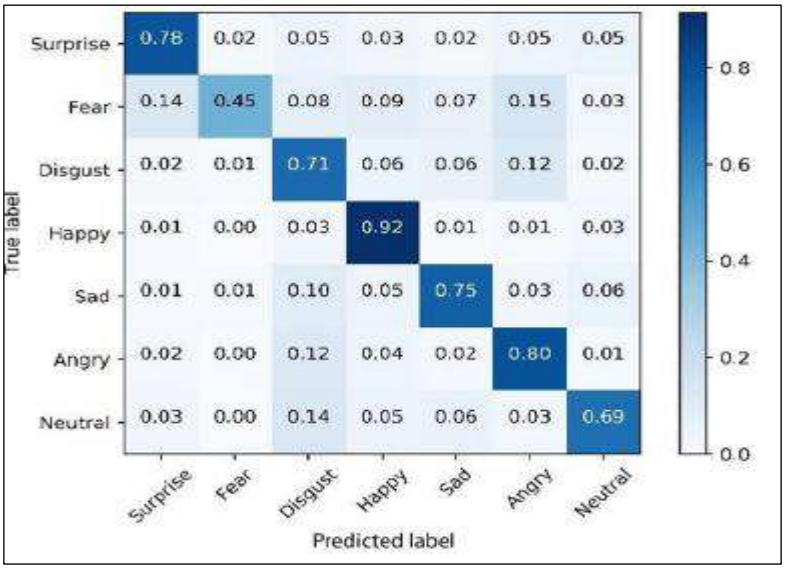

Figure 6: Confusion matrix results.
Source: Authors, (2026).

The prior concealed state vector is then multiplied by this new cell state following its passage via a "tanh" function (h_{t-1}). Our suggested model's whole architecture is depicted by

$$y = W_d X_t + B_d \tag{21}$$

Where,
y = output of the output layer, which is the target image's face emotion
X_t = the CNN-Bi LSTM model-learned vector
W_d B_d = bias and weight of the CNN-Bi LSTM model

Equation (28) defines the output or dense layer to which the fixed or variable length vector representation as the Bi-LSTM's output is fed in order to classify facial images into the different emotion classes of happy, sad, angry, disgusted, neutral, fear, and surprise. The multi-head attention mechanism can simultaneously identify many important patterns or qualities by employing numerous "heads" to calculate attention from different data viewpoints (Figure 6). Furthermore, the transformer structure makes parallel processing possible, which speeds up learning and simplifies the management of massive volumes of data. The combination of these two architectures enables the model to concurrently take into account a large number of patterns and characteristics in audio data since the transformer is skilled at learning the intricate hierarchical structures of data and the Bi-LSTM is good at identifying the temporal qualities of audio data.

IV. RESULT AND DISCUSSION

The CNN-Bi-LSTM model was implemented using TensorFlow and the Anaconda platform. An NVIDIA GTX 1650 Ti graphics card, 16 GB of RAM, and an Intel i7-10750H 2.6 GHz processor were used for the training and validation procedures. The CNN-Bi-LSTM model was trained using a batch size of two and a learning rate of 0.00005 through trial and error throughout the training phase. 168 of the 210 video examples are used for CNN-Bi-LSTM training, and 42 are validated using 5-fold cross validation.

Table 1: Proposed Model Performance Evaluation for YouTube Dataset.

Modality	Accuracy (%)	Sensitivity (%)	Specificity (%)	F-score (%)	MCC (%)
Audio	85.80	94.33	81.04	85.65	79.15
Text	93.25	94.30	96.52	91.42	90.75
Video	93.15	93.53	95.56	92.91	91.81
Video & Text	91.96	92.53	92.53	90.93	89.26
Audio & Text	93.16	95.54	91.96	90.39	85.71
Video & Audio	94.34	95.74	92.20	90.04	91.60
All Modalities	97.70	95.53	98.19	95.65	94.97

Source: Authors, (2026).

The CNN-Bi-LSTM model's effectiveness is assessed using a variety of modalities in Table 1. To provide the best fusion analysis results, the proposed model combines text, visual, and auditory modalities based on the observation. The YouTube dataset produces findings that are more closely related to both combined and individual sequences, with the best. Figure 7 displays the various modalities' performance on the YouTube dataset.

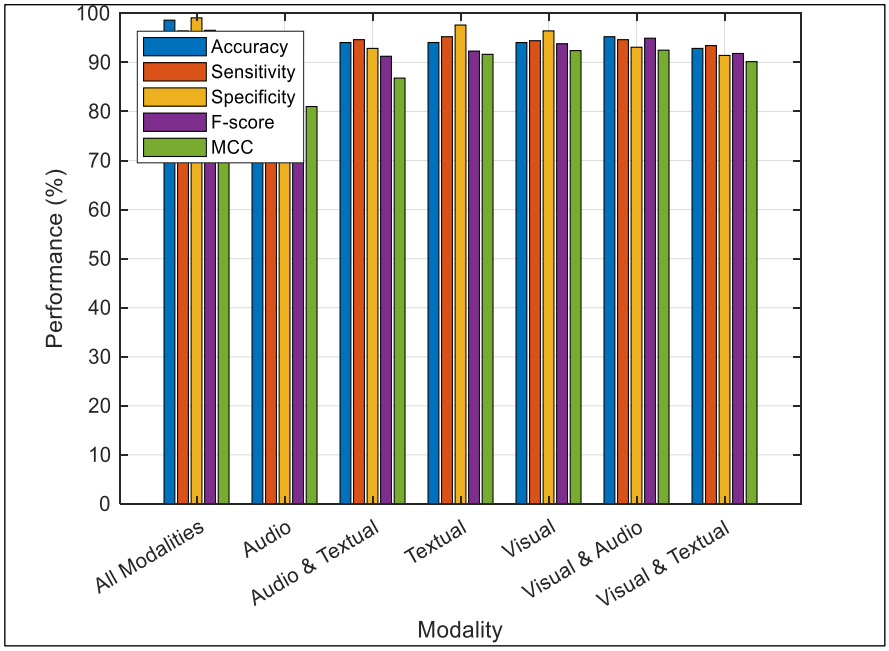

Figure 7: SHAP features Performance Measures on YouTube Dataset.
Source: Authors, (2026).

Furthermore, all three modalities are used to assess the proposed SHAP technique on the SAVEE dataset in MSA. The performance of all combined modalities on the SAVEE dataset is shown in Table 2.

Table 2: Performance Evaluation based on SAVEE Dataset.

Modality	Accuracy (%)	Sensitivity (%)	Specificity (%)	F-score (%)	MCC (%)
Audio	84.81	89.51	92.51	92.58	91.10
Textual	93.71	99.51	98.00	97.05	96.54
Visual	95.54	97.43	96.20	91.50	90.32
Visual & Textual	90.19	89.51	84.23	87.86	86.01
Audio & Textual	90.77	96.04	92.57	84.18	81.32
Visual & Audio	93.16	96.23	88.40	91.76	91.03
All Modalities	99.71	97.91	98.23	100.00	98.60

Source: Authors, (2026).

Combining the modalities according to MCC (99.71%), F-score (97.91%), Specificity (98.23%), Sensitivity (100%), and Accuracy (98.60%) yields the optimal response. Figure 8 displays the performance of the different modalities on the SAVEE dataset. To fuse all modalities using feature level fusion, the feature vectors from each modality are collected and used as the input for the classification phase. The integration of heterogeneous feature vectors, or feature level fusion, is the issue that the model that is currently being described attempts to solve.

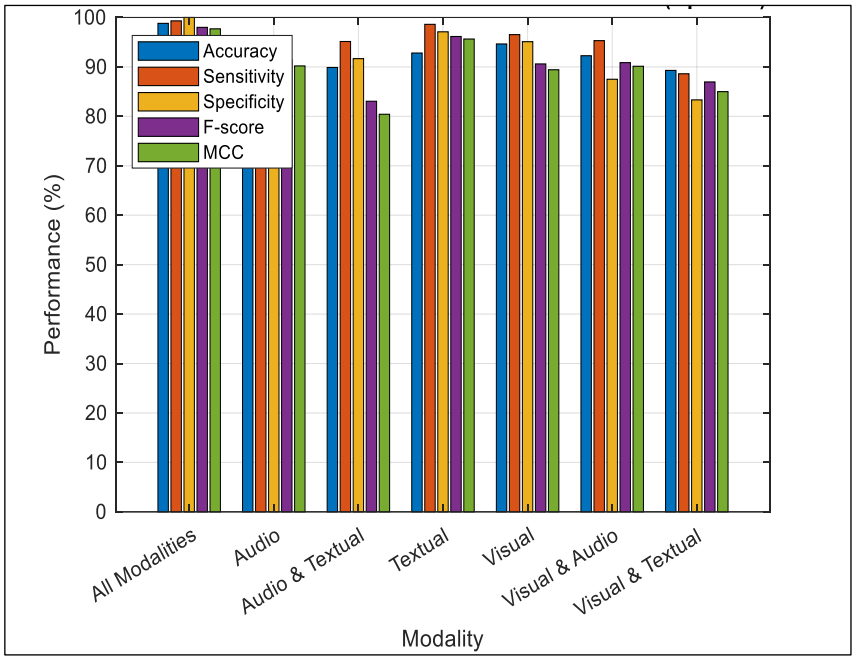

Figure 8: SAVEE Dataset Performance Measures.
Source: Authors, (2026).

Figure 9's output graphic breaks down high-dimensional feature vectors into two halves so you can see how similar two photos are to one another. More distant points imply larger differences, while closer points show comparable feature patterns. Understanding feature distribution, identifying outliers, and getting ready for tasks like clustering or classification are all made easier with the help of this visualization.

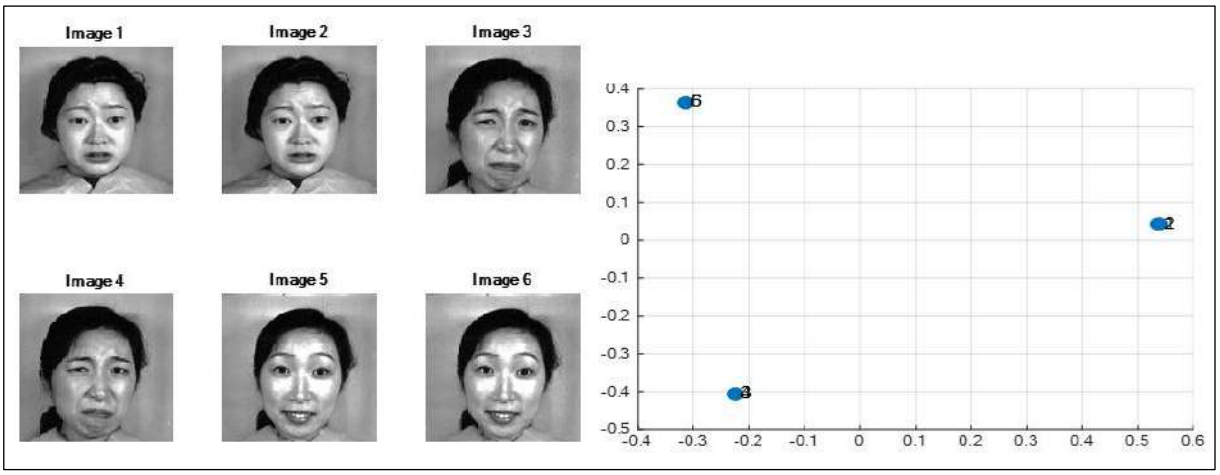

Figure 9: Feature fusion.
Source: Authors, (2026).

Following the collection of various features, the judicial feature standards were chosen using the relief strategy and subsequently submitted to the CNN-Bi-LSTM algorithm. Because the CNN-Bi-LSTM model uses a bi-directional long- and short-term memory neural network, it performs worse than the CNN-LSTM model in every temporal data processing error.

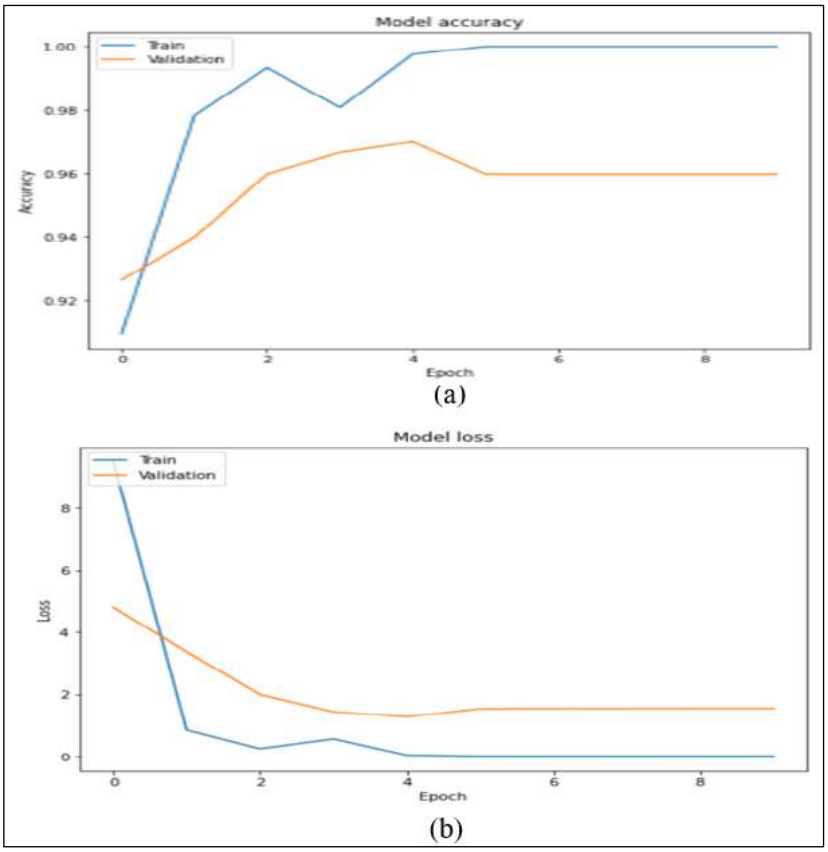

Figure 10: CNN-Bi-LSTM Accuracy and Loss plot.
Source: Authors, (2026).

First, of the four models, the CNN and LSTM models have the lowest prediction accuracies and the shortest average calculation time due to their comparatively simple architectures. Out of the six models, the enhanced CNN-Bi-LSTM-attention model has the lowest prediction error and the highest prediction accuracy (Figure 10). The CNN-Bi-LSTM-attention model has a more potent temporal data-processing capability than the CNN-Bi-LSTM model because it incorporates an attention mechanism that can handle some temporal features that the network missed and weigh the channels, allowing the model to focus on important temporal features. It can produce forecast accuracy with the least amount of error and has a high degree of generalizability (Table 3). CNN-LSTM-attention has a greater total error and a lower prediction accuracy because it cannot handle time-series data in both directions and cannot extract enough long-term features (Figure 11).

Table 3: Proposed dataset Comparative Analysis.

Metric	YouTube Dataset	SAVEE Dataset
Accuracy	98.60	98.20
Sensitivity	97.74	98.74
Specificity	97.14	97.14
Precision	96.77	97.77
NPV	98.33	99.33
FPR	2.86	2.86
FNR	5.26	5.26
F1 Score	95.74	95.74
MCC	91.99	91.99
Balanced Accuracy	98.94	98.94
Youden's Index	0.92	0.92

Source: Authors, (2026).

The CNN-Bi-LSTM hybrid model's ability to identify emotions is seen in Table 4.8, which compares classification models on two datasets. For better emotion recognition, this combined strategy makes use of the advantages of CNNs (feature extraction) and Bi-LSTMs (sequence modelling). The CNN-Bi-LSTM model showed enhanced sensitivity and accuracy on the YouTube dataset and SAVEE, which were utilized to assess its performance. The relief-random forest model is more accurate (94%) and sensitive (91%), as shown in Table 4.8. The YouTube data's sensitivity.

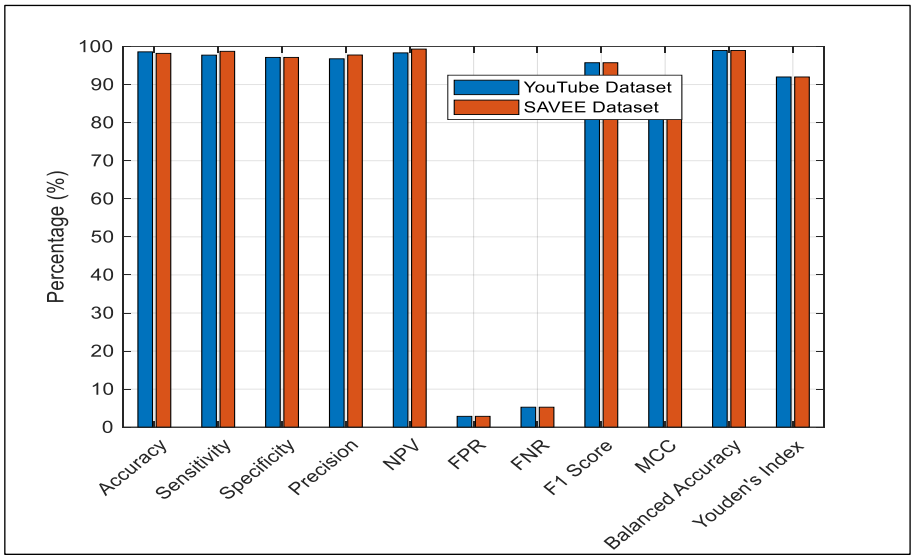

Figure 11: Proposed dataset Comparative Analysis.
Source: Authors, (2026).

The CNN and LSTM models have the fastest calculation times when it comes to model computational efficiency. They are the least precise, nevertheless, and have the worst computational error. The CNN-LSTM model has the second-highest computation time after the CNN and LSTM models because to its comparatively simple structure. The CNN-Bi-LSTM-attention model performs better than the CNN-Bi-LSTM-attention and CNN-LSTM-attention models in terms of computational efficiency and model prediction accuracy.

Table 4: Proposed dataset Comparative Analysis.

Models	Dataset	Accuracy (%)	Sensitivity (%)
MKL-CNN [28]	YouTube	88.60	87.36
INCA-SoftMax Classifier [29]	SAVEE	95	81
Relief-random Forest [30]	YouTube	94.01	91
CNN-Bi-LSTM model	**YouTube**	**98.60**	**97.74**
	SAVEE	**98.20**	**98.74**

Source: Authors, (2026).

Out of the six models tested, the CNN-Bi-LSTM-attention model performed the best, achieving the highest prediction accuracy and the lowest prediction error for both inbound and outbound predictions.

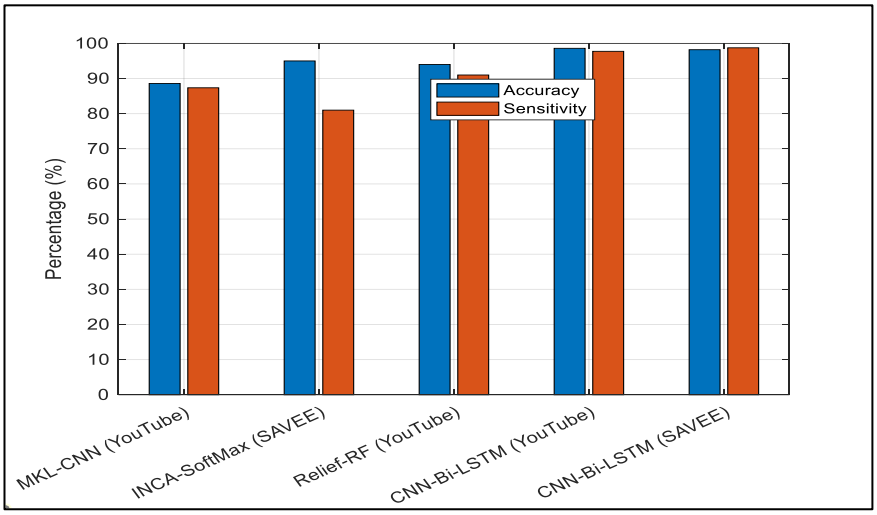

Figure 12: Proposed and Existing Methods Comparative Analysis.
Source: Authors, (2026).

Figure 12 and Table 4 demonstrate the great prediction efficiency of the CNN-Bi-LSTM-attention model. The accuracy of the departing and arriving inventory prediction is higher than that of the other models. Therefore, out of all the models currently in use for emotion recognition and experimental data, the CNN-Bi-LSTM-attention model is the most successful.

V. CONCLUSION

In order to create a reliable and effective emotion detection system, this study investigated a multimodal strategy that integrated text, speech, and video data. By utilizing a variety of emotional cues, it may be possible to increase accuracy and dependability. A comprehensive analysis of multimodal inputs is made possible by the architecture's integration of CNNs (for audio) and CNN-Bi-LSTM (for video), which effectively recognizes emotions by identifying subtle patterns in both audio and visual data. Future studies should concentrate on refining the model to lower processing requirements, enabling real-time processing, and guaranteeing deploy ability on devices with constrained computing capability in order to overcome the constraints of our multimodal emotion-recognition system and enhance its capabilities. Creating CNN-Bi-LSTM versions and distilling models are two techniques that could maintain good accuracy while consuming fewer resources.

Other modalities, such facial expressions and physiological clues, can also be used to improve the ability to identify emotions. This expansion would require the development of SHAP-based fusion techniques that can handle the diversity and complexity of data from several sources. It is essential to lessen dependence on huge annotated datasets. Methods such as few-shot learning, transfer learning, and synthetic data generation can increase robustness, boost data efficiency, and allow for efficient use in scenarios with limited data. As a result, this work provides a variety of potential avenues for further research. To make the system viable for real-time applications, more research is therefore required to create lightweight architectures or use model quantization and pruning strategies. Furthermore, by taking cultural differences in emotional manifestations into consideration, we hope to create broadly applicable models.

ABSTRACT

Cloud computing is a computer paradigm that delivers IT resources as services, such as platforms, apps, and infrastructure, via the Internet. The cloud Computing offers the infrastructure needed to process and compute any kind of data resource, and it is used to handle massive volumes of data. Large, well-known businesses have moved their processing and storage to cloud computing in recent years. Businesses and organizations may lower their infrastructure costs by utilizing cloud computing. Businesses can test their apps faster, more effectively, and with less maintenance. Cloud computing enables the IT team to adjust resources to fluctuating and changing requirements. Allocating resources in cloud computing is intrinsically difficult since more and more people are using various cloud apps in some infrastructure. The majority of resource allocation solutions now in use focus on performance, which is impacted by the volume of applications from scientific and business domains. This article presents an analysis of meta-heuristic approaches for resource allocation in cloud computing systems. When allocating resources in the cloud, the examined meta-heuristic algorithms can achieve much better performance, lower costs, shorter turnaround times, better resource usage, and increased energy efficiency.This study compares several scheduling algorithms for cloud and grid systems using three well-known metaheuristic approaches: Particle Swarm Optimization (PSO), Genetic Algorithm (GA), and Ant Colony Optimization (ACO).

I. INTRODUCTION

A group of advanced on-demand computing services that were first made available by for-profit companies like Amazon, Google, and Microsoft are collectively referred to as cloud computing. It refers to a paradigm wherein a computing infrastructure is perceived as a cloud from which people and companies may readily access applications from any location in the world [1].To lower energy expenses and provide end-user assistance through negotiated quality of service (QoS), which is created in the form of Service Level Agreements (SLA), the resource pool must be professionally controlled.Three primary cloud models are available: Platform as a Service (PaaS), Software as a Service (SaaS), and Infrastructure as a Service (IaaS). These are the three main ways that services are frequently supplied [2]. A single physical computer may run many programs thanks to the resources' high heterogeneity and virtualization.

When necessary, an appropriate physical system is used to instantiate the user programs, but they are confined to a virtual machine. It is debatable if the apps' requirements for CPU, memory, processing speed, network bandwidth, and reaction time are reasonable. Based on client demand, resources are combined and made accessible.Cloud companies like Flexiant, Microsoft, Amazon, Google, Gogidi, and Others constructed several data centers to accommodate the resource requirements of a huge number of users [3]. Cloud data centers have numerous advantages, but they can have drawbacks, such as high-power usage [4]. Each of the many resources in these data centers has a corresponding power usage. The ability to execute HPC applications on cloud infrastructures has increased the popularity of cloud computing [5]. The resource allocation strategy is utilized to ensure that all application requirements are fulfilled. For all of these reasons, one of the maingoal in a cloud computing system is resource allocation.

In addition, industry and researchers are concerned about lowering energy usage and carbon footprints, as well as providing user applications with adequate resources to meet quality of service (QoS). Energy usage and resource use are strongly linked.Furthermore, for green manufacturing, energy usage during machine operations and idle time should be considered [6]. In the construction industry, the severity of falls from height is even more alarming: 65% of accidents involve this type of occurrence, and more than half result in death [5].

In Rio Grande do Sul, the scenario is equally concerning. In 2023, 384 work-related deaths were recorded, representing a 35% increase compared to 2022. Among these cases, 320 were typical accidents, 63 were commuting accidents, and 1 was due to occupational illness. It is noteworthy that workers with precarious employment relationships—such as self-employed and unregistered workers—accounted for 50.01% of fatal typical accidents, with self-employed individuals representing 38.13% of occurrences [6].

I.1 FOUR TYPES OF CLOUD

1. **Public Cloud** - Public users can access and utilize the public cloud. The third-party organization that owns and operates it offers internet-based services to customers who only pay for the services they utilize. Nonetheless, public cloud settings are frequently more vulnerable to security flaws and intrusions [7].
2. **Private Cloud** - A private cloud is used only by one company. Because the business manages the infrastructure and data directly, it offers better control and increased security whether it is hosted on-site or by an outside supplier.
3. **Hybrid Cloud**: A hybrid cloud uses standardized technologies to combine private and public cloud infrastructures. Businesses may reroute excess traffic to the public cloud using this integrated approach's flexibility and scalability to preserve service availability and avoid disruptions.
4. **Community cloud**: A particular community with common issues is supported by shared cloud infrastructure, which is shared by certain organizations (e.g., governance, education and compliance). It may be managed by the groups or by a third party, and it may be located on or off campus.

I.2 SCHEDULING ALGORITHMS ANALYSIS

There are two kinds of algorithms for work scheduling:

1. **Heuristic**:This problem-solving method uses specific guidelines and suggestions (strategies) to do a focused search. The aim is to identify feasible, realistic solutions that take into account the limitations of the problem [8]. Round robin, min-min, priority-based, and first-come, first-served scheduling are examples of heuristic scheduling methods.
2. **Metaheuristic**:Metaheuristic algorithms draw inspiration from physical processes, evolutionary biology, and natural phenomena such as swarm intelligence. They use techniques including problem space exploration, local search, randomization, and searching for possible answers. Complex optimization issues are solved using metaheuristic algorithms [9]. It finds the best option out of a plethora of alternatives. Unlike classical algorithms that may provide exact answers, metaheuristics provide approximate solutions that are deemed appropriate for practical reasons [10]. Examples are PSO, GWO, and Jaya.The ultimate goal of cloud computing resource computation is to minimize cloud customers' financial expenses while optimizing revenues for cloud providers [11].

However, compared to alternative methods like analytical processes and identical numerical programming, conventional procedures are simpler to comprehend and utilize. Approaches do not ensure that the result will be created correctly [12]. Programming for cloud computers is associated with a set of issues called NP-hard drives because there are so many potential solutions, and it takes time to choose the optimal one. To solve these problems, none of the methods can get the right answer in a multinomial amount of time. Finding a more effective solution in the near term is preferable when it comes to cloud computing. For such problems, meta-heuristic-based approaches have demonstrated the ability to obtain optimal solutions in a sensitive time frame [13].Heuristic approaches have been applied without guaranteeing accuracy or viability for a workable answer at a minimal computing cost. Examining different strategies to enhance the efficiency of metaheuristics in algorithms increases the efficacy of heuristic processes that employ metaheuristics approaches.

Larger integration rates, less coverage of optima, longer computation durations, more complex operators, and the development of a binary or real search environment are other characteristics of contemporary algorithms.Strong scheduling techniques must be used in cloud computing in order to optimize resource consumption and system efficiency[14]. Teaching Learning Based Optimization (TLBO) The TLBO methodology is a metaheuristic optimization method that draws inspiration from educational environments. Because of its bias, troubleshooting optimization may be simpler [15]. Thus, gravity serves as a means of transmitting information among separate entities [16]. Despite being suggested, the path frequently develops into a comprehensive response to multiple iterations, unlike GA, and does GSA techniques avoid being locked in the local optimum [17].

II. ALGORITHMS USING META-HEURISTICS FROM 1975 TO 1997

Ant colony efficiency solves optimization problems using the same method [18]. Scatter search can be used in cloud computing by developing a "Scatter Search" metaheuristic algorithm on a cloud platform to tackle complicated optimization issues or by using a "Scatter/Gather" pattern for dispersed activities. Particle Swarm Optimization (PSO) the Particle Swarm Optimization technique is a suitable meta-heuristic algorithm for optimizing continuous nonlinear functions. The idea of identifying the optimal solution was motivated by the notion of bird cruelty, which is frequently seen in animal groups such as flocks and the sea [19]. Each candidate (birds, fish, insects) is treated as a particle in particle swarm optimization, which uses a community known as a swarm and develops them using random circumstances and velocities. Assuming a cross between the evolution of the Pareto method of optimization and the evolutionary approach, The Improve PSO (IPSO) algorithm has been used in this work to establish a resource scheduling approach for quality-of-service constrained resources.

According to the study's findings, the model can boost productivity and enhance search speed while indicating a specific height [20]. The PSO process suggests a more methodical virtual machine allocation strategy and a more effective resource allocation energy model to maximize energy usage in the cloud data center. The PSO stiffness function in this method differs from the remaining finishing point between resource utility and energy consumption. This approach can escape down to local optima, common to traditional approaches [21]. The Metaplan Complex scheduling and optimization problems, especially those requiring resource allocation, are resolved in cloud computing by using meta-heuristic algorithms. In situations when workloads are constantly changing, they successfully provide almost ideal results. Complex optimization issues like load balancing, virtual machine (VM) migration, and resource allocation are handled in cloud computing through the use of simulated annealing.

By mimicking the real annealing process, which entails progressively cooling a material to its lowest energy state, this technique helps identify the best way to allocate cloud resources. Tabu Search is a metaheuristic optimization method used in cloud computing to solve challenging issues such as work scheduling, load balancing, and resource allocation. A "tabu list" of previously explored movements or solutions is kept up to date when investigating solutions in order to prevent becoming trapped in local optima. Unaffected algorithms Use cloud computing's biological immune system ideas to solve security, load balancing, and optimization problems. Reactive search optimization in cloud computing involves using self-tuning, adaptive algorithms to optimize cloud resource allocation and scheduling in response to changing conditions.

Differential Evolution is used in cloud computing as a powerful optimization algorithm for complex problems like task scheduling, data center selection, and resource allocation. ACO learns from the destructive nature of some ant species. These ants use a pheromone to mark a specific track in the ground, which the other ants in the colony may follow. We learned how to properly allocate cloud resources in this paper in order to optimize cost, service quality, time, and resource load balance. The response has been the modified ACO algorithm. More planning is being done for this effort, though, including the resources' qualities and how well they match the job criteria, as well as the primary sources of qualified applicant resources.

III. METHODS OF META-HEURISTICS FROM 2001 TO 2009

Harmony Search Algorithm (HS) The Harmony Search algorithm has received a lot of attention lately. It is a metaheuristic technique that seeks to achieve the perfect harmony by simulating the singer's development. The HS method is easy to apply, rapidly yields the correct answer, and gives a sufficient solution for the required length of time. Because of these benefits, the HS algorithm has been used to solve issues requiring the application of different technical contexts [22]. Making effective use of cloud resources requires a systematic approach to resource planning. This method uses makespan to analyze the correctness of the answer and relies on HS, a novel meta-heuristic tool. The CloudSim 3.0.3 program has been utilized as a cloud simulator to assess the Harmony Search algorithm's performance. According to this study, the number of cloudlets has been increasing with variable makespan (in seconds) when employing a cloud scheduling method based on Harmony Search.[23].

Optimization in Renewable Energy Systems: Recent Perspectives addresses every significant area in which optimization methods have been used to lower uncertainty or enhance outcomes in renewable energy systems [24]. Less waiting time is achieved by the hybrid TLBO and grey wolves optimization algorithm (GW) algorithm, which precisely balances priorities and takes performance into account based on time, cost, and avoiding local optimum traps.In terms of makespan and load variation, the Grey Wolf Optimization Algorithm with Simulated Annealing (GWO-SA) outperforms all other methods [25]. Artificial Bee Colony Algorithm (ABC) This approach to continuous optimization issues was initially introduced in 2005. The employed and unemployed bees in this strategy just update the 1D food position. One solution update rule is used by the artificial agents for the whole search. It has two kinds of bees: those that work and those that don't. Whereas other bees locate food sources using the information that employed bees supply, employed bees gather fluid from food sources and advise other unemployed bees of food locations. It is an energy resource consumption process model that has been studied to optimize cloud resources and improve their use.

The method of powering resources of the same size as the model is what the ABC uses when assigning functions to cloud computing resources. Additionally, through server interfaces, visualization makes it possible to reduce cloud power utilization since it reduces user-desired procedures. In accordance with the ABC-based energy-conscious resource consumption approach, the architecture allocates functions and resources to the cloud. A comparison between the efficacy of the proposed technique and existing approaches is made using the CloudSim tool. According to the test findings, the recommended process works better than existing methods by reducing the energy and running time of cloud-based programs. A genetic algorithm (GA) is a kind of evolutionary algorithm that finds excellent answers to challenging optimization and search problems. It was inspired by natural selection. It functions by generating a population of potential solutions that change through crossover, mutation, and selection over the course of several generations. This method is designed to maximize resource usage while minimizing job completion time and cost [26].

Table 1: Algorithms Using Meta-Heuristics From 1975 to 1997.

Sr. No	Algorithm	Proposed	Year	Description / Key Idea
1.	Genetic Algorithm	Holland [27]	1975	Laid the foundation for evolutionary computation.
2.	Scatter Search	Glover[28]	1977	Introduced a structured combination of solution vectors.
3.	Metaplan	Mercer and Sampson[29]	1978	Early conceptual model for metaheuristic planning.
4.	Simulated Annealing	Kirkpatrick et al.[30]	1983	Motivated by the process of metallurgical annealing.
5.	Tabu Search	Glover[31]	1986	Used adaptive memory to escape local optima.
6.	Ant Colony Optimization	Dorigo[32]	1992	Ant foraging behavior was modeled to determine the best routes.
7.	Immune algorithm	Mori et al.[33]	1993	Based on the principles of biological immune systems.
8.	Reactive Search Optimization	Battiti and Brunato[34]	1994	Combined machine learning with metaheuristic optimization.
9.	Particle Swarm Optimization	Kennedy and Eberhart[35]	1995	Influenced by the social behavior of fish schools and flocks of birds.
10.	Differential Evolution	Storn and Price[36]	1997	Developed for continuous optimization with differential mutation.

Glowworm Swarm Optimizationis a swarm intelligence technique used in cloud computing for work scheduling and resource allocation. is mostly used in cloud computing for scheduling tasks and allocating resources. Honey bee Mating Optimization: It optimizes the way jobs are distributed among virtual machines (VMs) and data centers using ideas derived from honey bee mating behavior in order to accomplish objectives such as lowering makespan, increasing resource usage, and improving load balancing.Shuffled frog leaping algorithm is used in cloud computing for complex optimization tasks like resource allocation, task scheduling, and energy management. Imperialist Competitive Algorithm is a meta-heuristic optimization technique used in cloud computing to address challenging issues like resource allocation and service composition.

It was motivated by historical imperialism and competition.Intelligent Water Drops A meta-heuristic optimization method inspired by the natural flow of water droplets is used to solve cloud computing problems such as workflow scheduling and virtual machine (VM) allocation. River formation dynamics is a metaheuristic for work scheduling and resource optimization that draws inspiration from nature. In order to determine the most effective routes for distributing cloud resources, including virtual machines (VMs), to user workloads (referred to as "cloudlets"), it analyzes how water creates riverbeds. Firefly Algorithm (FA) The Firefly Algorithm falls within the categories of meta-heuristic, swarm intelligence, and nature-inspired. It turns out that certain fireflies employ brilliant light activity to communicate, find partners, and warn predators of danger.

The firefly algorithm's objective function is linked to the flashing light characteristics of the firefly population. This aim may determine the proper distance function between any two fireflies since the optical principle of light intensity specifies that the distance between any two fireflies is about equal in the square of the area. Cuckoo Searchutilized in cloud computing to solve optimization issues such as intrusion detection, virtual machine (VM) consolidation, and resource scheduling. By seeing eggs as solutions and nests as possible solutions to a problem, it uses the natural behavior of cuckoos to identify the best answers. In dynamic, complicated contexts, cloud applications use computer science (CS) to increase security, lower power consumption, and improve quality of service (QoS).

IV. METHODS OF META-HEURISTICS FROM 2009 TO 2024

Gravitational Search Algorithm (GSA) fundamentally operates on the principles of gravity and the interaction of mass. The approach adopted by GSA is grounded in Newtonian physics, and its researchers comprise a diverse assembly of masses. Within GSA, an exclusive system for these masses is implemented. By leveraging gravity, each mass within the network can observe the conditions of other masses. GSA is very good at tackling nonlinear problems, and it has been used to allocate resources in cloud computing environments. In addition to providing resources for jobs with the lowest mean flow and span of time with load balancing other ways, the suggested method demonstrates that it receives about the same application reaction for resource allocation when compared to the GA and GSA without fuzzy improvements. Bat Algorithm is a metaheuristic optimization method that may be used to address complicated issues in cloud computing, particularly those related to work scheduling. In order to decrease processing time and maximize resource usage, the algorithm employs "virtual bats" to determine the most effective way to assign jobs to available resources. Spiral Optimization is a meta-heuristic algorithm that finds the optimal method to divide up scarce cloud resources among different jobs in order to improve performance or decrease cost.

Table 3: Methods of Meta-Heuristics from 2009 T0 2024.

Sr. No	Algorithm	Proposed	Year	Description / Inspiration
1.	Gravitational Search Algorithm	Rashedi et al. [47]	2009	Based on mass interactions between agents and the law of gravity.
2.	Bat Algorithm	Yang [48]	2010	Inspired by the echolocation behavior of bats.
3.	Spiral Optimization	Tamura and Yasuda [49]	2011	Models spiral movements for global and local search efficiency.
4.	Teaching Learning Based Optimization	Rao et al. [50]	2011	Simulates the effect of teaching and learning in a classroom.
5.	Krill Herd	Gandomi and Alavi [51]	2012	Influenced by the way krill individuals in seas crowd one another.
6.	Swallow Swarm Optimization	Neshat et al. [52]	2013	Based on the collective and dynamic flight behavior of swallows.
7.	Interior Search Algorithm	Gandom [53]	2014	Inspired by interior design and object placement strategies.
8.	Gradient Evolution Algorithm	Kuo and Zulvia [54]	2015	Combines gradient-based methods with evolutionary search.
9.	Water Wave Optimization	Zheng [55]	2015	Mimics the propagation, refraction, and breaking of water waves.
10.	Killer Whale Algorithm	Biyanto [56]	2016	Inspired by the social hunting behavior of killer whales.
11.	Rain Water Algorithm	Biyanto [57]	2017	Based on the collection and flow of rainwater in nature.
12.	Hydrological Cycle Algorithm	Zheng [58]	2018	Models the complete natural water cycle process.
13.	Emperor Penguins colony	Wedyan et al. [59]	2019	Simulates huddling and cooperation among emperor penguins.
14.	Aquila Optimizer	Harifi et al. [60]	2020	Inspired by the hunting and attacking strategies of eagles.
15.	Colony Predation Algorithm	Jiaze Tu et al. [61]	2021	Models group predation and cooperative hunting in animal colonies.
16.	Dwarf Mongoose Optimization	Agushaka et al. [62]	2022	Based on the cooperative hunting and social behavior of mongooses.
17.	Improved Chicken Swarm Optimization with Differential Evolution	Faramarz et al. [63]	2023	Hybrid strategy that combines Differential Evolution with Chicken Swarm Optimization for improved performance.
18.	Hybrid GWO-Salp Swarm	Krish Rustagi et al. [64]	2024	Merges Grey Wolf Optimizer with Salp Swarm Algorithm for better convergence and exploration.

Krill Herdis an optimization method with biological inspiration that is applied in cloud computing to issues including resource allocation, workload scheduling, and virtual machine (VM) deployment. In order to obtain the best answers, it mimics the herding behavior of krill, frequently seeking to enhance aspects like cost reduction, load balance, and energy efficiency. Swallow Swarm Optimization:can be used in cloud computing for tasks like scheduling, load balancing, and resource allocation, where its clever swarm behavior aids in the discovery of effective solutions.

Its special characteristicsexplorer, aimless, and leader particlesallow it to perform better than conventional techniques by accelerating convergence, avoiding local optima, and skillfully striking a balance between exploration and exploitation. Interior Search Algorithmis not a particular cloud computing technique, but rather a metaheuristic optimization algorithm influenced by interior design concepts. By improving the cloud environment, it is utilized in cloud computing research for tasks like resource assignment and energy-efficient virtual machine allocation. By identifying the best answers in expansive search spaces, which are typical in cloud computing, this method may resolve complicated, large-scale issues like load balancing and resource scheduling.

Gradient Evolution Algorithm (GEA)is a metaheuristic optimization technique that applies a gradient-based methodology to challenges such as neural architecture searches and difficult optimization issues. It is used in cloud computing to optimize multi-objective, complicated issues such as resource allocation and work scheduling. Water Wave Optimizationis a metaheuristic inspired by nature that is used in cloud computing to address difficult optimization problems like resource management and task scheduling. WWO finds the best answers in the search space by simulating the behavior of shallow water waves utilizing operators including propagation, refraction, and breaking. Killer Whale Algorithm is a cloud computing optimization method that uses natural inspiration to solve difficult problems including work scheduling, resource allocation, and load balancing.

In order to identify the optimum use of cloud resources, it mimics the cooperative hunting behavior of a killer whale pod, with a leader looking for the best answers and the members carrying out the "chase" or exploitation.Hydrological Cycle Algorithm is an optimization technique inspired by nature that applies the water cycle's concepts to cloud computing issues including load balancing and work scheduling. Solutions are represented by the algorithm as "water drops" that flow, evaporate, and condense according to their "fitness" or quality.Emperor Penguins colony refers to a series of bio-inspired metaheuristic optimization algorithms that use emperor penguin huddling behavior to address challenging cloud computing issues including resource scheduling and Quality of Service (QoS) management. Aquila Optimizer is a metaheuristic method that is used in cloud computing to handle complicated optimization issues, especially those involving task offloading and resource allocation.

It is a nature-inspired algorithm that effectively finds the best answers by imitating the Aquila bird's hunting style. Although the algorithm's use in cloud computing is still in its infancy, it has the potential to lower metrics like response time, execution time, and energy usage. Colony Predation The meta-heuristic optimization technique known as an algorithm is modeled after the cooperative hunting approach of social animals like wolves and lions. Complex optimization issues like load balancing, resource allocation, and job scheduling are resolved by cloud computing. Dwarf Mongoose Optimization (DMO)is use in this particular field is still in its infancy, it can be hosted on-premises or by a metaheuristic algorithm inspired by the foraging behavior of dwarf mongooses that can be applied to cloud computing challenges outside vendor It is used to optimize cloud resource allocation, task scheduling, and other complex problems by imitating the cooperative strategies of the animal.

Hybrid GWO-Salp Swarm is a metaheuristic method used in cloud computing to solve difficult optimization issues like resource allocation and job scheduling.By combining the advantages of both algorithms, GWO-SSA enhances performance and gets around the drawbacks of each one when applied separately. It is a nature-inspired algorithm that solves optimization issues by simulating wolves' hunting behavior. Its success in solving problems has led to its rise in popularity. Alpha, beta, delta, and omega are the four tiers of dominance that the wolves fall into. The omega wolf has the lowest place in the hierarchy, whereas the alfa wolf represents the leader. The search for the best answer is guided by the dominance level.GWO Steps: 1) The wolves move to encircle the prey by changing postures. By getting closer to the best answer, the wolf adjusts their locations. 2) The top three solutionsalfa, beta, and deltaact as leaders in prey hunting. When it comes to possible roles, they are the most knowledgeable.

Wolves enhance the general hunt for the answer by taking positions that are more advantageous to their leaders. 3) Prey attacking: In this phase, they focus their search on potential answers.There are several noteworthy and significant meta-heuristic algorithms in the field of resource management in cloud computing systems. Examples include Honey Bee Mating Optimization (HBMO), Ant Colony Optimization (ACO), Firefly Algorithm (FA), Artificial Bee Colony Algorithm (ABC), Glowworm Swarm Optimization (GSO), Cuckoo Search (CS), Genetic Algorithm (GA), Simulated Annealing (SA), and many more. Some of the most important metaheuristic techniques are included in the table. Cloud computing resource allocation uses meta-heuristic techniques like Teaching Learning Based Optimization (TLBO), Artificial Bee Colony (ABC), Harmony Search (HS), Ant Colony Optimization (ACO), Gravitational Search Algorithm (GSA), Cuckoo Search (CS) Algorithm, Firefly Algorithm (FA), Genetic Algorithm (GA), Shuffled Frog Leaping Algorithm (SFLA), and Particle Swarm Optimization (PSO). The section that follows discusses them.

V.CONCLUSION

These days, cloud computing is the most popular topic among IT firms worldwide. Businesses that employ cloud computing for the implementation and scalability of IT for business processes stand to gain a great deal from it. Cloud computing services are being adopted by an increasing number of businesses, including zoological organizations and accounting firms. This paper examined a few meta-heuristic algorithms for cloud resource allocation. These evaluations look at a variety of methods to make meta-heuristics more successful. Nonetheless, the meta-heuristic algorithms under consideration are adept at attaining much better performance, lower costs, shorter turnaround times, better resource utilization, and increased energy efficiency when allocating resources on the cloud. Future resource allocation in the cloud may make use of other meta-heuristic techniques not included in this study.

ABSTRACT

Depression is an increasing concern among students adversely affecting academic performance and mental well-being. Early prediction is important for timely intervention. This paper aims to classify students into "Depressed" or "Not Depressed" categories utilizing the Depression Student Dataset. A comparative analysis of several traditional machine learning (ML) approaches, counting Gradient Boosting (GB), Support Vector Machine (SVM), Logistic Regression (LR), Random Forest (RF), XGBoost, LightGBM, AdaBoost (AB), Naïve Bayes (NB), and Decision Tree (DT) was performed to evaluate their predictive abilities. To enhance accuracy of prediction, this paper proposed an optimized LR model fine-tuned utilizing GridSearchCV. The optimized model shows superior performance with an accuracy rate of 98%, outstanding all other algorithms in this study. The findings highlight the efficiency of model tuning in improving depression classification results. This research proposed a robust framework for used ML to classify depression among students, contributing to early prediction and support strategies.

I. INTRODUCTION

Depression is a mental illness that can devastate mental stability, interfere with day-to-day functioning, and in certain situations, worsen into psychological trauma [1]. When psychological stress, anxiety, or depression is present, the human body issues a variation of chemicals, which causes a shift in nonverbal body language. These psychological conditions can be broadly categorized as depression, anxiety, or psychological stress, with anxiety being the initial stage and the most gradual [2]. Depression is the greatest severe phase of the psychological state, which may have a long-term detrimental effect on the individual's biological and cognitive health. It can arise from minor issues in daily routine. Stress is the second phase of the cognitive state, where the psychological state is concentrated due to the ongoing impact of anxiety [3]. Depression is a long-term disorder or disease mourned by most individuals. It is one of the most extraordinarily undertreated and underdiagnosed states of cognitive illness. It has stood to be a significant problem in the health, social, and economic sectors. It has also been a significant mortality problem and is slowly growing above the levels as the most significant disorder with zero to no treatment.

It is constantly connected to other underlying cognitive diseases and can induce the patient to trigger other latent cognitive diseases [4]. Due to the individual complexities and challenges of a studious life, Students are more likely to suffer from psychological anguish, which makes their cognitive health a significant global issue. Depression, which is a prevailing cognitive health condition among students, particularly degrades their social relations, educational attainments, and general well-being. It is essential to promptly and adequately identify these conditions to deliver timely intervention and assets. Approximately more than 260 million individuals universally suffer from depression disorder. Studies have shown that the prevalence of depression in students is higher than in the universal population with a range of 15% to 86% [5]. Determining whether someone is depressed can be done in a number of ways. The prediction of student depression has been done using traditional statistical approaches (TS).

Regression analysis has been employed in certain studies to observe the predictive value of a number of traits, counting social support, early life events, life events, parenting style, and stressful life events. Relationship studies have shown the significance of the association among traits like sadness, subjective social status, parenting style, social exclusion, and dark personality via calculating correlation coefficients. The organizational equation model enables a thorough examination of the difficult relations among a number of predicted traits counting psychological resilience, early trauma, coping mechanisms, perceived social support, gratitude, and parent-child attachment. This method helps students understand the indirect and direct ways of influencing depression.

There are some problems with employing TS approaches to forecast depression among students. First, TS approaches might not fully represent the complexity of depression because they presume linearity and independence among predicting factors. Furthermore, the number of forecasters must be in line with the taster size for conventional multivariate regression techniques. Thus, it is impossible to adequately assess the data and make use of any predictive features with this approach [6]. Also, obtaining a straightforward examination and consultation by a psychiatrist is the most reliable procedure, yet it is expensive and takes a long time. Multifarious self-administered psychometric tests for estimating depression are also commonly available.

Nevertheless, these tests are typically lengthy. The enormous number of questions prevents the taker from answering them with detailed answers, which can lead to incorrect estimation outcomes. The major disadvantage of these approaches is that the individual acknowledges that she or he is being experimented on for depression. This may induce damaging feelings in the issue and cause assessment refusal [7], [8]. To solve the problems found in traditional methods, we employ Artificial Intelligence (AI), including ML techniques, which have delivered developed analysis techniques for designing a depression prediction approaches. ML aims to develop approaches that can train to comprehend complicated patterns.

This advantage is useful in finding solutions to new problems, given past data and solution. Strategies are trained via ML and obtain regular-states and well-organized results. The promise of using ML methods in healthcare has shown to be feasible and remarkable due to their capacity to learn from huge amounts of heterogeneous data types and provide a valuable clinical insight. ML-based methods enable mental health practitioners to make prediction decisions and provide an effective understanding of cognitive problems. Through the development of insights from amorphous medical data, ML techniques aid in healthcare diagnosis and prediction. Patients with high-risk medical conditions can be identified and treated early thanks to the prediction results.

In order to help medical practitioners, anticipate the prognosis of depressive illnesses and support effective treatment outcomes, ML techniques enable arbitration among various behavioral features. Complex health data can be interpreted and visualized using these techniques. An influential theory on the prediction of depressive disorders can be developed thanks to visualization. The intricacy of depression is not adequately captured by the conventional clinical case identification approach. The design of the manifestation associated with depression disorder can efficiently be anticipated and detected by employing ML techniques. Consequently, the ML-based prediction approach is an efficient alternative for depression predictive investigation [9].

In this study, we proposed a hybrid method for predicting depressive illness. Gradient descent (GD) and LR were coupled to enhance the efficacy and performance of student depression prediction. To enhance the evaluation methods of cognitive health in pedagogical settings, this research will investigate how well measurement instruments using that hybrid model capture depressive illnesses. This effort to bridge the gap between advanced data driven procedures and traditional psychometric screening methods is considered in this study. It will also enhance students' overall mental well-being and the early identification of any cognitive health problems. The main contributions of our analysis are:

This study successfully reveals the pattern and rate of depressive illness in different student groups. In addition, a new scale for identifying student depression was developed. Hybrid ML models can better detect and screen for depressive illnesses in students. This is essential to implement timely and effective intervention, and to reduce the long-term deleterious effects of the disorders. Through the use of advanced data mining and psychological testing mechanisms, this research contributes to the academic literature. It creates as well a baseline for future research in the field of technology and cognitive care.

II. RELATED WORK

Recently researchers have presented studies on predicting student depression utilizing several ML techniques. The performance varied greatly depending on the technique and data utilized. In this section, we will present some of these studies. By [10] used ML models to forecast the risk characteristics associated with students' depression. The analysis instance consisted of 3984 students aged 15-10 years. The dataset was analyzed employing ML to forecast the risk characteristics associated with student cognitive health symptoms. The proposed utilized five ML techniques: ANN, RF, SVM, DT, and NB for prediction. The results demonstrated that the SVM technique had the highest accuracy of 92.5%.

According to [11] proposed a practical approach to predict student depression depending on ML techniques. Multiple ML techniques are employed, such as LR, RF, SVM, LDA, KNN, and NB. Based on performance analysis, the experimental outcomes reported that the RF model surpassed other techniques for the depression forecast by 89%. In turn [8] investigated models to forecast students' depression and reveal essential individual and family features. This investigation indicated individuals at threat of depression and recognized influential individual and family features in around 170 of data of families involved. The forecast accuracy of three ML techniques, SVM, Sparse Logistic Regression (SLR), and RF, were compared. The RF technique demonstrated the best accuracy of 86.27%.

By [12] proposed an effective study to forecast the student depression of an individual based on text input. The proposed model applied ML models, including LR, DT, RF, NN, KNN and a Hybrid Stacking (HS) model. The hybrid model utilized LDA as a feature selection process and integrated five ML classifiers. After comparing the performance of all ML approaches and the HS method. The HS model is achieving a better accuracy of 97%. According to. [6] proposed multiple ML models, such as KNN, LR, Non-linear SVM (N-SVM), and RF, to forecast differences in depression among students. The proposed approach utilized a dataset of 5,534 students and estimated personality characteristics. The results showed high performance in the forecast task, with the N-SVM achieving 95% accuracy.

In turn [13] proposed intelligent approaches for student depression prediction based on ML techniques. Three approaches were utilized to predict and categorize student depression in a dataset of 787 students via a number of phases, counting pre-processing, testing, and training. LR, KNN, and DT are the ML approaches applied in this work. With an accuracy rate of 77%, the results show the LR approach performed the best in terms of prediction. The study also revealed that male students are twice as likely to be obese compared to female students, that two out of five students suffer from mild depression, that 90% of students with depression do not seek treatment, and that male students generally have a higher BMI than their female counterparts.

By [14] proposed effective method to predict student depression utilizing multiple ML techniques including SVM, KNN, LR, DT, and NB. DASS21 was utilized to acquire data from 400 students. Various analysis matrices, like accuracy, precision, F1-score, and specificity were employed to compare the techniques. The finding results showed the KNN performed best, followed by LR. In turn [15] Utilized ML techniques to develop a student depression predictive approach. Multiple ML methods were applied in this proposed approach, including XGBoost, RF, DT, and LR, to detect persons who are more likely to have diagnosable depression. The collected dataset contained around 60,000 students and was partitioned into a 10:90 ratio for testing and training.

The proposed approach utilized cross-validation to improve model performance and investigated multiple evaluation measures such as Area Under Curve (AUC), sensitivity, and accuracy. Results indicated discriminative solid power in XGBoost, LR, and RF accuracy of 70%. According to [5] proposed an efficient approach for predicting student depression. The proposed approach uses a combination of ML algorithms with the General Health Questionnaire-12 (GHQ-12), a widely used tool for measuring psychological distress. First, with the help of a skilled psychiatrist, a full survey has been created for influential depression screening.

The questionnaire contains GHQ-12, job, sociodemographic, and career-related questions. Then, 16 various ML techniques were applied to investigate the dataset and determine predictors and trends of student depression in this demographic, including LR, NB, SVM, DT, Extremely Randomized Tree (ERT), RF, XGB, LGBM, CatBoost, KNN, GBM, AdaBoost, LDA, SGD, QDA, and ANN. Among the ML techniques, ERT has reached the highest accuracy of 90.26%.

III. RESEARCH METHOD

The research methodology of this work focuses on utilizing ML algorithms to classify students as either "Depressed" or "Not Depressed" based on the Depression Student Dataset. The objective is to evaluate how well these models predict depression. The workflow is shown in Figure 1, showing a step-by-step approach that contains dataset details, preprocessing steps, models, and evaluation metrics.

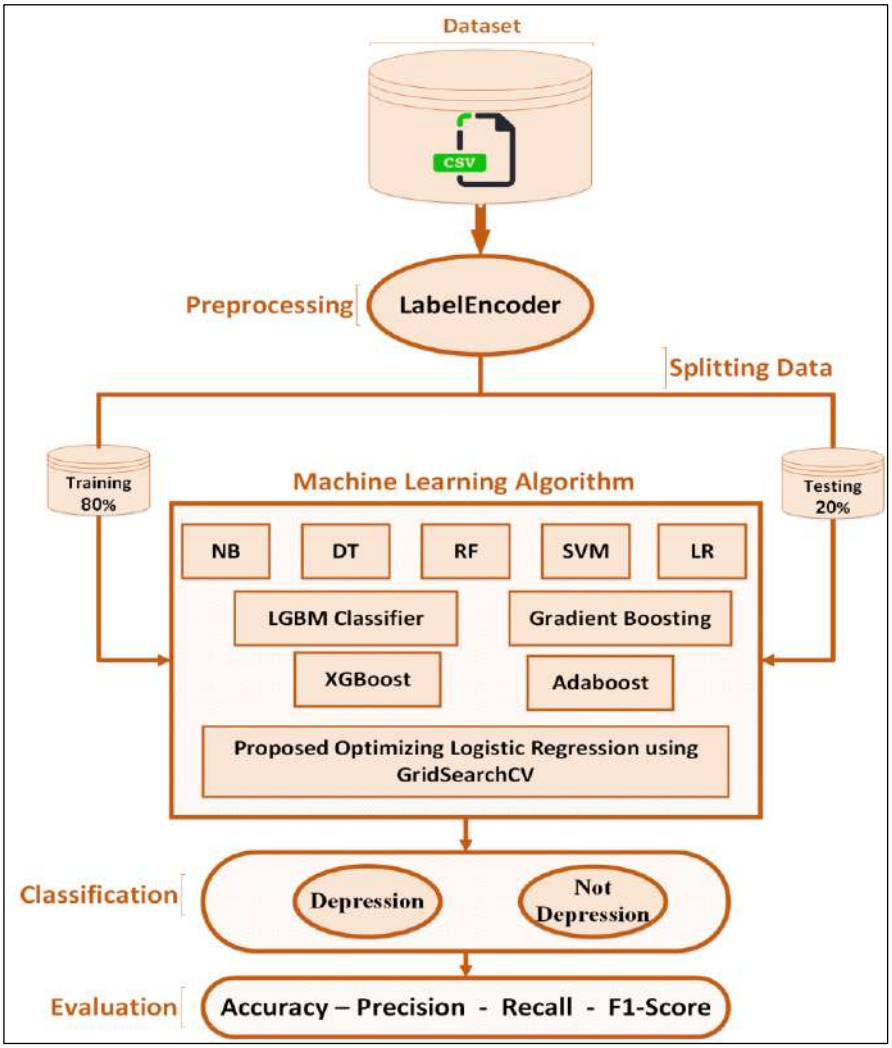

Figure 1: Workflow of the proposed depression detection model.
Source: Authors, (2026).

III.1 DATASET DETAILS

The Depression Student Dataset finds the connection between mental health and various other factors such as personal, academic, and lifestyle. Key attribution includes gender, age, financial stress, food practice, study hour, sleeping hours and academic pressure, satisfaction of study family history of psychiatric illness and symptoms of depression and suicidal thoughts. The dataset is also used for understanding the effects of factors such as sleep quality, diet and academic workload on mental well-being; applications include risk assessment for mental health, prevention strategies on various student populations. The dataset includes 502 samples with several attributes. The dataset of this study obtained from Kaggle that is available on the following link "Depression Student Dataset".

III.2 PREPROCESSING

Data preprocessing is an important step before applying ML algorithms, as it guarantees that the dataset is in a format that can be used to train models. The preprocessing methods used in this work are as follows:

III.2.1 Label Encoder

It was applied to convert non-numerical labels (such as "Male", "Female") into numerical values [16]. This is important for ML models that require numerical input. The encoding process ensures that individually unique label in a categorical feature is transformed into a corresponding numeric representation.

III.2.2 Splitting Dataset

The dataset was divided into training and testing parts, with 80% of the data utilized to training models and 20% for model performance testing.

III.3 MACHINE LEARNING ALGORITHMS

In this work various ML algorithms were chosen to evaluate performance in predicting depression. These models vary in their approach to classification, and their performance will be compared utilizing evaluation metrics. The following algorithms are utilized in this study:

III.3.1 Logistic Regression

LR is a ML algorithm utilized for binary classification problems, where the result variable has two possible classes, such as Depressed or Not Depressed. Modeling the likelihood that a given input point belongs to a specific class is the fundamental concept of LR [17], [18]. LR uses a logistic function (also known as the sigmoid function) to predict probabilities that are mapped between 0 and 1, as opposed to LR, which predicts continuous values. It is hence appropriate for categorization jobs.

LR determines the input features' weighted sum as shown in Equation (1):

$$z = \beta_0 + \beta_1 X_1 + \beta_2 X_2 + \cdots + \beta_n X_n \tag{1}$$

X are the input features, β are the weights, or coefficients, that the model learns throughout training.

The sigmoid function is utilized to transform the weighted sum Z's output into a probability as shown in Equation (2):

$$p = \frac{1}{1+e^{-z}} \tag{2}$$

The expected likelihood that the instance belongs to the positive class is represented by the result p.

III.3.2 Support Vector Machine

SVM is a supervised ML method that performs exceptionally well in classification tasks and it may also utilized for regression problems, [19]. Finding a hyperplane that best divides data points from several classes while optimizing the margin among them is the key objective of SVM [20]. The distance among the closest data points from individually class, also referred to as support vectors, and the hyperplane is known as this margin. The greater the margin, the more effectively the model can generalize to new data, hence minimizing overfitting [21].

When data is not linearly separable, SVM employs a technique known as the kernel trick. Even if the data is non-linearly separable in its original form, this method allows for the discovery of a linear decision boundary via transforming it into a higher-dimensional feature space. Because of this, SVM is very good at handling complicated and non-linear data. SVM does, however, face several difficulties. It can be computationally costly, particularly when using sophisticated kernel functions or huge datasets.

III.3.3 Random Forest

One popular ensemble ML technique for the regression and classification tasks is RF. With the help of bagging (Bootstrap Aggregating) it constructs a "forest" of DTs, each fitted with some part of the data. By averaging (for regression) or majority voting (for classification) the predictions of the ensemble trees, we obtain the final prediction. RF decrease overfitting because of the randomness on both data subsets and feature selection by enhancing model generalization [22]. It supports missing values, does not need feature scaling, and presents you with feature importances. In contrast, although RF achieves high accuracy and is fairly robust, it sometimes encounters excessive computation time and prediction becomes slow with many trees or large datasets. Despite these limitations, RF is still widely used as it is a versatile, easy to use ML technique that performs well in a variety of tasks.

III.3.4 Gradient Boosting

GB is an ensemble ML technique utilized for classification and regression tasks. Models are created one after the other, with separately new model fixing the mistakes of the ones that came before it [23]. In order to generate a powerful prediction model, it integrates weak learners, usually DT. GB uses gradient decent to train trees to reduce residual errors from the prior model, in contrast to RF which creates trees independently. Based on the gradient of the error function, this procedure iteratively modifies the model. Although GB excels at handling complicated datasets and yields high accuracy, its computational cost and hyperparameter sensitivity necessitate careful adjustment for best results.

III.3.5 Extreme Gradient Boosting

XGBoost, the gradient boosting version for regression and classification problems [24], is a refined and scalable implementation of GB. It is an extended version of classic GB by improving speed, accuracy and trying to avoid overfitting. Similar to other methods such as AdaBoost, XGBoost works in a consecutive manner and each tree that we build tries to correct the errors made by the previous trees. It adopts DT as the base learners, and focuses on minimizing a loss function by using a greedy procedure. XGBoost stands out for regularization (L1 and L2) to avoid overfitting, which makes it noisy and effective. It also includes tree pruning, column and row subsampling for improved generalization, and parallelization to speed up computation. Moreover, XGBoost has hyperparameters such as tree depth, learning rate and the number of trees to fit performance that have made it in favor of many ML competitions and industrial application.

III.3.6 Light Gradient Boosting Machine

LightGBM is efficient and scalable GB framework developed via Microsoft, designed for fast training and handling large data sets [25]. It is particularly favored for classification tasks due to its speed, accuracy, and low memory consumption. Like other GB methods, LightGBM builds an ensemble of DT sequentially, individually tree fixing the mistakes of the one before it. What sets LightGBM apart is its use of histogram-based learning, where feature values are grouped into discrete bins instead of evaluating all possible split points, which reduces computation time and memory usage, making it highly efficient for large datasets.

III.3.7 Decision Tree

For classification and regression tasks, its powerful supervised ML approach, DT is applied. Each node in the internal nodes of the tree image stands for an attribute, each branch represents a decision rule, and each leaf node corresponds to an outcome. This tree-like structure is formed by repeatedly splitting the data based on feature values [26]. To maximise class separation, or to minimize the error in prediction along all splits (not just at leaf nodes), the "best" split points are determined using Gini impurity, Entropy (for classification), or Mean Squared Error (for regression). Simple Make: (a) Decision trees have the risk of overfitting and deep decision trees in our setting are often DTs, although they are intuitive to comprehend and visualize. Ensemble/Bagging techniques like RF, GB or pruning can mitigate it. It -- and also like OVR which more we will discuss later -- tend to over-fit, but is flexible for both numerical as well categorical input.

III.3.8 Naive Bayes

NB is efficient probabilistic classifier that is frequently utilized for classification tasks, especially in text classification applications like sentiment analysis and spam detection. It allocates the class with the highest posterior probability after estimating the likelihood of class labels given a collection of features [27]. NB is regarded as "naive" as, given the class title, it presumes that the properties are unrelated to one another, which is often unrealistic but still works well in many situations, especially when feature independence is approximately true. Despite this assumption, NB can perform surprisingly well in practice, particularly in large datasets. Variants of NB, such as Multinomial NB for discrete data and Gaussian NB for continuous data, are utilized based on the type of data. Although its simplicity and assumptions may limit its performance in more complex datasets, NB remains a fast, scalable, and robust algorithm, widely utilized for text classification, spam filtering, medical diagnostics, and recommendation systems.

III.3.9 Adaptive Boosting

AB is a classification ensemble learning strategy that builds a strong classifier via combination some weak classifiers [28]. It trains a sequence of weak models, frequently decision stumps, with each model concentrating on fixing the mistakes of the one before it. After each model is trained, the weights of the misclassified instances are raised, giving harder cases more weight than the initial equal weights assigned to all training examples. The overall prediction is then obtained by combining the output of all weak classifiers and stronger classifiers contribute more to a more accurate final classifier.

AB improves the accuracy and mitigates over-fitting over individual classifiers, however AB can be sensitive to noisy data points and outliers because more weight is given to misclassified examples, which could magnify the noise from the mislabeled cases. Nevertheless, AB is a popular method because it is simple and does work well at boosting the performance of weak classifiers.

III.4 PROPOSED OPTIMIZING LOGISTIC REGRESSION USING GRIDSEARCHCV

This paper proposed an optimized LR model utilizing GridSearchCV, a technique that finds the ideal hyperparameters for the model via doing an exhaustive search throughout a given parameter grid. By methodically experimenting with different hyperparameter combinations, this methodology enhances the model's performance. For the LR model, we focus on tuning key parameters such as C (regularization strength), solver (optimization algorithm), and penalty (regularization technique). The parameter grid includes values for C ranging from 0.01 to 100, solvers 'liblinear' and 'lbfgs', and the 'l2' penalty.

The grid search is performed with 5-fold cross-validation to ensure robust evaluation of the model, with the goal of maximizing accuracy in classifying students as "Depressed" or "Not Depressed." The search is conducted by fitting the model with the training data and evaluating all parameter combinations, with the best hyperparameters selected based on their performance. After completing the grid search, the optimal hyperparameters are retrieved utilizing grid.best_params_, which fine-tunes the LR model for improved predictive performance.

III.5 EVALUATION METRICS

The performance of each ML model will be evaluated utilizing the following metrics [20]:

- Accuracy: The ratio of accurate forecasts (including true positives and true negatives) to all occurrences, which can be calculated by Equation (3).

$$\text{Accuracy} = \frac{\text{TP} + \text{TN}}{\text{TN} + \text{FN} + \text{TP} + \text{FP}} \tag{3}$$

- Precision: shows how many of the anticipated depressed students were actually depressed is indicated via the ratio of genuine positive predictions to all predicted positives, which can be calculated by Equation (4).

$$\text{precision} = \frac{\text{TP}}{\text{FP} + \text{TP}} \tag{4}$$

- Recall: The ratio of actual positives to true positive forecasts, which indicates the number of students who were accurately diagnosed as truly depressed, which can be calculated by Equation (5).

$$\text{Recall} = \frac{\text{TP}}{\text{FN} + \text{TP}} \tag{5}$$

- F1 Score: A balanced indicator of a model's capacity to accurately categorize both positive and negative cases is the harmonic mean of precision and recall, which can be calculated by Equation (6).

$$F - measure = \frac{2 \times (Recall * Precision)}{Recall + Precision} \tag{6}$$

These evaluation metrics will be calculated for each model to assess which ML algorithm provides the best predictive performance for identifying depression in students.

IV. RESULTS AND DISCUSSIONS

In this study many ML models were evaluated for their ability to classify depression in students, with the performance measured by accuracy as shown in Figure 2. The results of proposed model are summarized in Table 1. Our proposed method was the most accurate among the models compared, indicating the highest capability to detect depression among students. LR (97%), SVM (97%), and NB (97%) followed closely with strong results, demonstrating that simpler models can still perform very well in this classification task.

On the other hand, DT Classifier was very weak with accuracy of 81%, it indicates that the model tend to overfit, especially with depression data set is complex. As RF, GB, XGBoost and AB all reached 94%, but did not perform much better than the simpler models in this case. The better performance of proposed methods indicates that the applied algorithm – probably a specific combination of best features and hyperparameters – can extract the complex structure of dataset better than the rest. The results indicate that although traditional classifiers can achieve good accuracy, advanced models such as the proposed one would deliver a substantial advantage in performance, and be an effective method to address this category of classification challenge.

Table 1: Comparative Performance of Various ML Models and the Proposed Model.

Model	Precision	Recall	F1-score	Accuracy
LR	97%	97%	97%	97%
SVM	97%	97%	97%	97%
RF	95%	94%	94%	94%
GB	94%	94%	94%	94%
Xgboost	94%	94%	94%	94%
LGBM Classifier	96%	96%	96%	96%
DT	81%	81%	81%	81%
NB	97%	97%	97%	97%
Ada Boost	95%	94%	94%	94%
Proposed	98%	98%	98%	98%

The results obtained from different ML approaches for the prediction of the target variable are summarized in Table 2. The models of the state-of-the-art studies compared with optimized LR utilizing GridSearchCV, which is the proposed model in this study. The previous studies employed a range of algorithms, and the results varied significantly among models. For example, Qasrawi et al. [10] utilized multiple algorithms, counting DT, RF, ANN, and NB, and achieved a high accuracy of 92.6% utilizing SVM. While, Nayan et al. [11] explored a variety of models like LR, RF, LDA, KNN, and NB, with SVM once again yielding the highest accuracy at 91.49%. These results reinforce the strength of SVM in this context, as it outperforms many other traditional classifiers. Gil et al. [8] found that RF achieved the highest accuracy (86.27%) in their study, while Rahman et al. [12] was got an high 97% accuracy utilizing a hybrid stacking model. This hybrid model, which combined multiple algorithms, clearly benefited from the synergistic effect of the different classifiers. The hybrid approach suggests that stacking can lead to superior performance by leveraging the complementary strengths of various models, especially when no single model dominates across all metrics. While Hu et al. [6] utilized multiple models that counting RF and K-NN, but found that N-SVM (a variant of SVM) achieved the highest accuracy of 95.2%.

Villanueva et al. [13] utilized KNN and DT, but their RF model produced the high accuracy, although lower than many of the other models (77%), demonstrating that RF may not always perform optimally across all datasets. Zhai et al. [14] experimented with a combination of models, including DT, XGBoost, LR, and RF, but found that all models achieved an accuracy of only 70%. This suggests that while these models can be useful, further tuning or a different feature set might be necessary to improve performance. Mumenin et al [5] tested a broad range of algorithms, including LR, NB, SVM, DT, and ensemble methods like ERT, RF, XGB, LGBM, and KNN, with ERT (Extremely Randomized Trees) yielding the highest accuracy of 90.26%. This broad comparison underscores the complexity and variability of model performance, as different datasets may favor different algorithms. The proposed model of this work via LR through GridSearchCV achieved a high accuracy of 98%. This result is important because LR, although a simpler model compared to others like RF or Hybrid Stacking, shows competitive performance once hyperparameters were tuned utilizing GridSearchCV. The accuracy of 98% is very close to the best results stated in the literature. This suggests that with careful optimization, even simpler models can perform at the level of more complex algorithms.

Proposed model	2025	Proposed Optimizing LR using GridSearchCV	98

Source: Authors, (2026).

This study Proposed Optimizing LR Model shows high performance, outperforming many traditional ML techniques and even hybrid models, further proving the importance of optimization in improving predictive accuracy in depression classification tasks.

V. CONCLUSIONS

This work proposed optimized LR models and GridSearchCV for hyperparameter tuning classification problem. Very excellent accuracy of 98% has been achieved in the proposed approach and this is highly competitive compared with other state-of-the-arts ML techniques often employed for these monitoring tasks. This finding indicates that, with the right optimization, even those simpler models such as LR may achieve better performance than more-complicated methods including accuracy, interpretability and computational efficiency. The results indicate that well-calibrated traditional models such as LR can be just as effective as more complex approaches, providing a practical and resource-efficient solution. For future work, other feature selection techniques may be examined so that they can apply or ensemble the LR model and could improve the accuracy.

ABSTRACT

Fused Deposition Modeling is the standard commonly adopted for polymer due to its wide applications however, the mechanical properties achieved by FDM-fabricated components remain insufficient for many mechanical applications. The objective of this studywas to examine the outcome of build orientation on the tensile behaviour of FDM-printed ABS and CF-ABS specimens. ABS and CF-ABS were printed in the X, Y, and Z directions. X-oriented CF-ABS printed samples exhibited the highest ultimate tensile strength (28.90 MPa) with a Young's modulus of 2296.65 MPa; whereas, significantly weaker Z-oriented showed much lower strength than other samples because of weak interlayer bonding generally presented in all Z-oriented sample. Although CF-ABS becomes stiffer and stronger in the X and Y directions, the ductility stood exactly opposite since elongation dropped from 1.06% of ABS to 0.67% of CF-ABS. Taguchi-based DOE revealed that material type and build orientation were the most significant parameters influencing tensile performance. Overall, CF-ABS improved tensile property in certain directions for an optimal condition and provides orientation-based design guidance for to optimize FDM process parameters. The novelty of this study lies in the direct experimental comparison of orientation-dependent tensile behavior between ABS and CF-ABS using a Taguchi-based DOE framework under identical processing conditions.

I. INTRODUCTION

Additive Manufacturing (AM) has changed current manufacturing capabilities by enabling the manufacture of complex structures, reduction in material wastage and delivering immense possibilities for rapid prototyping. Unlike conventional subtractive processes, where material is removed from a workpiece of a material, additive manufacturing builds components layer-by-layer based on digital CAD models and leads to great design freedom and high material utilization. Over the past three decades, AM technologies have evolved from rapid prototyping tools to functional manufacturing processes to effective processes for producing functional end-use parts across industries including aerospace, automotive, and bio-medical and consumer electronics [1]. Among the numerous processes of additive manufacturing, Fused Deposition Modeling (FDM)/ Fused Filament Fabrication (FFF) is one of the most prevalent methods.

This is mainly due to its low-cost, high availability, and ability to process multiple types of thermoplastics. FDM operates by extruding a heated filament over a nozzle and placing it along one layer at a time over the predetermined pathway to create an object. On account of its ease of use and cost effectiveness, FDM has become a preferred choice for industrial applications requiring low-volume manufacturing and customized parts [2]. Despite the aforementioned advantages, FDM-printed parts exhibit certain mechanical limitations, particularly strong anisotropy in their material properties associated with layer-by-layer deposition. These limitations manifest as poor interlayer bonding, significant porosity and anisotropic mechanical response, which limit extensive application of FDM in

structural applications [3]. To overcome these challenges, process parameters such as layer thickness, raster angle, build orientation and reinforcement methods play major roles [4], all influencing final mechanical properties of printed parts significantly.

From basic polymer printing, FDM has evolved to include fiber-reinforced composites that bring about major improvement in the mechanical attributes. Reinforcements such as carbon fiber (CF), glass fiber (GF), and kevlar combined with thermoplastic matrices like acrylonitrile butadiene styrene (ABS) and polylactic acid (PLA) have been demonstrated to possess significantly improved stiffness, strength, and thermal resistant properties [5], [6]. Of these materials, Carbon Fiber-Reinforced ABS (CF-ABS) has been of particular interest due to its balanced mechanical attributes, ease of manufacturing and reduced warping when compared to pure ABS. CF-ABS consists of short carbon fibers in an ABS material; the result is a stiff and rigid material with increased tensile and flexural strength, but at the similar time lightweight. The addition of carbon fibers helps with load sharing efficiency and reduces heat expansion, making CF-ABS as a suitable candidate for high performance items which include aerospace components, automotive parts, and industrial tooling [7], [8].

Though, the mechanical concert of CF-ABS parts strongly depends on processing settings (mainly building orientation and fiber alignment), which affect interfacial adhesion and stress distribution in printed material [9]. Despite of CF-ABS having superior mechanical properties with respect to unfilled ABS, some challenges should be addressed for unlocking its potential in FDM applications. The main experiment lies in the anisotropic things of FDM-printed composites, wherein the properties of the fusions vary with the direction of printed deposits. Consider rephrasing to avoid repetition of FDM, parts have poorer adhesion in the Z-direction than in-plane properties (X- and Y-directions). This leads to less tensile strength and flexural strength, which makes Z prints vulnerable to delamination or breaking under pressure [10], [11].

Other considerations include the orientation and dispersion of fibers in the polymer matrix. The fiber orientation control in traditional composite fabrication processes such as injection molding or filament winding is not aligned, FDM-printed composites often suffer from random or non-uniform fiber orientations. This affects the stress allocation in-between polymer matrix and fibers of reinforcement, causing differences in mechanical property at different angles [12], [13]. Additionally, presence of voids and porosities related to insufficient melting between layers reduces the mechanical properties; thus, it is necessary to tune process parameters for enhanced interlayer bonding and reduced defects [14], [15]. Among influencing factors, build orientation is one of the supreme perilous limits affecting mechanical attributes to of FDM 3D in print parts. It governs the layer stack and how the layers bond, therefore determining strength, stiffness, and failure mechanisms.

Standard build orientations in FDM include the following: X-Orientation (Flat Build) in which the printing layers are parallel to the principal loading plane and as a result, improved layer-to-layer adhesion would be achieved at expense of out-of-plane strength. This orientation is suitable for tensile applications where higher elongation and formability are required [16-18]. Y-Orientation (Edge Build): Balances layer bond and in-plane strength, often providing the top tensile and flex assets. This is due to improved fiber orientation and stress transfer in the composite matrix [19-21]. Z-Axis (Vertical Build): This orientation is mechanically the weakest due to poor interlayer bond, hence low tensile strength and poor interlayer adhesion or build delamination tendencies. Such an orientation is, however, typically not applied for load-bearing applications [22-24]. Previous studies reported in the literature indicate that that the CF-ABS possesses higher tensile strength and flexural modulus along the Y-axis due to its improved fiber-matrix bonding and interlayer adhesion.

Furthermore, Z-oriented samples exhibit very different mechanical properties due to the significant decrease in interlayer adhesion between consecutive printed layers [25-28]. This discrepancy in performance highlights the necessity of tailoring build orientation for specific load bearing applications. The mechanical properties of FDM 3D printed ABS parts performed better because of including carbon fiber reinforcements. Improved stiffness, tensile strength and thermal stability could be attributed to carbon fibers, making CF-ABS composites promising for demanding applications. However, the level of these improvements is heavily determined by a number of considerations: Fiber Length and Content: Most FDM filaments use short carbon fibers (SCFs) sized in the range 100–500 μm. Fiber content, from 5 to about 30% wt., has a direct influence on mechanical properties. Higher fiber content increases the stiffness and strength respectively, but may reduce the ductility due to an increase of brittleness [29-34].

Fiber Orientation: Fibers can orient themselves in line with the direction you're printing owing to extrusion. This orientation will enhance mechanical properties along the axis of the filament and may compromise strength in transversal directions. Obtaining a homogeneous strength distribution is strongly predicated on accurate fiber angles resulting from optimization of slicing [35]. Interface Bonding: The fiber/ABS matrix adhesion must also be strong to ensure efficient load transfer. Low adhesion causes fiber pulling off and premature rupture in tensile loading. Surface modifications and/ or different polymer matrices have been studied in order to increase fiber-matrix interaction and enhance mechanical performance [36-38]. In order to maximize the benefits of CF-ABS in FDM, process parameters should be carefully optimized. Key factors impacting the mechanical behaviour of printed objects include: Layer Thickness: lower layer thickness (e.g., 0.1–0.2 mm) will increase interlayer bonding, but also extend printing time.

Thicker layer will be reducing anisotropy, but can give rise to poor surface quality and material defects [39-42]. Raster Angle and Infill Density: Changing the direction of fibers at different angles also affects load path and stress distribution. The non-raster orientation yields tensile strength due to fiber alignment relative to load (0°) and balanced mechanical properties in other directions (+/-45°). Higher infill densities (>50%) will increase the stiffness & strength of components, but at the same time expense of more material used and longer build time [43-45]. Temperature of the Nozzle and Printing Speed: Growth in the nozzle temperature induces flow of material and adhesive bonding between layers, which enhances interactions at interfaces. However, high temperatures can cause polymer matrix thermal degradation. For the printing speeds, being able to reach the ideal values is important since the trade-off between extrusion and mechanical performance can be maintained [46-48].

Because of the increasing industrial rising requirement for lightweight, high-performance and custom polymer composites, this study aims to present a holistic approach towards build orientation effects on mechanical characteristics (bending stiffness) to an FDM printed CF-ABS part. Tensile strength, flexural properties, and failure modes at two points were compared and show that this research offers vital criterion to optimize print settings in order to strengthen the material [49-52]. The outcomes will contribute to the broader area of additive manufacturing by addressing key questions related to anisotropic mechanical performance and fiber alignment, fostering

the adoption of CF-ABS composites for structural applications. This paper is prepared as follows: In Section 3, materials and methods utilized in this investigation will be detailed, including the investigational set-up and test method. Section 4 boons the results and discussion, focusing on the key results and their suggestions. Finally, Section 5 closes the paper with a summary of the main findings. The purposes of the current study stand:

- To experimentally investigate the tensile behaviour of FDM-printed ABS and CF-ABS components.
- To estimate the result of build orientation on tensile strength and deformation characteristics.
- To provide a through comparison between ABS and CF-ABS under identical printing conditions.
- To offer practical recommendations for material and orientation selection in structural FDM applications.

I.1 RESEARCH GAP

Existing publications on FDM-printed ABS and carbon-filled ABS mainly concentrate on individual impacts of process variables, for example infill density, raster angle or extrusion temperature. However, systematic comparative analyses in relation to the orientation-dependent tensile behavior of neat ABS vs CF-ABS under a controlled DOE-based environment are limited. On the other hand, most studies routinely reported lack of consistent experimental procedures where anisotropy in build direction is correlated with statistically validated mechanical response.

I.2 NOVEL CONTRIBUTIONS OF THE PRESENT STUDY

In light of the aforementioned limitations, this effort provides a methodical examination on the orientation-dependent tensile characterization of FDM-printed ABS and CF-ABS parts with controlled processing conditions. The principal novel contributions of this work are mentioned below:

- A comparison study on tensile specimens of ABS and CF-ABS prepared under the same FDM process parameters.
- An in-depth analysis regarding the effects of build orientation (X, Y and Z) upon the modulus, strength and ductility.
- Design of experiments (DOE) to statistically assess the relative importance of material type and build orientation.
- Provision of practical design-based guidelines based on the choice of building orientations for load-carrying polymer and composite parts fabricated by FDM.

The findings of this study would be helpful for improved understanding of anisotropic mechanical behavior in polymer composites FDM printing and provide useful suggestions for the selection of optimal build orientation in engineering applications.

II. LITERATURE REVIEW

Additive Manufacturing (AM), mostly Fused Deposition Modeling (FDM), has developed polymer processing, where Acrylonitrile Butadiene Styrene (ABS) is a broadly used thermoplastic because of its cost efficiency, impact resistance and manufacturing simplicity [1]. However, neat ABS also has inherent disadvantages like poor interlayer adhesion, warping and moderate tensile strength which make it unsuitable in structural application [2]. These problems arise due to the layer-wise deposition method, which results in anisotropy and weak interlayer binding [3]. In order to overcome these limitations, Carbon Fibre-Reinforced ABS (CF-ABS) material has been established by combining short carbon fibers (CFs) into the matrix of the ABS [4]. Such reinforcement significantly improves tensile strength and rigidity, reduced warping [5].

Carbon fibers (CFs) have been used to improve interlayer adhesion, decrease anisotropic properties of the filaments of a polymer in terms of participating in matrix composites and making composite [6] applications like; aerospace, automotive and medical devices industry. Mechanical properties of CF-ABS are strongly reliant upon the fiber content, distribution and interfacial adhesion [7]. It has been demonstrated by studies that an optimal concentration of CF (5–15 wt. %) provides a combination of strength and ductility and any further increase in the fiber content would contribute to the brittleness [8]. Good fiber orientation in compounding results in an increase in load-carrying capacity and poor dispersion may produce voids, decreasing mechanical properties [9].

Surface treatments such as acid etching and coupling agents improve fiber-matrix adhesion, which reduces fiber pull-out during loading [10]. FDM printed parts exhibit anisotropic nature due to the cascade deposition, resulting in significant variation in mechanical properties depending on printing direction [11] X-Direction (Flat orientation): Layers are stacked perpendicular to load direction Enhanced tensile strength and ductility owing to continuous stacking of filaments [12]. Y-Orientation (Edge Build): It offers better tensile and flexural strength due to improved fiber orientation and load transfer [13]. Z-Orientation (Building Up): Shows the worst mechanical properties due to poor bonding between layers, leading to delamination under load [14]. According to the research, Y-aligned CF-ABS specimens show higher strength, while Z-aligned samples suffer from layer-to-layer adhesion problems and void occurrences [15].

The mechanical performance of CF-ABS depends significantly on FDM processing parameters which require careful tuning [16]: thinner layer height (0.1–0.2 mm) increases interlayer adhesion but also lengthens the printing time, whereas thicker layers lead to a worse structural integrity [17]. Complementary heating plates can reduce warping and increase interlayer adhesion and strength [18]. A 0° screen angle maximizes the tensile strength for fibers aligned with the direction of load [19]. ±45° raster angles provide the maximum shear strength which makes them suitable for impact resistant applications [20]. Higher infill densities yield higher stiffnesses while also increasing material usage; 80% is an optimal compromise [21]. Hotter nozzle temperature result on better interlayer bonding while it introduces danger of thermal degradation to the polymer matrix [22].

The optimal speed for printing (50–75 mm/s) is a trade-off between mechanical operation and printing rate [23]. The anisotropic nature of FDM printed with CF-ABS leads to specific failure modes [24] Delamination: This is the dominating mode in Z oriented prints due to low interlayer adhesion as in [25]. Fiber Pull-Out: Occurs when interfacial strength between the fiber and matrix is weak, which reduces reinforcing effects [26]. Matrix Crack: Composites with high fiber content were reported as brittle [27]. Shear-Induced Degradation: commonly observed at ±45° raster directions that leads to slow decay instead of catastrophic failure [28].

Few works differentiate between CF-ABS and other reinforced polymers: PC- ABS versus CF-ABS: Polycarbonate ABS (PC-ABS) outperform CF-TPE in tensile strength as well as flexural strength, especially at higher infill density [29]. ABS/TPU Blends: Up to 20 wt. % of thermoplastic polyurethane (TPU) could be blended. % improves the interlayer bond but with no loss in yield strength [30]. Hybrids: Glass fibers (GF), graphene oxide fillers can be added to enhance thermal stability and mechanical properties of CF-ABS [31]. Although many successes have been achieved, several challenges still remain: The research on the hybrid CF-ABS/glass fibers, CNTs or Kevlar fiber-based composites is very scarce [32]. ABS/CF/GF hybrid composites are reported to possess improved wear resistance and thermal stability [33].

The techniques of AIML related to optimization FDM parameters are less mature [34]. Predictive modeling may accelerate the process of material properties optimization [35]. Most of works concentrate on static mechanical behaviors, and little information about fatigue performance, creep resistance and environmental degradation has been presented [36]. Results of the accelerated aging indicate that ABS is more affected by UV and heat exposure than PLA [37]. The principal limitation of important FDM printing is the evenness of the bed temperature and the continuity of filament feed [38]. -The porosity of the recycled ABS is larger and this reduces the mechanical strength in spite of a minor molecular degradation [39]. -Wear: GF/ABS composites obtain the lowest wear rates, which makes it suitable for high-wear applications [40].

Electrical Conductivity: The vertical printed ABS/carbon black composite exhibits 40% less charge transfer resistance than the horizontal printed one, which is very advantageous to sensing [41]. Hybrid reinforcement (CF + GF + CNTs) for enhancement of multifunctional properties [43]. AI-based parameter tuning for improved mechanical properties [44]. Extended durability tested under mechanical, thermal, and environmental stresses [45]. Sustainable AM technologies, including recycled materials and low-energy printing [46]. CF-ABS composites have a significantly enhancing effect on the mechanical behavior of FDM-printed parts, which is also affected by the printing direction and process parameters. However, anisotropy, interfacial adhesion and long-term reliability are still problematic [47].

II.1 INFILL ARCHITECTURE AND DENSITY

The tensile strength of FDM polymers and composites is strongly dependent on infill architecture and density. Seshaiah Turaka et al. modified infill from 20 to 80% at 0.32 mm layer height on a CreatBot F430, and they determined CF-ABS performance with an 80% infill density reached a tensile strength of 36.92 MPa, being the highest among other configurations (with a 64.74% higher flexural and a and also improved flexural and compressive performance linked with lower infill configurations. Moreover, honeycomb pattern also delivered high results [1]. Consistent with this, improving infill and the refined lattice (such as Tri-hexagonal) increased ABS UTS on Ultimaker machines [20]. In Stratasys machines, ABS-CF10 displayed a significantly improved tensile and flexural strength in relation to ABS-M30; for the CF level type, 80% sparse design presented the best performance at strength over weight rate [40].

II.2 ORIENTATION-INDUCED ANISOTROPY

Build orientation significantly affects tensile and flexural performance in both ABS and CF-ABS due to anisotropic interlayer bonding. The horizontal (X) orientation provided the maximum tensile and flexural strength, followed by vertical (Z) orientation, which yielded the minimum; approximately twice as much amount of strain energy was absorbed in case of horizontal samples related to the vertical ones [4]. The tensile strength of ABS was reduced by 44.3% when changing the printing orientation from 0° to 90° (UP-Box) [9]. For CF filled systems, Z-strength of the CF-ABS was 47% lesser than the flat builds but stiffness increased by about ~90% with CF in the flat orientation [13]. In conventional FDM research, tensile properties of ABS parts relating to the injection-molded ABS were found as 65±72%, which are affected by rasters and air gap with the axial direction performing better among them [38].

II.3 RASTER ANGLE, LAYER HEIGHT, AND GEOMETRY

Introduction The tensile strength and flexural resistance of SCFR-ABS decreased by 22% from 31.5 to 24.6 MPa and by 15%, respectively, with a raster orientation angle ranging from zero to 15 degrees; however, certain angles (e.g., 60°) promoted crack deflection for tougher specimens [23]. Integrity studies showed that 0/90° rasters outperform ±45° in tensile/fracture behavior in ABS/PLA settings [24]. ABS tensile strength increased by 33% at 0.1 mm/5 (0°) after improving the rasters of ABS with a chamber temperature higher to reduce voids and therefore improve strength [25]. 0° rasters, 0.8 mm nozzle, 0.15 mm layers achieved the least number of cracks development and the longest fatigue life time under thermo-mechanical stresses of ABS [26].

II.4 INFLUENCE OF CARBON-FIBER REINFORCEMENT AND MATRIX SELECTION

This is because usually CF reinforcing will increase stiffness/strength and reduce ductility. 50% overall infill, hexagonal with 5–15 wt% CF At a load of 0.1 kg, hexagonal (CF-ABS) structure has reached a strength of 21.41 MPa (~24% higher than ABS) and the modulus equals to 1.47 GPa [3]. The tensile strength of the 13 wt% CF filled sample (CF-ABS) was about 30% that of ABS; a 50% infill often led to significant enhancements [8]. For flexural tests, it was reported that CF-ABS had a 58.7% increase in modulus compared to ABS with P450 orientations outperforming P0 and ±45° [14]. It is crucial to select an appropriate thermoplastic matrix: The tensile strength of CF-PA6 was roughly 68% higher than that for CF-ABS, whilst the latter's modulus was about 106% greater than that of CF-PA6; the thermal degradation onset temperature for CF-ABS exceeded 270 °C [43-54]

II.5 PROCESS-ASSISTED STRATEGIES AND NANO-MODIFICATION

Anisotropy can be reduced by help in processing. Additional heating at 160 °C could boost the strength under tension of CF/ABS by 31% and enhance the ductility by a factor of 439%, while reducing warpage from 12.3 mm to as low as 1.7 mm at a full infill density [27].

In high-temperature composites, a tensile strength was achieved by CF/PEEK of 94 MPa at 440 °C nozzle and 280 °C bed temperatures, where low thickness layers combined with a slow speed induced high interlayer adhesion [30]. Nano-fillers and additives also help with the mechanical properties: 2 wt% graphene oxide in ABS increased tensile strength and modulus, but decreased elongation (5.8% to 2.9%) [32]. 10–20% v/v fine expanded-perlite fillers (≤90 µm), maintained ABS UTS near 21.7 MPa; coarse/more load reduced strength because pore and layer dislocation [37]. ABS+CNT outperformed ABS+CF in tensile strength in some cases (34.18 vs. 27.25 MPa) while a lower layer thickness improved the property by reducing the porosity [55-57]

II.6 MICROSTRUCTURE, VOIDS, RECYCLING, AND SCALE

Reducing the pore size improves the interfaces: roller-pressed LAAM CF-ABS (13 wt% CF) reduced micro void volume from 14.0% to 10.0% and improved interlaminar adhesion [36]. Recycling was found to have increased porosity (≈11%→17%) which caused in a 10% reduction in the stretchy strength of ABS and 25% reduction in strain at break (5.2%→3.9%) [39]. Nylon-12 CF (Fortus 900mc) achieved a UTS of 97.41 MPa for side orientation, but only 22.63 MPa in the upright position; solid infill improved strength at the expense of ductility [41]. Multi-function, multi-material printing magnifies the practical concerns (ensuring even bed heating and feed control) that must be resolved before mechanical improvement [42]. Porosity and tensile strength increased because recycling resulted in molecular degradation and void formation [47], [48]. The large-area AM process also suffers from thermal gradient, filament feeding instability and void defect [49], [50].

II.7 ARCHITECTED LATTICES AND STRENGTH–DUCTILITY TRADE-OFFS

Hierarchical honeycombs of ABS, CF-ABS (CF 15%) and CNT-ABS indicated that the compressive load was maximized for CF-ABS honeycomb's structure (924.63 N) and second order hierarchies improve stiffness [1-3]. Across several studies, factors including orientation (flat/side), raster alignment, minimum layer thickness, careful temperature control and higher but effective infill in addition to CF/CNT reinforcement collectively improve strength and stiffness – although ductility frequently decreases – with Z-direction failures again primarily dictated by poor interlayer bonding [4-8].

Despite comprehensive parameter studies, there is a dearth of DOE-directed orientation-specific tensile characterization of CF-ABS that (i) holds non-orientation parameters constant, and (ii) provides a full mechanical suite (UTS, yield strength, modulus, ductility, breaking stress) to quantify the strength–ductility trade-off for design considerations [9-13]. Previous studies involving changes of parameters (infill/raster/temperature) with orientation combined, thus obfuscating the origin of effects or focusing on non-tensile tests (compression/impact) or other matrix/geometries PA6, PEEK [14-20]. Focuses on build orientation (X/Y/Z) and material type (ABS vs CF-ABS) under constant process parameters, utilizes a Taguchi-based DOE for factor precedence, and showcases the influence of factors on performance by tweaking only one mechanical factor at a time.

Orientation specific values such as UTS, modulus, yield, break strength and ductility are provided in this analysis [21-26]. The results indicate when CF-ABS provides useful functionality (e.g., CF-ABS-X maximum UTS) and when regular ABS may be more appropriate due to ductility requirements, which provide some general guidelines for selecting between load-bearing and compliance-focused FDM parts [27-32]. The focus of this data-driven but concentrated orientation study addresses the identified gap and provides design-ready recommendations in a short-term horizon for polymer composite FDM. Hierarchical lattice designs and honeycomb infill patterns contribute towards the improvement of their compressive strength, stiffness along with energy absorption behaviour [51-54]. In order to address the identified research gap, this study employs a a DOE framework based on the Taguchi method in fine-tuning the impact of build orientations (X, Y, Z) and material types (ABS vs. CF-ABS) on tensile behavior.

All of the other printing settings – such as infill percentage, raster angle, nozzle temperature, print speed, and layer depth – were kept constant to isolate the effects of build orientation and material type. ASTM D638-type tensile samples were made-up using a Creality K1C industrial FDM printer, and mechanical testing was led using a digital uniaxial tensile testing machine. The mechanical properties (UTS, yield stress, break strength, Young's modulus and ductility) were analyzed using a statistics approach. The method enables that mechanical differences can be assigned reliably to orientation and reinforcement effects, in a reproducible and clear manner. CF reinforcement generally improves stiffness and load-bearing capacity but often reduces ductility [58-62]

II.8 SUMMARY OF LITERATURE

Build direction is well known to be an important influencing factor of the tensile properties for FDM-printed polymer components. In common, X- and Y-oriented samples are stronger and stiffer in tensile compared with Z-orientation due to the more level bonding within layer and decreasing interlayer failure [3], [9]. The anisotropic behaviour is largely owing to the layer-wise deposition process and poor inter-diffusion of molecules between adjacent layers [23]. However, the majority of published studies are based on a specific material system and there is little available work in comparing directly under same processing and material control. The tensile stiffness and load capacity of the composites containing CF-ABS have been enhanced, but issues related to adequate blending between fibre and matrix, formation of voids, anisotropy due to orientation continue to be critical [24], [30].

Most of the literature have addressed on filament/material approach while to date integrating of build orientation effect with CF reinforcement in tensile performance is scarce. Recently, some research activities have been observed to focus on enhancing interlayer adhesion, reducing anisotropy and multi-functional performance of FDM composites [57], [63], as well as developing AI/ML techniques for parameter prediction and optimization [64], [65] in addition to pursuing sustainable approaches including use of recycled polymers and eco-friendly composite manufacturing [58], [59]. Finite element analysis has also been employed to simulate stress and strain in FDM parts yet the available experimental–numerical correlation for CF-ABS systems under common tensile loading is inadequate [60-62], hence the capability to develop accurate predictive models of orientation-sensitive composite components is limited.

Table 1: Comparison of Existing Studies on Orientation/Parameter-Dependent Tensile Behaviour of FDM Printed ABS and CF-ABS.

Study	Material	Orientation considered	DOE used	Constant parameters	Key findings	How present study differs
Seshaiah Turaka et al. (2024) [1]	ABS, CF-ABS (Think Robotics, India)	Not explicitly (focus: infill density)	No (parametric study)	Yes (nozzle temp., speed, layer thickness fixed; infill varied)	CF-ABS at 80% infill showed 36.92 MPa tensile strength; higher infill + CF improves properties	Present work compares build orientations (X/Y/Z) for ABS & CF-ABS under controlled conditions instead of only infill variation
Vigneshwaran Karupaiah et al. (2022) [3]	ABS / CF-ABS (Nanovia, France; SCF 5–15 wt%)	Yes (reported best in Y-orientation)	No (multi-parameter comparison)	Partially (multiple infill patterns & densities varied)	CF-ABS with hexagonal + 50% infill → 21.41 MPa UTS, modulus 1.47 GPa	Present study gives direct ABS vs CF-ABS orientation benchmarking with consistent printing plan and experimental tensile testing
Anubhav et al. (2023) [4]	ABS+ P430	Yes (X vs Z)	No	Yes (100% infill; fixed layer thickness & temps)	Horizontal (X) highest strength; Vertical (Z) weakest; orientation dominates	Present study extends to two materials (ABS & CF-ABS) and reports full orientation response including stiffness and failure behaviour
Abdul Quader Shurjeel et al. (2021) [6]	CF-ABS / PC-ABS	Not explicitly	No	Partially (infill & raster varied)	0° raster and higher infill improve strength; PC-ABS > CF-ABS	Present work isolates build orientation effect (X/Y/Z) rather than raster angle/infill combinations
Olusanmi Adeniran et al. (2022) [8]	CF-ABS, CF-PA (15% CF)	Not specified	No	No (printing temperature varied)	CF-PA6 shows ~68% higher strength vs CF-ABS; CF-ABS higher modulus	Present study focuses on orientation-based anisotropy in ABS and CF-ABS (not matrix comparisons like PA)
E. A. Syaefudin et al. (2023) [9]	ABS / PLA	Yes (0°, 45°, 90°)	No	Yes (layer thickness fixed)	ABS tensile strength reduced 44.3% from 0° to 90°	Present work provides material reinforcement comparison (ABS vs CF-ABS) plus full tensile response with orientation mapping
J. Yan et al. (2023) [13]	ABS/CF-ABS, PLA/CF-PLA, PA & PETG composites	Yes (F vs Z)	No	Yes (temp/thickness fixed)	CF-ABS shows ~47% lower Z strength than F-direction; stiffness improved ~90% in F	Present study gives experimentally validated orientation ranking for ABS & CF-ABS using tensile coupons and constant settings
Kui Wang et al. (2019) [14]	ABS, CF-ABS, KF-ABS	Yes (0/90 vs ±45; horizontal vs side)	No	Partially	CF-ABS modulus increased 58.7% over ABS; orientation/raster affect flexural	Present work specifically benchmarks tensile UTS & stiffness across orientations for ABS and CF-ABS specimens
Chamil Abeykoon et al. (2020) [35]	ABS, CFR-ABS, CNT-ABS etc.	Yes (raster orientation 0°–90°)	Yes (optimization)	No (multiple factors varied)	Infill density + raster orientation significantly affect tensile strength	Present work is simpler + targeted: only ABS & CF-ABS with orientation-dominant tensile investigation, suitable for manufacturing design
S.-H. Ahn et al. (2002) [38]	ABS P400	Yes	No	No	Tensile strength depends on raster orientation/air gap; FDM ABS ~65–72% of injection molded	understanding to CF-ABS filament composite and produces orientation-dependent tensile benchmarks relevant to current low-cost FDM platforms

III.MATERIAL AND METHODS

Systematic experimentation was employed in this work to explore in what way build direction moves the tensile properties of FDM-printed ABS and carbon fiber-reinforced ABS (CF-ABS) parts. In order to obtain reproducible results, all samples were fabricated under controlled processing conditions, and tensile tests performed according to ASTM standards. Material type and build orientation effect was statistically evaluated using a structured Design of Experiments (DOE) methodology.

III.1 MATERIAL SELECTION

Fused deposition modeling (FDM) is utmost current additive manufacturing processes used to fabricate polymer parts, known for its low cost, simplicity and ability to produce complex objects with no material loss. This paper studies the tensile stress mechanical properties of Acrylonitrile Butadiene Styrene (ABS) and CF-ABS, in different orientations.The materials used in this learning were solid space filaments of nominal diameter 1.75 mm. The material properties, delivered by the manufacturer, are given in Table 2.

Table 2: Technical features of the filaments material made of ABS and CF-ABS.

Property		
Material	ABS	CF-ABS (carbon fiber reinforced ABS)
Filament Diameter	1.75 mm	1.75 mm
Colour	White	Black
Density (g/cm³)	1.05	1.11
Poisson's Ratio (ν)	0.36-0.38	~0.35–0.40
Modulus of Elasticity (E) (GPa)	2.62	5.21
Flexural modulus (GPa)	2	5.26
Ultimate Tensile Strength (UTS) (MPa)	47.0	46.0
Heat Deflection Temperature (°C)	90	76
Tensile strength At yield At break	 47 MPa 34 MPa	 36.8 MPa 46 MPa

Source: [66], [67].

Note that the carbon fiber filament reinforcement was not manually added by us but rather it was already present within the original CF-ABS supplied through vendor. The CF-ABS is a short carbon fiber–reinforced thermoplastic composite filament and the carbon fibers are well-dispersed in the ABS matrix during the extrusion of the filament [52], [63]. Thus, the reinforcing found in 3DP follows from the natural composite character of the filament and not a result of transferring reinforcement or adding continuous fibers to FDM process [64, 65]. This method offers enhanced stiffness and strength, but can still be used with standard FDM printing systems in the same processing conditions [58-62].

III.2 PRINTING PARAMETERS AND EQUIPMENT

Samples were fabricated using the Creality K1C industrial FDM printer, known for its accuracy, repeatability and wide range of applicable materials. Printing settings were kept consistent for all printed parts to provide uniformity. Table 3 presents the standardized development limits followed in the present study during the production of the specimens with the Creality K1C industrial grade FDM printer. A 100% infill was used to ensure fully dense samples and minimise internal porosity. The nozzle size is 0.4 mm and the deposit height is also set as 0.2 mm to balance between printing quality and printing speed. For high resolution prints, a print speed of 120 mm/s was maintained; as the optimum compromise between accuracy and construction time. The extrusion temperature was set at 245 °C to achieve sufficient filament flow and adhesion. This temperature was built on the manufacturer's recommended processing window for ABS and CF-ABS filaments, to provide optimum viscosity and uniformity of layer adhesion.

This temperature enables correct polymer chain hopping between adjacent layers, thus decreasing interfacial voids and the force of adhesion. Former researches reported that extrusion at temperatures ranging about 240–250 °C is the temperature to use for achieving a proper fit between stabilization of stable flow and prevention of high-temperature degradation, for ABS based composites. Therefore, a default temperature of 245 °C was defined to guarantee the same reliable and perfect print quality for all test prints with always a nozzle temperature at 215 °C ensuring good extrusion. To increase adhesion of the first layer and prevent warping, a hotbed temperature of 105°C was used. Cubic infill pattern selected for its strength and uniform distribution of the load. In addition, a cooling rate of 100% was used to regulate the solidification process and improve the bonding quality between layers. These settings were applied consistently on all builds to ensure consistency/reliability of the experimental results.

Table 3: Printing Parameters.

Process Parameters while printing Build orientation	
Infill density	100%
Nozzle Diameter (mm)	0.4
Layer height (mm)	0.2
Print speed (mm/s)	120
Extrusion Temperature	245 °C
Infill pattern	Cubic
Bed temp	105 °C
Cooling speed	100%

Figure 1: Creality K1C industrial-grade FDM printer used for specimen fabrication.
Source: [66].

The industrial-type FDM printer, Creality K1C used in this study is shown in Figure 1. Its exact construction and dual-gear mechanism ensured uniform extrusion quality for ABS as well as CF-ABS samples. The trials were conducted using a Creality K1C industrial-grade FDM printer with dual-gear direct driver extruder. All the specifications for the printer are given in Table 4. To ensure efficiency and dimensional precision, a quick printing method was used. The selected process parameters were based on a substantial review of prior studies and preliminary experiments to ensure optimization for the tensile properties of printed samples.

Table 4: FDM Printer specification.

Printing Technology	Fused deposition modeling
Build Volume	220x220x250mm
Product Dimensions	355x355x482mm
Printing Speed	≤600mm/s
Acceleration	≤20000mm/s²
Printing Accuracy	100±0.1mm
Build Plate	PEI flexible build plate
Printable File Format	G-Code
Layer Height	0.1-0.35mm
Extruder	Dual-gear direct drive extruder
Filament Diameter	1.75mm
Nozzle Diameter	0.4mm
Nozzle Temperature	≤300°C
Heat bed Temperature	≤100°C
Supported Filaments	ABS, PLA, PETG, PET, TPU, PA, ABS, ASA, PC, PLA-CF, PA-CF, PET-CF
Slicing Software	Creality Print, Cura 5.0 and later version

Source: [66].

III.3 INFILL DENSITY

The infill density was set to be 100 percentage for all samples, in order to ensure the fully dense properties of components and thus minimize the internal porosities as well as maximize the mechanical strength. This is in accordance with previous findings, where infill

density has a momentous effect on tensile properties of the structure as the fully dense ones result in enhanced load carrying capacity and uniform stress distribution.

III.4 INFILL PATTERN

A cubed infill pattern was selected due to significantly better isotropic properties and ideal load distribution versus other infill types. Previous research studies showed that stiffened cubic infill patterns possess better stiffness and strength with reasonable material usage.

III.5 PRINTING SPEED

The printing speed was determined at 120 mm/s based on the capacity of the printer and previous criteria of FDM-printed polymer composites. The lifting speed accelerates the printing but may cause a worse layer adhesion and surface finish. The speed selected achieved a balance between the production efficiency and the mechanical reliability.

III.6 LAYER HEIGHT

The layer height of 0.2 mm was chosen to enhance mechanical properties and surface finish. Previous studies indicate that a lesser deposit height results in better interlayer adhesion and tensile strength due to the more effective molecular diffusion and bonding between layers.

III.7 BUILD ORIENTATIONS

The building direction is an important consideration for the mechanical properties of FDM printed parts since AM processes are usually anisotropic. Three characteristic orientations of build, presented in Figure 2 were evaluated: X-Orientation (Flat): The layers are oriented perpendicular to the loading direction. Y-Orientation (Edge): Layers are oriented perpendicular to the load direction but still in-plane. Z-Orientation (Standing): The layers are arranged perpendicular to the loading direction and the interlayer bonding is the principal means of support. Furthermore, previous research results indicated that the tensile property of Y-oriented samples is supposed to be optimal due to the better order of layer bonding and stress distribution while Z-oriented was expected worse tensile strength because of relatively low interlayer adhesion. The X, Y and Z construction orientations are illustrated visually in Figure 2. These orientational factors have a large influence on layering and the interfacial adhesion that determines the anisotropy of tensile properties.

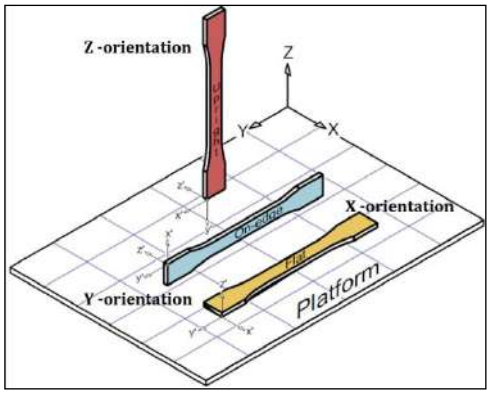

Figure 2: Diagram representation of the three Build orientations studied.
Source: [68].

III.8 DOE

An orthogonal array-based experimental (OAE) procedure was employed in order to systematically determine the effect of build orientation and material type on tensile strength of FDM printed specimens. The Taguchi method is a useful, statistically-based tool for minimizing the number of actual experiments required at a research stage and maximizing what one can learn about factor effects. In this study, two primary control factors were considered (A) Build Orientation with 3 levels (X-Y-Z), and (B) Material Type with 2 levels (ABS-CF-ABS). A L6 orthogonal array was selected, taking these factors into account, and all levels were equally represented only in six different trials. All trials were repeated 3 times to increase reliability and reduce random error.

The DOE meant to evaluate the result of build orientation and material type on key mechanical responses: Ultimate Tensile Strength (UTS), Yield Stress (σy), Break Strength σb, Ductility εb, Young's Modulus E. Signal-to-noise (S/N) ratio is a quality evaluation/criterion in the Taguchi method to quantify variability and robustness. For the properties requiring higher values (UTS, E), using the larger-the-better criterion, as in where S is defined mathematically by:

Taguchi Signal-to-Noise (S/N) Ratio – "Larger-the-Better" criterion Equation

$$S/N = -10\log_{10}\left(\frac{1}{n}\sum_{i=1}^{n}\frac{1}{y_i^2}\right) \quad (1)$$

Where:

- S/N = Signal-to-Noise ratio (dB)
- n = Number of experimental repetitions
- y_i= Measured response value for the i^{th} trial (e.g., tensile strength, Young's modulus)
- i = Trial index (i = 1, 2, …, n)

This "larger-is-better" criterion is used when the objective is to maximize the response, such as ultimate tensile strength or elastic modulus. Where n is the quantity of runs then y_1, y_2, y_n are the response. The averages of the levels were then computed and trend analysis was performed, main-effect and interaction diagrams plotted to provide an evaluation of the features' influence on mechanical properties. The "larger-is-better" expression (Eq. 1) enables that better mechanical properties correspond to higher S/N ratios, indicating good system parameters. To further analyze the effect of each factor, this study performed Analysis of Variance (ANOVA). The pure effect of each factor on the overall variance (in the response) was estimated using the following relation

Percentage Contribution of Factors (ANOVA) Equation

$$P_i = \frac{SS_i}{SS_T} \times 100 \tag{2}$$

Where:

- P_i= Percentage contribution of the i^{th} factor (%)
- SS_i= Sum of squares of the i^{th} factor
- SS_T= Total sum of squares

This equation quantifies the relative influence of each control factor on the overall variation of the response. Where P_i is the percent contribution of i^{th} factor, SS_i is sum of square for each such factor and SS_t is total sum of squares. These analyses indicated the key parameters with regard to tensile strength and modulus. The best combination of parameters that ensured the maximized strength and stiffness with minimum variability were calculated from S/N ratio and ANOVA analysis. As a consequence, the DOE framework delivered a systematic and statistically supported analysis procedure for optimizing FDM process parameters.

An L6 Taguchi array was used to study the orthogonal independent and interactive effects of two factors: material (ABS, CF-ABS) and build orientation (X, Y, Z). This procedure provided a clear view how each factor influences process performance. Each combination of factors was evaluated in triplicate to ensure statistical soundness, resulting in 18 tensile test samples (9 ABS and 9 CF-ABS). The response was characterized by tensile properties such as extreme load (N), ultimate tensile strength (MPa), percentage extension, break strength (MPa), yield stress (MPa) and Young's Modulus (MPa).

A Taguchi orthogonal array was working to reduce the number of experiments, but retain statistical power. The factors that were considered are; Factor A: Build orientation – (3 levels, X, Y and Z) Factor B Material type (2 levels, ABS and CF-ABS). An array L6 model was developed which resulted in six experimental conditions. All conditions were performed in triplicate creating six tensile samples. The analysis of S/N ratio was carried out under a "larger-is-better" criteria to find the finest level of parameters for determined value of tensile strength and modulus.

Table 5: Layout of L6 Array.

Run	Factor A – Orientation	Factor B – Material
1	X	ABS
2	Y	ABS
3	Z	ABS
4	X	CF-ABS
5	Y	CF-ABS
6	Z	CF-ABS

Source: Authors, (2026).

It was a deliberate choice to use only two factors for the DOE with tensile response since such measures limit the influence of orientation and type of material. This method simplifies the experimental complexity and provides a statistically meaningful correlation to anisotropy effects.

III.8.1 Experimental Factors and Levels

The experimental design was intended to explore the mutual effects of build orientation and material content on tensile strength. Two control variables were selected because they significantly influence the mechanical performance of FDM.

Table 6: Factors & Levels.

Factor	Symbol	Levels	Description
Build Orientation	A	3	X (Flat), Y (Edge), Z (Vertical)
Material Type	B	2	ABS, CF-ABS

Source: Authors, (2026).

All possible combinations of factors were evaluated for three replicates leading to 18 experimental runs (6 combinations × 3 repeats). One of the orthogonal arrays L6 was selected, it effectively handles two factors at three levels and reduces the number of experimental runs. This design guarantees statistical balance and yields sensitivity to a main effect without confounding.

III.8.2 Response Variables and Evaluation Criteria

The response variables selected were:

- Ultimate Tensile Strength (UTS, MPa)
- Yield Stress (σy, MPa),
- Break Strength (σb, MPa),
- Ductility (εb, %),
- Young's Modulus (E, MPa).

The Taguchi signal/noise (S/N) ratio technique and an ANOVA were used to analyze these responses for the identification of significant parameters and optimal conditions. For UTS and E, the larger the better criterion was rummage-sale and mean effect plots were used to analyse factor sensitivity for all other responses.

The Taguchi analysis workflow included:

a) Factor combinations from the L6 array.
b) Performing 3 replicates per condition to reduce experimental error.
c) Computing S/N ratios using Eq. (1) and identifying the important factors according to Eq. (2).
d) Graphing main and interaction effects for UTS, yield stress, and modulus to represent orientation–material interactions.

By this systematic approach, it was ensured that both material-type and orientation-effects were statistically verified which resulted in a comprehensive and reproducible conclusion about the tensile behavior of FDM reproduced composites. The use of DOE approach added a significant scientific value to this research. With the use of a Taguchi L6 orthogonal array, the study was efficient in determining individual and collaborating effects of build orientations and materials on tensile behaviour with minimal number of experiments executed. This factorial design verified that observed changes in tensile strength, modulus and elongation were statistically attributed to process variables rather than random error.

Objective ranking of the significance level of the parameters was carried out using S/N ratio and ANOVA estimations, and build orientation was found as most influencing parameter for mechanical variation closely followed by material type. Accordingly, the DOE procedure has enhanced peak strength and stiffness parameterization but also increased reproducibility and confidence concerning experimental results. The results obtained through this systematic framework confirmed the identification of an optimal print orientation-material combination in achieving improved mechanical properties in FDM-printed composite materials.

III.9 FABRICATION OF 3D PRINTING SPECIMEN

The tensile test specimens were designed built on ASTM D638 via SolidWorks. The 3D models were then converted into .STL file processed set-up which is often used for 3D printing and readable by slicing software. Slicing was performed on ORCA Slicer v2. 2. 0 with key process variables fixed to secure repeatability of production.The settings of the process were set as: Infill Density: 100%, Printing Speed: 120 mm/s, Layer Thickness: 0.2 mm, Infill Pattern: Cubic and Nozzle Diameter: 0.4mm.The STLs were added to the slicer, and for each part of build orientations were changed from X, Y onto Z axis to study how the parts behave mechanically. The slicing process also generated useful data such as nozzle position, weight to be expected for the object, desired length of filament and duration to print. Upon verifying these parameters, the finished files were exported and saved as G-code files.

3D printer Instructions were transferred to 3D printer through USB drive. 3D printing machine, dual-nozzle 3D printer was first fed with ABS or CF-ABS filaments, and then FDM (Fused Deposition Modeling) printing procedure was adopted. Each sample was printed as an individual data point to maintain consistency and avoid batch-to-batch effects of printing. The automatic printing system ensured uniformity of all the samples.Nine samples were generated using ABS and 9 samples using CF-ABS producing a total of 18 extracted tensile specimens. Three specimens per orientation (X, Y and Z) were printed for making comparisons. Once printing was complete, the samples were detached carefully from the print bed. If support were present, these were manually removed for accuracy in dimension. Each sample was later checked to confirm that it complied with the ASTM D638 typical dimensions. After that, the specimens were coded for tracking and prepared for subsequent tensile test.

III.10 TENSILE TESTING PROCEDURE

Tensile testing was done in accord with ASTM D638 that measures fracture behavior of an applied load, within its gauge lengths of the sample. Test method followed ASTM D638, which measured the tensile strength and elongation of a material. This process is commonly applied for woven, non-woven and felted structures however modified to be used as a technique for tensile testing of FDM-printed ABS and CF-ABS samples.Dimensions of the sample, such as gauge width and thickness, were measured with a micrometer prior to testing. A 25 mm length were marked for each sample. The acquisition signals were transferred into the tensile testing software in directive to ensure accurate stress-strain conversion.

Tensile testing was conducted using a uniaxial digital tensile testing machine (Shanta Engineering, Model: SET-T-20kN) at tension mode. The samples were clamped tightly with fixed and moveable clamps. The lower grip was fixed and the upper one had moved at a continuous crosshead speed of 10 mm/min until the sample failed. After fracture, the fractured sample was removed from the grips and its elongation measurements were obtained using vernier's caliper.The tensile testing system recorded and analyzed several mechanical properties including Ultimate tensile stress (MPa), Load at break (N), Elongation at peak (mm), Elongation at break (mm), Break strength (MPa), Percentage elongation at maximum load and NBS, Final dimensions of films (width, thickness, length in mm or cm); The final cross-sectional area of the test specimen (mm^2); Yield stress (Mpa);,Yield load (.N),Load-displacement curve.

Following the completion of testing, a representative tensile stress–strain curve was developed in the software to indicate the mechanical behavior of both ABS and CF-ABS under tensile loading. The recorded data were stored as a PDF for further analysis.This method of tensile characterization enables the repeatability and reliability for mechanical property assessment of FDM-printed ABS and CF-ABS materials under uniaxial tensile loading. The uniaxial digital tensile testing machine used for characterization of the mechanical properties of FDM-printed ABS and CF-ABS samples are given in Table 7. The equipment, manufactured by Shanta Engineering (Model: SET-T-20kN), operates between the modes of tension, and has a maximum load of 2000 kg suitable for strong materials.

Table 7: Tensile Strength Machine Specification.

Name	Uniaxial testing machine digital type testing machine
Make	Shanta Engineering
Model	SET-T-20kN
Max. capacity (Kg)	2000
Digital Panel	In build digital display with machine
Load Cell 1	1 kN
Load Cell 2	20 kN
Max. crosshead displacement without grips/fixtures (mm)	900
Displacement resolution (mm)	0.2
Column clearance(mm)	450
Machine Dimensions w × d × h in (mm)	1100 × 400 × 1800

Source: [66]

The testing machine is equipped with a digital display screen, which allows the user to easily see load displacement values, and accurate configuration test result in time. It offers two load cells—1 kN and 20 kN—ensuring that a large number of force applications can be carried out with high accuracy. Without grips and holders, this machine can accept specimens of varying size up to 900mm crosshead travel. For higher measurement precision, the system provides a displacement resolution of 0.2mm. Clearance of 450 mm between the columns allows enough space to align specimens and attach grips. The size (1100 mm × 400 mm × 1800 mm) of the machine can maintain test environment stable and reduce disturbance outside.This criterion collectively improved the accuracy, repeatability and reliability of tensile testing process which aids in determining mechanical properties for ABS and CF-ABS specimens under uniaxial tensile loadings

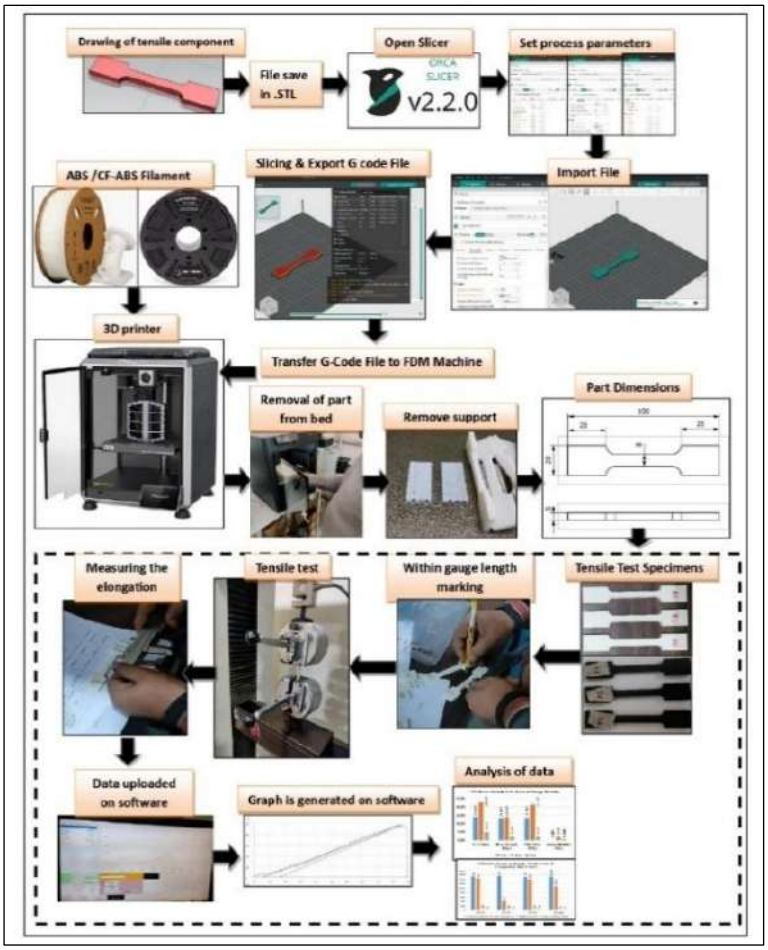

Figure 3: Flowchart of specimen preparation and tensile test with uniaxial digital tensile machine.
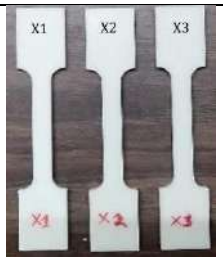
Source: Authors, (2026).

As exemplified in Figure 3, the procedure consisted of 3D printing, post-processing and tensile tests by means of digital uniaxial machine (20 kN) test.Numerical calculations displayed sequentially (Stress = 545.7 / 40 = 13.6425 MPa, Strain = 0.753 / 25 = 0.03013, etc.). The applied force during loading was directly recorded from the uniaxial testing machine. The cross-sectional area was measured for accuracy with a micrometer, prior to testing. The stress is of crucial importance because it has direct effect on the material selection and mechanical performance estimation.



Before testing	 ABS X Orientation	 ABS Y Orientation	 ABS Z Orientation
After testing	 ABS X Orientation	 ABS Y Orientation	 ABS Z Orientation

Figure 4: Tensile ABS samples at X, Y, and Z directions before and after tensile testing; reveals failure modes depended on orientation.
Source: Authors, (2026).

In Figure 4, differences in the failure of ABS samples are highlighted. ABS-Y displayed more resistance to factual failures as opposed to ABS-Z where brittle delamination was noted due to low interlayer adhesion. Figure 5 illustrates CF-ABS malfunctions. CF-ABS-X retained its structural integrity with increased UTS, whereas CF-ABS-Z fractured prematurely supporting the anisotropy trends.Visual evidence of failure modes helps in interpreting the behavior of materials under tensile loading. Connected with numerical data, these results provide a deeper insight into fracture mechanisms and anisotropic materials behavior.Three samples for apiece material (ABS and subtype CF-ABS) were printed in the X, Y and Z direction respectively according to ASTM D638 standard. A total of 18 tensile test samples were obtained in this way (2 materials × 3 orientations × 3 replicates). Average values from these three replicates of Ultimate Tensile Strength (UTS), Yield Stress, Break Strength, Ductility and Young's Modulus were calculated to establish statistical dependability. The SD for each group was also determined to demonstrate experimental variation.

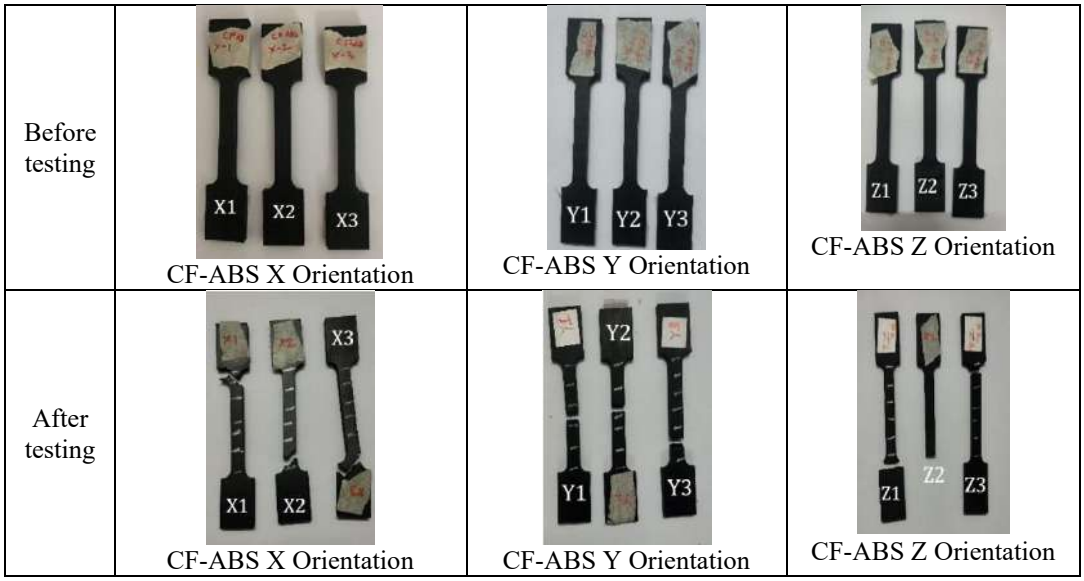


Figure 5: Tensile printed and tested X, Y and Z CF-ABS samples illustrating the influence of orientation.
Source: Authors, (2026).

Advanced microstructural characterizations and full fatigue tests were not attempted in the present report to keep focus and convince of feasibility. These issues are discussed as potential research directions in the Future Research Directions section.

IV. RESULTS AND DISCUSSIONS

In this section, the experiment outcomes of tensile tests of FDM-printed ABS and CF-ABS samples at various build orientations are reported and discussed. The results are interpreted to determine the effect of material type and build direction on tensile strength, elastic modulus and elongation at break. Trends are sought and discussion is provided as to the observed mechanical behavior, related to FDM process sensitivity. Tensile test consequences for FDM-printed ABS and CF-ABS samples in X, Y, and Z build directions are given in Table 8.

The results indicate that there are prominent variations on mechanical properties depending on material composition and printing orientation. The ABS-Y specimens exhibited the superior UTS of 23.48 MPa and a Young's modulus of 2077.26 MPa (stiffness), which contributes to improve the stiffness and load bearing in this direction. On the other end of the range, ABS-Z samples presented the lowest mechanical properties, with a UTS value as low as 4.93 MPa and even very diminished Young's modulus (321.48 MPa), thus underlining the natural anisotropy in filament-based printed materials where an influence by interlayer adhesion was shown to be especially important.

The experimental conditions and outcomes listed in Table 8 are a result of an organized DOE approach, which samples were manufactured and tested according to controlled parameter settings, to establish the influence of material type and build orientation on mechanical behavior. The DOE method was beneficial for systematic evaluation by ensuring statistical dependability and revealing significant patterns of tensile properties. These findings provide crucial insight into the anisotropic behaviors of FDM-printed materials and underscore the need for promoting build orientation to achieve improved mechanical performance. The distinct features of CF-ABS, especially in the X and Y directions, suggest its value for such applications that require enhanced tensile strength and rigidity.

Table 8: Tensile test for ABS and CF-ABS samples in various building orientations.

Material-Orientation	Maximum Load (N)	UTS (MPa)	Ductility	Break Strength (MPa)	Yield Stress (MPa)	Young's Modulus (E) (MPa)
ABS-X	635.56	15.86	3.01	10.93	13.75	452.74
ABS-Y	933.89	23.48	1.06	9.71	21.82	2077.26
ABS-Z	219.33	4.93	0.80	2.40	2.31	321.48
CF-ABS-X	1162.67	28.90	1.20	19.51	27.39	2296.65
CF-ABS-Y	826.00	20.40	0.67	20.14	18.45	2802.03
CF-ABS-Z	201.00	5.05	5.68	4.14	3.68	62.44

Source: Authors, (2026).

The specimens reproduced in the Y-orientation are found to have higher tensile properties than those printed in the X-orientation, as a result of better inter-layer bonding along loading direction. On the other hand, Z-oriented specimens can exhibit premature fracture due to poorer adhesion between layers (a common pattern in FDM process mechanics).

IV.1 ULTIMATE TENSILE STRENGTH

UTS of ABS and CF-ABS were evaluated for the X, Y, and Z orders. The results demonstrate significant material composition and print orientation dependences. Polymers ABS Material: Y-orientation (23.48 MPa), and X-orientation (15.86 MPa) had the highest UTS value, respectively. The lowest strength was achieved from the Z-orientation (4.93 MPa) due to poor interlayer bonding. 3.2 Comparison analyses of CF-ABS sample The UTS of the as-printed X-CF-ABS was found to have the highest value (28.90 MPa), and a significant improvement relative to ABS. However, Y-orientation had a slightly less UTS (20.40 MPa).) and still is considered the weakest in Z-orientation (5.05 MPa) similar to ABS. Y-orientation still provides the highest level of strength for ABS, likely due to better bonding between layers, while Z-orientation is weak in both cases because of delamination.

The comparatively reduced strength characteristics observed of Z-oriented specimens seem to be primarily resulted from the layer-by-layer printing technique that is typical for FDM, since in such case out-of-plane interlayer adhesion perpendicular to the loading direction is certain [4], [9]. However, poor interlayer adhesion is not the only cause. There are a few other things that contribute to this hole. First, the cooling rate gradient along the build height gives rise to thermal stresses that weaken the adhesion between successive layers; each layer deposited cools faster than its underlying one, leading to non-uniform solidification, different tract shrinkage and high residual stress on each layer where in turn will promote the generation of micro-voids and regions of concentrated stresses [21], [27], [30]. Furthermore, the repeated thermal cycling during deposition introduces internal stresses and partial debonding at the fiber-matrix interfaces [8], [14] which again detracts from interlaminar strength.

These effects – fiber asymmetry, rapid solidification, void formation and internal stress buildup – all contribute to decreasing the tensile strength and modulus in the Z-orientation more than just poor interlayer bond [9], [23], [27]. UTS for CF-ABS-X was the highest (28.9 MPa), which placed next ABS-Y (23.48 MPa). That is in line with the findings reported by [3] who reported approximately 21 MPa tensile strength of CF-ABS with 50% infill and hexagonal pattern. In same line, the present study can find [1] reported that CF-ABS with 80% infill had tensile strength of 36.9 MPa, which was a higher value compared to the present result and it was likely due to its higher infill density. In the end, while this experiment values are somewhat lower, the trends the present study seen seem to fit well with enhancements reported for CF incorporation and orientation optimization. A comparison of the UTS and ductility for ABS and CF-ABS coupons in different build directions (X-, Y- and Z-axis) is depicted in Figure 6. The bar chart illustrates the UTS (in MPa) for every material, and the line chart displays their corresponding ductility (elongation in %).

IV.2 ELONGATION OR DUCTILITY

The ductility provide information on how much the material can bend before it will break. Ductility Trends ABS: The maximum elongation was obtained in X-orientation (3.01%), followed by Y-direction (1.06%) and Z-direction (0.80%). CF-ABS: In the other trend, ductility ratio in Z direction (5.68%) was higher than that of X and Y directions (1.20%, 0.67%). It has been revealed that the failure modes were influenced by carbon fiber reinforcement, especially an improvement in interlayer adhesion in the Z-direction. Ductility and UTS are inversely related since greater orientations have lower elongations. UTS is improved while elongation is decreased by CF-ABS in X and Y directions. The Z-orientated CF-ABS exhibits a surprising increase in ductility which suggests fibre orientation influences in the weaker layers. Comparison of UTS and ductility between ABS-F and CF-ABS at different orientations are presented in Figure 6.

UTS and ductility for ABS and CF-ABS are scrambled with the printing orientations (X, Y, Z). UCT The tensile strength of CF-ABS material exceeds pure ABS in X-orientation (28.90MPa to 15.86MPa). For Y orientation, ABS has the maximum UTS (23.48 MPa) and CF-ABS has slightly lower value of 20.40 MPa. For materials in Z-orientation, the two exhibit the lowest UTS: 4.93 MPa for ABS and 5.05 MPa for CF-ABS. This is reasonable, as adhesion from layer-to-layer is weaker on this position. Ductility Evaluation: ABS-X (3.01%) and CF-ABS-X (1.20%) are found to have moderate ductility, with higher than that for pure ABS. The results demonstrate the Y-orientation has the lowest ductility (ABS: 1.06%, CF-ABS: 0.67%) together with higher UTS, suggesting a trade-off between strength and ductility.

Remarkably, the ductility of CF-ABS is considerably higher (5.68%) than that of ABS (0.80%) in Z direction, which might be attributed to enhanced interlayer adhesion achieved by CF enhancement. This is consistent with Figure 6, and it is confirmed that CF-ABS improves the tensile strength, particularly in X-orientation, but brings down ductility. On the other hand, with CF-ABS in Z orientation, ductility is significantly improved that may be good for some applications. As expected, tensile elongation at broken value of ABS samples were higher than CF-ABS. For example, the tensile ductility of ABS-Y samples was nearly two times higher than CF-ABS-Y. The limiting of ductility due to the addition of CF has been highlighted by [7], revealing that there was an increase in stiffness due to glass fiber restraint and strain capability decreased.

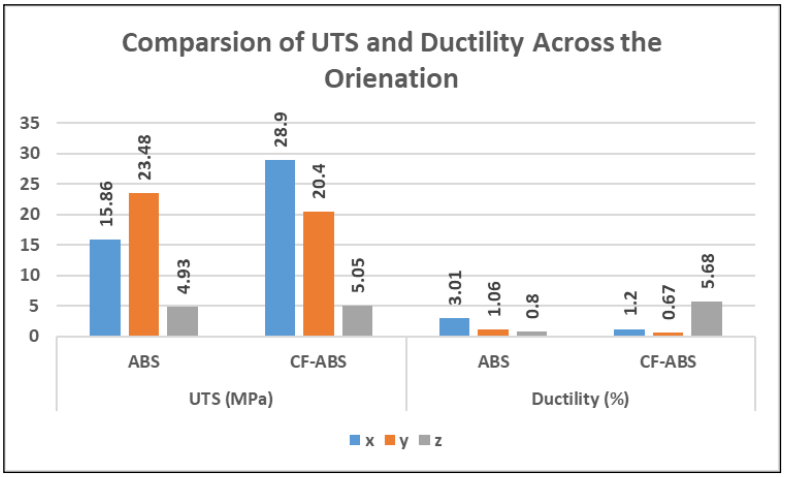

Figure 6: Bar chart comparing ultimate tensile strength (UTS) and ductility (%) of ABS and CF-ABS across X, Y, and Z orientations.
Source: Authors, (2026).

IV.3 YOUNG'S MODULUS

The modulus of CF-ABS-Y (2802 MPa) exceeded ABS-Y (2077 MPa), demonstrating approximately 35% increase. This is reliable with what previous studies indicate by [3] and a 1470 MPa modulus was reported for Cf-ABS between [14], who reported an increase of 58% in flexural modulus for CF-ABS comparing with ABS. The increase in moduli found in this study may be explained by the denser infill (100%) employed and finer print settings, which decreased the porosity.

IV.4 ORIENTATION DEPENDENCE

From the results, it is clear that Y-orientation printed specimens have better tensile strength because of enhances inter-layer connection in line with loading. In comparison, Z-oriented samples fail at an early stage due to weak layer bonding, which is in accordance with the FDM process being inherently anisotropic. For both materials, the Z-orientation specimens showed consistently lower performance and UTS decreased by more than 40% compared to those in X and Y orientations. By [4] and [9] have reported similar orientation-dependent anisotropy, with tensile strength reduction between 44 and 50% when comparing flat (0°) to upright (90°) orientations. Therefore, the present study like to highlight that poor adhesion between the layers is the principal limitation for Z-direction computer-controlled fabrication. Z-oriented samples collapse at low strains because of the poor interlayer bonding and residual thermal stress, which is characteristic to FDM process [11], [23]

The embedded carbon fibers act as the load-carriers, perfectly transferring stress from the polymer matrix to the stiffer fiber phase, resulting in upsurges in together tensile strength and elastic modulus [24], [26], [30]. In addition, the carbon fibers reduce the total thermal expansion coefficients and improve dimensional stability during printing due to denser layer interfaces and reduced warping [32], [35], [37]. This bonding at the fiber–matrix interface restricts polymer chains motion, which contributes to the increased stiffness as well as greater stress resistance under tensile loading [38], [42]. But these improvements come with certain concessions. Reduced chain mobility and stress localization at the fiber ends reduces ductility and strain to failure, contributing to a more brittle fracture behavior [44], [48]. Besides, introducing of carbon fibers a little bit more complex expelling process is encountered during extrusion; therefore, wear and tear of the nozzle are greater and need to deal with well-controlled print temperature for avoiding channel clogging and causing an uneven consumption.

Despite these limitations, the mechanical advantages of CF-ABS—particularly its increased strength, stiffness and interlayer adhesion—make it a compelling choice for structural or load-bearing applications where stiffness takes precedence over pliancy. Poor mechanical performance observed in Z-pullout samples is due not only to weak interlayer bonding but also to the thermo-mechanical response specifics of FDM process. During printing, the polymer filaments are deposited layer-wise in the direction of Z-axis leading to interfaces normal to the tensile load. This alignment concentrates stress between the layers, aiding in crack initiation and rapid delaminating under tension. Furthermore, the rate of cooling in the build direction is slower and not uniform as that along the X–Y plan, which leads to residual thermal stress and poor diffusion across layers. Reduced entanglement of the polymer chains, entrapped voids and nonuniform thermal gradients leads to less adhesion between layers then the X-Y plane, leading to lower tensile strength and stiffness in the Z-direction.

IV.5 STRESS STRAIN CURVE

The mechanical properties of ABS and CF-ABS with different orientation were characterized by stress-strain curves. The Y-orientation curves of both ABS and CF-ABS exhibit the greatest stiffness, which is consistent with the highest Young's modulus. CF-ABS-X orientation has the largest stress response, indicating its high load-bearing capacity. Z-orientation curves remain flat, indicating a brittle fracture through poor interlayer adhesion. Figure 7 demonstrations the stress–strain curves of ABS and CF-ABS specimens at different orientations. The steepest slopes represent Y-orientation of both the materials, demonstrating maximum stiffness and Young's modulus. CF-ABS-X has the best tensile response behaviour between all the samples and it is associated with its good load bearing ability.

ABS-Z and CF-ABS-Z reveal poorest performance indicating very low stress values since poor interlayer adhesion limits the cohesion of the material layers.The conclusion is the reinforcing CF-ABS have significantly improved the stiffness and loading capacity of the composite materials, especially in X- and Y-direction as shown in Figure 7.

IV.6 TENSILE STRENGTH RESULTS THROUGH LITERATURE COMPARISON

In command to verify the tensile behavior of FDM-printed ABS and CF-ABS, the UTS values obtained were compared with the referred literature standards. In the following work, ABS also exhibited the superior UTS in ABS-Y (23.48 MPa) higher than that of ABS-X (15.86 MPa), and significantly higher than that of ABS-Z (4.93 MPa) due to remarkable weak inter-layer bonding. Also, CF-ABS had the highest UTS value in case of CF-ABS-X (28.90 MPa) and hence exhibits lowest UTS value for CF-ABS-Z (5.05 MPa) proving a significant axis-dependent anisotropy (Table 8). By [1] reported 36.9 MPa at 80% infill, showing higher cell density leads to higher strength. For CF-ABS, [3] were able to achieve ~21 MPa at 50% infill which approximately in-line with the current CF-ABS-Y (20.40 MPa). Therefore, the CF-ABS-X UTS (28.90 MPa) is suitable performance for CF-ABS.

In general, this comparison authenticates the validity of current results and emphasizes on the influence of material and build orientation under uniform loading situation. The trend X/Y > Z, is in agreement with previous research [9-11], where the failure of specimens oriented parallel to the Z-axis occurs prematurely as tensile loading is applied perpendicular to deposited layers and inter-layer fusion interfaces. [13], [14] observed the tensile degradation in vertical positions to be significant as a result of polymer diffusion being limited and therefore bonding weakened.

Table 9: Comparison of UTS Results with Published Literature.

Study	Material	Key Print Condition / Note	Reported UTS (MPa)	Comparison with Present Study
Present study	ABS	Y-orientation (best for ABS)	23.48	ABS-Y = 23.48 MPa (Reference value)
Present study	CF-ABS	X-orientation (best for CF-ABS)	28.90	CF-ABS-X = 28.90 MPa (Reference value)
Karupaiah and Narayanan [3]	CF-ABS	50% infill, hexagonal pattern	~21	Close to CF-ABS-Y = 20.40 MPa
Turaka et al. [1]	CF-ABS	80% infill	36.9	Higher than present due to higher infill
Syaefudin et al. [9]	ABS	Orientation-dependent ABS study	Orientation trend confirmed	Confirms X/Y > Z for ABS
Anubhav et al. [4]	ABS	Orientation anisotropy in FDM tensile	Orientation trend confirmed	Confirms Z weakest due to weak interlayer fusion

IV.7 DISCUSSION ON MECHANICAL BEHAVIOUR OF CF-ABS

The high tensile strength value of CF-ABS can be attributed to the good load transfer from the polymer matrix to the incorporated carbon fibers. The stiff fibers lower the overall ductility of the composite, as indicated by its low elongation-at break compared to unmodified ABS. Therefore, while CF-ABS has the same high level of stiffness and strength, it slightly sacrifices flexibility and processability. These effects must be balanced through parameters tuning to achieve both good mechanical properties and print quality. This is due to the fact that while carbon fibers increase stiffness and load carrying capability, they also result in decreased ductility and a more brittle fracture mode. Despite the enhanced mechanical properties, the processing of CF-ABS is problematic owing to nozzle abrasion of clogging and fiber clustering.

In comparison to the tensile response, macroscopic observations of fractured CF-ABS samples (Figure 5) offer some knowledge on failure as well. In the case of CF-ABS samples, a diminished necking and relatively sudden break was observed in comparison to neat ABS ones that is indicative of the higher stiffness brought by the CF-ABS. Samples made of CF-ABS oriented along the Z-axis exhibited an early interlayer delamination, demonstrating that layer-to-layer adhesion was a controlling factor for failure. These macroscopic observations help in rationalizing the tensile trends obtained experimentally and verify the anisotropic behavior of FDM printed CF-ABS parts.

IV.8 MAIN EFFECT PLOTS

In all orientations, CF-ABS reported significantly higher maximum load than pure ABS. The highest maximum load measured was obtained for CF-ABS in the X-orientation with 1162.67 N and the lowest maximum load of 201.00 N for CF-ABS in the Z-orientation For both ABS (635.56 N) and CF-ABS (1162.67N), X-orientation occurred to be where the highest maximum loads were achieved, indicating good interlayer bonding when printed along this direction.-orientation also did comparatively well, -value of 933.89N for ABS and 826.00N for CF-ABS) The Z-orientation gave the worst of both materials, probably due to poor interlayer adhesion (219.33 N and 201.00 N for ABS and CF-ABS). During tensile applications the structural weakness of CF-ABS is obvious since it has a higher load carrying capability than that reported for ABS, particularly in X-orientation.

The primary effect plot of S/N ratio is depicted in Figure 8 since the effects of build site and material type on the maximum load (N). Higher UTS was detected in CF-ABS samples related to ABS samples. CF-ABS-X had the greatest UTS (28.90 MPa) but ABS-Z did not exceed 4.93 MPa. X-orientation: ABS (15.86 MPa) and CF-ABS (28.90 MPa) exhibit the maximum UTS. In the Y-orientation the values are slightly by CF-ABS (20.40 MPa) and better in ABS (23.48 MPa). Z-orientation has the least UTS (4.93 MPa in ABS, 5.05 MPa in CF-ABS), because their inter-layer bonding is low. The failure in the Z-orientation results from the delamination of layers. For the two materials, the X and Y directions have highest strength. The interaction plot for S/N ratios is depicted in Figure 9, the consequence of build direction and material on UTS.

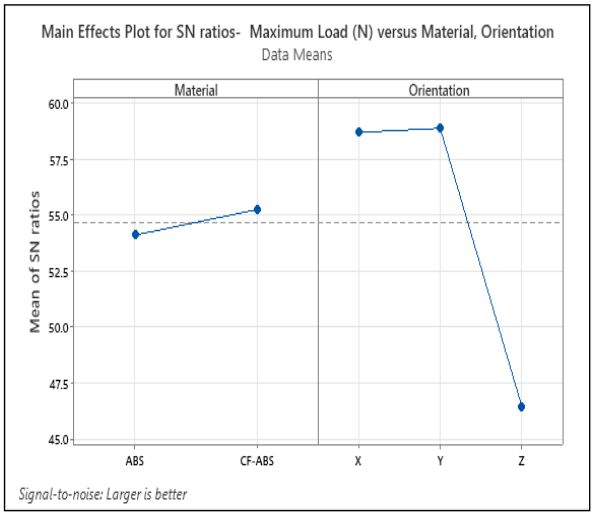

Figure 8: Main effect plot for SN ratios Maximum Load (N) versus Material, Orientation.
Source: Authors, (2026).

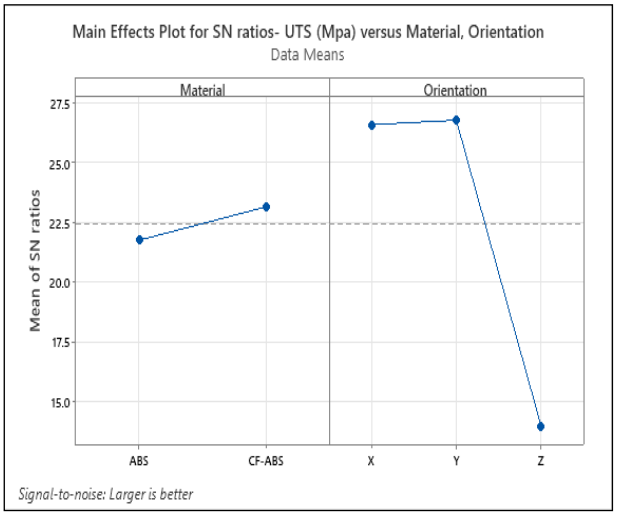

Figure 9: Main effect plot for SN ratios UTS (MPa) versus Material, Orientation.
Source: Authors, (2026).

The tensile strength of CF-ABS was improved. CF-ABS-Y showed the highest break strength (20.14 MPa), which may be associated with orientation-dependent load transfer and failure behaviour. CF-ABS-X came next with 19.51 MPa, revealing excellent strength at this direction. The maximum tensile strength was 20.14 MPa (in CF-ABS-Y) and the lowest was 2.40 MPa (in ABS-Z). Polymers in ABS-X and ABS-Y are characterized with lower tensile strengths at break (i.e., 10.93 MPa, 9.71 MPs, respectively). The introduction of a carbon micro pipe structure strongly improves sandwich properties, in particular strength and rigidity. Early failures were the ABS-Z and CF-ABS-Z with very low brake strength (2.40 MPa, 4.14 MPa). Z-orientation is not suitable for tension application because of its brittle failure. The primary effects plot for S/N ratios is presented in Figure 10, and it investigates the stimulus of build orientation and material type on break strength.

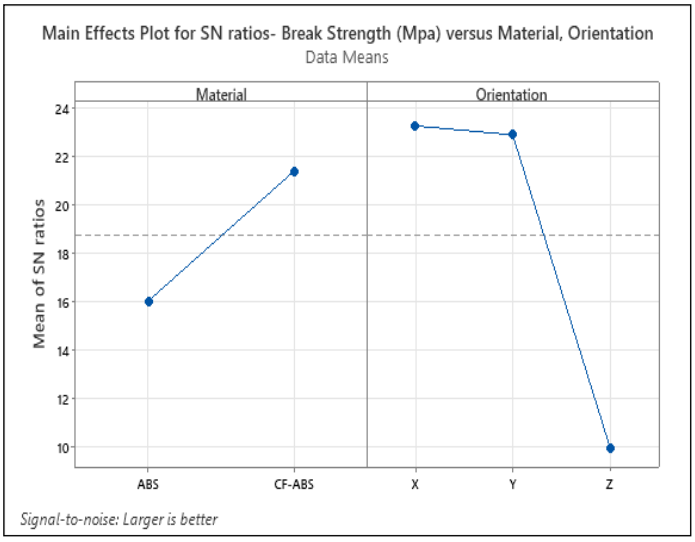

Figure 10: Main effect plot for SN ratios UTS (MPa) versus Material, Orientation.
Source: Authors, (2026).

CF-ABS exhibited stronger performance than ABS; CF-ABS-X had the highest yield stress of 27.39 MPa, while ABS-Z has the bottom (2.31 MPa). X-Orientation: The yield stress of CF-ABS (27.39 MPa) and ABS (13.75 MPa) were the highest. Y-orientation: ABS performed better (21.82 MPa) and CF-ABS had an acceptable value (18.45 MPa). Z-orientation: This is the least strong orientation with 2.31 MPa (ABS) and 3.68 MPa (CF-ABS). In particular, the CF-ABS substantially enhances yield stressing, particularly along X-orientation. Perhaps due to stress transfer, ABS-Y exhibits a higher yield strength than CF-ABS-Y. Due to its bad adhesion, the Z-oriented cut has the least good yield properties. The main effect plot for signal-to-noise (S/N) ratio is presented in Figure 11 which demonstrates the things of build orientation and material type on yield stress (MPa).

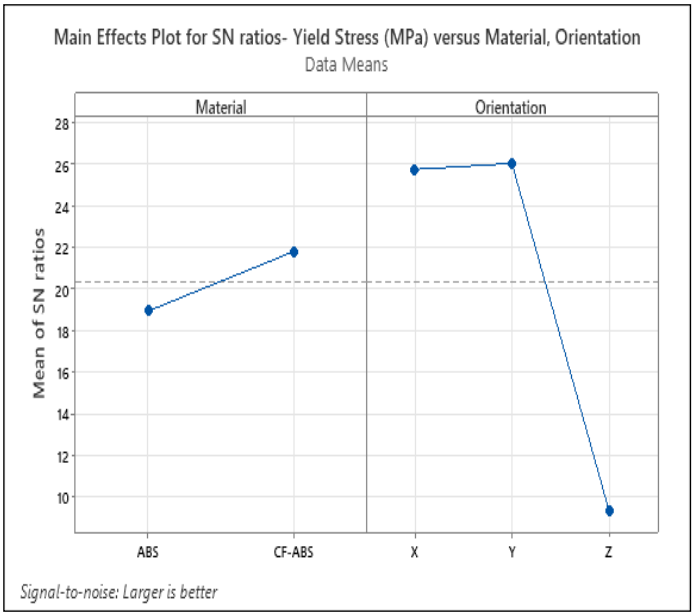

Figure 11: Main effect plot for SN ratios – Yield Stress (MPa) versus Material, Orientation**.**
Source: Authors, (2026).

Figure 11: Yield Stress (MPa) vs Material main effect plot for SN ratios Orienta In all orientations CF-ABS had higher Young's modulus which means its stiffness is high. The maximum reported was 2802.03 MPa by CF-ABS-Y and the minimum of 62.44 MPa by CF-ABS-Z. Y-direction: ABS was the strongest (2077.26 MPa), and CF-ABS had the highest stiffness (2802.03 MPa). X-orientation: ABS (452.74 MPa) is worse than CF-ABS (2296.65 MPa). Z: Low stiffness (62.44 MPa for CF-ABS, 321.48 MPa for ABS). CF-ABS significantly increases Young's modulus, so it is great for structural parts. Z-orientation is weak due to low rigidness and is not good for load bearing purposes. Z is the weakest, followed by X and then Y. The main effect plot for S/N ratios is given in Figure 12 which considers the effects of build orientation and material type on E in (MPa).

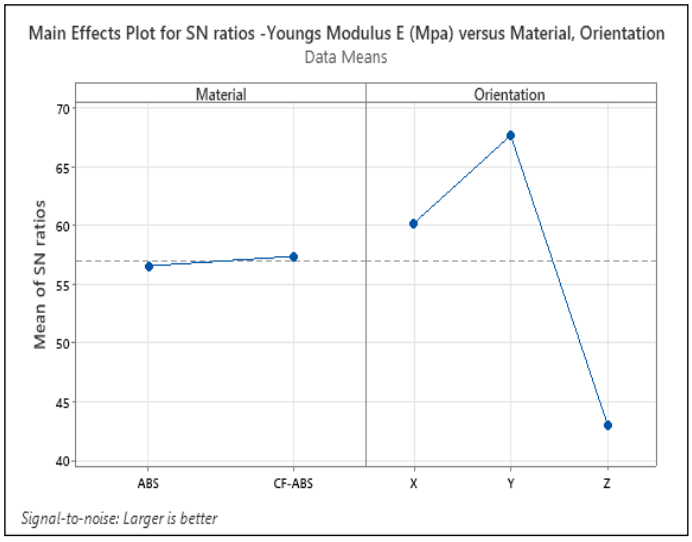

Figure 12: Main effect plot for SN ratios - Young's Modulus E (MPa) versus Material, Orientation.
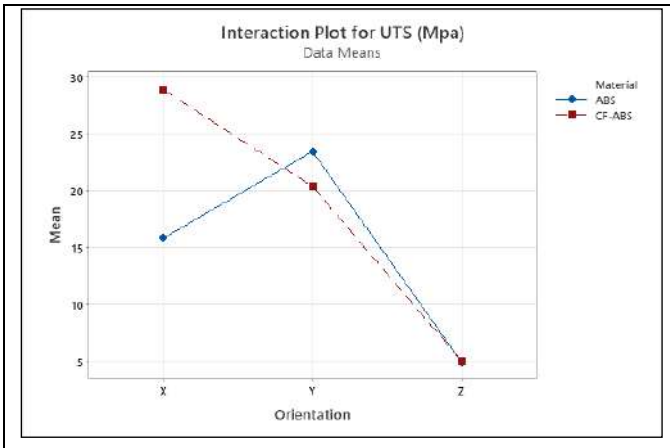
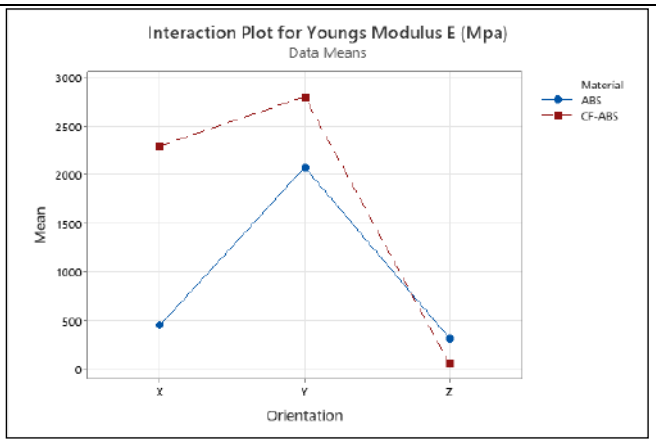
Source: Authors, (2026).



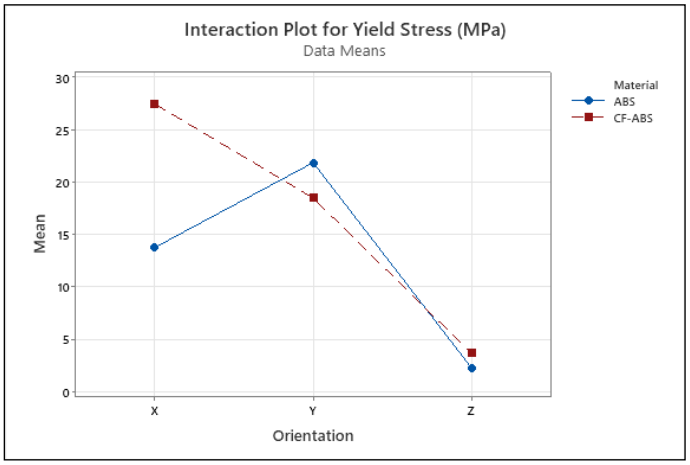
In the case of ABS, CF-ABS shows a huge improvement in all mechanical properties. Orientational Variability: shows maximum overall performance towards Young's modulus, break strength and UTS. Next, the present study placed X-orientation, which has moderate stiffness but is strong. Since the Z orientation exhibits weak interlayer bonding, it is not recommended for tensile load-bearing applications. Failure Modes: In the Z-orientation, weak interlayer bonding or delamination led to failure. Y and X orientations present better load-bearing capacity and crack-resistance. Design Implication: For strong parts, print CF-ABS in X or Y directions. The inclination and material type have large effects on mechanical properties are also supported by S/N analysis.

IV.9. INTERACTION PLOT



The most significant effects of the orientation and material (ABS versus CF-ABS) are shown in Figure 13 for selected mechanical parameters. UTS: the UTS of CF-ABS is significantly higher in X (28.90 MPa) than that of ABS (15.86MPa). Although CF-ABS-X showed the highest UTS, the Y-orientation exhibited competitive tensile performance; this variation may be attributed to fibre alignment effects and interlayer bonding characteristics. Similarly, the Z-orientation remains to be the weakest for both materials.

- Young's modulus: CF-ABS-Y has excellent load bearing capacity with the highest stiffness (2802 MPa). Y-orientation is also the highest performing orientation, with a strong ABS-Y (2077 MPa). Low stiffness is observed in Z-direction, particularly for CF-ABS (only 62 MPa).
- Yield Stress: For CF-ABS-X and ABS-Y, the same ranking was observed as for UTS. The Z-orientation is the worst for both materials.
- Break Strength: The maximum break strength (~20.14 MPa) is shown in Y-orientation for CF-ABS. Orientation in Z remains the weakest, while orientation along X is also strong.



These graphs provide some evidence for the idea that Y-orientation is best for ABS and X-orientation is best for CF-ABS due to better fiber alignment.

IV.10 FAILURE MODE INTERPRETATION

The failure behaviour of FDM-printed ABS and CF-ABS tensile samples were markedly affected by the build orientation, indicating that the inherent anisotropy involved layer-by-layer fabrication. Discrepant fracture behavior in the X-, Y-and Z-oriented samples may be due to different interlayer bonding strength and load transfer efficiency [48], [49]. X and Y oriented parts in-plane tensile failure, where the load applied was parallel to filament deposition. A higher tensile strength and stiffness of these orientations were presented by an enhanced stress distribution and the more intense interlayer fusion, where the Y orientation displayed also the most sustained fracture process [50–53].

Z-oriented specimens suffered from early interlayer delamination due to the tensile action being perpendicular to the layer that are stacked. This led to a brittle fracture with low-ductility nature, which was dominated by poor adhesion of the interlayer rather than strength of filaments [54–57].The CF-ABS samples presented a higher stiffness and a lower ductility with respect to the neat ABS, suggesting an evolution toward more brittle failure. The reinforcement of short carbon fibers was better in X- and Y-directions with the failure continued to be controlled by interfacial strength and fibre continuity in the Z direction across layers [58], [63-65].In general, the data demonstrate that the role of build orientation in failure behavior is more pronounced than that of material type and underscores the significance of orientation-aware design criteria when employing CF-ABS filaments for load-carrying FDM applications [59–62].

The current work aimed to examine influence of build orientation and physical type on quasi-static tensile act FDM-printed ABS and CF-ABS samples at constant processing parameters. Other key variables like raster angle, layer thickness, and extrusion temperature or infill pattern were deliberately fixed to isolate orientation effects which constrains the direct transferability of the findings to other parameter combinations [46], [54]. Moreover, the procedure was limited to monotonically loaded tension and a detailed analysis of microstructure information including fracture surfaces was not within the scope of this study [55], [59]. Further work is needed for the more detailed evaluation of the performance of CF-ABS for load-bearing applications including microstructure assessment, fatigue properties and multi-parameter optimization [60–62].

V. CONCLUSIONS

Orientation dependent tensile properties of ABS and CF-ABS composite prepared by FDM were examined in the existing work. It can be observed from the consequences that material and build orientation significantly influenced the mechanical performance:

- The highest rigidity (2077.26 MPa) and the UTS value (23.48 MPa) exhibited the orientation ABS-Y.
- CF-ABS-X orientation showed the reinforcing effect of carbon fibers with their highest UTS (28.90 MPa).
- Because of poor interlayer bonding, the Z-directional samples invariably demonstrated low strength and modulus.
- ABS is also more ductile than CF-ABS, which makes it that reducing strength to increase ductility.

In general, CF-ABS is more suitable for structural and loadbearing applications because carbon fibers dramatically improved tensile strength and stiffness with particular dominance in X and Y directions. Yet, its application in systems that require large flexibility might be restricted due to the decreased stretchability. Use CF-ABS (20%) in the X or Y position for parts requiring high Structural rigidity: brackets, holders, holsters etc. For applications that need flexibility or impact absorption, plain old ABS may still be better. The following conclusions were drawn from these experimental studies of FDM-printed orientation-dependent tensile behavior of ABS and CF-ABS.

- Anisotropy is regulated by direction: Z-orientation consistently produced the lowest strength due to weak interlayer bonding while Y-orientation in ABS and X-orientation in CF-ABS showed the highest tensile mechanical performance.
- The modulus of CF-ABS samples was 35% higher and the UTS approximately 25% greater than that of neat ABS, which confirmed that carbon fibers enhanced stiffness.

- Trade-off of strength and ductility: CF-ABS improved strength while reducing ductility, meantime tidy ABS is better in applications that requires flexible or impact resistant.
- Trends supported by DOE-based analysis: Taguchi main-effect and S/N plots provided evidence of orientation and material being the two most influential parameters for tensile behavior.
- Experimental values correlate with previous research: The credibility of the data is enhanced as UTS and modulus show good agreement with other work on CF-ABS.
- Applications: Neat ABS can still be used when no structural bending is desired in the part, but it doesn't make sense for load bearing parts. CF-ABS printed in the X or Y orientations is more suitable for structurally relevant components.

A mannered analysis on tensile properties of FDM-printed ABS and CF-ABS parts in different building orientations was conducted in this study. The results demonstrate how material type and build orientation collectively influence UTS, yield stress, ductility and stiffness including material orientation and composition influence the mechanical performance, most notably yield stress, ductility, Young's modulus and ultimate tensile strength (UTS). The results demonstrate that the mechanical response of FDM-printed specimens is sturdily affected by construction orientation. Among all tested configurations, Y-oriented CF-ABS specimens had the highest mechanical strength (Young's modulus of 2802.03 MPa and UTS of 20.40 MPa). In contrast, poor interlayer adhesion led to very bad mechanical properties for both the Z-oriented samples of all material compositions; CF-ABS-Z being the worst (UTS = 5.05 MPa, Young's modulus = 62.44 MPa).

The ductility of ABS and CF-ABS materials exhibited a different trend; pure ABS presented higher elongation in the X and Z directions (3.01% and 0.80%, respectively), while the high stiffness of CF-ABS caused a reduction in its penetration capacity in all directions. Decision about stiffness and flexibility trade-off When the design of functional FDM parts with high tensile strength, there is possible to take into stiffening and correlatively flexible. With tensile strengths (UTS) 23.48 MPa and 20.40 MPa for ABS and CF-ABS, respectively, the Y-direction yielded the top tensile strength and stiffness in all cases. The X-oriented CF-ABS specimens possess greatly higher UTS (28.90 MPa) and elastic modulus (2296.65 MPa) than the all-other configurations, representing enhanced load-carrying capability by CF-ABS. The Z-orientation showed on the contrary to have the worst mechanical behavior which resulted in much lower values of UTS (4.93 MPa for ABS and 5.05 MPa for CF-ABS) and no resistance under tensile stress, thus highlighting also in this case (80%) its anisotropy of FDM printed materials.

Moreover, the results demonstrate ductility has been decreased with advance in tensile strength and modulus due to the incorporation of CF-ABS, predominantly in X- and Y-directions. CF-ABS can be used for applications requiring higher structural strength and mechanical durability in components made by additive because of its greater stiffness that is indicative of better load transfer effectiveness. The work expands the material design space of FDM thermoplastic composites and additive manufacturing in generality. The measurement technique provides quantitative verification of the effect of layers orientation and CF-ABS mechanical properties. In terms of bearing load, the CF-ABS was found to be a much better candidate than neat ABS for load-carrying applications, particularly in the Y-axis where tensile stress is distributed throughout coextruded fiber channel. The findings are also consistent with previous studies showing that layer bonding in the Z-direction is essentially poor requiring intentional modifications for applications demanding isotropic properties.

Moreover, the DOE-based method supplies a systematic approach to optimizing FDM parameters, thus enabling engineers and researchers to predict mechanical responses given material composition and printing orientation. This work sets the stage for further optimization investigation, particularly in hybrid and multi-material FDM printing. Although this work is a significant contribution, further studies are necessary to improve the mechanical belongings of FDM-printed composites. Future work should investigate: Advanced Infill Geometries: The influence of complex lattice structure and infill % on mechanical behavior. Failure analysis under cyclic loading conditions for long-term mechanical stability, is called fatigue and fracture analysis. Thermal and Environmental effects: Evaluate in performance at various humidity levels and temperature ranges, whether it's viable. FEA: Stress spread to predict modeling for design better solution. Multi-Material Printing Exploring dual-nozzle printing for structures with a functionally graded structure and gradient material properties.

This paper has demonstrated the influence of material arrangement and orientation on tensile behaviour for FDM parts. Although from the Z-structure perspective it still remains a drawback, CF-ABS exhibits significantly greater strength characteristics, especially at the Y axis. The insights from this work provide useful guidelines for developing stronger and more reliable FDM-printed polymer composites. The potential FDMÂ has in high-performance is likely to be augmented as new hybrid materials, better deposition control and advanced computer modeling are developed. In general, mechanically motivated process design decisions for build orientation and material selection of FDM manufactured polymer and composite parts for load-bearing applications are presented here. Results of this work may be used to optimize mechanical performance while considering the inherent anisotropy of FDM process by designers and engineers.

VI.STUDY LIMITATION

The tensile behavior of FDM-built ABS and CF-ABS specimens was studied in the present work, mainly focusing on the build orientation with fixed processing conditions. In order to attribute mechanical variability solely to orientation, parameters including raster pattern, layer height and thickness, infill percentage and extrusion temperature were deliberate kept constant which inherently limits the generalizability of the results into other parameter sets. Also, the testing program was limited to monotonic tensile loading and performance and behavior under cyclic fatigue, impact loading, time-dependent deformation, or environmental exposure were not considered. Furthermore, the microstructural and fracture-surface analyses were beyond the scope of this work such that a more detailed interpretation about fibre–matrix bond, internal void shape and interlayer damage mechanisms for (vertical-printed) specimens was narrowed down.

VII.FUTURE RESEARCH DIRECTIONS

In the current research, parameter-based optimization studies of FDM printed ABS and CF-ABS parts are pilot attempt. As both X and Y build orientations consistently outperformed in terms of tensile behavior, the study will be narrowed down to ABS-X, ABS-Y, CF-ABS-X and CF-ABS-Y only for future designs [3], [9]. A Taguchi-based DOE of ~25 specimens will be used, by changing speed, layer thickness and infill density to establish optimum tensile properties [23], [30]. Tensile experimental results will be cross-validated with FEA under the same loading conditions to check numerical-experimental consistency [34], [44]. Moreover, hybrid ABS–CF-ABS specimens with different CF-ABS layer thicknesses will be fabricated and investigated using experimental tests FEA and analytical equations for load transfer efficiency and stiffness improvement [13], [24].

The present work is restricted to the quasi-static tensile behaviour of FDM printed ABS and CF-ABS test pieces for given printing conditions. Further microstructural analysis at a higher-level such as SEM fractography and calibrated X-ray attenuation from micro-CT based defect/void quantification was omitted, so the effect of fibre dispersion, porosity and interlayer defects with tensile failure could not be explicitly linked in a quantitative manner to the mechanical performance observed. Furthermore, long-term durability behaviour such as those under fatigue, creep and environmental ageing was not studied in the present work. in future work, will be directed towards a more advanced microstructure–property correlation and development of validated predictive tools through FEA which can possibly be complemented with ML techniques in order to improve reliability prediction of orientation-sensitive CF-ABS composite parts.

ABSTRACT

Reliability prediction of Web services has become very important in related research communities. Especially, predicting the Quality of Service (QoS) for active users has been a hot issue of research and application. On the other hand, with the rapidly growing in number of service providers and users, resulting in a large number of data sets. It has a big impact to the QoS such as managing and monitoring for describing functional and non-functional characteristics of Web services. Therefore, we will certainly struggle at processing large data sets in the future, unless the issues are resolved quickly before it happens. In that context, QoS prediction on big data set is an urgent problem to be solved. In this paper, we present a new model for handling this problem based on autoencoder, it is called autominibatch. We use this model to cope with large data sets by using Backpropagation and Mini-batch gradient descent for predicting QoS values of Web services. This also is a new method for evaluating prediction of the field of web service quality. Our experiments were performed on two data sets in the WS-DREAM data set and the experimental results have proved the effectiveness of the proposed model.

I. INTRODUCTION

Web services are a system which is designed applications to allow the computer to communicate with each other via network. Service providers were established based on the needs of users, with increasing demands of users and a highly profitable business environment with considerable potential for growth. As a result, many Service providers tend to move in the same direction as business and marketing plans, which provides the direction on the potential market environment, leading to multiple providers may offer functionally identical services. On the other hand, QoS also depends on many other factors such as transmission on the network, implementation mechanism and hardware. Therefore, the user desires to know how to choose a QoS from service providers such as latency, availability and reliability. However, almost service providers nowadays focus on the profit and growth. Moreover, in e-commerce and other online environments, the QoS properties of each service are pre-determined by the service providers, but because of its promotion purpose, they often exaggerate to attract more users. Hence, QoS is one of the important factors to build service-oriented applications [1-3].

The QoS property may have different values to different users (e.g., response time, availability, throughput etc.), to measure the efficiency of QoS properties, it depends on the user who uses that web service. If a recommender system can exploit the information of web service providers based on the relationships between the consumers, services and service providers, the accuracy of the forecast will be remarkably improved. But almost service providers only introduce the web services to the consumer without warning anything about their service quality provided by them to the consumer, if any, it is mainly for promotion purposes. Therefore, many studies have focused on solving this problem as Collaborative Filtering (CF) approach [4-6] and some other studies such as a Bayesian network based QoS assessment model [7], decision tree [8] and latent semantic models [9]. Some recent research publications about the use of machine learning focus on prediction for web service as learning with multi-agent techniques [10] and Latent Factor models [9]. However, all of them have not mentioned for processing large data sets. This is one of new challenges which we should have solution to deal.

Currently, the traditional algorithms are not able to handle efficiently for large and sparse data sets. Therefore, the need of new models which automatically extracts the necessary information to users with accurate and effective ways in the continuous increase of growing data is necessary. To overcome the drawbacks described above, we propose Autominibatch model. The model is inspired by previous applications of Deep Learning in a wide range of pattern recognition tasks as applications including image classification, processing and generation [11-13], application to exploit and extract the document [14] and sound modeling [15]. Additionally, it also has been applied for different missions such as: image noise reduction, number identification, document recovery. From these practical applications, we have constructed algorithms based on the Back propagation and mini-batch gradient descent in order to be appropriate for predicting the QoS of Web service and meet the performance requirements on processing big data and we have also proven the convergence for our model. Here are our contributions in this paper.

- We introduce a new model (autominibatch) based on autoencoder for predicting the QoS values.
- Especially, we have used mini-batch gradient descents to improve the convergence time for processing large data sets effectively.

The remainder of this paper is organized as follows: Section 2 introduces to motivation for our approach. In Section 3 we present the model. In Section 4, we present the learning the model. Section 5, we apply the proposed approach to experimental evaluation and report the reliability prediction results. Finally, we conclude our work and some future directions in Section 6.

II. MOTIVATION

Big data is a broad term of a too big or complex data set while traditional algorithms are often not designed to process. Recently, some research have been expanded from different methods to solve large data sets. However, the current approach only focus on the processing without considering other important functions. E.g. processing-data time and the speed of algorithm convergence must meet the processing time in the context of a very large data set. With this reason we have a desire to find out how to improve the data processing speed fast and effectively, this is the main motivation for our approach. Authors [16] have proposed a method based on mini-batch training gradient descent, this method has two advantages: Firstly, After just b examples, can improve the parameters. Second, don't have to wait until we cycled through all the data, and don't have to update parameters after every example. This is very important for dealing with large datasets and this is also the first time we have applied mini-batch Gradient descent to predict the QoS in Web field.

III. THE MODEL

Let X be a vector of m visible units $(X = (X_1 + X_2 + \cdots + X_m))$ where consisting of m service user and n web service, called the user-service matrix. Every entry $r_{i,k}$ in matrix represents the a vector of QoS values (e.g., response time, failure-rate, etc.), that is observed by the service user i on the Web service k. Let F denotes the number of h hidden units $(h = (h_1, h_2, \ldots h_F))$, it can be thought of as representing stochastic binary features that have different values for different users. An important proplem in applying autoencoder to cope with the missing QoS values efficiently. In this paper, we constructed the model for predicting the QoS values, the model use a different autoencoder for every user (as shown in Figure 1). Each service user is considered as a single training case for an autoencoder which had a softmax visible layer symmetrically connected to a set of binary hidden layer. Each hidden unit could then learn to model a significant dependency between different values. Each autoencoder has a single training case, but all of the corresponding weights and biases are tied together, so if two users have the same values, their two autoencoders must use the same weights between the softmax visible units for that web service item and the hidden layer.

Let a_i^l denotes the activation of the total weighted sum of inputs and the bias term to unit i in layer l. We have

- For $l = 1$, we have $a_i^{(1)} = r_{ij}$ to denote the $i = th$ input.
- For $l = 2$, we have:

$$\begin{Bmatrix} a_1^{(2)} = f(W_{11}^{(1)} r_{ij}^{(1)} + W_{12}^{(1)} r_{ij}^{(2)} + \cdots + W_{1(m\times n)}^{(1)} r_{ij}^{(K)} + b_1^{(1)} \\ a_2^{(2)} = f(W_{21}^{(1)} r_{ij}^{(1)} + W_{22}^{(1)} r_{ij}^{(2)} + \cdots + W_{2(m\times n)}^{(1)} r_{ij}^{(K)} + b_2^{(1)} \\ \vdots \\ a_F^{(2)} = f(W_{z1}^{(1)} r_{ij}^{(1)} + W_{z2}^{(1)} r_{ij}^{(2)} + \cdots + W_{z(m\times n)}^{(1)} r_{ij}^{(K)} + b_F^{(1)} \end{Bmatrix} \quad (1)$$

And

$$\begin{Bmatrix} h_{W,b}(X_1) = a_1^{(3)} = f(W_{11}^{(2)} a_1^{(2)} + W_{12}^{(2)} a_2^{(2)} + \cdots + W_{1F}^{(2)} a_F^{(2)} + b_1^{(2)} \\ h_{W,b}(X_2) = a_2^{(3)} = f(W_{21}^{(2)} a_1^{(2)} + W_{22}^{(2)} a_2^{(2)} + \cdots + W_{2F}^{(2)} a_F^{(2)} + b_2^{(2)} \\ \vdots \\ h_{W,b}(X_m) = a_F^{(3)} = f(W_{F1}^{(2)} a_1^{(2)} + W_{F2}^{(2)} a_2^{(2)} + \cdots + W_{FF}^{(2)} a_F^{(2)} + b_F^{(2)} \end{Bmatrix} \quad (2)$$

Similar to $l = 3; l = 4; \ldots; l = s_l$
The following general formula

$$a_i^{(l)} = f(\sum_{j=1}^{F} W_{ij}^{(l-1)} a_j^{(l-1)} + b_i^{(l-1)}) \quad (3)$$

And calculating in the encoding step of the autoencoder as follows

$$h_{W,b}(X) = a_i^{(l+1)} = f(\sum_{j=1}^{F} W_{ij}^{(l)}.a_j^{(l)} + b_i^{(l)}) \quad (4)$$

Equation (4) may be rewritten as:

$$h_{W,b}(X) = a_i^{(l+1)} = f(\sum_{j=1}^{F} W_{ij}^{(l)}.f(\sum_{j=1}^{F} W_{ij}^{(l-1)}a_j^{(l-1)} + b_i^{(l-1)}) + b_i^{(l)}) \quad (5)$$

We can rewrite the general formula as follows

$$h_{W_1,W,b,b_1(X)=f(W_1.f(W.a+b)+b_1)} \quad (6)$$

where $f(.)$ is *activation functions.* Here, we set the activation function f to be the sigmoid function.

Table 1: Notations of model.

Notations	Explanation
S_l	denotes the number of layers in the model and we called label l as L_l
L_1	is the input layer
L_{sl}	is the output layer
W, b	denote parameters
W_{mn}^l	denotes the weight associated with the connection between unit n in layer l, and unit m in layer $l+1$
b_m^l	is the bias associated with unit m in layer $l+1$.
$h_{W,b}(X)$	is a hypothesis that outputs a real number
a_i^l	Activation (output) of unit i in layer i of the network.

IV. LEARNING MODEL

Suppose we have a fixed training set of m training examples, we train the model using mini-batch gradient descent. In detail, we define the overall cost function to be

$$J(W,b) = \frac{1}{m}\sum_{u=1}^{m}\frac{1}{2}\left\| h_{W_{Ls_l},b_{Ls_l}}(X^{(u)}) - X^{(u)} \right\|^2 + \frac{\lambda}{2}\sum_l \|W_l\|^2 \quad (7)$$

The first term of $J(W,b)$ is an average sum-of-squares error term, The second term is a weight decay term to help prevent over-fitting and decrease the magnitude of the weights. Our goal is to minimize the total cost function $J(W,b)$ as a function of W and b. To train the model, we initialize each parameter $W_{ij}^{(l)}$ and $b_i^{(l)}$ to a small random value near zero (Normal $(0,\varepsilon^2)$ distribution for some small ε, say *0.01*. Then apply algorithm 1 to train Autoencoder such as mini-batch gradient descent. The parameters *W,b* is updated by performing an update for every mini-batch of m training examples:

$$W_{ij}^{(l)} = W_{ij}^{(l)} - \alpha\frac{\partial}{\partial W_{ij}^{(l)}}J(W,b,X^{(u:u+m)}) \quad (8)$$

$$b_i^{(l)} = b_i^{(l)} - \alpha \frac{\partial}{\partial b_i^{(l)}} J\left(W, b, X^{(u:u+m)}\right) \tag{9}$$

where α is the learning rate. There are two reasons to use the mini-batch for updating the parameters: Firstly, reduces the variance of the parameter updates, lead to more stable convergence. Second, can make use of highly optimized matrix optimizations common to state-of-the-art deep learning libraries and computing the gradient w.r.t. a mini-batch very efficient. To compute the partial derivatives above, we use the backpropagation algorithm to compute these partial derivatives.

$$\frac{\partial}{\partial W_{ij}^{(l)}} J\left(W, b, X^{(u:u+m)}\right) = \left[\frac{1}{b_1} \sum_{u=k}^{k+(b_1-1)} \frac{\partial}{\partial W_{ij}^{(l)}} J(W, b, X^{(u)})\right] + \lambda W_{ij}^{(l)} \tag{10}$$

$$\frac{\partial}{\partial b_i^{(l)}} J\left(W, b, X^{(u:u+m)}\right) = \frac{1}{b_1} \sum_{u=k}^{k+(b_1-1)} \frac{\partial}{\partial b_i^{(l)}} J(W, b, X^{(u)}) \tag{11}$$

Where b_1 is mini-batch size.

Algorithm 1: One iteration of the mini-batch gradient descent algorithm.

Set $\Delta W^{(l)} := 0, \Delta b^{(l)} := 0$ for all l
Parameter: mini-batch size b_1
k=1;
Repeat {
u:=k;
Repeat {
- Compute $\nabla_{W^{(l)}} J(W, b, X^u)$ and $\nabla_{b^{(l)}} J(W, b, X^u)$
- Set $\Delta W^{(l)} \leftarrow \Delta W^{(l)} + \nabla_{W^{(l)}} J(W, b, X^u)$
- Set $\Delta b^{(l)} \leftarrow \Delta b^{(l)} + \nabla_{W^{(l)}} J(W, b, X^u)$

$u := u + 1;$
Until $u > (k + b_1)$
$k := k + b_1;$
Until $k > m$;
Update the weights and biases (5.8) and (5.9)

$$W_{ij}^{(l)} = W_{ij}^{(l)} - \alpha \left[\frac{1}{b_1} \Delta W^{(l)} + \lambda W^{(l)}\right] \quad \text{using the formula (5.8)}$$

$$b_{ij}^{(l)} = b_{ij}^{(l)} - \alpha \left[\frac{1}{b_1} \Delta b^{(l)}\right] \quad \text{using the formula (5.9)}$$

Source: Author, (2026).

To make predictions, we give the training set of one user and a new query service *q*. The input layer for a specific unit represents the probability which service *q* will be predicted the QoS value *k*. As such the expected rating for item *q* is computed as

$$r_q = \sum_k k . \frac{f\left(\sum_{j=1}^{F} W_{ij}^{k(l)} a_j^{(l)} + b_i^{k(l)}\right)}{\sum_k f\left(\sum_{j=1}^{F} W_{ij}^{k(l)} a_j^{(l)} + b_i^{k(l)}\right)} \tag{12}$$

V. EXPERIMENTAL

V.1 DATA SETS DESCRIPTION

We have used public real world Web-service QoS data set for our experiments. This is WS-DREAM (*http://www.ws-dream*) data set, it is a Distributed Reliability Assessment Mechanism for Web Services and allowing users to carry out a reliable and quality assessment web service in a collaborative manner. We conducted experiments the algorithm from two different data sets in WS DREAM. *Dataset 1*[17]: The data set monitor 100 Web services by using 150 distributed computer nodes located all over the world. The obtained results are contained in 150 files, where each file includes 10,000 Web Services invocations on 100 Web services by a service user, there are totally more than 1.5 million Web service invocations and each line in the file is a web service invocation result. We randomly extract 100 files, each file includes 1000 Web service invocations on 100 Web services by a service user, there are totally more than 10.000.000 Web service invocations. *Dataset 2* [18]*:* Real-world QoS evaluation results from 142 users on 4,532 Web services on 64 different times. The obtained results include two files: Response-time (RtRate) and Throughput (TpRate), where each file has collected 4,532 Web services from public sources on the Web. 142 distributed computers from the Planet-Lab are employed for evaluating the QoS performance of Web services in 64 times intervals. Each of the dataset 1 and dataset 2 was divided into two parts. A training set (80%) and a test set (20%). We randomly removed entries 10% on the data set as missing QoS values.

V.2 EVALUATION METRIC

To evaluate the proposed model, we use both the Mean Absolute Error (MAE) and the Root Mean Square Error (RMSE) metrics to measure the prediction missing QOS value of our model. The evaluation rules are given by the following forms:

$$MAE = \frac{\sum_i [r_i - p_i]}{N} \tag{13}$$

$$RMSE = \sqrt{\frac{\sum_i (r_i - p_i)^2}{N}} \tag{14}$$

Where p_i is the standard deviations of the predicted values, r_i is real QoS value, N is the sum of the absolute difference over all pairs.

To prove the effectiveness of the proposed model, we compare our model with the following approaches:

***RBM* [19]** describe a class of two-layer undirected graphical models based on Restricted Boltzmann machines (RBM), it show that learning can be performed efficiently by using Contrastive Divergence (CD).
***AutoRec* [20]** This paper presents a novel autoencoder framework for CF, it is called AutoRec, the model is used backpropagation algorithm and fine-tuning by gradient descent.

V.3 EXPERIMENTAL RESULTS

We first set the parameters in the AutoMinibatch model with mini-batch size 300, number of hidden layers in the model (*Layer=150*), learning rate of *0,01* and tuned the regularisation strength $\lambda \in \{0.001; 0.01; 0.1; 10; 100\}$. For RBM, we train the RBM with $F = 100$, the weights were updated using a learning rate of *0.01*, momentum of *0.9* and CD learning was started with $T = 1$. For AutoRec, we tuned the regularization strength $\lambda \in \{0.001; 0.01; 0.1; 10; 100; 1000\}$ and the appropriate latent dimension $k \in \{10; 20; 40; 80; 100; 200; 300; 400; 500\}$. We selected training all models for between 200 and 300 passes (epochs) through the entire training two data sets. The values of these parameters were found above, empirically evaluating was found to yield quite good results. The RMSE and MAE values of all methods on both datasets are shown in Table 2. The results show that AutoRec have performance better RBM and AutoMinibatch obtains smaller MAE and RMSE values consistently, which indicates better prediction accuracy.

Table 2. Prediction quality on both datasets.

Methods	***Dataset 1***		***Dataset 2***			
			Response-time		*Throughput*	
	MAE	*RMSE*	*MAE*	*RMSE*	*MAE*	*RMSE*
RBM	0.3708	0.6111	0.3520	0.5839	0.4321	0.7583
AutoRec	0.3609	0.6028	0.3382	0.5812	0.4191	0.7335
AutoMinibatch	**0.3355**	**0.5780**	**0.3134**	**0.5591**	**0.4011**	**0.7190**

Source: Author, (2026).

Figure 2 and Figure 3 are the results of the models (RBM, autoRec and AutoMinibatch) on two datasets. The x-axis shows the number of epochs and the y-axis displays the MAE/RMSE of the models. We observed a faster rate of convergence for RBM when using the CD learning with T=2. This also shows that learning CD significantly improves performance of the RBM model. However, compared to AutoRec, RBM has slower convergence speed. Especially, AutoMinibatch has the fastest convergence speed, this indicates that AutoMinibatch give the lowest MAE, RMSE values on two datasets.

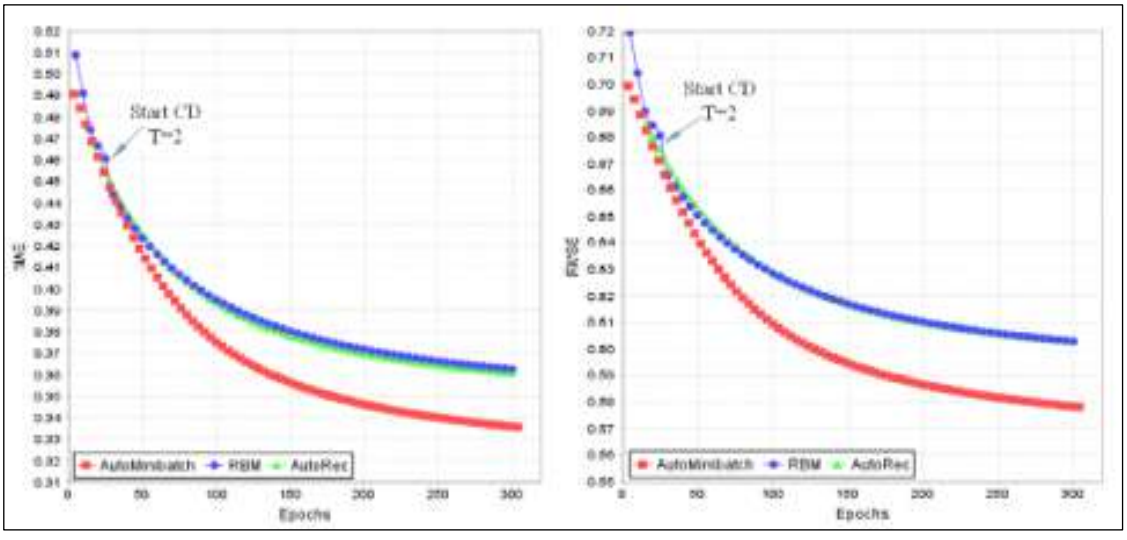

Figure 2: Performance of various models on dataset 1.
Source: Author, (2026).

The y-axis displays MAE or RMSE and the x-axis shows the number of epochs, or passes through the entire training dataset.

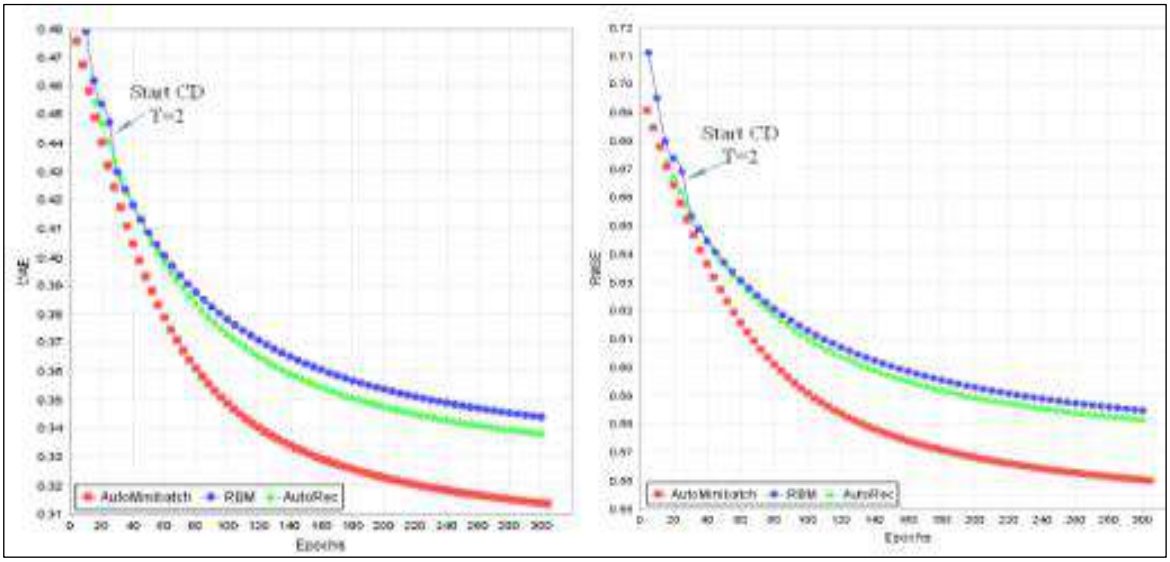

Figure 3: Performance of various models on dataset 2 (Response-time).
Source: Author, (2026).

The y-axis displays MAE or RMSE and the x-axis shows the number of epochs, or passes through the entire training dataset. On the other hand, AutoMinibatch model has the number of free parameters is very large. So, to find a satisfying combination of parameters for the model is not an easy task by the following reasons:

- First, all these parameters are involved in the curve.
- Second, sometimes they reinforce each other or destroy each other or even make it more complex.
- Finally, we must have the time required to evaluate a set of parameter settings, it is not easy to combine the effective parameters.

In that context, we presented a way to add three experiments below with the aim of this study is to clarify the individual effect of each parameter on the model.

Learning rate: We first study the influence of the learning rate for faster convergence, we set three different parameters for learning of $\gamma = (0.01; 0.001; 0.0001)$ and all remaining parameters like in the experiments above. Figure. 4 and Figure. 5 display the results of the learning rate on two datasets and they have a different impact on the convergence. If we set the learning values γ to be too small $\gamma = 0.0001$. The result is almost a straight line and it almost does not affect the learning model, therefore, this value will not be appropriate for the model. The results show that the value $\gamma = 0.01$ the convergence rate is faster than $\gamma = 0.001$, so, we can conclude that the $\gamma = 0.01$ offers best result of the model.

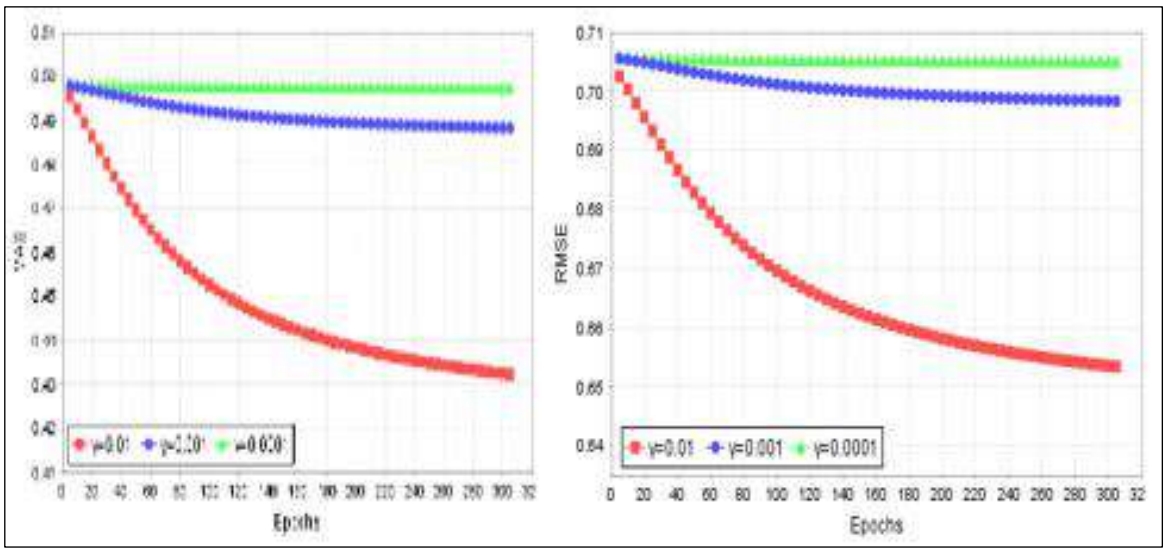

Figure 4: The effect of learning of various models on dataset 1.
Source: Author, (2026).

The y-axis displays MAE/RMSE and the x-axis shows the number of epochs, or passes through the entire training dataset

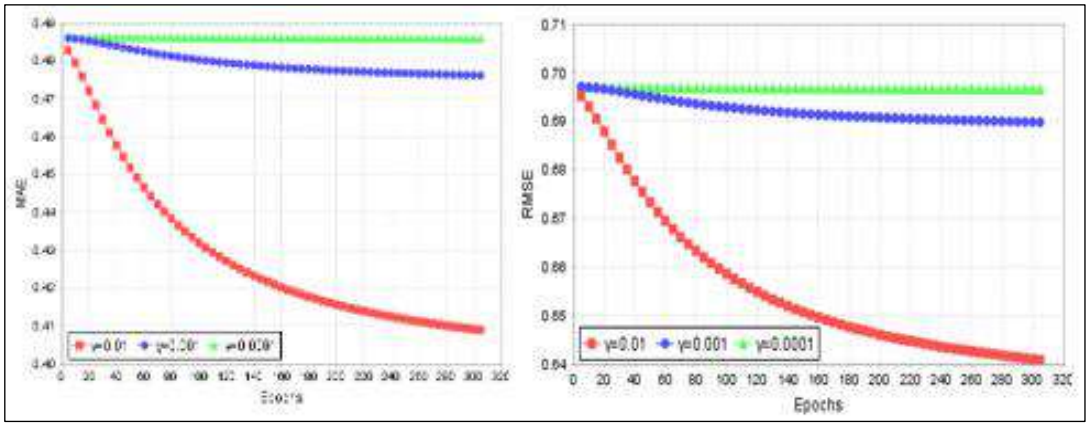

Figure 5: The effect of learning of various models on dataset 2 (Response-time).
Source: Author, (2026).

The y-axis displays MAE/RMSE and the x-axis shows the number of epochs, or passes through the entire training dataset.

The number of hidden layers: The determination of the number of layers and the number of nodes in each layer are a very important part in deciding model architecture. Therefore, we firstly examines how to determine them for effectiveness. There are two issues related to select the number of layers and the number of nodes in each layer: First, the hidden nodes are not directly interacting with the external environment, but they have a tremendous influence on the final output. Second, depending on the training data that we can choose the number of different hidden nodes, but if we choose too many hidden layers and hidden nodes, it can lead to over-fitting. To demonstrate the influence on the number of hidden layers and hidden nodes in each layer in the model, we choose three different values: 50 layers (Layer=50), 100 layers (*layer=100*) and 150 layers (*layer=150*) and each layer we choose 200 hidden nodes. The results which are illustrated in Figure. 6 and Figure. 7 show that there is a huge difference in the speed of convergence among various hidden layers. With *layer=150*, the convergence rate is the fastest.

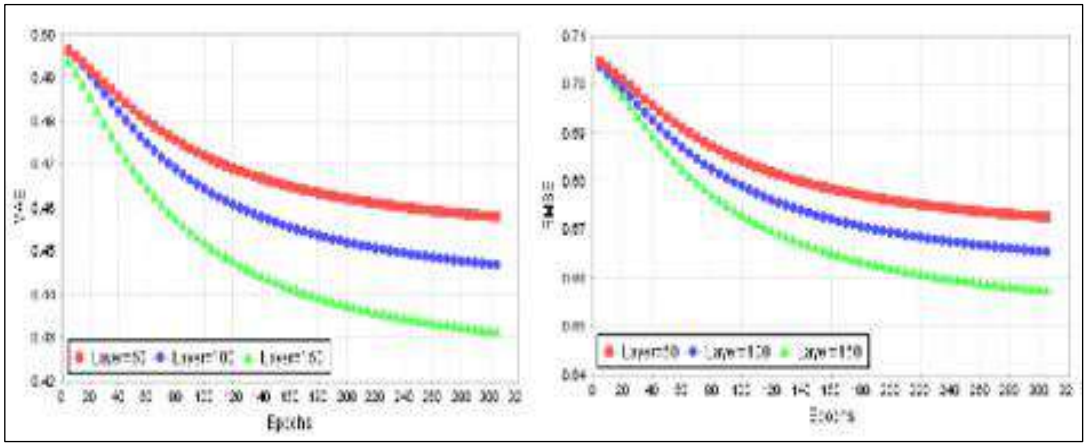

Figure 6: The effect of the number of hidden layers on dataset 1.

The y-axis displays MAE/RMSE and the x-axis shows the number of epochs, or passes through the entire training dataset.

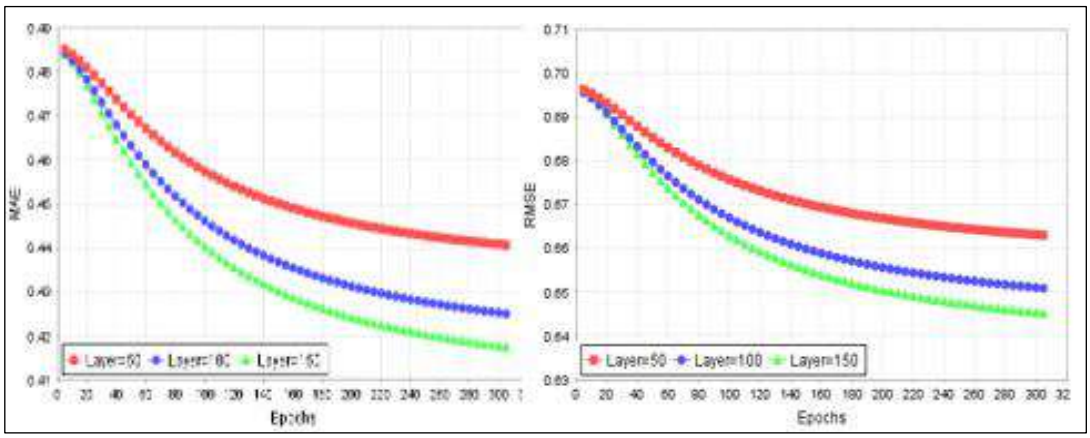

Figure 7: The effect of the number of hidden layers on dataset 2 (Response-time).
Source: Author, (2026).

The y-axis displays MAE/RMSE and the x-axis shows the number of epochs, or passes through the entire training dataset.

Mini-batch size: Mini-batch size will directly affect the number of times that update parameters in the model. To experiment, we also choose different mini-batch size as follows: *mini-batch size=100*, *mini-batch size=200* and *mini-batch size=300*. All other parameters as above experiment. The result in Figure 8 and Figure 9 show that all the mini-batch seem to be almost equal. But if we look carefully, we will see different results, in which *mini-batch size=300* has the best result. Basing on the experimental results above, we shown that the following parameters have the best convergence: Learning rate with $\gamma = 0.01$; The number of hidden layer is 150; and mini-batch size=300. However, depending on the datasets there will be different parameters.

VI. CONCLUSION AND FUTURE WORK

In parallel with the development of e-commerce, service oriented systems have become one of the most dynamic research areas. The objective of the systems is to recommend QoS to users, but to identify whether a service provider is good or bad, it depends on many different factors. If we want to predict the Web service reliability for the current user or helping users find appropriate Web service providers, we'll force them to collect more detailed information about each user and maintain data for all users. On the other hand, the skyrocketing number of users and service providers lead to a huge volume of data. To contribute to the solving of the above problems, in this paper, we introduced a new model called AutoMinibatch with two goals: First, adding a new method for evaluating prediction the field of web service quality. Second, opening for predicting QoS on large data sets based on an autoencoder.

The model used backpropagation and fine-tuned by mini-batch gradient descent. Experimental results obtained are very satisfying and better than what we expected. AutoMinibatch has faster final convergence than RBM and AutoRec. In addition, we also demonstrate how to choose the parameters (Mini-batch size, the number of hidden layer and learning rate) for the best efficiency. The best results obtained from experiments: Mini-batch size=300, the number of hidden layer is 150 and learning rate is 0.01. In the future, we will orient some work that needs to be done here. First, We will finish building a system of collecting information of QoS values from different service users and predicting the missing QoS values for active users based on the Autominibatch model. Second, algorithms typically do not take into account any form of implicit feedback for making inferences. Normally this feedback information has only a small number of ratings in the training set, but it is a very useful source of information for the other users. So, the architecture of the AutoMinibatch model has been modified to take all this extra information into account and called a conditional Autominibatch model.

ABSTRACT

Preterm birth (PTB) is a leading cause of neonatal mortality worldwide, underscoring the need for accurate early prediction. This study presents a machine learning framework combined with hybrid feature selection to predict PTB risk in nulliparous women using data from electronic medical records collected during prenatal consultations. Clinical, demographic, and physiological data were obtained from the publicly available nuMoM2b dataset, covering three gestational intervals: 6–13 weeks, 16–21 weeks, and 22–29 weeks. Data preprocessing and standardization were performed using Differential Evolution (DE) to enhance quality and improve model performance. A hybrid feature selection approach, integrating the Dragonfly Optimizer with entropy-based relevance ranking, was employed to identify informative and non-redundant predictors, reducing dimensionality and noise while maintaining clinical interpretability. A Multilayer Perceptron (MLP) classifier trained on the selected features differentiated term and preterm deliveries. The framework achieved 88.41% accuracy, AUC = 0.80, precision = 85.84%, recall = 87.24%, and F1-score = 88.15%. Incorporating ultrasound features such as cervical length and Plasticity Index further improved predictive performance. Notably, at the third prenatal consultation, the model reached 85.62% sensitivity for predicting very preterm infants. These findings highlight the importance of ultrasound measurements and demonstrate that integrating machine learning with evolutionary optimization and entropy-based feature selection can significantly enhance early PTB risk detection. The approach enables timely interventions for high-risk pregnancies, potentially improving maternal and neonatal outcomes. This study underscores the value of computational methods in clinical decision support and emphasizes how machine learning can transform prenatal care for nulliparous women.

I. INTRODUCTION

High-risk pregnant women can get prompt preventative measures to lower their risk of preterm birth by being identified early [1]. Although invasive screening and imaging tests have the potential to be successful screening techniques, they are still in the experimental stage due to their high cost, potential risks, and limited accessibility [2]. Non-invasive screening techniques using machine learning (ML) algorithms based on comprehensive pregnancy surveillance data alongside multilevel information connection to delivery records, without the need for any additional physiologic or imaging tests, have the potential to support clinical decision making to predict adverse pregnancy outcomes and guide pregnancy management [3]. The frequent medical care that survivors of preterm birth need, which has a detrimental effect on their quality of life and mental health, further strains the family economy and health care system [4]. Therefore, early detection of preterm birth is essential to enable medical professionals to perform prompt therapies to enhance infant outcomes. Because of the intricacy of the system, no set standards have been established for the prediction of preterm birth [5].

At the moment, evaluation of biochemical markers, cervical measurement, and risk factors serve as the primary foundation for clinical evaluation of PTB [6]. However, not all of these diagnostic methods are therapeutically acceptable for every pregnant woman because of their lack of safety or cost-effectiveness, even though they may be able to identify particular preterm birth characteristics [7]. For instance, examinations like cervical measurement and biochemical marker assessment will put the expectant mother under more physical and mental stress, and the expense of the tests will put more financial strain on the family [8]. The main driving force for our work is the importance of making an accurate prediction of PTB. These forecasts are essential to manage the logistical aspects of newborn care as well as for starting prompt interventions, particularly in areas with a shortage of advanced care facilities.

Steroids to encourage lung maturity and magnesium sulfate injections to safeguard the developing brain are essential treatments when access to skilled neonatal care is restricted. Accurately anticipating preterm birth also makes it easier to transfer patients either prenatally or postnatally to facilities that can offer critical care in situations where the required facilities are not available immediately, improving outcomes for both mothers and newborns [9]. Finding preterm birth risk factors is the main goal of the majority of current research on the prediction of PTB. Numerous risk factors have been demonstrated to increase the likelihood of preterm birth, namely body mass index (BMI), maternal family history, cervical length, vaginal hemorrhage, and depression [10], [11].

In recent years, a lot of research has focused on the use of Electronic Medical Records (EMRs) to predict premature birth. For instance [12] employed a stabilized sparse logistic regression approach to attain an AUC of 0.79 while concentrating on appropriate data preparation, addressing problems including data leaking and class imbalance. By merging racial-ethnic groupings [13] were able to predict PTB in nulliparous women utilizing data from almost 2 million patients, achieving an AUC of 0.67 [14] used a C5.0 Decision Tree to develop a model that achieves a sensitivity of 90.9% and a specificity of 71.8%, surpassing the prediction quality of costly and invasive fibronectin marker testing. By [15] utilized a variety of ML models to predict the delivery of extreme PTB (before 28 weeks), and they were able to get an AUC of 0.827 using an ensemble of LSTM models.

I.1 IDENTIFIED RESEARCH GAPS:

Although there is growing interest in using ML to predict preterm birth (PTB), existing models struggle to handle feature redundancy, integrate temporal clinical data, and achieve high sensitivity in the early stages of pregnancy. Although DL has been applied to EMR in a number of recent studies, many of these studies either ignore the temporal evolution of risk factors throughout prenatal Consultations or depend on static feature sets. For instance, Traditional time-series LSTM techniques by Zhang et al., (2022) [16], enhances prediction performance but frequently depend on insufficient gestational data, which restricts their use in late-trimester categorization. Similar issues with interpretability and dimensionality found by [17], they use ensemble methods to Electronic Health Record data, which affected their practical clinical applicability. On full multi-Consultation EMR data [18] showed that ensemble approaches can be adopt moderate accuracy, but they had trouble with feature interpretability and redundancy.

Crucially, the majority of current models do not dynamically include ultrasound-derived factors such as cervical length and plasticity index over gestational intervals. For extremely preterm and severe preterm forecasts, this omission results in decreased accuracy, especially in the later trimesters when intervention is essential. Furthermore, not much research has available in terms of hybrid evolutionary techniques (such DE or Dragonfly Optimization) in combination with entropy-based methods for novel and comprehensible feature selection in medical datasets. Additionally, there is discussion about an efficient feature fusion method for multi-Consultation data, which is crucial consideration for longitudinal PTB prediction. Thus, a significant research gap still exists in creating an end-to-end system for accurate and interpretable PTB risk prediction that uses publically available EMR datasets such as nuMoM2b and integrates DL classification, hybrid feature selection, and adaptive feature preprocessing.

I.2 OBJECTIVES

The objective of this research is to use longitudinal EMRs from publicly accessible nuMoM2b datasets to create a novel ML framework for early PTB prediction. The study specifically tried to address the limitations in existing research gaps by (i) integrating temporal clinical data from multiple prenatal Consultations, (ii) integrating ultrasound-derived parameters such as cervical length and pulsatility index to improve predictive sensitivity , and (iii) implementing a novel hybrid feature selection approach that combines entropy-based relevance ranking with evolutionary optimization techniques (e.g., Differential Evolution and Dragonfly Optimization) to manage feature redundancy and guarantee clinical interpretability. By using this method, the study hopes to facilitate clinically useful risk assessments that enhance the outcomes for mothers and newborns.

I.3 MAJOR CONTRIBUTION OF THIS PAPER:

In order to overcome a number of shortcomings in discussed methods, this study offers an innovative ML framework for the early PTB. The following are this study main contributions:

- Integration of Multi-Consultation Prenatal-EMR Data: This study integrates longitudinal data from three different prenatal intervals (6–13, 16–21, and 22–29 weeks), which captures the changing nature of risk variables during pregnancy.
- Methodology for Hybrid Feature Selection: The Dragonfly Optimization Algorithm and entropy-based relevance ranking are used to provide a novel hybrid feature selection approach. This approach dynamically provides a balance among redundancy and feature relevance which is lack from conventional filter or embedded selection methods.
- Ultrasound Feature Fusion: The model incorporates clinical data that are generally left out of many PTB prediction models, such as cervical length and pulsatility index, but are generated from ultrasound. The model sensitivity to identify the extremely preterm and very preterm babies, particularly in later trimesters, is increased by the inclusion of these data.
- Data Preprocessing using Evolutionary Optimization: To improve data quality and reduce the imbalance and noise in prenatal records, the system uses Differential Evolution (DE) for preprocessing and standardizing clinical variables from our previous study.

- Interpretable DL Model: To overcome the common shortcomings of DL models, a MLP classifier is trained using the optimized feature set to achieve excellent accuracy which guarantees the model transparency and clinical application.
- Validation on Public Dataset: The methodology is validated on the nuMoM2b dataset to ensure the reproducibility and encouraging the open research. The experimental results show better performance in terms of accuracy, AUC, sensitivity, and specificity when compared to baseline models.

II. THEORETICAL REFERENCE

II.1 LITERATURE REVIEW

The relevant literature on PTB prediction using ML and DL techniques is included in this section. By [19] utilized readily available variables from prenatal visits and machine learning to forecast premature birth in nulliparous women. Five-fold cross-validation was used to assess Elastic-net regularized logistic-regression models on data from 8,830 women at three prenatal visits who were part of the nuMoM2b dataset. Along with noteworthy gains in sensitivity and specificity, AUC values rose from 0.6161 in the first visit to 0.7087 in the third. The predictive capacity of the models was significantly improved by the additional measurements. Interestingly, at the third prenatal visit, the model's sensitivity for predicting very-preterm and extreme-preterm infants was 0.8254 and 0.9295, respectively. By [20] aims to create a Risk Prediction Conceptual Model (RPCM), a ML model, for PTB prediction. This work proposes a feature selection method based on the concept of entropy. The goal of the unique strategy is to forecast the classifier's accuracy at the greatest level by identifying the best maternal features that causes PTB from the obstetrical dataset. We then gather obstetrical data from rural communities' Community Health Centers (Kamdara, Jharkhand).

To categorize the considered data into term birth and PTB, the recommended method is utilized to the data gathered to determine the great maternal features of pregnant women. At the end, SVM classifier secured improved performance of 90.9% accuracy. By [21] predicts neonatal mortality and neonatal morbidities such as necrotizing enterocolitis, retinopathy of prematurity, and bronchopulmonary dysplasia in very low birth weight infants using machine learning. Time series data and clinical characteristics gathered at Helsinki University Hospital's Children's Hospital's neonatal ICUS as our predictors. We look at nine distinct classifiers. In order to increase classifier sensitivity, our systematic analysis also includes various data pretreatment techniques. When it comes to predict the classes, the analyzed classifier AUROC is 0.922, 0.899, and 0.846, respectively. According to [22] suggests a ML-based PTB prediction model. All of the patients in this study were chosen from a Chinese hospital, and the data evaluated ranged from 2008 to 2018. 4775 of the 9550 pregnant women who were enrolled in the research had PTB. 4775 individuals in all were chosen at random to serve as controls. The accuracy (0.816) and AUC (0.885) of the RF model based on 27 weeks of gestation were the highest when compared to other approaches.

By [23] create, train, and evaluate ML models for singleton pregnancies at various gestational intervals that predict preterm birth (less than 37 weeks gestation). The models were developed using complete data using 22,603 singleton pregnancies from prospective based on populations cohort research conducted in 51 hospitals through midwifery clinics in Wenzhou City, China, during 2014 and 2016. To build prediction models, the top 10%, 25%, and 50% of predicting features were selected. Employing the training data set with five-fold cross-validation, prediction models were developed for internal validation. AUC results were utilized to assess the model performance. After 26 weeks of gestation, the CatBoost-based prediction model outperformed the others with an accuracy of 0.81 and an AUC value of 0.70 (0.67, 0.73). According to [24] intends to use a reduced PSG-based system that solely uses airflow data to find sleep apnea in pregnant nulliparous women. For sleep-disordered breathing (SDB) studies, we used the nuMOM2b dataset, which included 3012 female participants. It is based on computer-aided diagnostic tool to detect sleep apnea in expectant mothers automatically. Wavelet coefficients are used to extract the L1- norm features.

To automatically identify apnea, the chosen features are subsequently passed into a variety of ML classifiers. Using the RUS-Boosted tree classifier, the created model achieved the best accuracy of 83.9% with the F1 score of 0.91. In turn [25] utilized ML techniques to find the main predictors of PTB among clinical and dental factors. We collected cohort data from 60 women who had cesarean sections for singleton infants (30 PTB, 30 FTB). PTB and spontaneous PTB (SPTB) were the dependent variables. For the ML analysis, 15 independent variables which includes10 clinical and 5 dental factors were chosen. The key predictors of PTB and SPTB were found using the Random Forest (RF) variable significance. The relationships among the predictors and PTB/SPTB were examined using Shapley additive explanation (SHAP) values. Pregnancy BMI, modified gingival index (MGI), preeclampsia and two more factors were the top five that were identified as major factors to predict PTB based on RF variable relevance. Mother age, Premature rupture of the membranes and pre-pregnancy BMI were among the key predictors of PTB/SPTB that showed positive relationships with SHAP levels.

The necessity of integrated medical and dental care during pregnancy is highlighted by the positive correlations shown among these predictors and PTB. By [26] suggests a two-phase approach in which Phase I will construct a graphical user interface (GUI) based on ML for the early PTB prediction and will choose the key factors that cause PTB based on the opinions of experts and a review of the literature. Using paper based data collected from a Jharkhand hospital, 15 sociodemographic factors are extracted from digitized birth dataset (DD-I). To determine their connection with PTB, parameters are statistically examined. With a mean accuracy of 88.02% (with SD.: 0.001), the RF learner is then examined as the superior for early prediction, outperforming traditional manual methods.

These studies demonstrate the increasing interest in predicting preterm births using EMRs. There is still a sizable gap in the literature, though, as many of the discussed models either don't assess the model performance at various pregnancy stages. By concentrating on readily available characteristics that can be gathered during routine prenatal visits and evaluating the model's prediction power at various pregnancy stages, our study aims to close this gap.

III. MATERIALS AND METHODS

Write in detail the research project, including background and limitations. The selection of materials and methods, procedures and equipment must be justified so that the work can be reproduced. Modifications or new methods must be described in detail. You must clearly define the universe and specify how the sample was selected and why it is representative.

Data processing represents the practical development of a theoretical basis, deriving the model equations to program the calculation algorithm, according to the need. In materials, they include the technical specifications and the quantities, the origin and, if necessary, the method for its elaboration . The proposed architecture in Figure 1 presents a robust, ML pipeline designed for accurate PTB using EMR. The process comprises of five phases including data preprocessing, data structuring (Temporal), feature selection, classification and model assessment. Data Preprocessing: Initially the raw clinical data is preprocessed to remove the records with missing or irrelevant features, no indication of birth type as PTB or full term, or unrelated risk factors. Differential Evolution (DE) based preprocess on medical PTB data from our previous research is used to optimize this process for data cleaning. The cleaned dataset is divided into training and testing subsets of 70:30 stratified sampling. To class imbalance is addressed by SMOTE (Synthetic Minority Oversampling Technique) method.

Temporal Data structure: The training data is further divided longitudinal subsets based on prenatal Consultations intervals as baseline, Consult1 (6 to 13 weeks), Consult2 (16 to 21 weeks) and Consult3 (22 to 29 weeks). This segmentation helps model for risk factors evolution among the gestation. Feature selection using H-EDFO: This hybrid approach combines entropy-based feature relevance score with the DFO. It ranks the features based on their clinical relevance and removes the redundant or less informative features by improving the interpretability and performance. Classification using MLP: The optimized feature subset is fed as input to MLP that classify the outcomes as PTB and non-PTB. Model evaluation and Interpretation: The final phase states include discrimination and calibration analysis to evaluate the model performance and reliability using the metrics accuracy, sensitivity and AUC across various gestational stages.

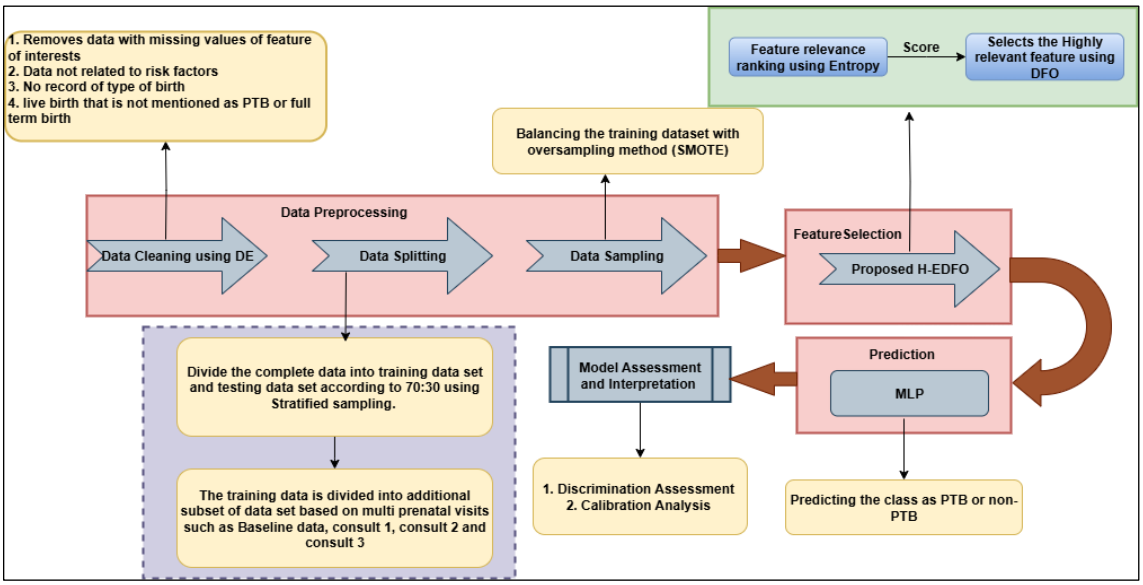

Figure 1: Proposed architecture of PTB prediction using longitudinal EMR data from nuMom2b dataset.

III.1 DATA SET DESCRIPTION AND SELECTION

One useful tool in our research is the Nulliparous Pregnancy Outcomes Study: New Mothers-to-Be (nuMoM2b) dataset made publicly available by the NICHD DASH repository (2015), served as the dataset for this investigation. Its usage in this study didn't require any further ethics clearances or data use agreements [27] which is an extensive collection 10038 nulliparous women with singleton pregnancies [27] who were sourced from eight clinical facilities connected to research institutes are included in the dataset respectively, Western Reserve University (Site 1), Columbia University (Site 2),Indiana University (Site 3), Magee-Women's Hospital (Site 4), Northwestern University (Site 5), University of California Irvine (Site 6), University of Pennsylvania (Site 7), and the University of Utah (Site 8) [19].

The nuMoM2b study's main goals were to: (1) identify maternal traits that influence or predict an adverse pregnancy outcome, such as genetics, epigenetics, and the body's response to environmental influences and pregnancy (2) identify specific elements of placental growth and function that lead to a poor pregnancy outcome; and (3) outline the genetic, growth, and developmental characteristics of the fetus that are connected to a poor pregnancy outcome.

The requirement of study inclusion and exclusions are listed in Table 1:

Table 1: Considered inclusion and exclusion data requirements of prenatal Consultation.

Inclusion	Exclusion
Pregnant women who were nulliparous (defined as having no previous pregnancies longer than 20 weeks), (2) identify specific elements of placental growth and function that lead to a poor pregnancy outcome; and (3) outline the genetic, growth, and developmental characteristics of the fetus that are connected to a poor pregnancy outcome.	1) Maternal age <13 years, 2) history of at least three spontaneous abortions, (3) identified fetal aneuploidy, (4) a surrogate pregnancy, (6) multifetal pregnancy reduction, (7) involvement in an intervention study that could impact maternal or fetal morbidities/mortality (8) previous enrollment in the nuMoM2b study, (9) planned pregnancy termination, and (10) inability to give informed consent

Source: Authors, (2026).

Based on the dataset description, collection of data is based on interviews, clinical measurements, ultrasounds, self-administrated questionaries and medical records review at the scheduled Consultations as stated in Table 2. To guarantee data consistency and integrity across trial sites, particular data collection protocols were adhered to at every Consultation. Standardized training on data collection procedures was provided to all study staff, and frequent monitoring Consultations were carried out to make sure study protocols were being followed. Some inaccuracies might have remained, and some data might still be outside of expected ranges or otherwise illogical in spite of these data quality control procedures. Before performing analysis and deciding how to handle inaccurate data, investigators utilizing the data must assess fields of interest.

Table 2: Gestational time periods of prenatal Consultations of the dataset.

Consultation	Gestation weeks	Predictors
Consult 1	6 to 13 weeks	35
Consult 2	16 to 21 weeks	51
Consult 3	22 to 29 weeks	73
Consult 4	Delivery time	-

Source: Authors, (2026).

Of the 10,038 individuals, 9,289 agreed to share their anonymised data for research purposes, and 9,127 volunteered to share their baby's data. Numerous variables were covered by the information gathered, such as physiological measurements, food habits, psychosocial factors, demographics, and pregnancy outcomes. The [28] publication contains a detailed explanation of the procedures used in the Nulliparous Pregnancy Outcomes Study. To ensure model stability and dependability, logistic regression-based prediction models usually recommend a minimum of 10 events per predictor variable (EPV)[29]. 7,59 preterm births were among the 8,830 individuals in our final analytical sample. With each Consultation, the number of predictor factors are listed in Table 2. All models demonstrated suffic29ient statistical power by exceeding or meeting the minimum suggested criterion of 10 EPV. Furthermore, the minimum of 2,000 participants advised through reviews for reliable and broadly applicable ML applications in healthcare is significantly exceeded by our sample size of 8,830 participants [30].

Dataset Variables:

A methodical, multi-step procedure was used to choose the candidate predictor variables. We found established predictors of preterm birth through a thorough assessment of the literature [31-33], including clinical variables, specialized imaging data, and biological markers. Some known predictors have the potential to have a high predictive value, but they were not included in database because of the resource-intensive factor. Clinically accessible predictors that were easily obtainable throughout standard prenatal care were the main focus of our final variable selection process. A number of criteria were used to evaluate the variables, including availability in the routine prenatal Consultations, cost-effectiveness, and proven clinical relevance from published research. As shown in Table 3, the selected factors included demographic data, non-invasive evaluations, medical history, family medical history, and standard diagnostic procedures. The selection of these variables was informed by cost-effectiveness and feasibility concerns, as they can be gathered quickly, cheaply, and without requiring invasive or resource-intensive procedures. As a result, ordinary clinical practice can easily implement the prediction models [34].

Table 3: nuMom2b dataset identified characteristics with variables.

Characteristics	Variables
Basic Preconception	maternal age, height, BM), adoption of assisted reproductive technologies, PTB family history, pregnancy complications, hypertension, and cervical excisional procedures/surgery history (Loop Electrosurgical Excision Procedure (LEEP)/conization),
Lifestyle	Mental stress, alcohol consumption, tobacco usage, and maternal vitamin-D deficiency
Sociodemographic	ethnicity, marital status, educational attainment, and socioeconomic status
Obstetric/Pregnancy	Vaginal hemorrhage, serial transvaginal cervical length, gestational diabetes and hypertension, and cervical insufficiency
Medical History	history of obstetrics, diabetes, and hypertension prior to pregnancy

III.2 DATA PRE-PROCESSING

III.2.1 Data Cleaning Using DE for Analyzing Missing Data

A comprehensive analysis of missing data patterns was carried out, which included a review of the dataset documentation and a close look at the data gathering methods. Even while many variables had incomplete data patterns lacking a clear documentation explanation, several variables displayed systematic missingness that was related to specific therapeutic regimens.

The research by [35] utilizes the DE based preprocessing to handle the missing values of medical datasets. In this study used the same model to handle missing and irrelevant data of nuMoM2b dataset. DE is the population based approach that searches globally to find the optimal imputation values. The steps for DE based imputation is shown as follows:

Step 1: Preprocessing

- The dataset is divided into continuous and categorical values
- Normalize the continuous features values in the range [0, 1]
- Categorical values are encoded using one-hot encoding

Step 2: Fitness function: The candidate imputation is evaluated using clinical constraints such as cervical length in the range 15 to 50mm.

Step 3: DE optimization

- Population is initialized for the candidate imputation
- DE operations such as mutation, crossover and selection are applied as:

Step 4: Post processing: Reverse Normalization and selects the categorical variables with the variables having highest probability of DE search. The value of mutation factor is declared as 0.6 and number of population N is 50 for 100 iterations with crossover value of 0.8.

Nonetheless, certain variables were missing for systematic reasons that could be explained. Missing entries were taken to mean that there was no tobacco use or bleeding beyond spotting for variables like "Usage of Tobacco in Consult-1" and "Bleeding in Vaginal" at all three Consultations, respectively, and were imputed appropriately. Only in the event that the results of the uterine artery Doppler at Consult-2 were abnormal and uterine artery Doppler ultrasonography at Consult-3 is required during data collection. This procedure is in line with a study by Hofstaetter et al., that found that the uterine artery Pulsatility Index (PI) did not change significantly with gestational age in uncomplicated pregnancies [36].

Therefore, we randomly selected from the normal PI (Pulsatility Index) range appropriate among 22 and 29 weeks, as reported in the study by [37], to impute these missing values for cases with missing data of "Left uterine artery -PI at Consult-3" and "Right uterine artery - PI at Consult-3" where Consult-2 measurements were normal. This strategy was required to preserve the dataset's integrity while taking into account the clinical judgment that guides these assessments. Before variable extraction for every Consultation, imputation was done once for every training dataset. Based on this analysis, the records inclusion and exclusion are stated in the Figure 2.

There were 749 of the 10,038 women who were first enrolled in the nuMoM2b research were disqualified because their risk factor information was lacking. There were 438 of the 9,289 women who still had data available were disqualified (432 had no birth type record, 4 had live births without records, and 2 had stillbirths without records). There were 21 more participants were disqualified because their data was missing more than 80% of the time. These cases mostly involved very early preterm deliveries or early pregnancy loss, for which data from follow-up Consultations could not be obtained. A final analysis sample of 8,830 women with adequate data through delivery of 8,071 with full-term births and 759 with preterm deliveries was obtained through this systematic filtering approach.

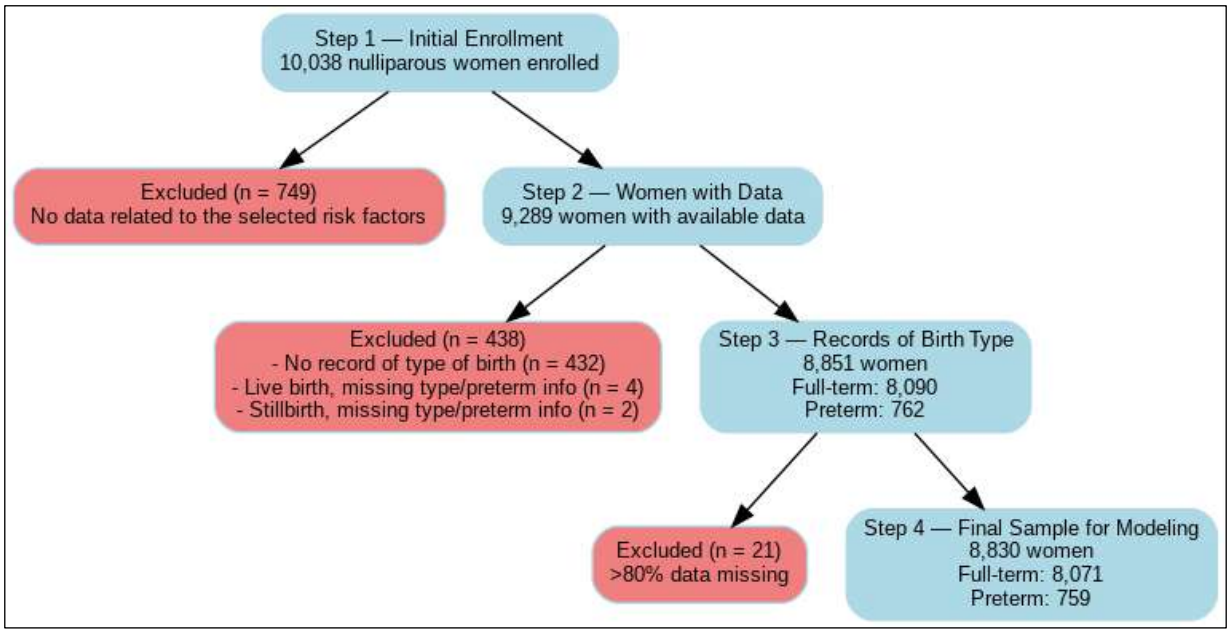

Figure 2: Records inclusion and exclusion based on preprocessing.
Source: Authors, (2026).

III.2.2 Temporal Data Splitting

A total of 35 variables were accessible during the initial Consultation, 51 during the second Consultation, and 73 during the third Consultation. Basic data, such as ethnicity, level of poverty and obesity, pre-gestational diabetes, marital status, and educational attainment, were gathered during the initial Consultation (dataset B).

Furthermore, we have fundamental measurement factors (such as surveys and questionnaires) that are measured at all three Consultations, including BMI, smoking, vaginal bleeding, level of stress, gestational diabetes and hypertension diagnosis (dataset C1, C2, and C3). Following that, ultrasound measurements were added to the data at the second and third Consultations (datasets U2 and U3). The overview of dataset is described in Table 4.

Table 4: The overview of dataset.

Datasets	Variables
B	poverty, color, marital status, education, obesity level, and prenatal diabetes diagnosis
C1	Basic assessments during consultation 1 include BMI, level of stress, smoking, gestational diabetes, vaginal bleeding and hypertension.
C2	fundamental measurements Weight, body mass index, smoking status, vaginal hemorrhage, gestational diabetes, and hypertension during the second consultation
C3	Weight, BMI, smoking history, vaginal-bleeding, gestational diabetes, and hypertension are the fundamental parameters taken at consultation3.
U2	Pulsatility Index and cervical length ultrasound measures at consultation2
U3	Pulsatility Index and cervical length ultrasound measures at consultation3

III 2.3 Data Sampling

Given that preterm births and other unfavorable pregnancy outcomes affect a smaller percentage of the population than term deliveries, the nuMoM2b) dataset is naturally unbalanced. Machine learning classifiers may become biased toward the majority class as a result of this imbalance, making it harder for them to identify high-risk situations. The Synthetic Minority Oversampling Technique (SMOTE) [38] is used as a data-level balancing technique prior to model training in order to overcome this. By interpolating between a data point and its closest neighbors in feature space, SMOTE [38] creates synthetic samples of the minority class, lowering the possibility of overfitting that can happen with straightforward minority sample duplication.

This preserves specificity while increasing the classifier's sensitivity to uncommon occurrences, like extremely premature birth. The method improves the representation of minority patterns in the training set while maintaining the original data distribution, and it has been demonstrated to be successful in medical prediction tasks, especially when paired with feature selection and ensemble classifiers. After preprocessing the nuMoM2b dataset, SMOTE was applied in this study to produce a balanced input set for predictive modeling, preventing majority-class dominance from overshadowing early markers of preterm birth.

III.3 FEATURE SELECTION USING PROPOSED H-EDFO

In ML, choosing a subset of exceptional factors during the creation of the prediction model is referred to as feature selection, which is also referred as feature- subset selection. The existence of duplicate and unnecessary features in any dataset, but particularly in medical datasets, can lower prediction accuracy and negatively affect the model's performance. To cut down on training time and improve the classifier's predictive accuracy, the primary objective of any feature selection technique is to choose the optimal feature subset by eliminating superfluous and irrelevant characteristics from the datasets. The variables selections are based on systematic process.

Based on the literatures, the identified PTB predictors includes clinical variables, biological markers, and specific imaging findings as shown in Table 3. Clinically useful predictions that could be obtained and were included in the database using the suggested H-EDFO approach were given priority in the final variable selection. The proposed conceptual framework for H-EDFO is show in Figure 3. To improve predictive modeling in medical datasets, the suggested approach uses a feature selection and fusion strategy based on multi-subset entropy and Dragonfly Optimization (DFO). The preprocessed nuMoM2b dataset is first divided into several subsets that correspond to various stages of consultation and clinical classifications.

Entropy-based feature ranking is applied to each subset in order to measure the discriminative ability of specific features. In order to optimize the selection process and determine the most pertinent properties from each subset, the ranking features are further put through DFO-based feature subset selection, which simulates the static and dynamic swarming behaviors of dragonflies (Meraihi, 2020) [39]. A union procedure is then utilized to fuse the chosen features from each subset, creating an ideal feature set that removes redundancy and maintains complementary information. With increased accuracy and computing efficiency, this fused set can be applied to downstream tasks like illness risk classification or prediction.

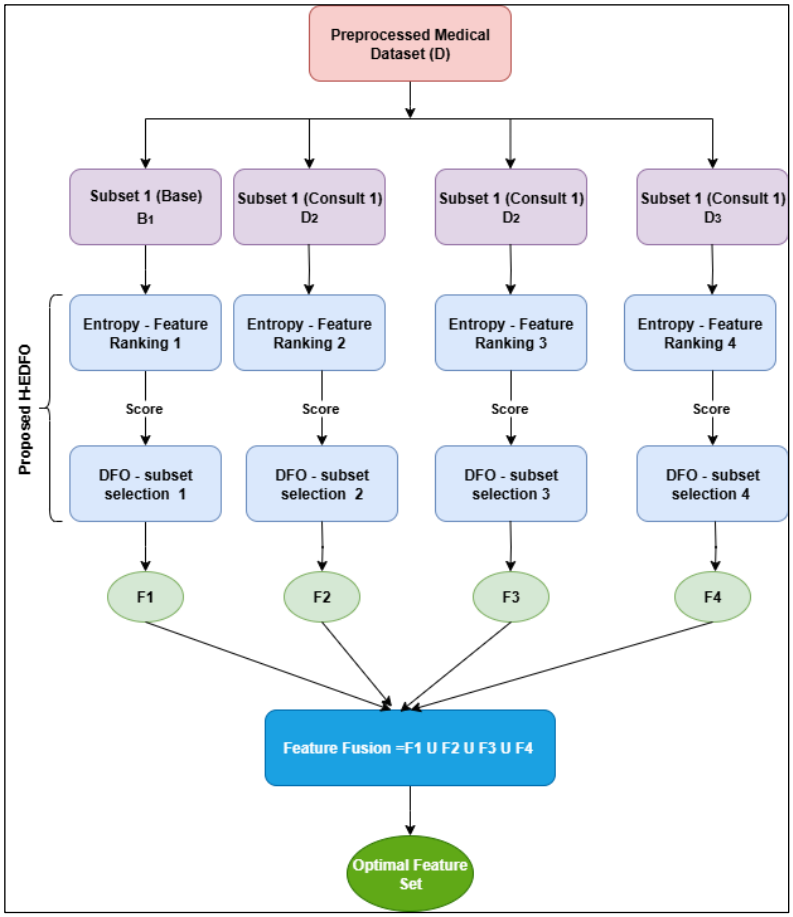

Figure 3: Proposed FS conceptual framework.
Source: Authors, (2026).

Entropy notion

Strongly correlated attributes cannot be included in a feature subset, per the study in [40]. Additionally, the more independent the attributes are from one another, the more information they will have, which will ultimately produce better results than data that is not visible. The feature selection strategy works better for medical datasets, which are the subject of current study since they are more sensitive. To extract most relevant features from the PTB dataset, an entropy-based feature selection strategy is described by this section. These characteristics are used to categorize all birth cases into PTB and term birth. The entropy-based feature ranking is shown in Algorithm 1.

Algorithm 1: Entropy based Feature Ranking

Step 1: Assume the medical dataset is D having N attributes such that $\mathcal{F}_i$ $where$ $i = 1,2, \ldots N$. Let A_0 is the group of features of original dataset.

Initially, $\mathcal{F}_0 = \{F_1, F_2, F_3, \ldots F_4\}$. Since D is divided into four subsets such as B, C1, C2 and C3 and after the feature selection we will get four feature subsets such as fs1, fs2, fs3 and fs4 respectively. F is the fused subset derived from the subsets and Initialize $fs_k = fs_0$ for $k = 1,2,3,4$.

Assume P is the problem for classification defined from set of N attributes called F_i $where$ $i = 1,2,3, \ldots, N$ and consider F denotes the features resultant from actual dataset.

Step 2: Initialize $F = fs_0 = \{\mathcal{F}_1, \mathcal{F}_2, \mathcal{F}_3, \ldots, \mathcal{F}_N\}$

For every subset $C_i \in D$ where i=1,2,3,4 do

For every attribute $\mathcal{F}_i \in fs_o$ do

Compute Gain (S, $\mathcal{F}_i$) using Eqn (1)

$$Gain(S, \mathcal{F}_i) = Entropy(S) - \sum_{v_j \in \mathcal{F}_i} \left({\left|S_{v_j}\right|}/{|S|} \right) \quad (1)$$

$$Entropy(S) = \sum P_m log_2 P_m \quad (2)$$

Where v_j denotes of attribute $\mathcal{F}$ values and S is amount of samples of P and non-zero probability s$\in S$ is denoted as P_m of class 'c' among 'm'.

End-for

calculate

$$R = (\text{MAX } _gain(S, \mathcal{F}_i) - \min _gain(S, \mathcal{F}_i)/n) \quad (3)$$

Where i=1,…n and R is the threshold of the chosen variables.

For every attribute Compute$\mathcal{F}_i \in f_0$ do

If $Gain(\mathrm{S}, \mathcal{F}_i) < R$ then

Update $fs_k = fs_k = \{\mathcal{F}_i\}$ removes $\mathcal{F}_i$ from fs_k

End-if

End-For

End-For

Pass theses selected attributes scores to DFO for optimized feature selection. The sample feature name with entropy score is listed in Table 5. Based on the entropy score values, the features are ranked and ordered its importance. These scores are given as input to the DFO as fitness function for optimal feature selection.

Table 5: Feature rank and entropy score of each feature.

Dataset	Feature Name	Entropy Score (0–1)	Rank
B (Baseline)	Maternal Age	1.000	1
	BMI at Enrollment	0.942	2
	Race/Ethnicity	0.912	3
	Gravidity	0.871	4
	Smoking Status	0.836	5
	Education Level	0.801	6
	Previous Preterm Birth	0.764	7
	Household Income	0.725	8
	Marital Status	0.691	9
	Health Insurance Type	0.654	10
C1 (First Trimester Clinical)	Systolic BP	1.000	1
	Diastolic BP	0.956	2
	Fundal Height	0.928	3
	Fetal Heart Rate	0.899	4
	Hemoglobin Level	0.866	5
	Cervical Length	0.825	6
	Uterine Artery PI	0.791	7
	Weight Gain (trimester)	0.756	8
	Urine Protein	0.724	9
	Blood Glucose Level	0.688	10
C2 (Second Trimester Clinical)	Cervical Length (mid)	1.000	1
	Amniotic Fluid Index	0.952	2
	Placental Position	0.917	3
	Fetal Biparietal Diameter	0.881	4
	Abdominal Circumference	0.842	5
	Femur Length	0.805	6
	Uterine Artery Notching	0.768	7
	Weight Gain (mid)	0.734	8
	Hematocrit Level	0.703	9
	Glucose Challenge Test	0.667	10
C3 (Third Trimester Clinical)	Estimated Fetal Weight	1.000	1
	Amniotic Fluid Index (late)	0.948	2
	Cervical Dilation	0.913	3
	Fetal Head Circumference	0.876	4
	Abdominal Circumference (late)	0.844	5
	Femur Length (late)	0.809	6
	Blood Pressure (late)	0.772	7
	Proteinuria (late)	0.738	8
	NST Result	0.705	9
	Weight Gain (late)	0.668	10

III.3.1 DFO

In order to migrate and hunt, dragon fly optimizers (DO) [41] imitate the behavior of dragonflies. It could be dynamic or static. The minimum number of dragonflies (DF) in the static swarm is relocated to hunt other swarms nearby. The greater number of dragonflies in the dynamic swarm travel far together in a similar direction. Five weights such as food, opponent, cohesiveness, separation, and alignment along with inertia weights determine how DF moves. The two main features of DF in SI are exploration and exploitation. Low alignment with greater weight cohesion characterizes the exploitation search space, while high alignment with decreased weight cohesion characterizes the exploration search space. These weights are adjusted during the optimization procedure. The characteristics of DFO are shown in Figure 4 and its expressions are listed in Table 6.

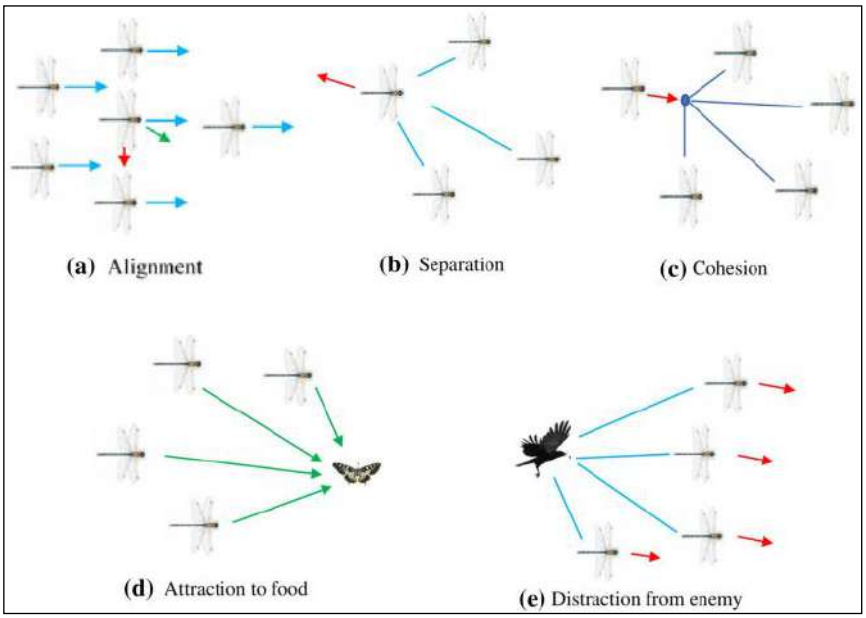

Figure 4: DFO characteristics.
Source: [42].

Table 6: Description of DFO characteristics.

Characteristics	Description	Expression
Separation	As indicated by Eqn (4), separation is the individual's avoidance of their neighbor.	$S_i = -\sum_{j=1}^{N} X - X_j$ (4) Where, X – current position, X_j is the jth neighbor position, N is the amount of neighbors and S is the separation motion of individual i.
Alignment	Eqn (5) is used to calculate the matching velocity between an individual and its neighbor.	$A_i = \frac{\sum_{j=1}^{N} V_j}{N}$ (5) A is the alignment motion, V is the velocity of neighbor j.
Cohesion	Eqn (6) is the measurement of the person with respect to the neighborhood center.	$C_i = \frac{\sum_{j=1}^{N} X_j}{N} - X$ (6) Where, C is the ith individual cohesion
Food	This is the motion of DF in the direction of its food attraction, as indicated by Eqn (7).	$F_i = X^+ - X$ (7) Where, F is the ith individual food attraction, X^+ is the food source
Enemy	This serves as DF's diversion from its adversaries and is indicated in Eqn (8)	$E_i = X^- + X$ (8) Where, E is the individual enemy distraction motion, X^- is the enemy position.

Source: Authors, (2026).

The step and position vector are used to update the individual DF position. Eqn (9) computes the PSO [42] velocity vector, which is comparable to the step factor Δx.

$$\Delta X_{t+1} = (S_i + A_i + C_i + F_i + E_i) + \omega \Delta X_t \quad (9)$$

Where t is the number of iterations and ω is the inertia weight. This inertia weight is added to the regular DO to create the best possible outcome. Eqn (10) improves the step vector's inertia weight.

$$\omega = \omega_{max} - \frac{\omega_{max} - \omega_{min}}{t_{max}} . t \quad (10)$$

Where t_max is the maximum iteration, t indicates the number of iterations, and ω_max and ω_min declare the dragonfly's beginning and ending values. The weights and the number of iterations are inversely correlated. The weight will drop as the number of iterations increases, making the global search capability stronger. Eqn (11) is used to update the location vector.

$$X_{t+1} = X_t + \Delta X_{t+1} \quad (11)$$

III.3.2 Hybrid E-DFO-Based Optimal Feature Selection and Feature Fusion

The entropy score of each features are treated as the fitness function of DFO for optimal selection using Algorithm 2.

Algorithm 2: Hybrid E-DFO based feature selection and fusion

Step 1: Input preprocessing datasets and Entropy score of each features.

Step 2: DFO encoding

Each DF position vector is a binary string such that 1 means feature selected and 0 means feature eliminated. For ex: [1,0,0,1,0] means feature 1 and 4 are selected.

Step 3: Initial population

- Instead of random population, the top entropy features are given as population
  For Example, dataset B – the top 5 ranked features are having the probability P~0.8 and low ranked features are having the probability P~0.2.

Step 4: Fitness function

The multi objective fitness of DFO is combined as:

$$F = \alpha Accuracy + \beta Entropy_{Score} - \gamma Feature_count_penalty \quad (12)$$

Where, Accuracy is the model accuracy of the selected featuers, Entropy_Score is the selected features entropy mean, Feature_count_penalty is penalizing much features selection and α, β and γ are the weights controlling parameters.

Step 5: DF searching behavior:

Separation, Cohesion and Alignment are adjusted to select bitstrings, food attraction moves towards increased fitness solutions and distraction from enemies avoid poor solutions.

Step 6: Feature fusion: The find optimal features from all the datasets are fused to find the optimal feature set as in Eqn (13) where F1, F2, F3 and F4 are the feature sets from the considered four data subsets.

$$F = F1 \cup F2 \cup F3 \cup F4 \quad (13)$$

The extracted features and optimal feature subsets are discussed in result section.

III.3.3 Classification Using MLP

To forecast the models with several learning procedures and minimal limitations, this work used a Python tool to create a feed forward back propagation algorithm [43], one of the Multi Layer Perceptron (MLP) functions. A typical MLP consists of one input, one or more hidden layers, and one output layer. Most studies handle the transition using a single hidden layer as shown Figure 5. The pixel and transit model samples from the determination classes were used in the training procedure.

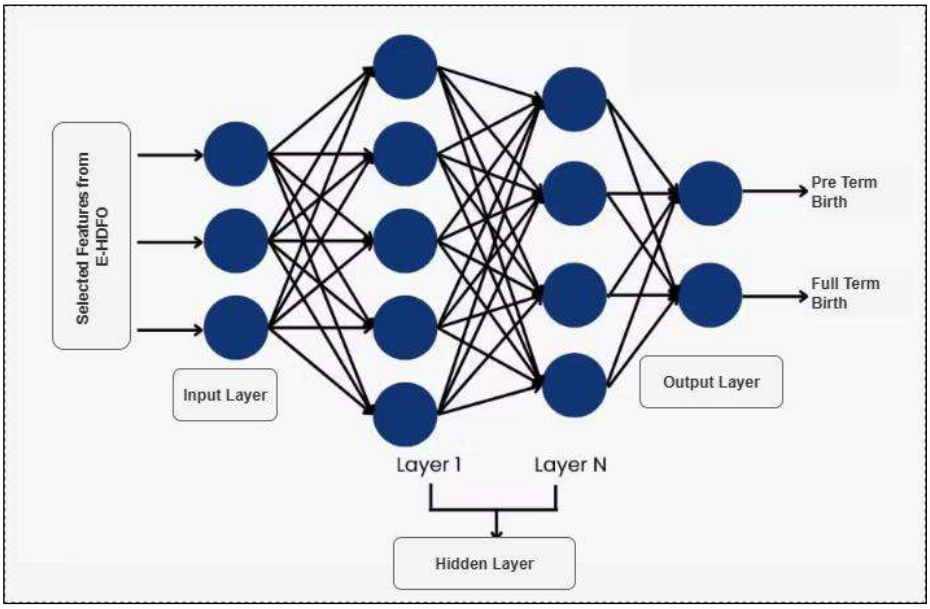

Figure 5: MLP structure for PTB prediction.
Source: Authors, (2026).

The training model, which looks at the beginning and ending learning rates, is where the MLP in the categorization begins. The hidden layer node is used to run the submodel, and all parameters—aside from the number of hidden layers—are set to their default settings. Based on several trials, the value is doubled if the overall accuracy is raised; if not, the final value is taken into account. The process of predicting PTB using MLP is shown in Algorithm 3.

Algorithm 3: MLP based PTB prediction

Step 1: Let X be the input with m features and Y is the output belongs to two classes such as 0 means non PTB and 1 means PTB

Step 2: Compute Entropy based feature ranking using Algorithm 1

Step 3: The entropy score is treated as the fitness function for H-EDFO and select optimal feature subset and fusion using Algorithm 2

Step 4: MLP based PTB classification

Let $X \in R^d$ be vector of fused features and $d = |F\ (fused\ feature\ set|$
An MLP among with L layers transforms X as,

$$h^{(1)} = \sigma(w^1 x + b^1) \tag{14}$$

$$h^{(l)} = \sigma(w^l h^{l-1} + b^1)\ where\ l = 1,2,3, \ldots L-1 \tag{15}$$

$$y' = \phi(w^L h^{L-1} + b^L) \tag{16}$$

Where, σ is the ReLu activation function and ϕ is the sigmoid activation function for output and y' is the predicted output as 0 or 1. The loss function is computed using Binary cross entropy loss as

$$Loss = -\frac{1}{N}\sum_{i=1}^{N}[Y_i \log(Y'_i) + (1 - Y_i)\log(1 - Y'_i)] \tag{17}$$

Steo 5: Prediction

A threshold T of 0.5 is used on while converting y' final decision

$$class = \begin{cases} 1 & Y' \geq T \quad (PTB) \\ 0 & otherwise \quad (non - PTB) \end{cases} \tag{18}$$

The hyper parameters of proposed PTB prediction system are shown in Table 7.

Table 7: Hyper parameters of H-EDFO-MLP based PTB prediction.

Approaches	Hyperparameter	Values	Description
Entropy-based Feature Scoring	Entropy	-	Shannon entropy used for each feature.
	Score Normalization	Min–Max scaling [0, 1]	Scales entropy values for uniform weighting in DFO.
Dragonfly Optimization (DFO)	Population size	30	Number of dragonflies (candidate solutions).
	Iterations	100	Maximum optimization cycles.
	Inertia weight (w)	0.9 → 0.4 (linearly decreasing)	Balances exploration vs. exploitation.
	Alignment coefficient (A)	1.0	Controls alignment behavior in swarm.
	Cohesion coefficient (C)	1.0	Controls attraction to swarm center.
	Separation coefficient (S)	1.5	Avoids overcrowding in search space.
	Food factor (F)	2.0	Attracts toward optimal solutions.
	Enemy factor (E)	-2.0	Repels from poor solutions.
	Selection threshold	0.5	Keeps features with probability > threshold.
MLP Classifier	Input layer size	Number of fused features	Matches output of DFO stage.
	Hidden layers	2	Depth for learning feature interactions.
	Neurons per layer	[64, 32]	First layer: 64, Second layer: 32 neurons.
	Activation function (hidden)	ReLU	Non-linear transformation.
	Activation function (output)	Sigmoid	Sigmoid for binary PTB
	Optimizer	Adam	Adaptive learning rate optimization.
	Learning rate	0.001	Controls step size in weight update.
	Batch size	32	Samples per gradient update.
	Epochs	100	Full passes over dataset.
	Loss function	Binary cross-entropy	Matches binary classification of PTB.
	Early stopping patience	10 epochs	Stops training if no improvement.
	Dropout rate	0.3	Regularization to prevent overfitting.

IV. RESULTS AND DISCUSSIONS

The WEKA toolbox (http://www.cs.waikato.ac.nz/ml/weka) or Python 3.12 and the Scikit-Learn package are used to conduct the experiment. The birth dataset's observations are thoroughly examined in order to predict birth cases. This is actually a binary class dataset, where all births that take place between weeks 28 and 37 are referred to as PTB classes with the label "1" while all births that take place beyond weeks 37 are referred to as Full Term Birth (FTB) classes with the label "0." As per our preprocessing and data splitting approaches, there were 8830 women with 8071 as full-term birth and 759 PTB are selected for analyzing the performance of the proposed model. Using AUC ratings obtained from 5-fold cross-validation comprising information from several prenatal consults, we assessed the predictive ability of the models. A thorough examination of pooled performance indicators such as accuracy, sensitivity, specificity, and AUC scores, came after this evaluation. The performance metrics are listed in Table 8.

Table 8: Performance metrics for classifiers.

Metrics	Expressions
Accuracy	$\frac{TP+TN}{TP+TN+FP+FN}$
Precision	$\frac{TP}{TP+FP}$
Sensitivity / Recall	$\frac{TP}{TP+FN}$
F1 score	$2*\frac{Precision*Recall}{Precision+Recall}$
AUC	$\int_0^1 TPR\left(FPR^{-1}(x)\right)dx$ $TPR=\frac{TP}{TP+FN}$, $FPR=\frac{FP}{FP+TN}$

Source: Authors, (2026).

IV.1 IMPACT ON PREPROCESSING MODEL

Table 9 shows the performance of the original dataset outcome with balanced and preprocessed dataset using DE model. The PTB prediction model's performance on the original dataset and the dataset preprocessed using Differential Evolution (DE) is contrasted in the preprocessing table you supplied. The DE-based preprocessing notably improves outcomes across all measures, such as accuracy, precision, recall, F1-score, and AUC. Accuracy increased from 0.772 to 0.834 and F1-score from 0.739 to 0.881, demonstrating improved predictive capabilities and a more balanced trade-off among precision and recall. It is crucial to compute the p-value using statistical tests like the paired t-test and McNemar's test to make sure that the observed gains are not the result of chance which is shown in Table 10.

The accuracy improvement is statistically significant ($p < 0.001$), according to the paired t-test, which indicates that it is very unlikely to have happened by accident. The distribution of misclassifications, on the other hand, does not significantly change according to McNemar's test ($p > 0.05$), indicating that the improvement is mostly attributable to increased performance and confidence on situations that are previously foreseeable rather than a change in the pattern of right and wrong predictions. Table 10 illustrates this statistical validation, which supports the assertion that DE preprocessing significantly improves the PTB prediction model.

Table 9: Impact on preprocessing data with original data using MLP classifier.

Metrics	Original dataset	Preprocessed dataset using DE	Improved %
Accuracy	0.772	0.834	6.2
Precision	0.701	0.818	16.7
Recall	0.827	0.892	7.9
F1 score	0.739	0.881	19.2
AUC	0.7	0.8	14.3

Source: Authors, (2026).

Table 10: Statistical validation (P test) for Preprocessing result improvement.

Test	Statistic	p-value	Interpretation
Paired t-test (accuracy per fold)	19.487	4.09×10^{-5}	DE significantly improves accuracy over the original dataset ($p < 0.001$).
McNemar's test (prediction changes)	29.0	0.188	No significant change statistically in the proportion of misclassifications ($p > 0.05$).

Source: Authors, (2026).

IV.2 IMPACT ON PROPOSED H-EDFO FEATURE SELECTION

There were 35 available variables at the first appointment, 51 available factors at the second consultation, and 73 available factors at the third consultation. The selected features for each dataset of multi consultation is shown in Table 11. Once the features are selected from each data subset, it is fused and the fused optimal feature set is shown in Figure 6.

Table 11: Selected feature subsets of each multi-consultation dataset using proposed H-EDFO.

Feature Name	Entropy score	DFO Feature selection		Feature Name	Entropy score	DFO Feature selection
B dataset				**C2**		
Maternal Age	0.92	1		Lab Hemoglobin	0.93	1
BMI	0.87	1		WBC Count	0.89	0
Smoking Status	0.84	0		Platelet Count	0.85	1
Blood Pressure	0.81	1		CRP Level	0.82	0
Parity	0.79	0		Glucose Tolerance	0.8	1
Ethnicity	0.75	0		Proteinuria	0.77	0

IV.3 IMPACT ON CLASSIFICATION MODEL WITH PROPOSED FEATURE SELECTION AS OVERALL PERFORMANCE

To assess the performance of the proposed model, the considered consultation datasets with Ultrasound data are combined together and form three datasets such as D1, D2 and D3 where D1 is the combination of B+C1, D2 is the grouping of B+C1+C2+U1 and D3 is the grouping of B+C1+C2+C3+U1+U2. We looked at the prediction performance for datasets 1, 2, and 3 in the section titled "Model performance improved when data from later prenatal consults were added" before moving on to the Sensitivity analysis on subgroups of PTB section to look at the prediction performance for the severity of preterm birth. In the section titled "Analysis of key variable contribution across three prenatal consult datasets," we also looked at the most crucial variables in the prediction. Based on the dataset's pooled AUC curves, which are likewise depicted in Figure 7, the model effectiveness summary is displayed in Table 12.

Table 12: Validated Gestational period-based datasets – AUC scores.

Datasets	Training	Validation	Testing
D1 =B+C1	0.7511±0.0121	0.7213±0.0225	0.7186±0.0217
D2=B+C1+C2+U1	0.7719±0.0138	0.7426±0.0204	0.7418±0.0136
D3=B+C1+C2+C3+U1+U2	0.8228±0.0092	0.8187±0.0125	0.7992±0.0227

Source: Authors, (2026).

Based on Table 12, the training data performance has been increased from Dataset 1 to Dataset 3 with the value of consult 1 as 0.7511 (Std. Dev as 0.0121) to Consult 3 as 0.8228 (Std. Dev as 0.0092). Similarly, the validation dataset performance also increased from D1 at consult 1 as 0.7213 (Std. Dev as 0.0225) to consult 3 as 0.8187 (Std. Dev as 0.0125). This pattern also reflected in testing data where the AUC scores improved from 0.7186 (Std. Dev as 0.0217) at consult 1 to 0.7992 (Std. Dev as 0.0227) at Consult 3. According to this pattern, predictive power significantly improves with the availability of more thorough gestational data, especially that gathered during the third consultation.

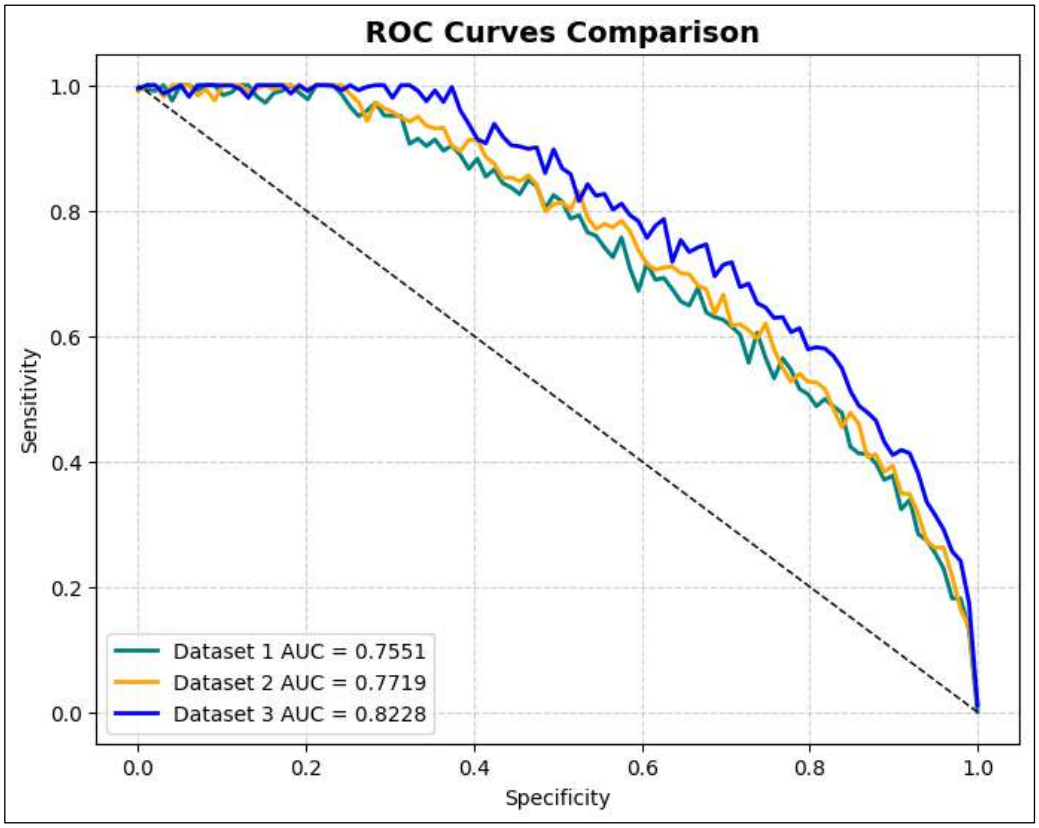

Figure 7: Pooled AUC curves of 6 test fold (B, C1, C2, C3, U1 and U2) merge into 3 datasets (D1, D2 and D3).
Source: Authors, (2026).

The pooled ROC curve in Fig 7, which is created by combining the five test-sets through cross-validation and calculating their combined ROC curve for each dataset, is shown in Fig 2. The AUC of the datasets having data from the first prenatal visit, the first and second prenatal consultations, and the dataset including data from all three prenatal consultations increased noticeably, it offers a visual representation of these improvements. The outcome demonstrated that adding data from consults 2 and 3 significantly enhanced the prediction ability, as seen by a discernible rise in AUC scores.

There appears to be a clear relationship among the amount of gestational data and the predicted accuracy of prenatal assessments, as seen by the improvement in model performance with the addition of later prenatal consult data.A closer look at several performance measures provided crucial information about the models' prediction ability. Table 13 provides more specific information about how predictive power changes when additional prenatal data becomes available over subsequent consultation.

The accuracy at consultation 1 is 72.63 % (Confidence interval of 70% to 73%) which is increased to consultation 2 as 72.83% (Confidence interval of 71.8% to 73.9%) and further improved in the consultation 3 including the selected feature variables as 88.41% with the confidence interval of 82.6% to 89.6%. Similarly, the precision, recall and F1 score values are also increased from consultation 1 to consultation 2 and getting optimum outcome with consultation 3. That proves the improved performance of proposed model efficiency on predicting the PTB with selected fused features with the consultation 3.

Table 13: Pooled performance metrics on the considered 3 datasets with confidence intervals of 95%.

Datasets	AUC score	Accuracy	Precision	Recall	F1 Score
D1	0.7511	0.7263 [0.7018,0. 7328]	0.7283 [0.7128, 0.7372]	0.7467 [0.7362,0.7563]	0.7232 [0.7128, 0.7392]
D2	0.7719	0.7283 [0.7182,0.7394]	0.7364 [0.7283, 0.7462]	0.7653 [0.7526, 0.7782]	0.7563 [0.7462, 0.7628]
D3	0.8228	0.8841 [0.8263, 0.8962]	0.8584 [0.8028, 0.8673]	0.8724 [0.8629, 0.9038]	0.8815 [0.8726, 0.8972]

Source: Authors, (2026).

As a whole, the importance of using efficient preprocessing, feature selection based classification is illustrated in Figure 8.

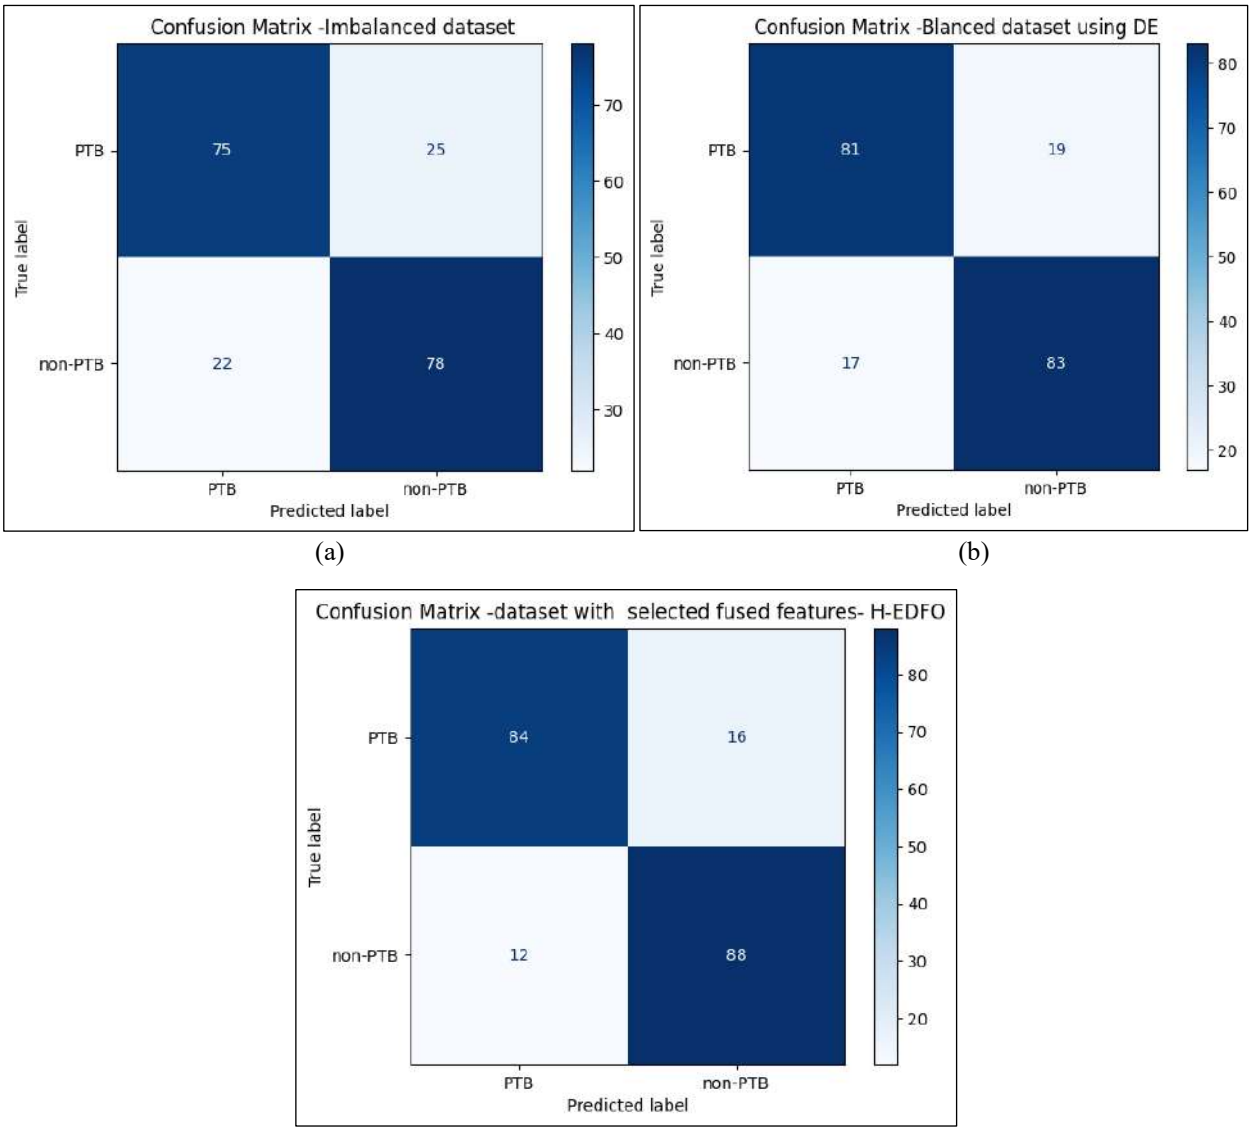

Figure 8: Confusion Matrix for the analysis (a) Imbalanced dataset (b) Balanced dataset (c) Proposed H-EDFO based selected fused features based Prediction.
Source: Authors, (2026).

Three confusion matrices that show how well PTB (preterm birth) prediction models perform under various feature selection and dataset preparation techniques are shown in the figure. The confusion matrix for the unbalanced dataset is displayed in Fig (a). The model misclassified 22 non-PTB instances as PTB and 25 PTB cases as non-PTB, while it properly recognized 75% PTB cases and 78% non-PTB cases.

Due to the model's propensity to favor the dominant class, the comparatively higher number of misclassifications highlights the detrimental effects of class imbalance. The matrix of confusion for the balanced dataset produced by Differential Evolution (DE) is shown in Fig (b). Following balancing, there were fewer misclassifications (19% PTB instances were incorrectly categorized as non-PTB, and 17% non-PTB cases were incorrectly classified as PTB), and the accurate classifications increased to 81% PTB and 83% non-PTB. This illustrates how dataset balance improves the model's capacity to identify minority class occurrences with greater accuracy.

The dataset with specific fused features acquired using the suggested Hybrid Enhanced Feature Optimization (H-EDFO) method is represented by the final confusion matrix in Fig (c) With 84% PTB and 88 non-PTB cases accurately categorized and the lowest misclassification rates (16% PTB cases wrongly projected as non-PTB and 12% non-PTB cases misclassified as PTB), this setup produced the best results. The enhancement demonstrates how well the suggested H-EDFO extracts the most pertinent and discriminative elements, increasing sensitivity and specificity.

IV.4 ANALYSIS ON PTB SUBGROUPS

PTB is defined by the WHO as delivery that occurs before 37 full weeks of pregnancy. Preterm birth is further divided into subcategories according on gestational age [44]. Understanding the variation in results and adjusting interventions appropriately depend on these classifications. These subcategories are described in Table 14.

Table 14: PTB sub groups with gestational age at the time of delivery.

Sub-Category	Gestational age	No. of patients
Extreme -PTB	<28 weeks	69
Very-PTB	28 to 32 weeks	63
Moderate-PTB	32 to 34 weeks	113
Late -PTB	34 to 27 weeks	514

Source: Authors, (2026).

A thorough analysis of our predictive models' pooled sensitivity with a 95% CI for each PTB subgroup across three datasets is given in Table 15. Extreme PTB (delivery before 28 weeks) showed the most remarkable performance, with sensitivity gradually increasing across data sets from 71% to 75% on dataset 1 to dataset 3 respectively. Given the seriousness of extremely preterm deliveries, Data Set 3's unusually high sensitivity is especially significant. The closeness of consult 3 to the delivery date for extreme-PTBs explains this very high sensitivity in Dataset 3. As a result, the data gathered at this visit are more suggestive of the imminence of preterm birth. Given that extremely PTBs necessitate the most urgent and extensive treatment, this great sensitivity is especially important.

With sensitivity beginning at 71.82% (95% CI: 0.7011- 0.7395%) in Dataset 1, peaking at 84.64% (95% CI: 73.82- 85.23%) in Dataset 2, and maintaining durable performance at 85.62% (95% CI: 72.81, 86.23%) in Dataset 3, very-PTB(28–32 weeks) demonstrated equally strong detection rates. The model's sensitivity was relatively modest but remained significant for moderately preterm babies (32–34 weeks). Dataset 1's 74.41% saw a significant improvement to 75.82%, while Dataset 2 had a minor decline to 76.83%. With sensitivity ranging from 74.32% in Dataset 1 to a peak of 75.63% in Dataset 2, before falling to 78.62 in Dataset 3, late-PTB (34–37 weeks) showed the most difficult to forecast. The model demonstrated moderate sensitivity levels when taking into account general-PTB prediction: 74.67% in Dataset 1, increasing to 76.53 % in Dataset 2, and retaining 87.24% in Dataset 3.

Table 15: Pooled Sensitivity analysis of PTB subgroups.

Subgroups	Dataset-1	Dataset-2	Dataset-3
Extreme PTB	0.7161 [0.7113,0. 7227]	0.7382 [0.7221, 0.7471]	0.7523 [0.7423-0.7625]
Very PTB	0.7182 [0.7011,0.7395]	0.8464 [0.7382, 0.8523]	0.8562 [0.7281, 0.8623]
Moderate PTB	0.7441 [0.7333, 0.7728]	0.7582 [0.7422, 0.7671]	0.7683 [0.7521, 0.7724]
Late PTB	0.7432 [0.7327, 0.7592]	0.7563 [0.7434, 0.7627]	0.7862 [0.7234, 0.7937]
General PTB	0.7467 [0.7362,0.7563]	0.7653 [0.7526, 0.7782]	0.8724 [0.8629, 0.9038]

IV.5 DISCUSSIONS

This study demonstrates the predictive performance of the proposed feature selection model PTB at multi-consulting which are more effective in consult 3 at the gestational age of 22 to 29 weeks, with Improved AUC of 0.7511 to 0.8228 at consult 3. These results are comparable to large scale analysis of existing literatures such as [45] employed ML algorithms such as gradient bossing and neural network with 16 million observations and obtained 0.64 as AUC score for PTB prediction. Huang et al., [19] employed ElasticNet based PTB prediction on multi visit data with the inclusion of all the variables and obtained the AUC score of 0.6161. The suggested model performed well using only easily accessible clinical factors as well as ultrasound data at Consult 3, despite the fact that both studies used much larger datasets and more sophisticated algorithms. This suggests that the timing as well as type of selected clinical data using the suggested H-EDFO is important than sample size.

The result highlights are pictorially illustrated in Figure 9 for better understanding. The analysis of PTB prediction based on efficient preprocessing, feature selection and classification using proposed models efficiently improves the performance on consult 3 during the 22 to 29 gestational weeks with the selected features. The DE approach improves the model performance on preprocessing data with balancing factors. The model with preprocessed data can improve 6% of accuracy without preprocessing data along with all variables. Further, the feature selection model is proposed to select the most influencing features of all considered visits using entropy and DFO methods. The entropy score is computed for all the base and consultation datasets variables and based on the score; the feature ranks are given. The entropy score is treated as the fitness function to find optimal feature subsets using DFO which selects the relevant features.

These selected feature subsets from all the considered consultation periods are fused as a single feature set for further processing. These results are analyzed and compared as a confusion matrix and accuracy without preprocessing is 77%, with preprocessing is 83.4% and with feature selection model, it is improved as 88% of accuracy. Hence, the proposed model efficiently improves the prediction of PTB with improved accuracy and in terms of other metrics too. Furthermore, the model efficiency is implemented with the combination of these consultations and framed three datasets by combining Base checkup, C1, C2, C3 along with Ultrasound 1 and Ultrasound 2 data. These three datasets are evaluated using the proposed framework in terms of AUC, Accuracy, precision, recall and F1 score. Noticeable results are obtained on dataset 3 by obtaining 0.8, 88.41%, 85.84%, 87.24% and 88.15% respectively than Dataset 1 and 2.

Which means, the dataset 3 is the combination of all the considered consultation data's fused feature sets. The selected features using proposed H-EDFO efficiently improves the performance while predicting the PTB. We also looked at the model's performance on various preterm birth subgroups, and the fact that the sensitivity varies among PTB categories highlights the significance of customizing model creation and validation for particular clinical situations. The other variant of PTB also predicted using the model and very PTB prediction secured the improved accuracy of 85.62% of accuracy on Dataset 3 than other datasets. It is proved that our model efficiently predicts the PTB on Dataset 3 with fused feature sets from all the consultation. To improve the predicted accuracy of our model, we used MLP to incorporate demographic, lifestyle, obstetric, and medical history data. This method outperformed more intricate models by preserving interpretability and usability, which are essential for clinical decision-making.

IV.6 IMPLICATIONS

IV.6.1 Theoretical Implication

The theoretical knowledge of how entropy-based ranking and DFO optimization might work together to provide optimal, clinically relevant feature subsets is advanced by the suggested H-EDFO framework. The results provide credence to the idea that longitudinal data integration is crucial for early and precise PTB risk assessment by demonstrating that the combination of variables from several consultations improves classification accuracy. The study further supports the idea of effective predictive modeling for medical diagnostics by demonstrating the possibility of combining clinical measurements with ultrasound data to get greater accuracy without the need for high-dimensional, resource-intensive datasets. The results of the confusion matrix, which demonstrate an improvement in accuracy from 77% (without preprocessing) to 83.4% (with preprocessing) and then to 88% (with feature selection), empirically support the theoretical idea that focused feature selection and methodical data preparation are essential to the success of predictive modeling.

In order to find clinically significant features across several consultation points, the suggested H-EDFO framework combines DFO optimization with entropy-based ranking, advancing methodological comprehension. The theoretical claim that the kind and timing of clinical data are just as significant as dataset size or model complexity is supported by the noteworthy AUC improvement from 0.7511 to 0.8228 at Consult 3. By showing that smaller but more carefully crafted feature sets can perform better than bigger, less curated datasets, this supports and expands on earlier findings in the literature and helps create effective and understandable AI models for medical diagnosis.

IV.6.2 Practical Implications

From a clinical standpoint, the suggested approach provides healthcare providers with a workable and affordable decision-support tool, especially in environments with limited resources. The performance improvements, especially on Dataset 3 (AUC: 0.8, Accuracy: 88.41%, Precision: 85.84%, Recall: 87.24%, F1 Score: 88.15%), show the model's potential as a useful clinical decision-support tool from the perspective of real-world applications. The approach can be readily implemented in healthcare settings with low resources or in remote areas because it just uses routinely collected clinical parameters and ultrasound data, negating the need for sophisticated computational equipment. Clinicians are able to implement timely treatments, including increased monitoring, dietary counseling, or expert referrals, thanks to the increased accuracy throughout the 22–29 week gestational period. These interventions have the potential to considerably lower PTB-related problems. Additionally, the model's high interpretability encourages adoption and confidence among medical professionals, which makes it appropriate for incorporation into electronic health record systems.

IV.6.3 Limitations

Compared to large-scale PTB prediction studies, the study's dataset was comparatively smaller, which would have limited its generalizability to larger populations. Because the data came from a particular hospital setting, it might not accurately reflect how PTB risk variables differ in various geographical or ethnic contexts. Even while the model performed well with a few features, several biological and environmental risk factors like genetic markers and comprehensive nutrition data were left out. Robustness must be confirmed by external validation in prospective clinical scenarios and on separate datasets.

V. CONCLUSIONS

This study integrated multilayer perceptron classification, Differential Flower Pollination optimization, and entropy-based ranking to develop and test the H-EDFO-MLP framework for preterm birth (PTB) prediction. Targeted feature selection, multi-consultation data fusion, and meticulous preprocessing all contributed to the framework's notable performance gains. Notably, the AUC rose from 0.7511 to 0.8228 at Consult 3, and accuracy increased from 77% without preprocessing to 88% with the suggested feature selection. Our approach, which just used readily available clinical and ultrasound characteristics, showed better prediction capacity than large-scale studies employing more intricate models.

These findings demonstrate that timing and data type are more important than computational complexity or dataset size. Our findings have ramifications that go beyond predictive modeling. First, utilizing this prediction model during the 22–29-week consult may assist doctors in identifying individuals who need close monitoring and early interventions, as indicated by the model's high sensitivity for very-PTB (85.62% at Consult 3). This timing coincides with important clinical decision points, like the prenatal corticosteroid injection and the planning of the mother's transfer to facilities equipped to provide newborn care.

Without the need for sophisticated computing resources or a large infrastructure, the model can be simply incorporated into current maternal care workflows by using readily available clinical and ultrasound characteristics gathered during normal prenatal consultations. Early interventions like closer monitoring, preventive treatments, or referral to higher-level care facilities are made possible by the increased prediction accuracy, particularly during the gestational window of 22–29 weeks. These actions have the potential to greatly lower negative outcomes. Additionally, the interpretability of the model increases physician acceptance and confidence in AI-driven suggestions.

Additionally, the method offers a framework that is scalable, meaning that it may be applied to other pregnancy risk evaluations or expanded to other populations with little retraining. To increase generalizability, the study will be expanded in future to encompass a variety of healthcare systems and demographics. combining biochemical, lifestyle, environmental, genetic, and ECG data to predict apnea levels and capture a wider risk profile of PTB. Putting in place online learning tools to enable the model to update continually when fresh clinical practice data becomes available.

ABSTRACT

Personalized Information Retrieval (PIR) aims to tailor search results to individual user preferences and contexts. With the exponential growth of digital information, traditional retrieval systems often fall short in delivering relevant results to diverse users. This study explores the integration of machine learning re-ranking algorithms into personalized information retrieval systems to enhance search relevance and user satisfaction. The LETOR based model is experimented for relevance re-ranking in personalized retrieval. A comprehensive analysis of LETOR based models are analyzed to find a best hybrid re-ranking framework based on the performance of each model. The findings demonstrate that the LGBMRegressor model demonstrated the most consistent and best performance across the majority of metrics.

I. INTRODUCTION

The digital age has ushered in an era of information overload, making efficient and relevant information retrieval a critical challenge. Personalized Information Retrieval (PIR) addresses this by customizing search results based on individual user preferences, behaviors, and contexts. Traditional PIR approaches often rely on static user profiles or heuristic-based methods, which may not adapt well to dynamic user needs. Recent advancements in machine learning have introduced re-ranking algorithms that can dynamically adjust search results based on learned user preferences. These algorithms offer the potential to significantly enhance the relevance and personalization of search outcomes. Machine learning personalizes search results for individual users by continuously analyzing and learning from a wide range of user data and behavioral patterns.

II. RELATED WORK

The methodology in the paper "Incorporating Explicit Subtopics in Personalized Search" (ExpliPS model) introduces a three-stage architecture to enhance personalized search by explicitly modeling user preferences for subtopics of a query. It uses BERT to generate dense vector representations for these documents as well the queries. The Final score is calculated by the weighted combination of document-query relevance and user-subtopic preference. The model is trained using a pairwise ranking loss, such as Bayesian Personalized Ranking (BPR), to ensure preferred documents are ranked higher than non-preferred ones [1].

Traditional personalized search models often rely on static representations of user interests derived from historical behaviors, such as past queries and clicked documents. These static profiles may not effectively capture the dynamic nature of user intent, leading to less accurate personalization. Moreover, documents are typically lengthy and encompass multiple topics, making fixed-length representations insufficient and potentially introducing noise into the user profile. To address these challenges, the author propose a method that constructs dynamic, intent-oriented representations of documents. The author suggest to use cross-attention or similarity-

based matching to measure the alignment between current candidate documents and the user's evolving interests to enhance relevance estimation by capturing subtle shifts in intent.

Training uses a pairwise learning-to-rank loss, such as BPR or hinge loss, encouraging more relevant documents to rank higher than less relevant ones [2]. Traditional neural relevance models often overlook the nuanced context of user queries, such as geographical location or professional role. This omission can lead to less personalized and relevant search results. Kong, D., Zhou, D., Huang, Z., & Sigalas, S. aims to address this gap by developing a model that incorporates both the content of documents and the contextual information associated with user queries.

The model uses a hybrid approach that fuses: Lexical Matching Features with Neural Semantic Relevance Features and Learning-to-Rank Layer. These features aim to capture deeper semantic compatibility between user intent and document meaning. Contextual Feature Representation model builds a composite user profile vector from various contextual signals. Each context field is embedded separately and then aggregated (e.g., via average or attention). The Learning-to-Rank (LTR) Layer is typically a feed forward neural network or gradient-boosted tree (GBT) model. Models incorporating context (e.g., title-location-query-document matching) consistently outperformed baseline models [3].

III. METHODOLOGY

III.1 PERSONALIZED SEARCH TECHNIQUES

Initial personalized information systems mainly relied on direct user feedback and fixed profiles to customize search outcomes. Nevertheless, these approaches frequently demonstrated a deficiency in their ability to adjust to evolving user preferences. Recent studies have investigated dynamic user modeling, integrating real-time behaviors and context-related data to enhance personalization strategies. Machine learning has transformed information retrieval by allowing systems to learn from data and enhance their performance over time. Re-ranking algorithms, in particular, have showed potential in changing the first search results to better fit what the user wants.

Methods like Learning to Rank (LTR) have gained significant traction, utilizing features derived from user interactions and the relevance of content [4].Combining user modeling with machine learning re-ranking has become a powerful way to get personalized information. Hybrid models effectively integrate long-term user preferences with immediate contextual cues, resulting in search results that are both accurate and personalized. Here is an overview of several commonly employed techniques:

III.2 COLLABORATIVE FILTERING

Collaborative filtering suggests content by analyzing the similarities among users. When individuals with comparable profiles express a preference for specific outcomes, it increases the likelihood that those outcomes will be presented to others within that same demographic. These systems offer the benefit of addressing the cold-start problem to a certain degree. Handling extensive datasets and determining user similarities can be resource-intensive and may struggle to adjust to evolving user preferences. [5].

III.3 CONTENT-BASED FILTERING

Content-based filtering emphasizes the attributes of items that a user has interacted with in the past, suggesting analogous content for future engagement. It constructs comprehensive user profiles by monitoring search queries, clicks, time spent on pages, and engagement patterns over time. This historical data enables the system to comprehend individual user interests and preferences, thereby customizing future outcomes accordingly. This approach effectively addresses the issue of initial data scarcity by providing recommendations despite minimal user interaction information. The system is capable of managing substantial volumes of data with high efficiency, rendering it appropriate for extensive online platforms. [6-8].

III.4 HYBRID METHODS

Hybrid models present a compelling strategy for enhancing personalization in machine learning, facilitating the development of systems that are more precise, resilient, and flexible. Integrating the advantages of various models allows for the tackling of personalization challenges and enhances user experiences [9-12].

III.5 CONTEXT-AWARE PERSONALIZATION

When offering recommendations or changing services, context-aware personalization models take into account the user's present condition and environment. These models utilize real-time data, including location, device type, time of day, and the user’s current session behavior, to deliver more relevant and customized experiences. A search for “leagues” might produce sports-related results if the user frequently accesses sports websites, or it could vary depending on geographic location or the time of the search [13].

III.6 REINFORCEMENT LEARNING

Personalization through reinforcement learning (RL) serves as an effective mechanism, enabling systems to evolve and understand user preferences progressively. By considering each user as an agent engaging with their surroundings, RL has the potential to tailor user experiences across multiple domains. Personalization driven by reinforcement learning presents a compelling method for customizing user experiences according to specific preferences and requirements. Through ongoing analysis of user interactions, RL systems are able to deliver increasingly relevant, engaging, and tailored services. Nonetheless, it is crucial to tackle the obstacles related to data needs, computational capabilities, and ethical implications [14].

III.7 NEURAL AND EMBEDDING-BASED PERSONALIZATION

It employs deep learning to learn user and item representations (for example, through embedding's). Embedding models serve as a category of machine learning models that aim to represent various forms of data, including text and images, within a continuous, low-dimensional vector space.

These embedding's capture semantic or contextual similarities between pieces of data, allowing machines to execute tasks such as comparison, clustering, or classification with greater efficiency. These models transform words into numerical vectors that encapsulate semantic meanings and the relationships that exist between them. Models such as Word2vec employ straightforward neural networks to acquire embedding's grounded in co-occurrence patterns. Transformers, such as BERT and GPT, along with CNNs, are adept at extracting intricate patterns and relationships through layered data processing. [15].

III.8 LEARNING-TO-RANK FOR PERSONALIZATION

Learning to Rank (LTR) is a type of machine learning that changes the order of items in a list based on how relevant or important they are. This is very helpful for making recommendations and search engines more personalized. The system analyzes user interactions and various data sources to forecast the optimal ranking order, thereby enhancing the personalization and relevance of the results. LTR models can be developed through a range of techniques, such as point wise, pairwise, and list wise approaches. Learning to Rank serves as an effective mechanism for personalization, allowing systems to provide users with more pertinent and engaging outcomes by analyzing their interactions and behaviors [16-20].

IV. PROPOSED METHODOLOGY

For any user query, a relevance function can take into account any one or multiple factors such as:

1. Text similarity
2. Query properties
3. Document properties
4. User and context properties

When considering a system based on the user and context properties we can derive any one of the systems like: General Traditional Search, Personalized Search and Recommendation systems. When considering personalized search both user input (query) and user preferences are part of the relevance parameter. This implies that search personalization should be implemented with utmost care. The search may end up annoying or be biased to users with their favorite documents while they were particularly looking for something else if the emphasis was on historical user behavior and too little on the current search intent. This illustrates the importance of providing users with enough historical data to confidently tilt search results in a particular way.

Additionally, remember that personalization will mostly impact exploratory inquiries and confusing user input. The search algorithms should already cover clear navigational inquiries. Learning-to-rank (LTR) is the process of creating statistical models for relevance ranking. The model is trained to identify the best options from certain data, rather than manually creating a structured query and weights for all text similarity, query attributes, and document properties. The information is presented as a decision list. The behavior-based personalization is examined with LTR, which means that the user attributes is extracted and will be utilized in our LTR training process by leveraging historical user activity.

An initial set of search results is generated using a standard retrieval model, such as BM25, based on the user's query. The Microsoft Learning to Rank (MSLR) dataset MSLR-WEB10K is used to conduct the experiment. These datasets are used in learning to Rank (LTR) problems, where each instance (document) is associated with a query, a set of features, and a relevance label. The baseline ranking score is based on the original document order, without using any model and the predicted ranking scores is calculated.Then the following hybrid re-ranking framework is trained and tested that integrates user profiling with machine learning algorithms to enhance Personalized Information Retrieval.

- LightGBM (using LGBMRanker).
- LGBMRegressor (using LambdaRank)
- XGBoost-based Learning-to-Rank model (using XGBRanker)

For Learning to Rank models like LightGBM's ranker, the model needs no of documents for each query as input. This is done using group info (an array) where each value is the number of documents for one query. Then the unique query IDs and the number of times each appears are calculated and found (i.e., how many documents are associated with each query).Then the counts (documents per query) is extracted, which is used as training group or testing group. When training ranking models, rankings per query is evaluated, so Group documents are done correctly by query. The model must know how many documents are associated with each query. So we now load the MSLR training/testing data and separate the features, labels, and query IDs.

Then calculate how many documents belong to each query (group info). This is essential input for Learning-to-Rank models that optimize rankings on a per-query basis. Then the documents are sorted by predicted score (descending), and the same order is applied to simulate the ranked list. ndcg_score needs relevance and ideal relevance values. So the actual relevance list based on predicted ranking is calculated and found. The ideal ranking scores is simulated, assuming perfect prediction order of k=10 to evaluate top-10 results only. Then the true relevance score is converted into a binary vector considering (≥1) for relevant, 0 for irrelevant. The average_precision_score() computes precision across all ranks and it adds score if there's at least one relevant document. Then find the

index of the first relevant document (relevance ≥1). Use the formula [1 / (rank of first relevant doc)] for finding the MRR score and then find the average of each metric across all queries. Learning to Rank models on multi-query datasets is evaluated for the dataset.

Then the training and testing is done using LightGBM's LGBMRanker. LGBMRegressor is a regression model, not specifically designed for ranking. It's commonly used as a point wise LTR baseline, where the model predicts relevance scores directly. This ranking approach comes under the point wise approach, where each document is scored independently. This method ignores query groups, meaning it doesn't model interactions between documents within the same query. It's less effective than pairwise or list wise models like LGBMRanker (LambdaRank), but useful as a simple baseline. Then we train for the XGBoost-based Learning-to-Rank model (XGBRanker) using the NDCG objective, and applies it to predict document ranking scores. It's similar in purpose to LGBMRanker, but uses the XGBoost instead of LightGBM. Learning to Rank (LTR) algorithm is employed, such as LambdaMART, to re-rank the initial search results. The model is trained on labeled data to predict the likelihood of a document being relevant to the user.

V. EXPERIMENT

V.1 DATASET

The testing of the framework is done using the MSLRWEB10K dataset, which includes user queries, click-through data, and relevance judgments. It consist of 136 features with 10K Queries in each fold with a total count of 5 folds.

V.2 FEATURES

For each retrieved document, we extract a set of features, including:

- Query-document relevance scores
- User-document interaction history
- Temporal and contextual factors

V.3 BASELINE MODELS

The retrieval models evaluated are:

- Baseline ranking quality based only on the original document order.
- LightGBM (using LGBMRanker).
- LGBMRegressor (using LambdaRank)
- XGBoost-based Learning-to-Rank model (using XGBRanker)

V.4 EVALUATION METRICS

Performance was assessed using standard IR metrics as mentioned below:

- **Mean Reciprocal Rank (MRR) -** measures the average reciprocal rank of the first relevant document for a given query. MRR is calculated as

$$RR = 1/Q * \Sigma (1/rank_q),$$

Where Q is the number of queries and rank_q is the rank of the first relevant result for query q.

- **Normalized Discounted Cumulative Gain (NDCG) -** Normalized Discounted Cumulative Gain (NDCG) is a more comprehensive metric that considers both the relevance of retrieved documents and their position in the ranked list.

$$NDCG@10 = DCG@10 / IDCG@10$$

DCG@10 is the Discounted Cumulative Gain for the top 10 results. IDCG@10
Is the Ideal Discounted Cumulative Gain for the top 10 results.

- **Mean Average Precision (MAP) -** Mean Average Precision (mAP) is calculated by averaging the Average Precision (AP) across all classes or categories in a dataset.

$$mAP = (1/n) * sum (AP),$$

Where 'n' is the number of classes or categories.

VI. RESULTS

The graph depicts the result for all three re-ranking techniques for MSLRWEB10K dataset by having the relevancy score on the y-axis for each Metrics for all the three re-ranking techniques along with original order without re-ranking

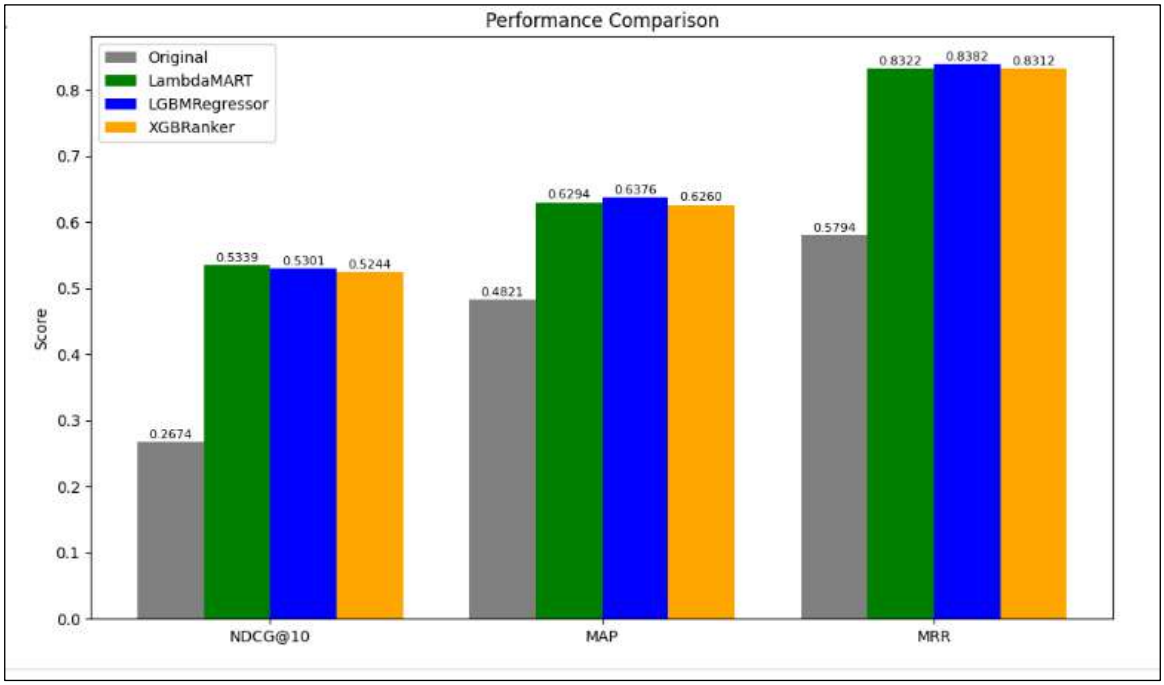

Fig 1. Performance Comparison of Proposed Model based on MSLRWEB10K dataset.
Source: Authors, (2026).

VII. CONCLUSION

This study demonstrates the efficiency of Re-ranking models and its performance. Among the evaluated models, LGBMRegressor demonstrated the most consistent and best performance across the majority of metrics. It achieved the highest scores in both MAP (0.6376) and MRR (0.8382), and also gives good performance in NDCG@10 (0.5301). Although LambdaMART slightly outperformed in NDCG@10, the overall results indicate that LGBMRegressor offers a better balance of ranking quality and retrieval effectiveness, making it the most effective model in this comparison.

ABSTRACT

A precise river width measurement is crucial for various river modeling, habitat evaluation, flood risk analysis, and other hydrological environmental, and technical applications. Conventional techniques is time-consuming and error-prone, such as direct field measurements. Nowdays fast and accurate riven identification and its width measurement is highely needed to save human life during flud and other natural disaster. Recent deep learning technology can greately be applied to identify and measure width of river automatic, fast and accurate from a remote place. The proposed deep learning based method is executed in two steps, identification of river and river width measurement. Deep learning based segmentation is used to identify river from remote sensing image. The accuracy of the semantic segmentation to identify river depends on rich spatial data and the resolution of the remote sensing images. In this work proposed SegRivWidth algorithm for automatic river width measurement from segmented images. The obtained results are compared with the ground truth river width and found better accuracy. The obtained results are also compared with the existing methods in terms of Average Absolute Error (AAE) and Root Mean Square Error (RMSE). The proposed SegRivWidth has an RMSE of 4.76 m and an AAE error of 2.16 m for the river width measurement.

I. INTRODUCTION

Measuring river width from remote sensing images involves using satellite or aerial imagery to capture the river's spatial extent. This process typically requires first identifying the river area from the remote sensing images. This is possible with the help of the Semantic segmentation method that identifies and classifies each pixel of an image into predefined categories, such as land, water, urban areas, vegetation, and other features. Here the goal is to classify each pixel in the image into categories, such as "river" and "non-river from satellite or aerial images. These images are captured using satellites or drones equipped with sensors such as optical, infrared, or radar.

The resolution, light conditions, cloud, and type of sensor used play an important role in determining the accuracy of the segmentation. Once the images are preprocessed to improve the quality of the image then semantic segmentation can be performed. This is typically done using deep learning methods, particularly convolutional neural networks (CNNs) or more specialized models like U-Net[1], SegNet[2], and FCN[3] which are commonly used for segmentation tasks. The River semantic segmentation accuracy depends on the varying water conditions, cloud cover, shadow, and complex river structures such as sharp curves, and multiple branches present in the images.

Many researchers proposed a different methods for the identification of the river and river width from the aerial images. An end-to-end deep learning-based U-Net neural network for segmentation of river state from drone-based images proposed by [4]. The methodology was tested on river areas in southern Poland, demonstrating its effectiveness with a Dice coefficient of 0.8524. Moreover a novel deep-learning framework for the accurate extraction of water bodies from high-resolution remote sensing imagery presented by [5]. The authors address challenges such as indistinct boundaries and shadow misclassification by leveraging the DeepLabV3+ architecture and an innovative fusion mechanism for high- and low-level features. The proposed method demonstrates superior performance, achieving an overall accuracy of 99.284%, IoU of 95.58%, precision of 97.562%, recall of 95.486%, and F1 score of 96.513%.

Since river width is one of the two basic dimensions of river extent (width and length) and one of the main components of river discharge (width, depth, and velocity). Thus, through river extent, river flow, or both, the river width is linked to it and is of great relevance among numerous applications such as environmental monitoring, flood monitoring, agriculture, water resource management, and urban planning. The aims to provide accurate and automated analysis of river conditions and the significance of river width measurements are underscored by recent developments in satellite-derived river discharge. The DeepRivWidth is a Deep learning-based semantic segmentation approach for river identification and width measurement in Synthetic Aperture Radar (SAR) images of Coastal Karnataka proposes a technique for precisely determining river widths using SAR views [6].

First, it identifies rivers and then quantifies their width using the advanced deep-learning algorithms of U-Net and DeepLabV3+. The suggested strategy outperforms current techniques in terms of accuracy, particularly in difficult weather situations. Sometimes the method fails to detect very narrow rivers and the presence of speckle noise in SAR images, which can affect the accuracy of width measurements.However super-resolution mapping (SRM) method to measure wetted river width (RWW) from remotely sensed imagery with a deep convolutional neural network (CNN) by the mixed pixel problem in coarse spatial resolution images addressed by [7]. The results were validated through experimental images taken from MODIS and Landsat data. The suggested method was not precisely measure the width of a narrow river. An innovative method based on Graph-Theory River Width Extraction from Remote Sensing Imagery presented by [8].

The proposed GrabRiver method automates the entire process from image preparation to river width calculation, utilizing graph theory to maintain river connectivity and accurately measure river widths. The method demonstrates high accuracy in experiments conducted on the Mekong and Mississippi Rivers, with results showing a strong correlation with reference measurements. The presence of clouds, cloud shadows, and snow can impact the accuracy of river width. RivWidthCloud suggested by an innovative algorithm for automating river centerlines and width calculations from optical satellite images in the presence of clouds, cloud shadows, and snow [9]. The proposed method shows high accuracy, with a root mean square error of 99 meters. Various types of river surfaces and widths measurements from satellite images such as tiny, thin, small, and large rivers proposed by [10]. The suggested method used an improved random forest algorithm combined with artificial neural networks (RF-ANN) for river surface extraction and an automated river width extraction (ARWE) method.

The error occurs for various types of extraction of 10.9%, 4.9% .1%, and 0.6% respectively. The suggested method did not accurately calculate river width when the river width is less than 10 meters. Howerver DeepLabV3+ Convolutional Neural Network (CNN) model automatically segmented different types of river channel borders and river width using a Voronoi Diagram method presented by [11]. The model accurately classifies all four types of rivers with an accuracy of 0.97. When islands are present, the method does not accurately determine the width of the river. A novel approach of RivWidth tool used raster-based classifications from remotely sensed imagery to automatically calculate river widths [12]. In computer vision, segmentation is a subject that has been extensively researched and applied to a variety of tasks, including medical image analysis, identification of roads, buildings, ships, and other types of applications [13-17].

Moreover, the First step of river width calculation is river identification and it is formulated as a semantic segmentation problem in this work. Then traditionally many methods are available to measures width of segmeneted images such as thresholding [9], manual delineation, and NDWI-based approaches [18]. They have some restrictions because choosing the ideal threshold value is a challenge in thresholding method for river width calculation. Manual delineation is subjective and takes a lot of time. The atmospheric conditions, sensor characteristics, and water qualities can all cause mistakes in NDWI-based approaches. However, The work on semantic segmentation of rivers from aerial images is still limited. The system that combines the automatic identification of river and river width computation from remote sensing imagery is still limited.

II. METHODOLOGY

The goal of this work is to create a system that uses remote sensing images to automatically identify rivers and compute the widths of a river. The proposed approach comprises three main processing steps data augmentation, river identification using SegNet method, and River width calculation based on the centerline extraction as shown in Figure 1. River centerline extraction is done using the skeleton and distance matrix calculation method.

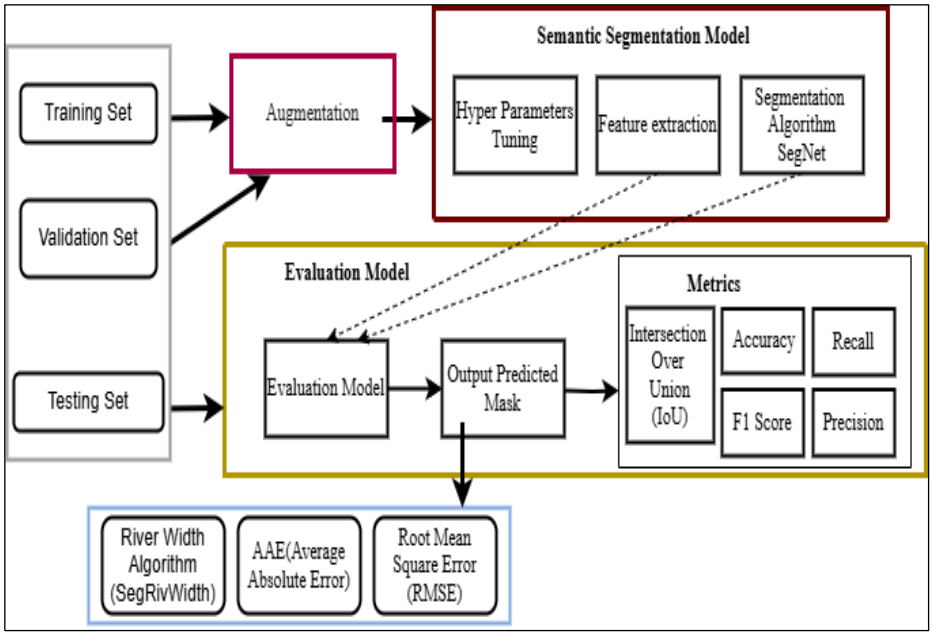

Figure 1: Block Diagram of Semantic Segmentation Model of River.
Source: Authors, (2026).

Dataset SegNet models of rivers were trained, validated, and tested using the Riwa V2 dataset [19]. These images were gathered by cellphones, drones, and unmanned aerial vehicles (UAVs). This images of rivers are different in sizes, including small, narrow, large, and tiny. Additionally, to test the trained model's performance in a variety of meteorological and seasonal settings, river photos were obtained throughout the year, including spring and rainy seasons as shown in Figure 2. A total of 1128 images in the original dataset were divided into three subsets at random: 70% of the images are used for training, 15% are used for validation, and the remaining 15% are used for testing.

Figure 2: Dataset Samples.
Source: Authors, (2026).

II.1 DATA AUGMENTATION

The original dataset is expanded by data augmentation to enhance SegNet model's accuracy and generalization for a larger dataset [20]. Generalization is the ability of a model to learn hierarchical features from data, which allows it to function effectively on a variety of tasks outside of its original training dataset. To improve the model's capacity to manage occlusion and scale fluctuations, methods such as random cropping, rotation, and scaling can be employed to intentionally increase the variety of the training data. The original images are randomly altered to achieve the augmentation [21], mostly through the use of geometric modifications such as cropping, rotations up to ±45o, and flipping them horizontally and vertically.

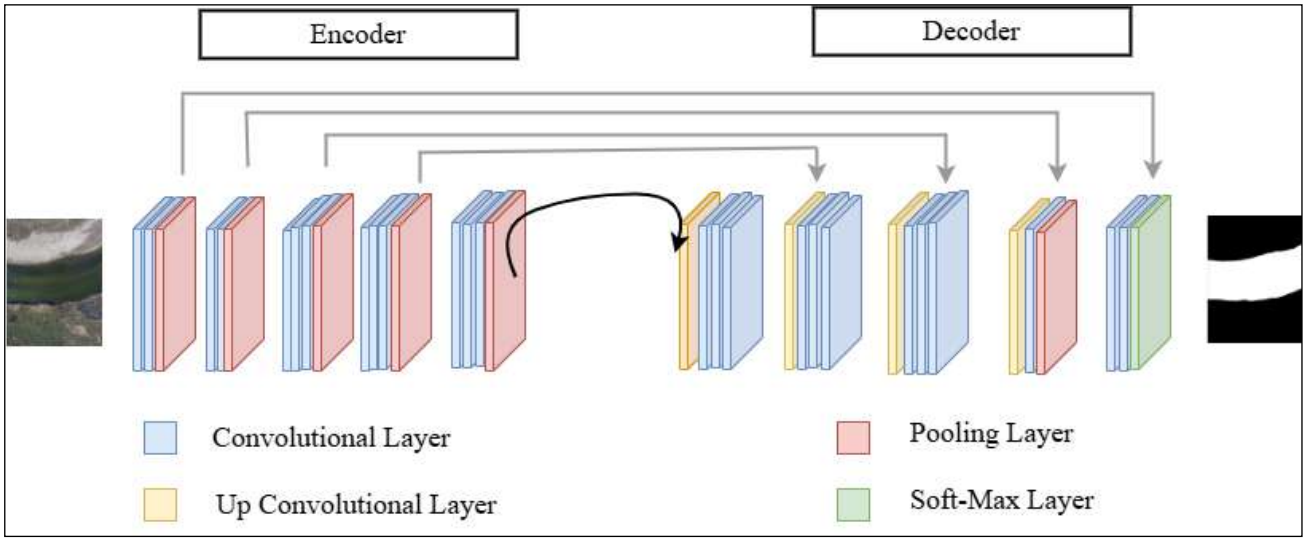

Figure 3: The Architecture of SegNet Model.
Source: Authors, (2026).

II.2 SEGNET-BASED RIVER IDENTIFICATION

Semantic segmentation is used to identify rivers from remote sensing imagery. It is a process to partition the images which have similar types of characteristics. This work uses a SegNet architecture for semantic segmentation as shown in Figure 3. SegNet is a specialized deep learning architecture that uses an encoder-decoder structure made up of CNNs and pooling layers to identify image pixels. It is created especially for semantic segmentation applications. The encoder component of SegNet consists of several convolutional layers followed by pooling layers that collect high-level characteristics from the input image.

It down-samples the image and it reduce spatial dimension. On the other hand, the decoder part generates pixel-wise segmentation masks and refines feature representations by up-sampling rather than down-sampling, while maintaining the structure of the encoder. Skip connections across relevant layers help to preserve spatial information lost during encoder down-sampling, improving segmentation accuracy. The final segmented image is obtained by applying a softmax layer to every pixel in the output feature map. This process assigns a probability distribution across a binary class of river and background. An encoder and a decoder, each with 13 convolutional layers, make up the SegNet framework as shown in Figure 3

The encoder layers first make use of a 64x64 convolution layer with a small receptive field. They include both BN (Batch Normalization) operations and ReLU activation functions. Similarly, the 128x128 convolution layer appears on two levels, the 256x256 convolution layer appears on three layers, the 512x512 convolution layer appears on three layers, and the 512x512 convolution layer appears on three layers. To preserve the feature maps' spatial dimensions, max pooling operations are carried out after each convolutional layer. A 3x3 kernel size filter with the same padding is used at the encoder side in conjunction with convolution, while a 2x2 kernel size filter with stride = 2 is used at the decoder side.

II.3 RIVER WIDTH MEASUREMENT ALGORITHM

Algorithm 1:River Width Calculation

Input: Predicted Output of test dataset $\hat{G}_{test}$
Output: Average River width mW^{model}

for each sample of test set **do**
  $\hat{G}_{gray} = f(col2gray(\hat{G}_{test}))$ /* convert color image to grayscale image */
  $\hat{G}_{thresh} = f(gray2thresh(\hat{G}_{gray})$ /* convert into threshold image */
  $dist = copy(\ \hat{G}_{thresh}\ )$ /* threshold image copied into distance */
  $dist_{trans} = DT(dist, euclidiane_{dist})$ /* applied distance transform on the threshold image */
  $skele_ton = skeleton(copy(\ \hat{G}_{thresh}\ ), medial_axis)$ /* to get skeleton medial axis)
  $centerline_{dist} = dist_{trans} * skele_ton$ /* to get centerline distance */
end for
for $skele_ton \neq 0$ **do**
  $avg = mean(centerline_{dist})$
end for
$mw^{model} = 2 * avg$ /* average River width */

Source: Authors, (2026).

The river width calculation algorithm SegRivWidth is given in Algorithm 1. The width of the river is calculated using the binary segmentation map made up of the river pixels in the foreground class $\hat{G}_{test}$. River width is defined as the distance between two locations on the riverbank that is orthogonal to the river's centerline. The two-step method to calculate river width is River centerline calculation and measurement of the distance between two locations on the riverbank that are orthogonal to the river centerline.

DT (Distance Transform) is applied on the thresholded river grayscale image. Then the medial axis of the extracted river is calculated using the skele_ton. This skeleton is then taken to represent the river's centerline using $centerline_{dist}$ .Let's use RPi, i = 1, 2, …, N to represent the N pixels on the river centerline. The closest point RPj ($Pj \in Pi$) on the river centerline is initially identified given a point on the river bank Q. Using the formula of river width calculation is

$$mW^{model} = \sigma\,(2\,Dist(Q, RP)) \tag{1}$$

Where $DIST$ (RP, Q) is the Euclidean distance between locations P and Q .This width mW, which is in the unit of pixels, can be multiplied by a scaling factor σ to convert it to the metric unit (meters).

II.4 PERFORMANCE MATRICES

Different performance metrics are used for river identification and river width calculation as described in the following section.

II.4.1 River Identification Metrics

Performance metrics like accuracy, precision, recall, IOU, and F1 score are commonly used to assess the effectiveness of semantic segmentation. The test dataset's confusion matrix served as the base for calculating the various evolution metrics. They described themselves as:

$$\text{Accuracy} = \frac{TP + TN}{TP + TN + FP + FN}, \tag{2}$$

$$\text{Recall} = \frac{TP}{TP + FN}, \tag{3}$$

$$\text{Precision} = \frac{TP}{TP + FP}, \tag{4}$$

$$\text{Flscore} = 2 \times \frac{\text{precision} \times \text{recall}}{\text{precision} + \text{recall}} \tag{5}$$

$$\text{IOU} = \frac{TP}{TP + FP + FN}, \tag{6}$$

False Positive (FP) indicates the number of river pixels that are incorrectly classified, False Negative (FN) indicates the number of background pixels other than river pixels that are incorrectly classified, True Positive (TP) indicates the number of river pixels that are correctly classified, and True Negative (TN) indicates the number of background pixels other than river pixels that are correctly classified. The model's overall performance across all classes is shown by accuracy. A recall is calculated by dividing the number of correctly identified positive samples by the total number of positive samples in the test set. The precision of an image is defined as the proportion of accurately predicted positive samples among all expected positive samples. The F1 score is a representation of the precision and recall harmonic average values. The Predicted and original image overlap ratio is represented by the IOU.

II.4.2 River Width Metrics:

The effectiveness of the proposed method for river width calculation mw^{model} is compared with the river width of the ground truth images mwg. The Average Absolute Error (AAE) and Root Mean Square Error (RMSE) are used to measure the performance of the method. They are defined as under:

$$Average\ Absolute\ Error = \frac{absolute(mw_g - mw^{model})}{N} \tag{7}$$

$$Root\ Mean\ Square\ Error = \sqrt{\frac{\sum(mw_g - mw^{model})^2}{N}} \tag{8}$$

Where N is the total number of locations considered for river width measurement

III RESULT AND DISCUSSION

III.1 RIVER IDENTIFICATION TRAINING PHASE

The River Identification Training Phase used two semantic segmentation algorithms, FCN and SegNet, trained on the RIWA V2 dataset. This dataset is divided into three parts: test, validation, and training. The SegNet and FCN are trained independently on the same dataset using identical training, validation, and test split. The model is trained and evaluated on Google Colab with an NVIDIA T4 Tesla GPU, 12 GB of RAM, CUDA version 12.2, and an Intel Xeon CPU running at 2.00 GHz. The deep learning library PyTorch is used to train the model. The Learning Rate £ of the model is initialized by the 1x10-2, Batch Size β of 4, Hidden Layers of 64, and image size of 512x512 pixels. The proposed model used a Binary Cross Entropy (BCE) loss model. It used Adam optimizer for FCN and SegNet to optimize the weight parameters of the model.

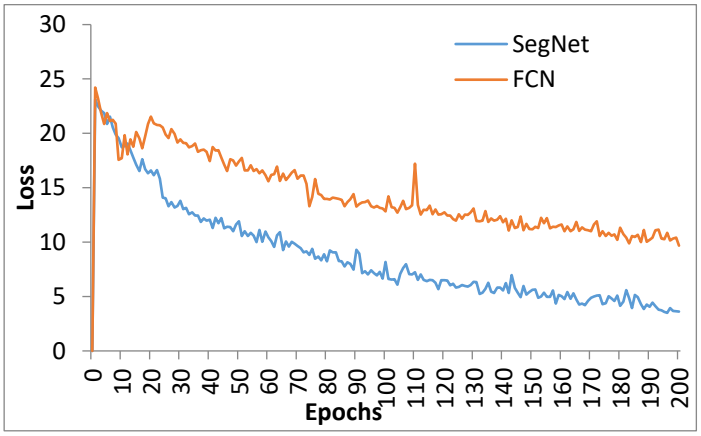

Figure 4: Loss curve during Training Phase.
Source: Authors, (2026).

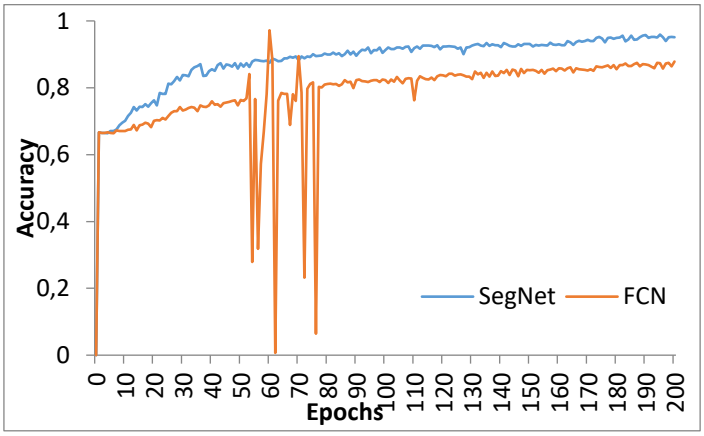

Figure 5: Accuracy Curve during the Training Phase.
Source: Authors, (2026).

During the training phase of the model (FCN and SegNet) the Loss, Accuracy, IoU score, and Training Time are calculated. Both of the models are trained for 200 epochs and the graph of epochs vs loss and epochs vs accuracy is shown in Figure 4 and Figure 5 respectively. Result shows SegNet model performed better than the FCN model. The Training time required for the FCN is approximately 6 hrs whereas the training time for the SegNet is approximately 6 hrs and 25 min. Moreover to measure the effectiveness of the model IOU score is also measured for the validation and training phase of the FCN and SegNet model as shown in Table 1. Both algorithms demonstrate competitive performance, with FCN achieving an IoU score of 78.25% and SegNet achieving an IoU score of 89.55 % during the validation phase. Both method FCN and SegNet methods segmented images accurately but compared to FCN, SegNet produces a more accurate river segmentation as shown in Figure 6.

Table 1: Training Phase Evaluation Parameters.

Model Name	IoU score (Training Phase) (%)	IoU score (Validation Phase) (%)	Training Time
FCN	89.55	78.25	5 hrs and 55 min
SegNet	92.48	88.67	6 hrs and 25 min

Source: Authors, (2026).

III.2 RIVER IDENTIFICATION TESTING PHASE

Table 2. Testing Phase Evaluation Parameters.

Model Name	Precision (%)	Recall (%)	F1 score (%)
FCN	78.89	77.92	78.40
SegNet	85.56	89.23	87.35

Source: Authors, (2026).

The semantic segmentation of rivers from Aerial images is challenging due to the presence of multiple water bodies, shadows, and backgrounds with similar kinds of features. The performance precision, recall, and F1 score of FCN and SegNet algorithms are compared with ground truth values. It can be seen that both the algorithms perform well and achieve good competent results as shown in Table 2. The SegNet achieves the recall value of 89.23% however the FCN achieves 77.92% of recall value. Further F1 score of FCN is 78.40 % while 87.35 for the SegNet Method. However, it was observed SegNet method is more accurate than the FCN method for semantic segmentation of the river as shown in Figure 6.

III.3 RIVER WIDTH RESULTS

Table 3: River width results.

Test Image	Actual Width mw_g (meter)	mw^{FCN}(meter)	mw^{SegNet} (meter)
1	37.76	39.2	36.44
2	18.22	15.85	17.27
3	45.98	48.71	47.78
4	30.67	20.97	25.7

Source: Authors, (2026).

A comparison was made between the estimated and actual river widths. Actual river width is determined by ground truth images. The measured width at a few locations using the segmentation findings from SegNet and FCN is displayed in Table 3. Both the method FCN and SegNet are used to calculate the width of the river from the river segmented output images. The estimated width is not same actual river width as segmentations boundary errors. As Segmentation boundary errors results due to inaccurate object boundaries during image segmentation method which leads further error for river width calculation. Segmentation boundary error depends on algorithm such as edge based, region based or deep learning based algorithm that misclassify river segment. The segmented river images further analysed for the river width measurement that compounded the initial error segmentation and river width measurement algorithm error. It means if the boundary is narrower than the actual object then width will be underestimated.

Using the segmentation findings of FCN, the average absolute measurement error was 4.06 m, whereas using the segmentation results of SegNet, it was 2.16 m. Additionally, using the FCN segmentation map, the root mean square error (RMSE) was 5.22 m while using the SegNet segmentation map, it was 4.76 m. The more precise segmentation map produced by SegNet is the primary reason the estimated river width using SegNet segmentation method is more accurate than the FCN method. This finding is the significance of precisely identifying rivers and calculation of river width. The suggested method for measuring river width performs noticeably better than the previously published research as shown in Table 4.

Table 4. Comparative analysis with published work.

Algorithm	AAE Error (m)	RMS Error(m)
RivWidthCloud (9)	43.1	99.2
DeepRivWidth (6)	20.05	24.9
RWW (2)	-	14.41
GrabRiver(8)	26.05	47.3
Proposed: SegRivWidth	2.16	4.76

Source: Authors, (2026).

IV. CONCLUSION

Using Deep learning can be done river segmentation and width measurement fast and automatic from remote place to save humen life during natural disasters. The suggested method first identifies the river images from the aerial images using semantic segmentation and then calculates the width of the river. The use of CNN-based encoder-decoder type architecture eliminates the requirement of human intervention for adjusting the threshold value and seed point of the input image. Both the FCN and SegNet model's evaluation parameters were compared during the training, and testing phase. The result shows that the SegNet Model accurately classifies the image pixel of rivers from the input images. Moreover, the visual result also conveyed that SegNet is superior to the FCN method for river semantic segmentation. The SegRivWidth measures the width of the river from the segmented result and would be used for the better management and planning of water resources.

The input to the SegRivWidth algorithm is a Semantic Segmented image that is used to calculate the river width and compare it with the original ground truth width measurement. However, the accuracy of the river width measurement depends on how the river image is identified properly from the aerial images. The AAE and RMS error is calculated for the SegNet model and compared with the other five methods reported recently in the literature. The river width calculation for the SegNet model had an AAE error was 2.16 m and an RMS error was 4.76 m. These findings of the river width performed better than the methods currently used for extracting river width. This method would be used for automatic calculation of river width, flood monitoring, agriculture, water resource management, and urban planning.

ABSTRACT

Accurately evaluating and choosing viable embryos for implantation is crucial to the success rate of in vitro fertilisation (IVF). Traditional evaluation techniques mostly rely on the subjective and variable eye observation of embryologists. This study suggests a deep learning-based automated embryo classification framework that combines image preprocessing, segmentation, and classification in order to overcome these drawbacks. First, to improve the contrast and clarity of small morphological characteristics in embryo photos, Contrast Limited Adaptive Histogram Equalisation (CLAHE) is used. The enhanced images are then subjected to a sprint semantic segmentation network (SSS-Net) to ensure that only relevant features support classification and accurately differentiate the embryo region from the backdrop. Using a hybrid Convolutional Neural Network–Long Short-Term Memory (CNN–LSTM) model, the last step successfully classifies embryos into different quality categories. This method captures both spatial and sequential feature dependency. The experimental evaluation demonstrates the durability and dependability of the proposed framework with high precision, recall, F1-score, and accuracy, demonstrating strong predictive performance. When compared to conventional techniques, the combination of sophisticated preprocessing, effective segmentation, and hybrid deep learning architecture greatly increases classification consistency. All things considered, the suggested method offers an automated, scalable, and objective tool for evaluating the quality of embryos. It may also help embryologists make clinical decisions and eventually increase the success rates of IVF.

I. INTRODUCTION

About 80 million couples worldwide suffer from infertility, a serious issue and major clinical condition that affects 8–12% of couples [1]. Globally, the infertility rate has been steadily rising, and in many West African groups, it is even getting close to 50% [2]. According to estimates, only half of the 6.1 million infertile Americans receiving therapy are receiving fertility-related care [3]. One popular and successful assisted reproductive method for treating infertility is in vitro fertilisation (IVF). Using a manual fertilisation process, IVF involves cultivating embryos in an incubator for three to five days until they reach the blastocyst stage.

Based on important morphological characteristics, the best embryos (blastocysts) are chosen and returned to the patient's uterus [4]. To boost the likelihood of pregnancy, several blastocysts were transferred in the past. But it caused mothers and newborns to have repeated pregnancies and other gestational problems. In order to lower the chance of multiple pregnancies, it is advised to transfer a single viable blastocyst [5]. In the past, skilled embryologists have closely examined the morphological features of blastocyst components using time-lapse imaging to physically assess the embryo's viability.

Pregnancy is significantly impacted by the various morphologies of the blastocoel (BL), inner cell mass (ICM), trophectoderm (TE), and zona pellucida (ZP), which are the fundamental components of the blastocyst [6]. Sperm-egg binding depends on ZP, a protective glycoprotein coating that envelops the oocyte. ZP thickness reduces when the embryo moves on to the blastocyst stage and is highly correlated with IVF success. A layer of cells called TE is necessary for the production of the fluid that makes up the placenta. There is a substantial correlation between embryo viability and TE morphology and quality [7]. Because the survival and potential of the subject embryo depend on the features of its component parts taken together, the morphometric evaluation of the blastocyst is a crucial goal for an embryologist [8].

I.1 OBJECTIVES

- To design and implement a fully automated system that objectively classifies embryo images, reducing dependence on manual visual inspection by embryologists.
- • To use Contrast Limited Adaptive Histogram Equalisation (CLAHE) to emphasise fine morphological details that are essential for precise analysis and to improve image contrast.
- To employ a Sprint Semantic Segmentation Network (SSS-Net) for precise embryo delineation, ensuring that only relevant morphological features are analyzed.
- To develop a hybrid CNN–LSTM model that effectively integrates spatial (from CNN) and temporal or sequential (from LSTM) information for robust embryo quality classification.

I.2 CONTRIBUTIONS

- The study minimises human subjectivity and inter-observer variability in traditional evaluation methods by introducing a fully automated deep learning-based system for assessing embryo quality.
- By enhancing the visibility of subtle structural elements in embryo photos, Contrast Limited Adaptive Histogram Equalisation (CLAHE) makes it easier to segment and classify images later on.
- The embryo zone is precisely separated from the backdrop using a specialised segmentation network called SSS-Net, guaranteeing that classification models only concentrate on biologically significant features.
- More robust classification performance is achieved by the suggested hybrid CNN–LSTM model, which incorporates both temporal (developmental) dependencies and spatial patterns in embryo morphology.
- The framework has been thoroughly tested using a variety of performance metrics, including precision, accuracy, recall, and F1-score, and shows better predicted reliability and consistency than conventional visual assessment techniques.

Section 2-Related Work: This part examines the body of research on methods for evaluating the quality of embryos, with an emphasis on both current developments in deep learning-based image analysis and more conventional visual evaluation techniques. Section 3: Methodology: This section provides a detailed description of the suggested automated embryo classification framework, including the use of CLAHE for picture preprocessing, the Sprint Semantic Segmentation Network (SSS-Net) for embryo segmentation, and the hybrid CNN–LSTM architecture for classification. Section 4: Findings and Analysis The experimental findings are shown and discussed in this section, along with a comparison of the suggested framework's accuracy, precision, recall, and F1-score with baseline and conventional approaches. Section 5-Conclusion: This section outlines the study's practical implications for clinical IVF applications, highlights the key findings, and makes recommendations for possible future research routes.

II. RELATED WORK

The research article [9] that conducted a multicenter randomised clinical experiment comparing traditional morphological evaluation of embryos in IVF with deep learning (iDA Score). Given that the clinical pregnancy rate was 48.2% based on morphology and 46.5% based on iDA Score, deep learning did not demonstrate noninferiority (risk difference -1.7; 95% CI -7.7, 4.3; P=0.62). The paper [10] a study that improved the embryo selection during IVF by developing a deep learning algorithm based on time-lapse imagery and self-supervised contrastive learning.

With an AUC of 0.57 based on prior transfer knowledge and 0.64 without it, the algorithm, which was trained on 1,580 videos of 460 patients' embryos, predicted the success of implantation. The experiment [11] that developed and evaluated machine learning models to forecast blastocyst incidence during IVF cycles. With fewer characteristics and better interpretability than SVM and XGBoost, LightGBM was the best. The percentage of 8-cell embryos and long culture embryos, as well as the number of cells on Day 3, were significant predictors. The article under review [12] which compared the application of an AI platform to support FSH dosing and timing of trigger stimulation in IVF among 291 patients.

AI assisted treatment demonstrated a slightly greater MII oocytes count, total oocytes recovered, and FSH consumption which indicated that AI could be used safely to maximize ovarian stimulation. The study [13] in which the authors proposed IVFormer with VTCLR, an AI that predicts the embryo status and live-birth rates using multi-modal and unlabelled data. The algorithm outperformed the physicians in the euploidy ranking, suggesting that it could be a non-invasive and reasonably priced way to choose embryos. The study [14] that looked at the effects of adding 15% additional training data to iDAScore v2.0, a technique used to predict sustained pregnancy following single vitrified warmed blastocyst transfer (SVBT).

With over 15% of training data, iDAScore v2.0 outperformed iDAScore v1.0 or Gardner grading in predicting ongoing pregnancy (iDAScore v2.0 AUC scores 0.736 vs. 0.720 vs.The article [15] that has developed a Convolutional LSTM-based artificial intelligence system that can analyse the last two hours to anticipate the morphology of embryos up to 23 hours in advance. In order to facilitate early and non-invasive embryo selection, the system separated transferable embryos from those that should be avoided. The research [16] which created DeepEmbryo a machine learning-powered device that can predict the success of the pregnancy based on three time-lapse images of the embryo.

DeepEmbryo was able to outperform algorithms that only used the final image and outperformed five trained embryologists, with as high as 75% accuracy. The study [17] under consideration at the possibility of AI involvement into the surgical decision-making process, but patient safety, ethics, transparency, interpretability, and collaborative work on responsible AI application in healthcare are the key concerns. The article [18] which comprises a review of the microfluidics in sperm selection of IVF and ICSI. Microchannel chips are able to sort highly motile sperm with low impacts and DNA damage, enhancing success rates, yet commercialization and species applications are problematic.

It is the study [19] where the models of MLCS live birth prediction were compared to the national registry of SART. MLCS was superior to SART in the recognition of patients with better live birth chances and it has potential in personalized counseling and clinical decision making. The study [20] that trained a hybrid AI model with day-5 images of the blastocysts and clinical and laboratory data to determine the chances of implantation. Heatmaps have been used to reveal inner cell mass, trophectoderm and blastocyst growth and have been shown to be useful in interpretable embryo level decisions. The article [21] who created three AI models, including clinically-based MLP, image-based CNN, and a combination of the two to forecast clinical pregnancy and live birth in single embryo transfer.

The accuracy of the fusion model was 82.42 and AUC was 0.91. The research under consideration [22] that constructed an AI system by applying Attention Branch Networks to predict live birth based on 141,444 embryo images of 470 transfers. Embryos with a score of more than 0.341 showed much better live births, which argue in favor of non-invasive selection. This study [23] systematic review of CNN models to assess embryos through time-lapse monitoring in 22 retrospective studies using 522,516 images of 222,998 embryos. CNNs also performed better than embryologists, particularly in the classification of blastocyst stage.

The corresponding article [24] which is a review of AI usage in embryo grading and pregnancy prediction based on multi-modal data. There are data scarcity, multi-modal features combination, and generalization of models. It is [25], which described an AI system based on Convolutional LSTM that predicts embryo morphology and separates transferable embryos, helping to select embryos early on in a non-invasive procedure. The research [26] where five ML models have been compared in relation to the use of GA feature selection in predicting IVF outcomes. AdaBoost using GA had an 89.8% accuracy and female age, AMH, endometrial thickness, sperm count and embryo quality were found to be significant predictors.

The study [27] that produced ML models that predicted the outcomes of live births of 11,938 Chinese IVF couples. Best were logistic regression and Random Forest (AUROC of~0.67), where maternal age, progesterone and estradiol made the greatest contributions. The resemblant article [28] an overview of AI in ART labs, which includes data gathering, record keeping, embryo selection, and automation to decrease subjectivity and human error. The corresponding research article [29] which reported the use of AI software in ART to facilitate IVF processes, minimize interobserver discrepancy, discover how to optimize drug dosing and enhance gamete quality. Closely connected is the review article [30] that examined the current state of ML to determine the quality of sperms and oocytes, and emphasised its value in the accurate assessment of the gametes and the possible increase in the ART success.

The researchers [31] who have suggested hill-climbing feature selection based on ML models as predictors of IVF pregnancy success. Significant variables were age, AFC, number of MII, and embryo transfer day that enhanced prediction. The article [32] which compared ML (SVM and neural networks) and logistic regression in terms of IVF outcomes. ML was superior to logistic regression in terms of the number of oocytes recovered, embryo quality, clinical pregnancies and live births. The work [33] that developed machine learning algorithms to calculate the optimal number of embryos to transfer in order to maximise the transfer rate. SVM and ANN achieved the best accuracy (95.83% and 91.67), suggesting the potential for individual embryo-transfer decisions. The corresponding article [34] a review of deep learning to automatically grade IVF blastocysts.

Automated techniques can usually be as good or better than embryologist performance. The paper [35] which introduced a two-stage deep learning method of automatic tracking of follicular growth with SFR-Net based on 3D UNet and Multi-Scale Residual Blocks with a DICE score of 85.84. It is related to [36] reviewing AI in ART, which includes image analysis, personalised protocols, and workflow automation, with ethical, regulatory, and sustainability issues being addressed. The experiment is [37] where the authors used end-to-end deep learning to infer embryo ploidy using 690 raw time-lapse videos on their dataset and achieved a baseline AUC 0.74, showing evidence of the ploidy assessment can be non-invasive. The corresponding piece [38] which reviews AI based automated embryo assessment at different stages of development, which is associated with higher selection efficiency, enhanced performance over manual assessment, limitations and future research priorities.

III. PROPOSED METHODOLOGY

The proposed approach offers a deep learning-based pipeline for automated embryo categorisation in in vitro fertilisation (IVF) to improve the accuracy and objectivity of assessing the quality of embryos. The framework's three primary stages are preprocessing, classification, and segmentation. CLAHE is used during the preprocessing phase to improve the contrast and brightness of embryo images. This makes it easier to see minute morphological details that are necessary for precise analysis. To make sure that only pertinent characteristics are used in following phases, the improved images are subsequently run through a SSS-Net, which successfully separates the embryo region from the surrounding background and artefacts

A hybrid CNN–LSTM model is employed for the classification stage. The CNN component extracts deep spatial information to improve the model's capacity to identify developmental trends in various embryo pictures, while the LSTM component records temporal and sequential correlations. The suggested method yields performance metrics with exceptional resilience and dependability, including as accuracy, precision, recall, and F1-score. This integrated approach reduces human subjectivity and promotes better clinical judgement during IVF procedures by providing a strong tool for automated evaluation of embryo quality.

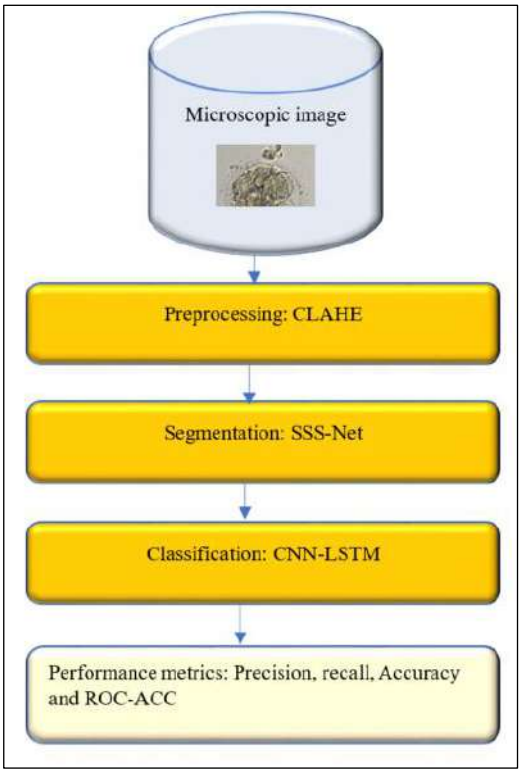

Figure 1: Flow diagram of proposed embryo selection.
Source: Authors, (2026).

III.1 DATASET: EMBRYO CLASSIFICATION BASED ON MICROSCOPIC IMAGES

The embryo images are arranged within subfolders under the train and test directories. Each image is saved in JPG format and is labelled with a prefix. Images corresponding to day-3 embryos have the prefix D3 while images related to day-5 embryos bear the prefix D5. This prefix-based categorization allows for easy identification of the embryo's developmental stage.

III.2 PREPROCESSING: CLAHE (CONTRAST-LIMITED ADAPTIVE HISTOGRAM EQUALIZATION)

Adaptive Histogram with Contrast Limitations An image processing technique called equalisation is used to increase an image's contrast. Instead of using a complete image, CLAHE works in a tile call, which is a small portion of an image. The histogram's use is distinct from its general use, where each tile is changed by calculating the function of the condition of being contrasted colour. The distributed value for each tile contrast is added to the histogram of the resolution region approximation to it. The adjacent tiles then joined to prevent induced borders. To prevent enhancing any potential noise in the image, the contrast will be kept to a minimum, mostly in areas that are uniform. The image x has greyscale equalisation in the Histogram, and the value is greyscale up to 256. In contrast, the following formula should be used to find the probabilities at pixel level I in an image:

$$D_x(i) = D_{(x=i)} = \frac{n_i}{n}, 0 \leq i < L \quad (1)$$

In this case, the variable L denotes the image's overall grey level count, which is typically 256, and the variable n denotes the dataset's pixel count. The image histogram for the pixel into an index to i is represented by the variable $D_x(i)$.

III.3 SEGMENTATION: SPRINT SEMANTIC SEGMENTATION NETWORK (SSS-NET)

In order to precisely identify and characterise important blastocyst components, this work presents a lightweight semantic segmentation framework for embryological investigation. By avoiding computationally costly preprocessing methods, the suggested SSS-Net enhances image contrast without sacrificing speed. Instead, it uses skip connection blocks (SCBs) in the encoder to directly handle the raw input images and recover biassed and rich feature representations. By using a shallow upsampling block, the decoder effectively and simply reconstructs spatial features.

SSS-Net produces a five-channel segmentation mask at the output, with each channel representing a different class: background, blastocoel (BL), trophectoderm (TE), zona pellucida (ZP), and inner cell mass (ICM). By assigning a value of "1" to each component pixel and a "0" to non-component regions, these masks enable accurate morphological evaluation of every blastocyst structure. By enabling the objective evaluation of blastocyst morphology, this segmentation aids in the precise determination of embryo viability.

Encoder Block

Since the decoder's complexity equals that of the encoder, conventional semantic segmentation systems usually employ identical encoder and decoder architectures, significantly increasing the number of trainable parameters.

On the other hand, the suggested SSS-Net minimises model complexity and computational cost by introducing a shallow semantic segmentation architecture with a lightweight upsampling module that employs a small number of transposed convolution layers. Figure 2 depicts the SSS-Net layer-by-layer design. The network uses three stride convolutions rather than several pooling layers to gradually shrink the feature map size while retaining learnable weights in order to protect important spatial information and prevent excessive feature loss. Additionally, by lowering feature transfer impedance issues that are commonly observed in conventional architectures, dense connections are utilised to offer efficient feature propagation between layers.

Within each Skip Connection Block (SCB), a point-wise convolution $\text{Conv}_{1,1}$ receives the input feature I_i from the Rectified Linear Unit (ReLU) activation of the preceding SCB, while a separable convolution Conv_{Sep} processes the same I_i in parallel. The resulting point-wise features G_i from $\text{Conv}_{1,1}$ are simultaneously fed into two asymmetric kernel-based convolutions $\text{Conv}_{1,3}$ and $\text{Conv}_{3,1}$ and one standard convolution $\text{Conv}_{3,3}$, producing feature maps K_{A_i}, K_{B_i}, and L_i, respectively. The outputs from the asymmetric convolutions, K_{A_i} and K_{B_i}, are concatenated to form D_{A_i}, as defined in Equation (2). After Batch Normalization (BN) and ReLU activation, this combined feature becomes D'_{A_i}, which is subsequently utilized for further feature fusion and representation learning.

$$D_{Ai} = K_i^A © K_i^B \tag{2}$$

The depth-wise concatenation between the features K_{A_i} and K_{B_i} is represented by the symbol ©. After the Batch Normalization (BN) and Rectified Linear Unit (ReLU) operations, the features F_i and L_i, generated by Conv_{Sep} and $\text{Conv}_{3,3}$, respectively, are transformed into F'_i and L'_i. The enhanced feature D_{B_i}, as expressed in Equation (3), is obtained by combining the asymmetric convolution feature D'_{A_i} with the outputs F'_i and L'_i from Conv_{Sep} and $\text{Conv}_{3,3}$. The spatial information from F'_i, imported from the preceding block, contributes to the refinement of the D_{B_i} feature representation. At the end of the SCB, a bottleneck point-wise convolution $\text{Conv}_{1,1}$, followed by Batch Normalization (BN), is applied to D_{B_i}, producing the final feature map D'_{B_i}. The activation function utilized in this stage, ReLU, is defined by Equation (4).

$$D_{Bi} = D'_{Ai} © L'_i © F'_i \tag{3}$$

$$D_{Bi}{}' = [D'_{Ai} © L'_i © F'_i]' \tag{4}$$

The depth-wise concatenation of features D′Ai, L′i, and F′i is displayed here by ©. The next SCB will have Feature D′Bi, the last feature from the suggested SCB that combines three distinct features. Unlike conventional semantic segmentation designs, SSS-Net has a unique shallow decoder block that uses only three transposed convolutional layers for upsampling. The feature map DBi', DBi ′undergoes three consecutive dimensional reductions twice in the final skip connection block (SCB), and the feature map is upsampled three times using these transposed convolutions to restore the original input dimensions. The shallow decoder architecture reduces computational complexity by using fewer layers for upsampling while maintaining effective feature reconstruction.

To improve deep feature learning, the decoder combines four convolutional layers that reduce the semantic gap between the decoder and the transposed convolutional layers. Three transposed convolutions gradually upscale the feature maps to the original resolution, providing detailed spatial information to the final pixel classification block. The pixel classification layer uses a Tversky loss function to reduce class disparity and improve segmentation performance. This layer consists of a curve function with filters corresponding to the number of target classes. The Tversky loss (TLoss) is mathematically defined in Equation (5).

$$T_{Loss} = \frac{\sum_{i=1}^{N} P_b^i G_b^i + \omega}{\sum_{i=1}^{N} P_b^i G_b^i + \omega + \alpha \sum_{i=1}^{N} P_b^i G_b^i + \beta \sum_{i=1}^{N} P_b^i G_{nb}^i + \omega} \tag{5}$$

Where Pib and Gib, respectively, represent the likelihood that a pixel is part of the blastocyst and non-blastocyst components. A blastocyst and a non-blastocyst component are reflected in the gib and ginb pixels of the ground truth, respectively.

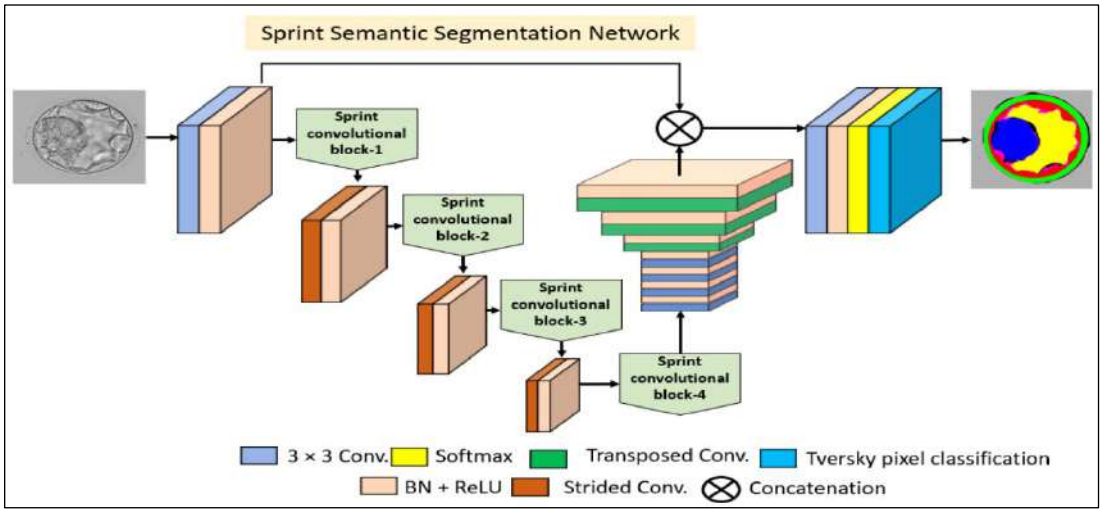

Figure 2: Architecture of SSS-Net.

III.4 CLASSIFICATION: CNN-LSTM

An activation value is produced by convolutional neural networks, or CNNs, after the different inputs are computed using mathematical functions. Artificial neurones are similar to the neurones in the human brain, which receive and process a wide range of input signals and responses. CNN is composed of several layers of artificial neurones and processes the images using a powerful algorithm. Complex objects and patterns can be learnt by convolutional neural networks (CNNs). They are made up of millions of parameters, several hidden layers, an input layer, and an output layer. The three layers that make up CNN are convolutional, pooling, and fully connected (FC). Using the output from the previous layer, the following layer pulls features from the photos, such as edges and corners. The first layer that is utilized to extract features from images is the convolutional layer.

The Convolved Feature's size is decreased by the second Pooling layer. To link neurons between two layers, weight and bias are applied to the neurons in the completely connected layer. When all features are added to the fully connected layer during the dataset training phase, overfitting takes place. By excluding a small number of neurons during training, a dropout layer shrinks the model's size and boosts performance. The model can be trained faster and achieve better results by using the rectified linear activation function. It is a linear function that will immediately output the input if the value of t is positive; else, it will output zero. As the last layer's final output and activation layer, Soft-max functions as a multiclassifier.

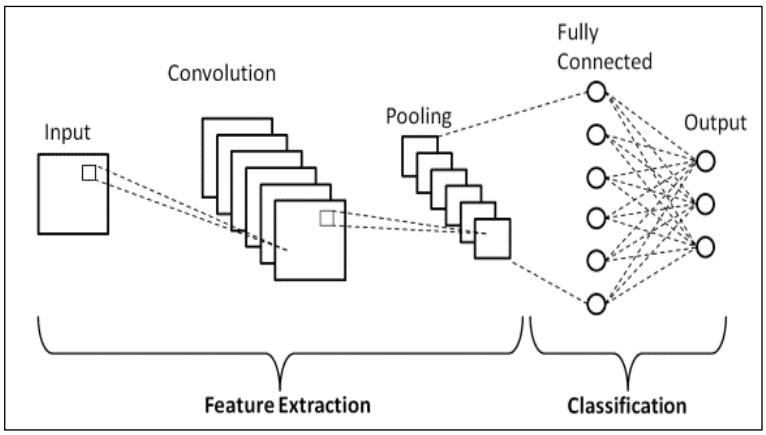

Figure 3: Architecture of CNN.
Source: Authors, (2026).

III.5 LSTM (LONG SHORT-TERM MEMORY)

The LSTM network's distinct memory cell layout enables it to disseminate and store data across multiple time steps. The cell state is the main component that stores temporal information and allows the network to recognise dependencies in sequential data. Three distinct gate types input, output, and forget gates are combined in the LSTM architecture to guarantee efficient learning of long-term dependencies. Together, these gates regulate how information enters, moves through, and exits the cell. Time-series meteorological data was used to train LSTM-based neural networks to predict the stages of embryo selection. The model's ability to effectively handle temporal patterns was utilised in this investigation. The organisation of the LSTM architecture is depicted in Figure 4.

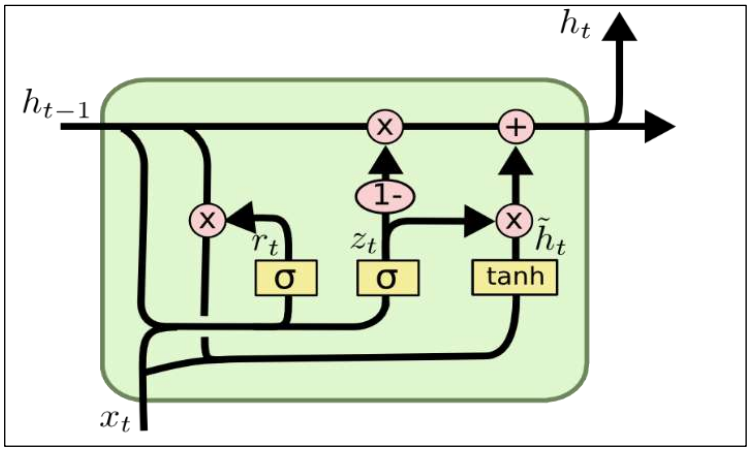

Figure 4: Structure of LSTM.
Source: Authors, (2026).

Because LSTM gates are sigmoid activation functions, they often yield a value between 0 and 1. The input, forgotten, and output gates' mathematical expressions are as follows.

$$i_t = \sigma(w_i[h_{t-1}, x_t] + b_i) \tag{6}$$

$$f_t = \sigma(w_f[h_{t-1}, x_t] + b_f) \tag{7}$$

$$o_t = \sigma(w_o[h_{t-1}, x_t] + b_o) \quad (8)$$

$i_t, f_t \, and \, o_t - Input \, gate, forget \, gate \, and \, output \, gate,$
$\sigma - sigmoid \, function,$
$w_x - weight \, for \, input, forget \, gate \, and \, output \,,$
$h_{t-1} - previous \, the \, LSTM \, block \, at \, the \, time \, (t-1),$
$x_t - time \, slot \, at \, icurrent \, nput \,,$
$b_x - biases \;\; for \, input, forget \, gate \, and \, output \, gate.$

The output equations for the cell state, candidate state, and final state are expressed as follows:

$$\tilde{C}_t = \tanh\,(w_c[h_{t-1}, x_t] + b_c) \quad (9)$$

$$C_t = f_t * C_{t-1} + i_t * \tilde{C}_t \quad (10)$$

$$h_t = o_t * \tanh\,(C^t) \quad (11)$$

Whereas,
$C_t - cell \, state,$
$\tilde{C}_t - candidate \, for \, cell \, state \, timeslot(t).$

IV. RESULT AND DISCUSSION

The proposed embryo classification framework was evaluated using a dataset of annotated embryo images collected from IVF procedures. Standard assessment measures, such as accuracy, precision, recall, and F1-score, were used to evaluate the system's performance. After applying CLAHE preprocessing, a significant improvement in image clarity and contrast was observed, enhancing the visibility of key morphological structures. The SSS-Net segmentation model effectively extracted embryo regions, achieving precise boundary delineation and minimizing background noise, which improved the quality of input data for classification. The process is implemented in python language and google colab tool.

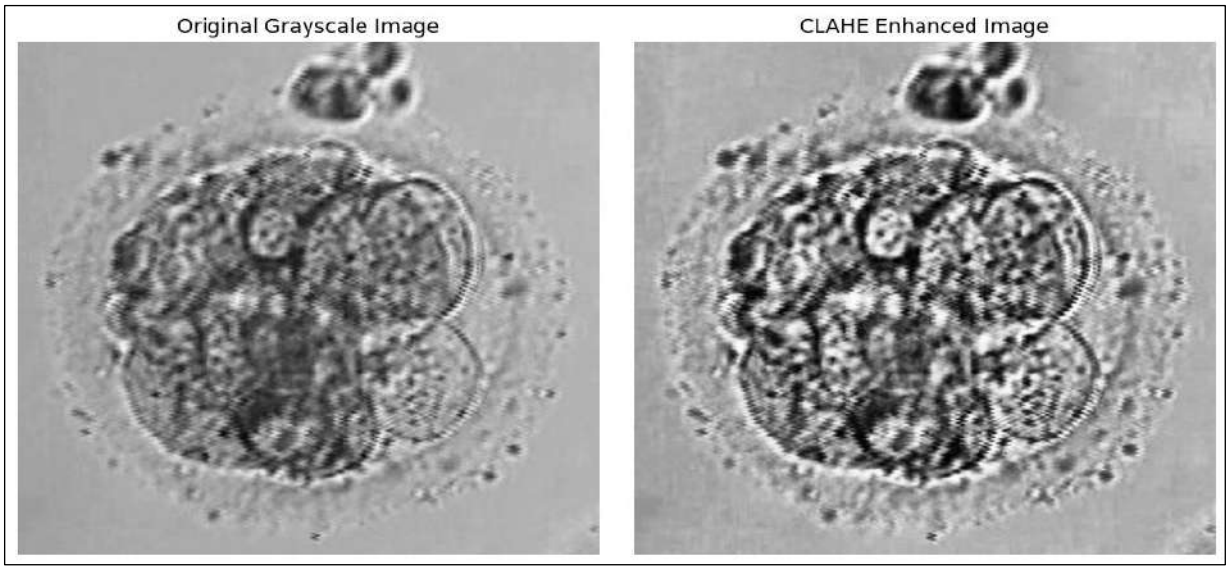

Figure 5: Preprocessed image.
Source: Authors, (2026).

The effect of CLAHE enhancement is illustrated in Figure 5, which compares the original grayscale embryo image with the contrast-enhanced version. As shown, CLAHE effectively increases the visibility of subtle embryo structures without introducing excessive noise, thereby improving the quality of data fed into the deep learning models for segmentation and classification

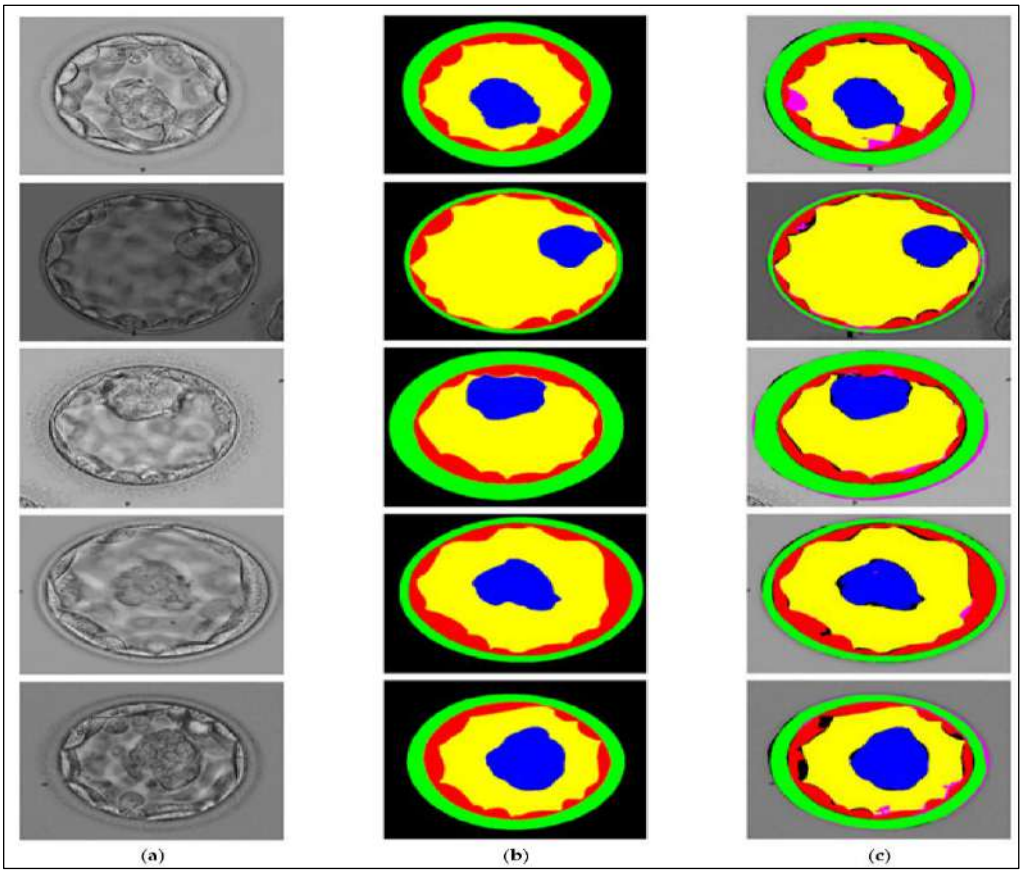

Figure 6: SS-Net for blastocyst component detection
Source: Authors, (2026).

Figure 6 displays the visual outcomes of blastocyst image segmentation utilising the suggested SSS-Net and the related ground truth (GT) images. The colours green, red, yellow, blue, and black/no (for GT/predicted) stand for the classes ZP, TE, BL, and ICM, respectively. The predicted image's pink hue indicates false negatives, or areas where the model was unable to detect a structure in the ground truth, with the GT = 1 and the anticipated mask = 0. On the other hand, false positive pixels areas that are mistakenly identified as belonging to a structure are displayed in black within the anticipated image when predicted mask = 1 and GT = 0.

Figure 7: Training and testing accuracy.
Source: Authors, (2026).

Figure 7, which displays the training and testing accuracy curves over all epochs, shows how well the suggested model performed during the training phase. During training, the model consistently improves its accuracy, reaching convergence after about 40 epochs. The testing accuracy follows a similar trend and stabilizes early, indicating that the model effectively learns discriminative embryo features without significant overfitting. The close alignment between the two curves suggests that the hybrid CNN–LSTM architecture successfully generalizes across unseen data, confirming the robustness of the proposed approach for automated embryo classification.

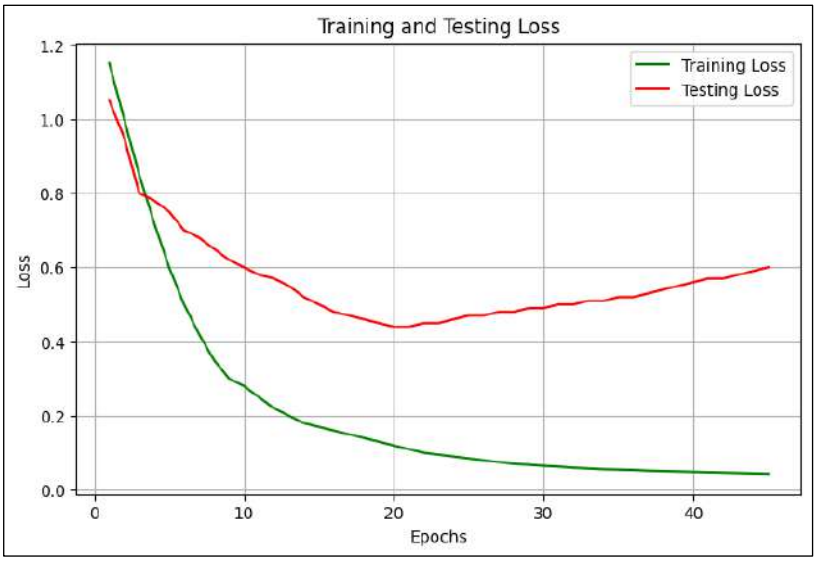

Figure 8: Training and testing loss.
Source: Authors, (2026).

The training and testing loss curves of the proposed model are presented in Figure 8. As shown, the training loss decreases steadily with the number of epochs, demonstrating the model's progressive improvement in minimizing classification errors. The testing loss also follows a downward trend and plateaus early, confirming that the network generalizes well to unseen data. The close correspondence between the two loss curves suggests that the model avoids overfitting and maintains strong generalization performance. These results further validate the effectiveness of the hybrid CNN–LSTM architecture in learning spatial and temporal embryo features essential for accurate classification.

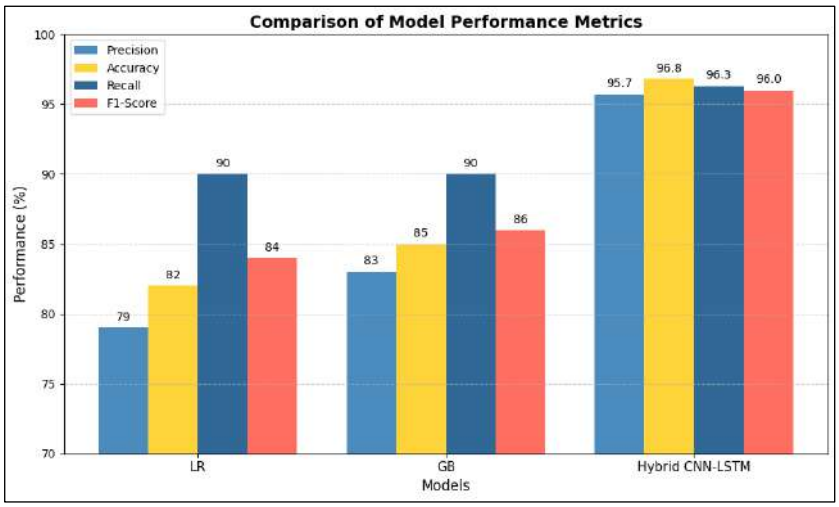

Figure 9: Comparasion model.
Source: Authors, (2026).

Figure 9 compares the performance of three models on the embryo classification dataset: Logistic Regression (LR), Gradient Boosting (GB), and the proposed Hybrid CNN–LSTM architecture. The outcomes unequivocally show that the hybrid model based on deep learning performs noticeably better than conventional machine learning techniques. With an F1-score of 96.0%, recall of 96.3%, accuracy of 96.8%, and precision of 95.7%, the Hybrid CNN–LSTM provides the best results on all performance parameters. This illustrates how well the model can categorise embryos and maintain a performance balance between sensitivity and precision. The traditional models (LR and GB), on the other hand, show a modest level of accuracy and a higher rate of misclassification, underscoring their poor capacity to capture intricate temporal and spatial embryonic aspects. These findings support the suggested hybrid deep learning model's effectiveness and resilience for accurate evaluation of embryo quality.

V. CONCLUSION

The deep learning-based system for automated embryo categorisation in IVF is presented in this paper, which combines sophisticated image preprocessing, segmentation, and classification methods. The visual clarity of embryo structures was greatly increased by using CLAHE for contrast enhancement, which made it possible to retrieve morphological details more effectively. By precisely separating embryo areas, the SSS-Net segmentation model decreased background interference and improved the dependability of the collected data. Both temporal and spatial dependencies in embryo images were well captured by the hybrid CNN–LSTM classifier, allowing for reliable and reliable classification across quality categories.

The system's ability to conduct accurate evaluations of embryo quality was confirmed by the experimental findings, which showed good F1-score of 96.0%, recall of 96.3%, accuracy of 96.8%, and precision of 95.7%, the Hybrid CNN–LSTM provides the best results on all performance parameters. The suggested approach provides increased objectivity, reproducibility, and efficiency above traditional manual examination. This strategy may prove to be a useful tool for embryologists in making decisions, helping them choose embryos and increasing the success rates of IVF. To improve model interpretability and clinical acceptability, future research might concentrate on growing the dataset size, adding multi-modal imaging data, and implementing explainable AI approaches. All things considered, the suggested approach is a major step forward for reproductive medicine's completely automated, data-driven embryo examination.

ABSTRACT

Among the many forms of cancer, liver tumours are among the most dangerous. Liver neoplasms can be effectively predicted, identified, and managed with the help of computer-aided technology and liver interventional surgery. Accurately understanding the morphological nature of the liver and its blood arteries is a crucial task. An essential part of medical analytic planning is the segmentation of liver tumours in CT scans. The enormous difficulty, however, lies in correctly identifying and segmenting the hepatic blood veins in CT scans. Finding and segmenting hepatic vessels manually in CT scans is an inconvenient and time-consuming process. In order to segment liver tumours, this study employs a variety of techniques to clean up the input images before feeding them into the STDCSL, an algorithm for short-term dense concat segmentation. Three parts make up the STDC-CT network: detail guidance, multi-scale contextual information, and small object attention extractor. Small affected area attention guides the merging of detailed and contextual information branches. This study proposes an improvement to the Barnacle Mating Optimizer (BMO), an evolutionary algorithm that takes its cues from nature, in order to fine-tune the STD-CSL parameters. Levy flight is used to enforce and replace the sperm cast equation, which improves the exploration phase of the original BMO. Next, the enhanced BMO (IBMO) is teamed up with the suggested STDCSL. The technology proves to be reliable and applicable to automatic analysis of liver tumours in everyday clinical practice, proving its generalizability. The method's great accuracy in stroke detection further supports its potential use as a clinical tool for preoperative clinical planning.

I. INTRODUCTION

Liver tumours pose a threat to people's lives and well-being globally; they are the second most deadly malignancy in terms of morbidity and death [1]. Liver tumour segmentation is the initial phase in the computer-aided diagnostic method for liver cancer, which is currently often employed in the diagnosis and treatment planning process using human abdominal computed tomography (CT) [2]. This process involves separating tumours from nearby organs and tissues in CT scans. While other imaging tests, including as ultrasonography and MRI, can aid in the diagnosis of cirrhosis, computed tomography (CT) is the gold standard [3]. A CT scan is a thorough kind of imaging because it produces detailed cross-sections of the abdomen.

Problems with tumour and lesion homogeneity during CT scan segmentation have been reported [4]. Liver tumour segmentation is not a good fit for the outcome. Accordingly, improved photos are suggested for better accuracy. The CT scan finds the tumour by noticing a change in the intensity of the pixels in the liver [5]. Hypodense tissue refers to the area of the liver that appears darker in comparison to the surrounding tissues. Furthermore, it has been noted that traditional tumour segmentation methods are computationally intensive [6]. Given the circumstances, a clinical setting would be less than optimal. A CT scan of the liver will typically show more than 150 slices, which is considered normal. Both the tumour and its surrounding areas exhibit low contrast and a great deal of form irregularity [7].

Computer Aided Design (CAD) technologies are currently the focus of global research efforts aimed at segmenting liver tumours from abdominal CT scans [8]. The current state of tumour segmentation is unreliable and ineffective due to its reliance on edge detectors. One of the techniques created for autonomous tumour segmentation using Deep Learning (DL) is the CNN [9]. CNNs remain a popular method among researchers for segmenting liver tumours. The diverse forms of liver tumours, along with low contrast and indistinct borders with nearby organs besides tissues, make tumour segmentation from liver CT images an arduous task, despite the attention of many scholars to this problem [10].

It is difficult to segment the liver tumour due to the surrounding muscle and the blurring borders caused by the slight difference in grey scale contrast between the tumour and other organs (e.g., the heart, kidneys, etc.) [11]. The liver tumour segmentation job is further complicated by the fact that tumour size and position might fluctuate from person to person, and that tumours can span numerous CT slices with small variations between them [12]. Consequently, recent studies have shown that a combination of deep learning and techniques based on local information works well. Many intensity-based methods have been created for the purpose of segmenting tumours and livers from CT images by statistically analysing their intensities [13]. Level set based active contour techniques are one of these more independently deployable alternatives.

In better match the liver tumor border in the test CT image, a level set contour - based technique is used to produce a coarse segmentation initial mask [14].The aforementioned models have shown promise in certain contexts, however input images with high resolution, complicated settings, and many small affected areas may not be suitable for their performance [15], [16]. It is also difficult to accomplish real-time, high-quality semantic segmentation due to the limited computing resources. Consequently, accomplishing real-time in semantic segmentation tasks while enhancing segmentation quality. The chief goal of this research is to mature a method for better liver tumour segmentation using input photographs.

- The purpose of this research is to contemporaneous a framework for tumour segmentation using target CT scans.
- The segmentation accuracy is enhanced by adjusting the parameters of the suggested model, which is integrated with the original Barnacle Mating Optimizer (BMO), which was enhanced by Levy Flight, in order to detect and divide up liver tumours.
- The Tversky loss function is employed to address the issue of severely imbalanced foreground and background voxels.
- Various metrics are used to conduct investigates on the publicly available LiTS dataset and the 3D-IRCADb01 dataset.

The break of the paper is prearranged as shadows: Section 2 mentions the related works; Section 3 provides the proposed organization with its mathematical expression; Section 4 mentions the result analysis and Section 5 concludes the research contribution.

II. RELATED WORKS

Using a single framework that combines segmentation and uncertainty estimation [17] provide a new reliable multi-phase liver tumour segmentation method called TMPLITS. Clinicians could benefit from the trustworthy outcomes in making a dependable diagnosis. For the purpose of parameterizing the segmentation besides uncertainty using evidence following the Dirichlet distribution, Dempster-Shafer Evidence Theory (DST) is specifically introduced. It is specifically defined how reliable the segmentation results are over multi-phase CECT images. However, to ensure the efficacy of the fusion technique grounded in theoretical analysis, a multi-expert is suggested for merging the multi-phase evidences. When tested against state-of-the-art approaches, TMPLiTS proved to be the clear winner. At the same time, we have confirmed that TMPLiTS is resilient, so we know that it will reliably work even when faced with disturbances. For better picture segmentation and to make better use of image spatial data [18] suggests an improved network construction called ELTS-Net that is based on the 3D U-Net model.

This would solve the problems caused by traditional approaches and the 2D U-Net network configuration. ELTS-Net improves upon the first network by enhancing the convolutional kernel's receptive field with dilated convolutions. In addition, the original convolutional module is replaced by an attention residual module, which primarily functions as an encoder and decoder. This module includes an attention mechanism and residual connections. The network may now gather channel and spatial contextual information on a global scale thanks to this design. In addition, the decoder network has deep supervision modules at several levels to supplement intermediate-level feedback. In doing so, we optimise the segmentation findings by limiting the network weights to the target regions. Results on the LiTS2017 dataset demonstrate that, in comparison to the model, the model performs better on liver and tumour segmentation tasks. The model achieves an accuracy of 95.2% for liver segmentation and 71.9% for tumour segmentation, representing an improvement of 0.9% and 3.1%, correspondingly.

The experimental consequences provide useful assistance for clinical diagnosis and therapy by validating ELTS-Net's superior segmentation performance compared to other comparator models.To overcome these obstacles [19] suggested SBCNet, a new model for dual-branch liver tumour segmentation. Better identification of tumour variability utilising an enhanced multi-scale adaptive kernel is made possible by our suggested method's contextual encoding module. In addition, the corresponding branch has a boundary enhancement module that uses contour learning in conjunction with the Sobel operator to improve boundary perception. Lastly, in order to further improve tumour segmentation, we suggest a hybrid multi-task loss function that takes into account both the size and boundary features of tumours at the same time. This will encourage interaction between the various tasks of the dual branches. With SBCNet producing competitive results when compared to other state-of-the-art algorithms for liver tumour segmentation, experimental validation using the publically accessible LiTS dataset proves the practical module.

First of its kind [20] suggests a dual-stream multi-level fusion outline (DM-FF) for direct accurate segmentation of liver tumours from non-contrast multi-modality images. In order to efficiently extract multi-level feature maps that correspond to a predefined representation of each modality, our DM-FF first builds an attention-based encoder-decoder. Then, DM-FF builds two kinds of fusion modules: one that uses learned features to get a common representation images, which lets you take advantage of similarities and boost performance, and another that uses segment decision evidence to find differences between modalities, which helps you avoid interference caused by conflicts between modalities. With the help of these three parts, DM-FF can accurately segment multi-modality non-contrast images by letting them work together.

When compared to eight state-of-the-art segmentation architectures, DM-FF improves performance and achieves a Dice of 81.20% in an evaluation on 250 patients using two MRI scanners and a variety of tumour types. According to the findings, our DM-FF greatly encourages the creation and use of non-contrast liver tumour imaging techniques. The attention connect network (AC-Net) was developed for automatic liver tumour segmentation and introduced by [21]. Our method, which is based on the U-shaped network construction, uses two crucial attention module (AAM) besides the vision transformer module (VTM)—to integrate spatial elements seamlessly, replacing conventional skip-connections. The VTM processes low-resolution feature maps using multihead self-attention and then reshapes the output into a feature map for later concatenation; the AAM computes axial attention across feature maps to enable feature fusion. In addition, we use a loss function that is exclusive to our method. We commence our procedure by pretraining AC-Net on the LiTS2017 dataset, and then we refine it with CT and MRI data obtained from Hubei Cancer Hospital.

Measurements for AC-Net's performance on CT data are as follows: a recall of 0.92, a Jaccard coefficient (JC) of 0.82, an normal symmetric surface distance (ASSD) of 4.59, a accuracy of 0.89. Metrics for AC-Net on MRI data are as follows: DSC = 0.80, JC = 0.70, recall = 0.82, ASSD = 7.58, HD = 30.26, pinpoint = 0.84. For the purpose of liver image segmentation [22] propose using hyper tangent Fuzzy C-Means (HTFCM). It got segmentation results that were nearly identical to the ground truth liver images by calculating the data point distance from the cluster centres using hyper tangent distance. Unfortunately, the liver images are too fuzzy for any state-of-the-art model to accurately pinpoint the tumours. However, the proposed model manages to do just that. This research shortened the processing time for early liver disease diagnosis, increased classification accuracy, and resolved the linear mapping problem using fuzzy logic. While classifying liver tumours, the suggested model improves accuracy to 99.58% and time by 2-25 s.In their ground-breaking AI-driven framework for liver tumour prediction [23] have brought together state-of-the-art methods to increase analytical depth and accuracy.

Histological Genomic Feature Extraction (MIRSLiC) are both included into the framework, which allows for a detailed comprehension of molecular markers and precise tumour segmentation in medical imaging. Furthermore, a multidimensional feature extraction module integrates acoustics, clinical data, videomics, and radiomics to produce a complete dataset. All of these factors work together to form a cohesive model that can predict tumour features, subtypes, and prognosis with great precision. Reliability is emphasised through model review and continual improvement integrative technique breaks new ground in liver tumour prediction by giving doctors practical information for individualised treatment plans. The model is tested extensively on various datasets, and the results show that it is accurate and reliable. Our model demonstrates remarkable accuracy and resilience in tumour segmentation, with a recall rate of over 92%, a precision of over 87%, and a Dice coefficient of over 0.89. Survival prediction accuracy in prognostic modelling routinely exceeds 84%, demonstrating the model's capacity to offer useful insights into the future course of liver cancer.

III. PROPOSED METHODOLOGY

In this section, the brief elucidation of liver cancer segmentation is mentioned with its mathematical expression from CT scan images. Figure 1 mentions the workflow of the proposed model.

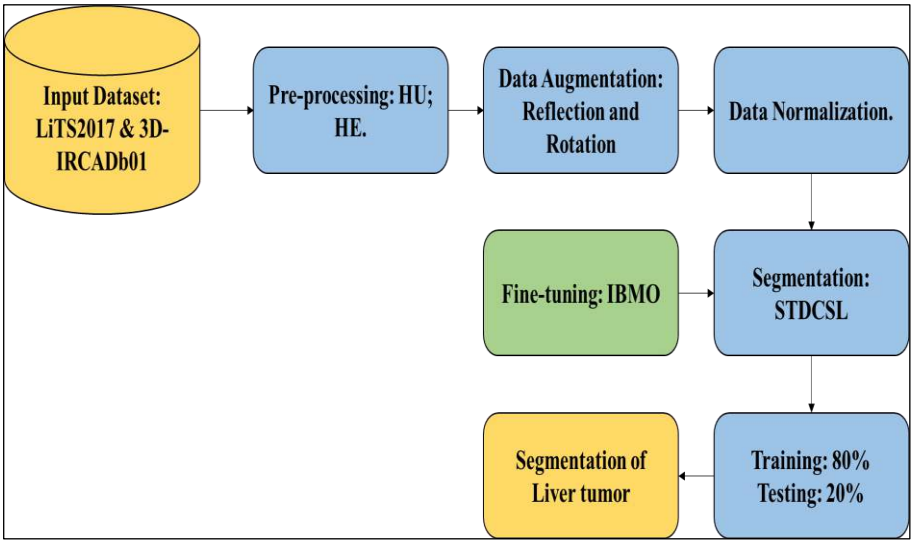

Figure 1: Workflow of the Research Work.

III.1 DATASETS

Popular datasets include 3DIRCADb, which is used to compare 3D picture reconstruction methods, and the LiTS2017 dataset, which is the official dataset given by the joint organising of MICCAI and ISBI competition for liver and liver tumour segmentation. Improvements in medical picture segmentation methods and a more fair evaluation of new approaches to liver tumour segmentation are the intended outcomes of these endeavours. Included in the LiTS2017 dataset are 201 CT images of humans. The official has annotated 131 of the 201 CT images, while the remaining 70 are raw CT scans without any commentary. The 70 in question served as the competition's performance test dataset, which explains why. Tumour diameters varied from 38 to 349 cubic millimetres, while the number of tumours per patient varied from 0 to 75. The data varied somewhat in quality because it came from a wide variety of universities using different technology. These slice samples had a resolution between 0.55 and 1.0 mm, a range of 0.45 to 6.0 mm for the spacing between slices, and 42 to 1026 slices for the total number of slices. Figure 2 presents the sample image of LiTS2017.

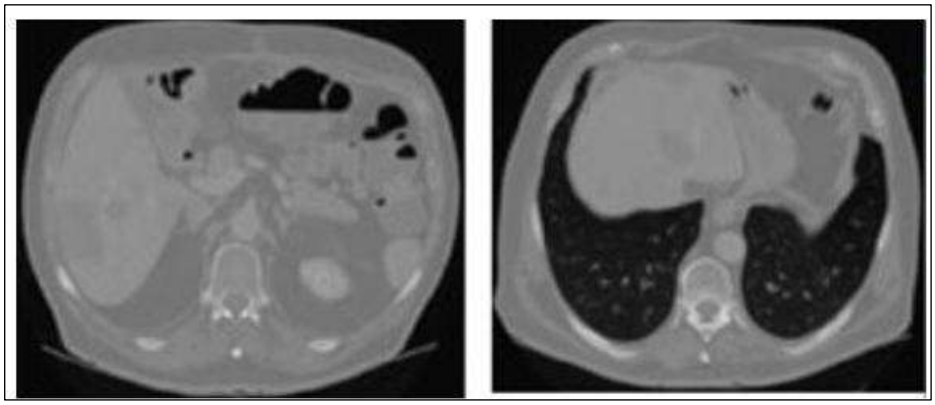

Figure 2: Sample of LiTS2017 dataset.
Source: Authors, (2026).

Three datasets, 3DIRCADb-02 and 3DIRCADb-01 [24], make up the 3DIRCADb dataset. While there are no liver tumours in the 3DIRCADb-02 dataset, there are 75 percent of cases with liver tumours in the 3DIRCADb-01 dataset, with tumour numbers ranging from 1 to 46. With dimensions ranging from 16.3 to 24.9 cm, 12.0 to 18.6 cm, and 11.0 to 20.2 cm, respectively, and voxel sizes ranging from 0.56 to 0.87 cubic millimetres, 1.6 to 4.0 cubic millimetres, the image had a resolution of 512 × 512 pixels. Figure 3 presents the sample image of 3DIRADb dataset.

III.2 IMAGE PRE-PROCESSING

Each slice was pre-processed as detailed in the following sections so that the liver could be differentiated from nearby organs.

III.2.1 Hounsfield Windowing (HU)

The Hounsfield unit (HU) is used in computed tomography (CT) scans to evaluate tissue density. The HU is specified as −1000 for air, zero for water, and +1000 for bone. Table 1 shows that the HU values for many organs and fluids fall somewhere in the middle of this range. In a typical windowing operation, the CT component of the image, allowing the operator to focus on certain tissues of interest. You can change the image's brightness using the window level. Shifts the focus by adjusting the width of the window.

$$HU = 1000 \times \frac{\mu tissue - \mu H_2O}{\mu H_2O} \quad (1)$$

By assigning a grayscale intensity to each value, the HU value is determined for each pixel; pixels with higher values are considered brighter. Navigate the DICOM slides using Hounsfield Windowing and adjust the range to [−100, 400] [−100, 400] [25].

Table 1: Hounsfield unit standards define for body organ.

Value for Body Organ	HU
1000	Bone
40 to 60	Liver
46	White Matter
43	Grey Matter
40	Blood
10 to 40	Muscle
30	Kidney
15	Cerebrospinal
0	Water
−50 to −100	Fat
−1000	Air

Source: Authors, (2026).

The liver can be better seen by applying HU windowing at each slice, with a HU range of −100 to 400 chosen. Although the image and organs got, it is evident that most organs are obstructed in CT image slices without the procedure. Hence, all slices undergo this HU windowing before being passed on to the subsequent phase.

III.2.2 Histogram Equalization

The liver and its surrounding tissues were not easily distinguishable, even though HU windowing allows for excellent organ visualisation. The resultant picture was normalised within the range of [0, 1] after applying histogram equalisation following window processing.

III.3 DATA AUGMENTATION

Every scan in the datasets under consideration has its unique tumour mask that denotes the tumor's and liver's precise position. Nevertheless, deep learning training cannot be conducted with the number of tumor-containing slices. So, the combined slice and its mask were subjected to data augmentation techniques like reflection, flipping, and rotation. To put it simply, data augmentation will boost network accuracy by increasing picture spatial variation [26]. The two methods of data enhancement that were employed are these:

III.3.1 Reflection

One way to increase the amount of data used to train a network is through reflection, which involves flipping the image along the x or y axis. The computational expense can be reduced by reflecting the liver pictures with their tumour masks.

III.3.2 Rotation

As a data augmentation technique, rotation entails turning the image to a new degree, effectively creating a new image. The photos of the liver and its masks are rotated by 90 degrees here.

III.4 IMAGE NORMALIZATION

A method for lowering inter-patient of picture intensities in a dataset is image intensity normalisation [27]. It will also lead to better segmentation results and make patient images more comparable. Hence, intensity normalisation is applied to liver CT scan results.

III.5 SEGMENTATION USING SHORT-TERM DENSE CONCAT SEGMENTATION LAYER (STDCSL)

Based on the STDC module's layout illustrated by the BiSeNet [28] model, the study effort suggests a new STDC backbone network. With the goal of improving real-time semantic segmentation performance, a new Detail Guidance Unit has been developed to supersede the original Spatial Path branch of BiSeNet. This module keeps low-level detail features while lowering the computational cost of the network. Nevertheless, there are still certain limitations to this network when it comes to segmenting small affected areas. For tiny impacted area segmentation tasks in particular, the detail information that the FFM module loses when it gradually reduces the maps could be beneficial. Additionally, the accuracy of tiny impacted area segmentation may be compromised due to the Detail Guidance Module in the STDC-Seg network primarily concentrating on low-level feature layers, potentially ignoring certain detail information in higher-level feature layers. So, here we present the STDC-CSL network, a new approach to small-scale segmentation that promises to be both accurate and fast.

III.5.1 Small Object Attention Extractor for STDC

So that the STDC backbone network could extract more useful features for minor recognition, we built (SOAE) module. From Stage 3 through Stage 5, we used convolutional layers with varying resolutions to extract various features from the input data. Different convolutional layers capture features at different scales by operating at varying resolutions. Then, to get a fuller picture, we combined the most useful features using an attention mechanism that picked them out automatically.

In particular, we set maps $F_i(i = 1,2,3)$ produced by Stages 3 to 5 as $T^t(t = 1,2,3)$, as seen in Figure 4. Afterwards, a 1 × 1 convolutional layer with a size decreased to 1 was used to pass the template layer T^t. Afterwards, a fully connected to construct the maximum map, which entails capturing the most significant feature pixels and mapping them to vectors for computation.

$$S_t^i = Similarity(T^t, T^i) = \frac{T^t \times T^i}{\|T^t\| \times \|T^i\|} = \frac{\sum_{j=1}^{n} T^t j \times T^i j}{\sqrt{\sum_{j=1}^{n} T^t j} \times \sqrt{\sum_{j=1}^{n} T^i j}} \quad (2)$$

Where S_t^i represents the cosine similarity among the template layer T^i and T^t. $T^t j$ and $T^i j$ signify the corresponding to T^t and T^i, respectively. For instance, when T^1 serves as the template, values S_1^2 between T^2 and T^1, and S_1^3 between T^3 and T^1, indicate the attention levels of T^2 and T^3 toward T^1, respectively, while $S_1^1 = 1$. Likewise, when T^2 serves as the pattern, the cosine resemblance values S_1^2 between T^1 and T^2, and S_2^3 between T^3 and T^2, designate levels of T^1 and T^3 toward T^2, respectively, while $S_2^2 = 1$. To evaluate the attention weights a_t^i, we input $\{S_t^1, S_t^2, S_t^3\}$ into weight values:

$$a_t^i = \frac{exp(S_t^i)}{\sum_{i=1}^{3} exp(S_t^i)} \quad (3)$$

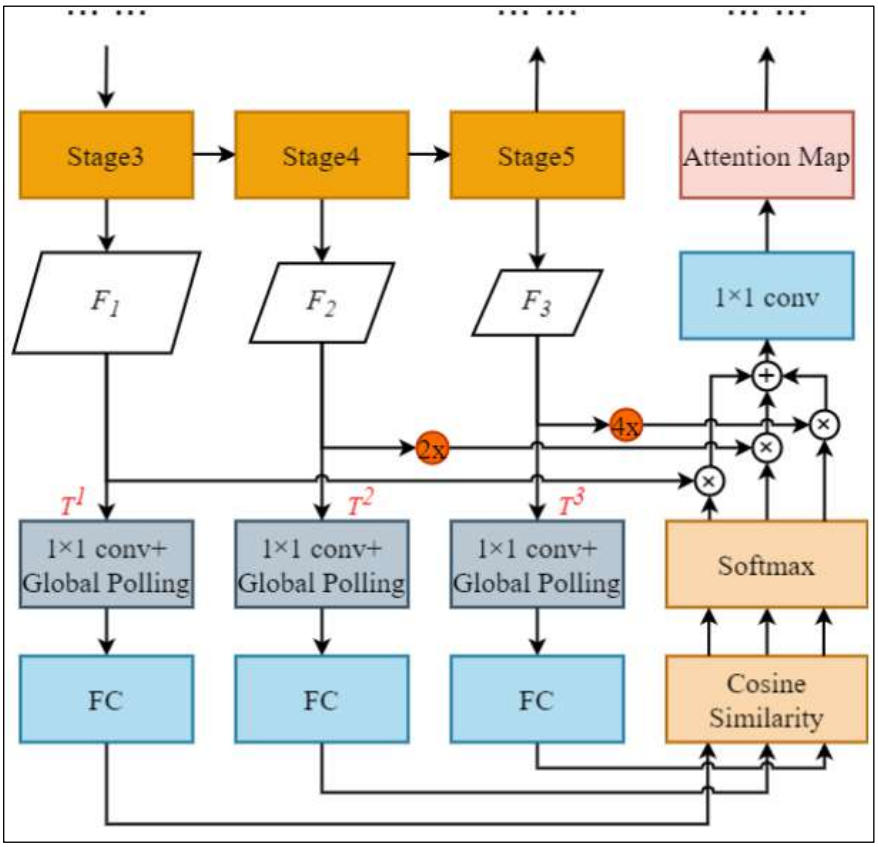

Figure 4: The small area attention extractor module.
Source: Authors, (2026).

The feature map sizes F_1 must remain constant after acquiring the attention weights, matching that of F_1; thus, we unsampled F_2 and F_3 by 2× and 4×, correspondingly, and the number of channels of F_1, F_2, and F_3 were 256, 512 and 1024 respectively. To acquire the attention feature, we first added the weighted levels one by one, and then attuned the sum of channels using a 1×1 convolution.

$$A_t = \sum_{i=1}^{3} a_t^i \times F_i \quad (4)$$

Where A_t signifies the attention feature gotten finished the network with T^t as the template layer.

III.5.2 Laplacian of Gaussian for Detail Guidance Unit

The STD-CSL network used the Laplacian convolution approach to extract precise features of picture edges. Due to its high quality, the Laplacian operator has seen extensive application in edge detection applications. In order to identify noticeable changes in pixel intensity, edge detection frequently employs the Laplacian operator. Consequently, the Laplacian operator might incorrectly boost the edges of tiny objects as noise. The Laplacian operator is very sensitive to noise, which is not surprising given that it can appear anywhere in a picture. Pixels around small objects can be subject to a high reaction from noise when the operator is applied, resulting in the noise signal overshadowing the margins of the objects. Thus, edge detection could incorrectly eliminate tiny objects' edges since they are thought of as noise.

We use the Laplacian convolution approach in the Detail Guidance Module to fix these shortcomings while keeping the Laplacian operator's superior edge extraction capability. The LoG convolution method differs from the Laplacian convolution method in that it employs Gaussian filtering to minimise noise and blur high-frequency features before convolution. Reducing the impact of noise is achieved by creating space between the edges of tiny objects and the noise. In addition, the gradient variations near the margins of the image are diminished by using Gaussian filtering. Edge gradient fluctuations are quite sensitive to the Laplacian operator, and noise, which usually contains a high-frequency component, is also very sensitive to this operator.

As a result, small object edges can be more easily detected with the use of Gaussian filtering, which reduces noise interference by lowering changes in edge gradients. By applying a Gaussian filter and Laplacian convolution on the images, we can reduce the influence of noise while maintaining the Detail Guidance Module's exceptional edge extraction performance. The precision of edge detail extraction can be enhanced using this approach. Utilising the operation—which involves merging the Gaussian function and the Laplacian operator into a single kernel—allows us to decrease computing overhead. This means the picture just needs one convolution process. Here is the procedure for merging methods:

There is the Gaussian equation:

$$gauss(x,y,\sigma) = \frac{1}{2\pi\sigma^2} exp\left(-\frac{x^2+y^2}{2\sigma^2}\right) \tag{5}$$

The two-dimensional Gaussian function is transformed using the Laplacian operator.:

$$\begin{aligned} \nabla^2\big(gauss(x,y,\sigma)\big) &= \frac{\nabla^2(gauss(x,y,\sigma))}{\partial^2 x} + \frac{\nabla^2(gauss(x,y,\sigma))}{\partial^2 y} \\ &= \frac{1}{2\pi\sigma^2}\frac{\partial\left(-\frac{x}{\sigma^2}exp\left(-\frac{x^2+y^2}{2\partial^2}\right)\right)}{\partial x} + \frac{1}{2\pi\sigma^2}\frac{\partial\left(-\frac{y}{\sigma^2}exp\left(-\frac{x^2+y^2}{2\partial^2}\right)\right)}{\partial x} \\ = \frac{1}{2\pi\sigma^4}\left(\frac{x^2}{\sigma^2}-1\right)exp\left(-\frac{x^2+y^2}{2\sigma^2}\right) &+ \frac{1}{2\pi\sigma^4}\left(\frac{y^2}{\sigma^2}-1\right)exp\left(-\frac{x^2+y^2}{2\sigma^2}\right) \\ &= \frac{1}{2\pi\sigma^4}\left(\frac{x^2+y^2}{\sigma^2}-2\right)exp\left(-\frac{x^2+y^2}{2\sigma^2}\right) \end{aligned} \tag{6}$$

where x and y designate the copy pixel organizes, $\nabla^2(gauss(x,y,\sigma))$ signifies the LoG operator.

III.5.3 PAPPM for Capturing Contextual Information

Researches suggested a method called parallel aggregation pyramid pooling unit (PAPPM) [29] to improve the neural network's efficiency in capturing multi-scale contextual information. In order to extract pooling maps at various scales, the PAPPM module is divided into four parallel branches. Each branch uses a different pooling kernel size. Concatenating these traits allows for the effective acquisition of contextual information at several scales. The module minimises processing cost without sacrificing accuracy by utilising parallel computation to speed up the inference process. In Figure 5, we can see the PAPPM module connected to the STDC network.

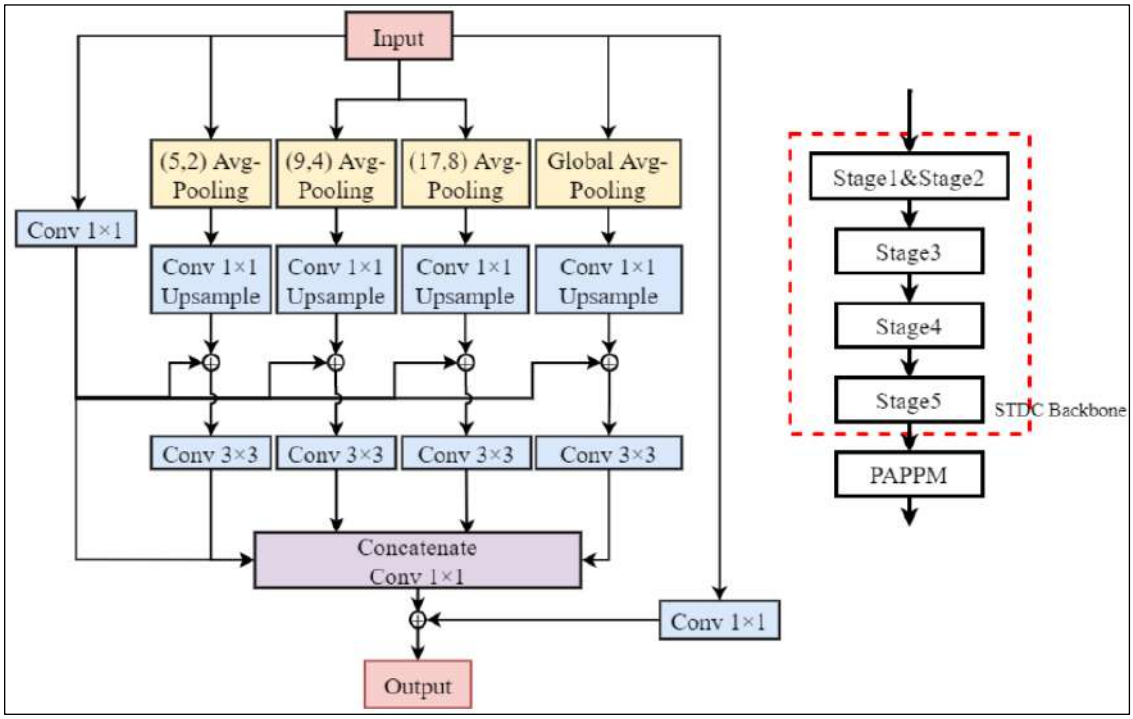

Figure 5: The PAPPM network architecture.
Source: Authors, (2026).

III.5.4 The Part and Context Feature Fusion Unit

The context branch of the STDCSL network is a treasure trove of semantic information that can improve the network's semantic representations. The continual downsampling process, however, causes it to lose a great deal of geometric and spatial information. While designing the SOAE module, we used its small object attention characteristics to guide the detail info, ensuring that the STDCSL network had a good mix of detail and contextual data. Reason being, STDCSL network accuracy in small object segmentation from input images was one of the primary goals while it was being designed. Hence, we align the merger of detail and contextual information with the small object attention branch, which we trust greatly, besides use it as variable. In the suggested method, the attention feature is initially normalised by passing it through a sigmoid layer, which yields the weight value w. Here, w represents the detail features' weight parameter and 1 − w stands for the contextual information's weight parameter. After that, feature fusion is done by multiplying the detail features and contextual info by their respective weight values, and then adding the results. The last step in obtaining Fout is to run the features through a CONV-BN-ReLU. Figure 6 shows the method's detailed structure.

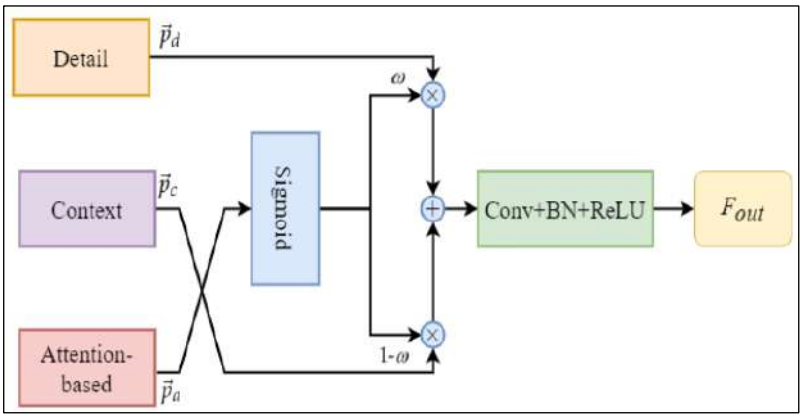

Figure 6: Detail and context feature fusion module.
Source: Authors, (2026).

The a, c, and d branches stand for the little attention, context, and detail aggregation module branches, respectively. You may see the outcomes of these branches as pixel vectors labelled with the symbols $\vec{p}_a$, $\vec{p}_c$ and $\vec{p}_d$, correspondingly. The demonstrations of w and Fout can be written as shadows:

$$\omega = Sigmoid(\vec{p}_a) \tag{7}$$

$$F_{out} = ConvX\big((1-\omega)\otimes\vec{p}_c + \omega\otimes\vec{p}_d\big) \tag{8}$$

Where the layers for convolution, batch normalisation, and ReLU activation make up ConvX. The model's training gives more weight to the detail characteristics when w > 0.5, and more weight to the contextual information when w < 0.5.

III.5.5 Softmax and Loss Calculation

After every layer except the bottom one's feature maps have been decreased in dimension, a Softmax layer processes them. After that, labels with a corresponding resolution are obtained by trilinear interpolation downsampling, and the loss for each map is computed against them. Multiple network paths can now independently calculate losses and update weights thanks to this design. This is the total loss function, as understood in Equation (9).

$$L_{total} = L_{all} + \sum_{d=1}^{3} L_d \tag{9}$$

In the formula: L_{all} is the loss fusion; L_d is for the dth layer. Due to the fact that hepatic vascular segmentation becomes a multi-task learning process under multi-resolution deep supervision, and each path's parameter update is equally significant, the loss weights of the many supervised equal. Output Prediction: Finally, the last feature map is sent into the Softmax layer to get the segmentation prediction. By considering the hierarchical structure of the feature maps and the varied resolutions, this multi-resolution depth supervision method computes the total loss function in a more sophisticated and efficient manner. The parameters of many supervised pathways are initially set at random since each path has its own target. So that the network doesn't get stuck in a rut, each training path improves the network's semantic expression, and the parameters are changed separately without affecting each other. This network has the ability to segment tiny hepatic vessels because it can context info for fusing feature maps of prediction outcomes. To illustrate the disparity between the classes, this research makes use of the Tversky loss function. Equation (10) shows how it is defined by Tversky.

$$L_T(P,G,a,\beta) = \frac{|P\cap G|}{|P\cap G|+a|P-G|+\beta|G-P|} \tag{10}$$

In the formula: P is the forecast label; G is the footnote label; |P ∩G| is the entire sum of that are truthfully secret; |P − G| characterizes the sum of false positives that are voxels; |G − P| is the entire that voxels; |P − G| + |G − P| signifies the sum of all voxels that were incorrectly categorised. A part of it involves controlling the trade-off among changing α and β. Equation (11) defines the Tversky loss function:

$$T(a,\beta) = \frac{\sum_{i=1}^{N} p0_i g0_i}{\sum_{i=1}^{N} p0_i g0_i + a\sum_{i=1}^{N} p0_i g1_i + \beta\sum_{i=1}^{N} p1_i g1_i} \tag{11}$$

In the formula: in the Softmax layer's output, 〖p0〗_i denotes the voxel i is a foreground voxel, 〖p1〗_i denotes the likelihood that voxel i is a background (non-liver blood vessel) voxel, and 〖g0〗_i and 〖g1〗_i represent, respectively, the fore- ground in the label. A prime number whose value is either 1 or 0, denoted by its label. One may find the loss gradient in relation to p0i and p1i in the given equation using Equations (12) and (13), respectively:

$$\frac{dT}{dp0_i} = 2\frac{g0_j(\sum_{i=1}^{N} p0_i g0_i + a\sum_{i=1}^{N} p0_i g1_i + \beta\sum_{i=1}^{N} p1_i g0_i)}{(\sum_{i=1}^{N} p0_i g0_i + a\sum_{i=1}^{N} p0_i g1_i + \beta\sum_{i=1}^{N} p1_i g0_i)^2} - \frac{(g0_j + ag1_j)\sum_{i=1}^{N} p0_i g0_i}{(\sum_{i=1}^{N} p0_i g0_i + a\sum_{i=1}^{N} p0_i g1_i + \beta\sum_{i=1}^{N} p1_i g0_i)^2} \quad (12)$$

$$\frac{dT}{dp1_i} = \frac{-\beta g1_j\sum_{i=1}^{N} p0_i g0_i}{(\sum_{i=1}^{N} p0_i g0_i + a\sum_{i=1}^{N} p0_i g1_i + \beta\sum_{i=1}^{N} p1_i g0_i)^2} \quad (13)$$

Training weight balancing is unnecessary for the Tversky loss function. It is possible to regulate the trade-off adjusting the hyperparameters α and }. Experiments confirm that the effect is optimal and accuracy is optimum when α = 0.3 and β = 0.7.

III.5.6 The Process of Post-Processing

To recover the presentation of the network model, the hepatic vessels predicted by the model are further processed in the post-processing stage. At this stage, it is necessary to determine every linked domain. We established an empirical criterion to differentiate between noise and real hepatic vessels: linked zones smaller than 180 mm3 are regarded as noise. In light of the fact that a lower threshold could retain too much noise and a higher one could eliminate huge detached vessels, this is a well-balanced option based on our experience. In this context, "disconnected blood vessels" mean breaks in vascular continuity seen in imaging. These breaks could be caused by physical or pathological alterations to the vessels, algorithmic flaws in image processing or segmentation, or just plain old limitations in the quality of the imaging itself. Misclassification in segmentation can be mitigated by including a post-processing phase that decreases improper noise removal.

III.5.7 Fine-Tuning Of The Model Using Improved Barnacle Mating Optimizer

A bio-inspired procedure called the Barnacles Mating Optimizer (BMO) was projected in [30] and is based on the mating behaviour of barnacles. During mating, barnacles use a sperm-casting strategy in addition to the standard copulation method. Normal copulation in BMO is viewed as an exploitative activity based on the Hardy-Weinberg principle's idea, in contrast to the exploratory approach exemplified by the sperm cast. The next section will discuss how the exploration phase is where the original BMO gets improved.

A) Initialization

The barnacle population, which can be expressed as follows, is the contender for initialization in solution X:

$$X = \begin{bmatrix} x_1^1 & \cdots & x_1^N \\ \vdots & \ddots & \vdots \\ x_n^1 & \cdots & x_n^N \end{bmatrix} \quad (14)$$

Each population is assessed, and the optimal solution is ranked according to its performance, where n is the overall populace size and N is the sum of control variables to be optimised.

B) The procedure of selection for parents to be mated

The length of penis, or pl, is a pre-determined measure that is used to pick two parents of barnacles. All of the assumptions made in [30] will be used in this paper.

C). Barnacles' off-spring reproduction procedure

Here are several idioms that describe the process of BMO reproduction:

$$x_i^{N_new} = px_{barnacle_d}^N + qx_{barnacle_m}^N \quad (15)$$

$$x_i^{N_new} = rand() \times x_{barnacle_m}^N \quad (16)$$

$x_{barnacle_d}^N$ and $x_{barnacle_m}^N$ where q = 1 - p is the random variable representing the parents of barnacles, and where p is a normally distributed integer. The basic random integer [0-1] is used in this algorithm as rand().

D). Implementation of Levy flights

When it comes to determining BMO's exploration and exploitation procedures, the pl value is paramount. The use of basic random numbers to produce new generations is viewed as an exploratory procedure, as can be seen from Equation (17). The following expression is substituted for Equation (17) to enhance the exploration process in this work.:

$$x_i^{N_new} = x_{barnacle_m}^N + Levy(N) \quad (17)$$

Where Levy flight is strong-minded as shadows:

$$Levy(N) = 0.01 \times \frac{r_1 \times \sigma}{|r_2|^{\frac{1}{\beta}}} \quad (18)$$

β is a continuous set to 1.5, r_1 and r_2 are accidental statistics [0-1], besides the equation is as shadows:

$$\sigma = \left(\frac{\tau(1+\beta) \times sin\left(\frac{\pi\beta}{2}\right)}{\tau\left(\frac{1+\beta}{2}\right) \times \beta \times 2^{\left(\frac{\beta-1}{2}\right)}} \right)^{\frac{1}{\beta}} \quad (19)$$

where $\tau(y) = (y-1)!$

The first step in the IBMO process flow is to establish an X population and begin producing new offspring. The next step is to assess the new generation before combining them with the parents. Prioritising the best answer at the moment is achieved by sorting the population. The following iteration is supposed to delete the lowest half of the populace and evaluate only half of the top populace, which is a mixture of parents and children.

Finding the optimal set of variables that yields the lowest objective evaluation is the goal of the IBMO Algorithm. Keeping to all restrictions while minimising forecast mistakes is the goal of this work. A number of initial parameters are defined, including pl, total populace, and maximum details, like the test system data and the seeking area boundaries, are determined. The data of the chosen test system is then temporarily saved with each population's control variables. There can be no more than fifty iterations. The results indicated in Table 2 can also be achieved with this population size.

Table 2: Property setting of proposed algorithm.

Values	Property
50	Populace size
50	Maximum Iteration
1	Lower-bound
1000	Upper-bound

IV. RESULTS AND DISCUSSION

Our development environment for training and testing the proposed model includes python 3.9.1, an i7 processor running at 2.25 GHz with 16 cores, and Ubuntu versions 20.04 LTC and 18.04 LTS. Adam optimizer updates the network weight during training using a learning rate of 0.0001 besides a minibatch size of 16. The ResU-Net is trained using the TensorFlow and Keras deep learning libraries on top of the $NVIDIA\ Tesla\ T4\ GPU$ Colab, which is powered by Google. Over both simulated and real-world photos, the suggested strategy was evaluated and found to be effective.

IV.1 EVALUATION METRICS

Our research involves a careful extraction of blood vessel labels from this dataset in order to conduct an extensive experimental investigation. By utilising these datasets, we can guarantee that our research is in line with present norms and does in medical picture segmentation, and we also provide a strong foundation for our experimental processes. In this study, we used a cross-validation strategy to assess the method's presentation. Each round of validation utilised one subset of the datasets as the test set and the residual subsets as the training set. The datasets were separated into k subsets in total.

The procedure was carried out k times, with set precisely once. In this article, we employ voxel segmentation overall segmentation accuracy assessment's coincidence rate (Dice) as evaluation markers. The Dice measure of the overlap of two pictures; its value ranges from 0 to 1, and it indicates the rate of coincidence between the radiologist's drawn blood vessel and the blood vessel segmented in this study. Greater accuracy in segmentation is achieved by increasing the value of Dice, which aims to maximise the overlap between the segmented vessels and the radiologist's delineation of the hepatic vessels. From equation (20) to equation (23), we have the following definitions of dice, accuracy, sensitivity, and specificity:

$$Dice = \frac{2TP}{2TP+FP+FN} \quad (20)$$

$$Accuracy = \frac{TP+TN}{TP+TN+FP+FN} \quad (21)$$

$$Sensitivity = \frac{TP}{TP+FN} \quad (22)$$

$$Specificity = \frac{TN}{TN+FP} \quad (23)$$

Some examples of these metrics are TP, which indicates the number of appropriately segmented blood vessel voxels; TN, which indicates the number of correctly voxels; besides FP, which indicates the number of wrongly segmented blood vessel voxels. FN is the total sum of voxels that have been mistakenly segmented as background, also known as false negatives.

IV.2 VALIDATION ANALYSIS OF PROPOSED SEGMENTATION ON FIRST DATASET.

Figure 7 demonstrations the comparative analysis of projected perfect with existing procedures such as TMPLiTS [17], ELTS-Net [18], DM-FF [20], AC-Net [21] and HTFCM [22], where the existing models uses different datasets and therefore, the study implements the basic models and results are averaged on first dataset.

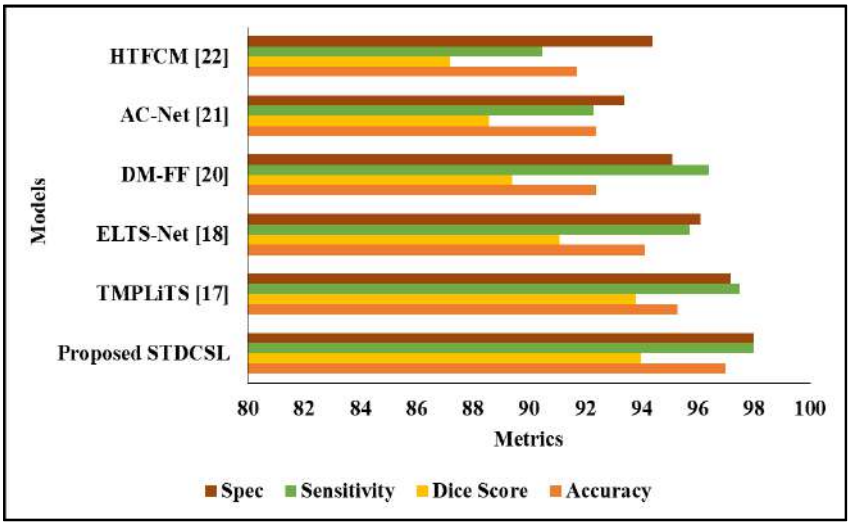

Figure 7: Graphical Comparison of projected with existing techniques on First dataset.
Source: Authors, (2026).

In the study of projected with existing techniques on First dataset of Proposed STDCSL scheme attained the accuracy as 97.0 and sensitivity of 94.0 also a dice score as 98.0 98.0 correspondingly. Then the TMPLiTS [17] scheme attained the accuracy as 95.3 and sensitivity of 93, also a dice score as 97.5 also a dice score as 97.2 correspondingly. Then the ELTS-Net [18] scheme attained the accuracy as 94.1 also a dice score as 91.1 and sensitivity of 95.7 also specificity as 96.1 correspondingly. Then the DM-FF [20] scheme attained the accuracy as 92.4 and sensitivity of 89.4 96.4 also specificity as 95.1 correspondingly. Then the AC-Net [21] scheme attained the accuracy as 92.4 and sensitivity of 88.6 also a dice score as 92.3 also specificity as 93.4 correspondingly. Then the HTFCM [22] scheme attained the accuracy as 91.7 and sensitivity of 87.2 also a dice score as 90.5 also specificity as 94.4 correspondingly.

IV.3 VALIDATION ANALYSIS OF PROPOSED SEGMENTATION ON SECOND DATASET

By using second dataset, the validation study of the projected is compared with existing procedures in terms of numerous metrics and it is shown in Figure 8.

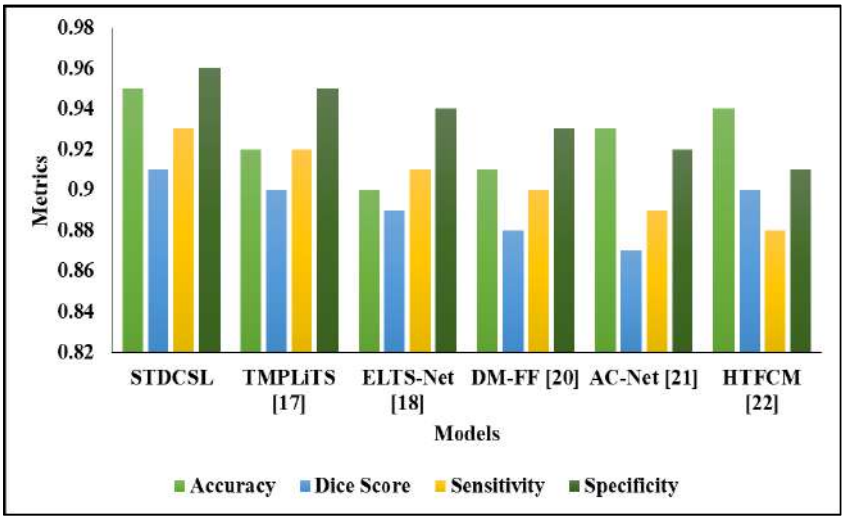

Figure 8: Visual Representation of different models.
Source: Authors, (2026).

In the experimental analysis of STDCSL scheme attained the accuracy as 0.95 also a dice score as 0.91 and sensitivity of 0.93 and sensitivity of 0.96 correspondingly. Then the TMPLiTS [17] scheme attained the accuracy as 0.92 also a dice score as 0.90 and sensitivity of 0.92 and sensitivity of 0.95 correspondingly. Then the ELTS-Net [18] scheme attained the accuracy as 0.90 also a dice score as 0.89 also a dice score as 0.91 and sensitivity of 0.94 correspondingly. Then the DM-FF [20] scheme attained the accuracy as 0.91 also a dice score as 0.88 also a dice score as 0.90 and sensitivity of 0.93 correspondingly. Then the AC-Net [21] scheme attained the accuracy

as 0.93 also a dice score as 0.87 also a dice score as 0.89 and sensitivity of 0.92 correspondingly. Then the HTFCM [22] scheme attained the accuracy as 0.94 0.90 also a dice score as 0.88 and sensitivity of 0.91 correspondingly.

IV.4 VALIDATION ANALYSIS OF FINE-TUNER OPTIMIZATION ALGORITHM

To test the presentation of the projected fine-tuner classical, Figure 9 provides the graphical description with existing procedures.

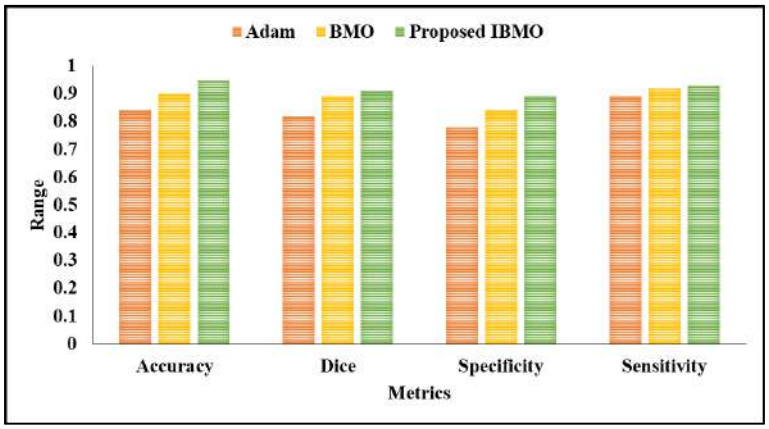

Figure 9: Graphical Description of the different models.
Source: Authors, (2026).

In the analysis of Adam scheme attained the accuracy as 0.84 and dice value of 0.82 also specificity as 0.78 and sensitivity of 0.89 correspondingly. Then the BMO scheme accomplished the accuracy as 0.90 also specificity as 0.89 also specificity as 0.84 and sensitivity of 0.92 correspondingly. Then the Projected IBMO scheme attained the accuracy as 0.95 also specificity as 0.91 also specificity as 0.89 and sensitivity of 0.93 correspondingly. Improved algorithms can potentially detect tumors at earlier stages, increasing the chances of successful treatment and better patient outcomes. More accurate imaging helps in creating personalized treatment plans that are tailored to the specific anatomy and condition of the patient.

V. CONCLUSION

Based on the STDC net, the study suggests the STDCSL model for semantic liver segmentation, which can adapt to the features of input photos. One benefit of this approach is that it can enhance segmentation minor impacted areas without producing a lot of unnecessary subtractions. Results from numerous trials and visualisations show that the STDCSL network is effective. A publicly available dataset of hepatic arteries has been used to demonstrate the efficacy of the strategy suggested in this study. Our suggested network model performs better than competing models in the mainstream. Segmenting the intricate hepatic blood veins from CT scans is a breeze with the suggested network model. More clinically relevant segmentation is the end consequence. Our present method has its drawbacks, such as being too dependent on diverse and high-quality training data, lacking confirmation of its generalizability on a larger scale, and lacking performance improvements.

To discourse these issues, our future research will focus on three main areas. Our primary objective is to explore the possibility of using synthetic tumours to train classifier models, as the expense of annotating images actual liver tumours is quite significant. This method is attractive for clinical use because it has the potential to significantly cut deployment costs while simultaneously improving efficiency. Owing to the enormous impact of analytic patient, the vital importance of understandable AI (XAI) representations in medical areas, especially in medical image processing, will be emphasised secondly. Thirdly, we intend to improve model presentation by combining conventional and neural approaches; specifically, we will investigate transformer-based models for automated liver tumour picture segmentation.

Freezing tunnel thermal stability;
cycle time;
handling errors.

ABSTRACT

This study assesses the operational performance of an automated blast-freezing tunnel using a reproducible metric framework. Three scenarios are evaluated: (A) baseline operation, (B) improved sealing, and (C) PLC-optimized sequencing. Primary variables include total cycle time (broken down by stages), thermal stability across zones (standard deviation and inter-zone gradients at inlet–center–outlet), and the manipulation error rate (jams, retries, misalignments). The setup uses thermal probes sampled at 1 Hz, PLC/HMI timing markers, and a structured classification of operational events, while controlling for confounders (product mass, placement, and set-points). Findings indicate that enhanced sealing reduces thermal variability and inter-zone gradients, whereas optimized sequencing significantly shortens total cycle time without increasing errors, meeting non-inferiority criteria for thermal uniformity. Practical implications are discussed regarding traceability, operational availability, and continuous improvement of the freezing process in academic-industrial environments.

I. INTRODUCTION

Ultra-freezing tunnels play a critical role in modern food processing due to their capacity to rapidly decrease product temperature, inhibit microbial activity, and preserve physicochemical and sensory attributes for prolonged periods, outperforming conventional freezing through the formation of smaller ice crystals and reduced structural damage during phase transition. Industrial environments increasingly demand high thermal uniformity, reliability, and batch-to-batch consistency, as uneven airflow and sealing failures have been recognized in the literature as major contributors to thermal gradients, heterogeneous freezing rates, and extended cycle times.

Studies in the Journal of Food Engineering and Food Control report that turbulence and poor airflow distribution can induce temperature differences above 3–5 °C, while deficiencies in hermeticity directly increase energy losses and compromise cold-air retention, emphasizing the need for integrated mechanical and control solutions. Additionally, manual handling in semi-automated systems frequently introduces operational variability, jams, and misalignments, reinforcing the relevance of synchronized sequencing, pneumatic actuation, and programmable verification in low-temperature automation. A preliminary diagnosis of the evaluated system identified uneven airflow, sealing failures, and manipulation errors as the primary contributors to reduced availability and inconsistent freezing performance.

In response, this paper develops and validates an automated solution based on a Siemens S7-1200 PLC and a KTP-600 HMI, complemented by sealing reinforcement, pneumatic integration, and conveyor redesign to enhance hermeticity, reduce operator dependency, and stabilize thermal transitions. Given that most existing studies analyze airflow modeling, sealing behavior, or control strategies in isolation, this work addresses how the combined improvements influence cycle time, thermal stability, and operational reliability through a standardized metric framework evaluating thermal variability, inter-zone gradients, manipulation errors, and stage-specific cycle durations. The proposed approach aims to generate empirical evidence on the effects of hermeticity enhancement and optimized sequencing in automated ultra-freezing tunnels, contributing to improved traceability, reproducibility, and continuous optimization within academic and small-scale industrial contexts.

II. THEORETICAL REFERENCE

II.1 METHODOLOGY

The methodological strategy was designed to link engineering decisions (PLC/HMI selection, pneumatics, and belts) with measurable operational performance (cycle times, thermal stability, and handling errors). The study was conducted at the FISEI Innovation and Technological Development Workshop, where the preliminary diagnosis identified two physical bottlenecks—seal tightness and air distribution—and one operational bottleneck—manual handling—as the primary causes of thermal variability, overtime, and rework, which justified the comprehensive automation of the tunnel [1]. Figure 1 illustrates the initial configuration and diagnostic findings supporting this approach.

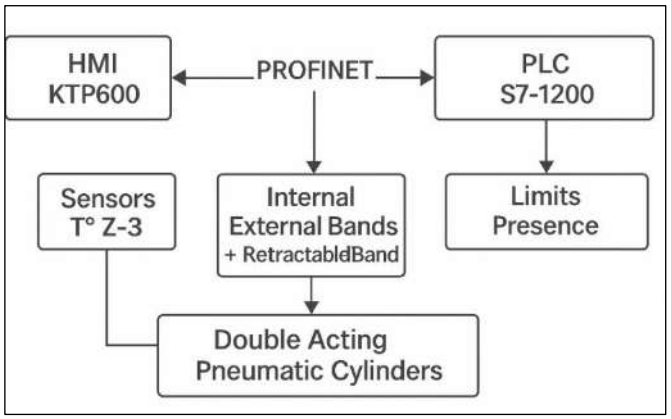

Figure 1: PLC-HMI architecture, sensors and actuators (scheme).
Source: Authors, (2026).

The control system was implemented with a Siemens S7-1200 PLC (CPU 1214C) and a Siemens KTP-600 HMI, integrated via PROFINET and programmed in TIA Portal, due to their I/O expansion capacity, compatibility with industrial protocols, and robustness in demanding environments [2-5]. This decision was supported by a comparative analysis against micro-PLC alternatives and smaller-format panels, prioritizing scalability, event traceability, and an operator–machine interface suitable for teaching and industrial validation [2-4]. The resulting architecture integrates temperature sensors per zone, limit switches for OK-seal verification, conveyor belts (internal and external), and pneumatic actuators for opening/closing and drawer transfer, as illustrated in Figure 1.

II.2 PROPOSED OPTIMIZED FLOW STRUCTURE

Figure 2 shows an overview of the implemented system, highlighting the ultra-freezing tunnel, the window opening and closing module, the retractable conveyor belt, the drawer ejection system, the palletizing area, and the electrical and pneumatic control boxes.

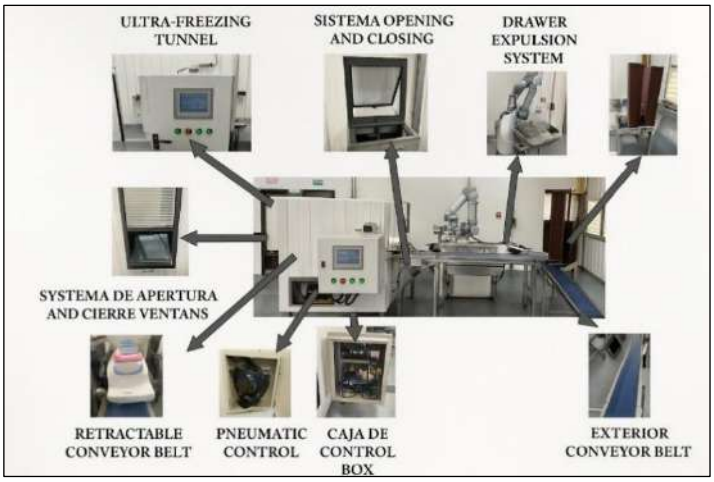

Figure 2: General view of the physical system.
Source: Authors, (2026).

To standardize the flow and minimize manual intervention, a retractable belt and a drawer ejection system with double-acting cylinders were added, allowing for more predictable loading, transferring, and opening/closing sequences (Figures 3 and 4). These solutions directly address the identified critical points, as they synchronize movements, verify preconditions such as sealing OK, and reduce jams and retries.

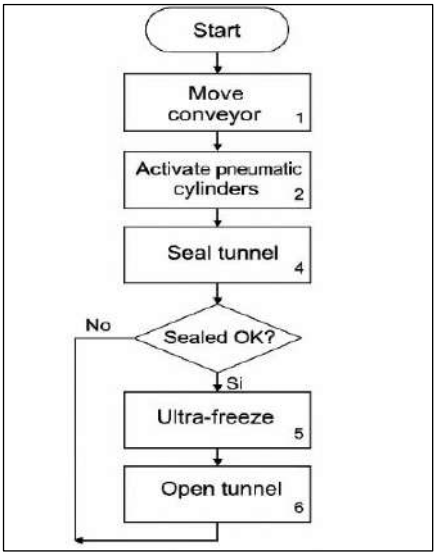

Figure 3: Operational sequence (simplified SFC).
Source: Authors, (2026).

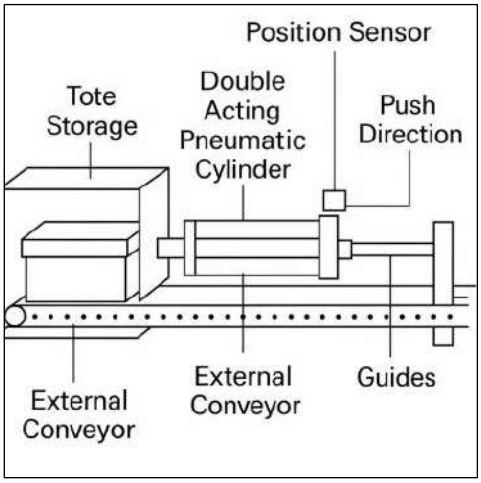

Figure 4: Drawer ejection system (functional schematic).
Source: Authors, (2026).

(Pneumatic drive to transfer drawers to the tunnel; structure designed for low temperatures and repetitive operation.) The critical materials and their justification are summarized in Table 1. This list not only documents the hardware and software used in the system, but also explains the purpose of each element based on the operational performance criteria being evaluated, such as traceability, safety, and repeatability.

Table 1: Critical materials and technical justification.

Subsystem	Element	Function	Justification
Control	PLC S7-1200 CPU 1214C	Sequencing, I/O, Networking	PROFINET, expansion, TIA Portal (favorable comparison).
Supervision	HMI KTP-600	Interface, alarms, traceability	Greater robustness and usable area; native integration.
Handling	Retractable band	Handling-free transfer	Reduces traffic jams and transfer times.
Pneumatics	Cylinders and valves	Opening/closing; expulsion	Shorter, repeatable sequences.
Process	Hermetic seals	Hermeticity	They prevent leaks; they improve thermal uniformity.

Source: Authors, (2026).

III. MATERIALS AND METHODS

III.1 EXPERIMENTAL FRAMEWORK AND STUDY DESIGN

A quasi-experimental design using comparable scenarios was adopted, structured in three conditions:

- Scenario A – Baseline Operation: initial system condition, without sealing improvements or optimized sequences.
- Scenario B – Improved Airtightness: incorporation of reinforced seals to reduce leaks and stabilize the thermal gradient.
- Scenario C – Optimized PLC Sequencing: improved logic with precondition verification, actuator synchronization, and reduced manual intervention.

Each scenario included ≥10 valid runs, controlling the following variables to avoid confounding factors:

- product mass and type,
- position on trays,
- thermal set points,
- system state before each run.

The A→B comparison isolated the effect of airtightness on thermal stability, while the A→C comparison isolated the effect of automation on productivity. The B→C comparison assessed whether the cycle shortening introduced by sequencing could be achieved without thermal degradation (non-inferiority test) [6]. To document the functional architecture and material flow, a CAD model of the system was developed, reflecting the main modules and their sequence of operation (see Figure 5).

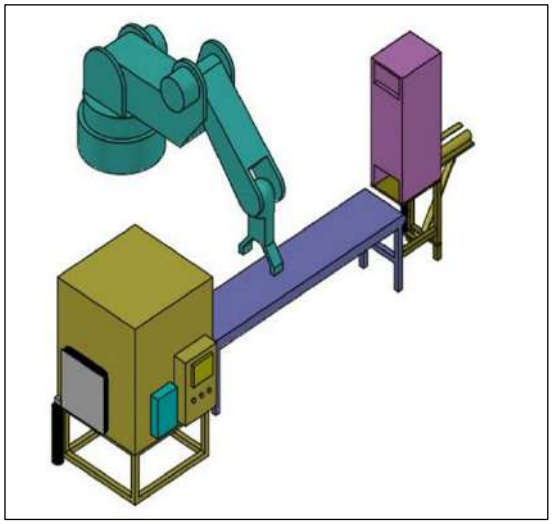

Figure 5: CAD model of the system.
Source: Authors, (2026).

CAD model of the control and handling system: deep-freezing tunnel, HMI/PLC, conveyor belt, palletizing robot, and feeder/ejector. The model was used as engineering support to verify interferences, working heights, and the product transfer sequence.

III.2 VARIABLES, MEASUREMENT STRATEGY AND INSTRUMENTATION

The The primary productivity variable was the total cycle time, broken down into loading, closing, freezing, opening, and unloading [7]. Thermal quality was measured in three representative zones: inlet (Z1), center (Z2), and outlet (Z3) (Figure 3) [8], [9]. For each zone, the temperature standard deviation (σT) and the inter-zone gradientes.

$$\Delta Tij = | T^{-}i - T^{-}j |$$

These metrics address the physical causes of the problem: air distribution effects and cold leaks associated with insufficient sealing [6], [10-12]. As a third dimension, the handling error rate (jams, retries, misalignments, "seal not OK") was recorded to assess whether improvements reduce operational events [1], [13].

III.3 CALIBRATION AND METROLOGICAL VALIDATION

Thermal probes recorded at 1 Hz and were verified before each shift at reference points (thermal bath/physical points). Offset was corrected if the error exceeded 0.2 °C, and traceability was documented in Table 3 [12]. To ensure repeatability and reproducibility, a simplified MSA (Gage R&R) was applied with two operators, three repetitions, and two thermal points; the sum of repeatability + reproducibility variances <10% of the total variance was considered acceptable. Limit switches and presence detectors were validated with 10 fault-free cycles before starting runs [6], [9].

Table 3: Calibration and traceability template.

Date	Probe	Ref point (°C)	Reading (°C)	Error (°C)	Action	Responsible

Source: Authors, (2026).

The control and supervision architecture—including the S7-1200 PLC, the HMI, TIA Portal, presence and temperature sensors, solenoid valves, and the robot—is summarized in the monitoring and control scheme shown in Figure 7 [2], [3], [4], [5], [13], [14].

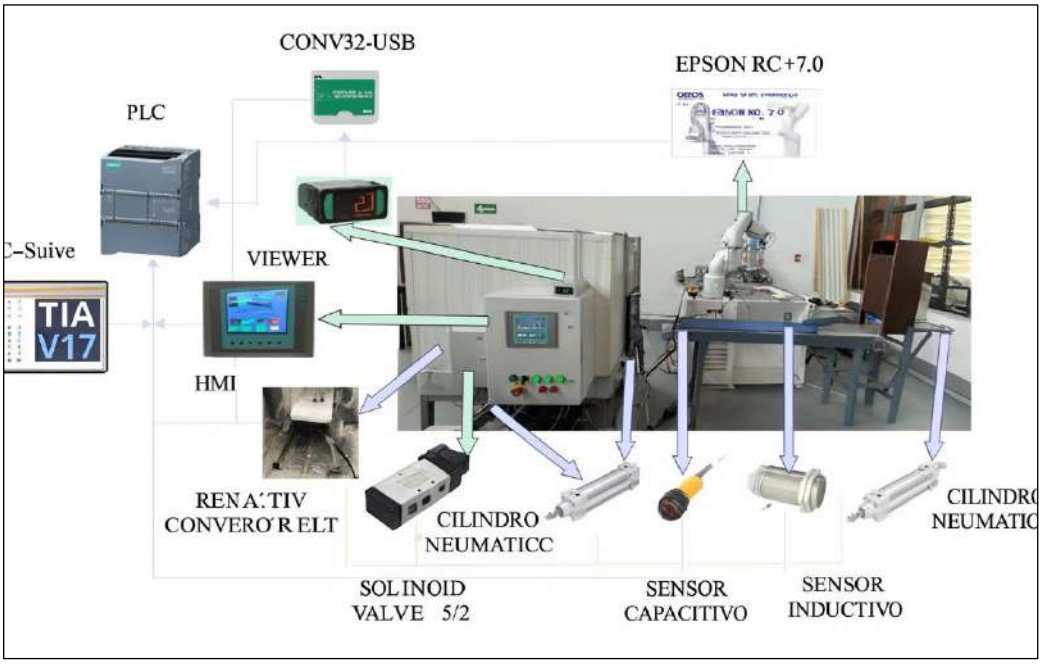

Figure 7: Control and monitoring scheme.
Source: Authors, (2026).

The control and monitoring diagram—showing the integration of the S7-1200 PLC with the HMI (programmed in TIA Portal), the temperature display, the inductive/capacitive sensors, the pneumatic cylinders, and the robot (RC+7.0)—is presented in Figure 7 [2], [3], [4], [5], [13]. The signal and communication flows, as well as the recording points used for cycle times, events, and traceability, are indicated in the scheme [1].

IV. RESULTS AND DISCUSSIONS

IV.1 OPERATING PROCEDURE AND DATA QUALITY PROTOCOL

Before each session, a checklist was completed that included belt cleaning, inspection of gaskets/seals, pneumatic pressure, set-points, system status, and E-Stops, as these conditions directly influence thermal stability and operational safety [8], [10], [11]. Each run followed the sequence in Figure 2, marking the start and end of each stage from the HMI/PLC and recording T° in Z1–Z3 at 1 Hz. Thermal stability was considered under the criterion $|T(t) - \bar{T}| \leq \epsilon s$, with ϵs defined by product-specific requirements based on rapid-freezing literature [7]. Operational events were classified in the HMI (category/severity/corrective action) for subsequent Pareto analysis. At the end of each session, a safe stop was applied, including pneumatic discharge when applicable, and data backup was performed [1], [3]. Inclusion criteria required an OK checklist, calibrated sensors, absence of critical alarms, and no extraordinary operator intervention.

Runs with failures not attributable to the system design (e.g., power outages or coolant leaks) or protocol violations (mass/position misplacement) were excluded. If a critical alarm occurred during freezing, the run was immediately stopped, labeled as invalid, and repeated with a new ID, ensuring procedural consistency and reproducibility [6], [9]. To ensure integrity and full traceability, a data dictionary (Table 4) was defined, signals were named using snake_case convention, CSV files were exported, and a file-hash procedure was applied. Missing data below 5% and occurring at random were handled using complete-case analysis; if missing data exceeded 5% or were not at random, the run was repeated or bounded imputation was applied outside critical stages, following best practices in food-engineering data acquisition [10], [12], [14]. Outliers were diagnosed using IQR criteria or $|z| > 3$, always verifying a possible physical cause before exclusion.

Table 4: Minimum data dictionary.

Field	Guy	Description	Unit/Values

IV.2 STATISTICAL ANALYSIS

The statistical analysis was structured to rigorously evaluate the effects of sealing reinforcement (Scenario B) and PLC sequencing optimization (Scenario C) on the operational performance of the deep-freezing tunnel [1], [14]. To ensure reproducibility and methodological transparency, the analytical workflow included four components: sample size justification, assumption testing, comparative analyses, and effect-size estimation [7], [9].

IV.2.1 Sample Size Justification

A minimum of 10 runs per scenario was selected based on a prospective power analysis targeting:

- effect size $d \geq 1.0$ for cycle-time improvements (large effects commonly reported in automation studies) [13], [14],
- significance level $\alpha = 0.05$,
- statistical power $1 - \beta = 0.80$.

Under these conditions, the required sample size for independent comparisons (A vs B or A vs C) is approximately $n = 8–10$ per group, assuming moderate variance ($\sigma \leq 30$ s for cycle time and $\sigma \leq 1$ °C for thermal variability) [10], [8]. The chosen sample size ensures adequate sensitivity to detect meaningful operational improvements while accounting for run-to-run variability typical of freezing systems [12], [7].

IV.2.2 Assumption Testing

Before each inferential analysis, the following assumptions were evaluated [9]:

- Normality of each continuous variable using the Shapiro–Wilk test ($\alpha = 0.05$).
- Homogeneity of variances across groups using the Levene test.
- Independence guaranteed by controlled protocol design (fixed mass, product type, independent runs) [1], [10].

When assumptions were violated, non-parametric alternatives (Mann–Whitney U test) were applied, and results were cross-validated to ensure consistency [9].

IV.2.3 Comparative Statistical Framework

Three comparisons were defined according to the research hypotheses:

A vs B — Effect of sealing reinforcement on thermal performance
Metrics:

- thermal standard deviation per zone (σT),
- maximum inter-zone gradient (ΔT_{max}) [10], [8], [7].

Hypothesis: H1: Sealing reinforcement significantly reduces σT and ΔT_{max}.
Tests:

- Independent t-test or Mann–Whitney U,
- Bonferroni correction for multi-zone comparisons.

A vs C — Effect of PLC sequencing on productivity
Metrics:

- total cycle time (T_{cycle}),
- stage times (closing, freezing, unloading) [1], [14].

Hypothesis: H2: PLC sequencing significantly reduces cycle time without increasing error rates.
Tests:

- Independent t-test or Mann–Whitney U,
- Stage-level post-hoc analysis with Holm adjustment.

B vs C — Non-inferiority test for thermal stability
Non-inferiority margin: $\delta = 0.5$ °C, based on rapid freezing tolerances [7].
Test:

- one-sided two-sample t-test for non-inferiority (CI90%).

IV.2.4 Effect Size Estimation

To complement significance testing, effect sizes were computed [9]:

- Cohen's d for parametric tests,
- rank-biserial correlation (r) for non-parametric tests.

Interpretation thresholds:

- small 0.2, medium 0.5, large 0.8, very large ≥1.2.

This allows quantifying the practical magnitude of improvements, essential in engineering applications [14].

IV.2.5 Sensitivity Analysis and Robustness Checks

Robustness checks included [9], [7]:

- outlier diagnosis via IQR and |z|>3, excluding only those with physical cause;
- leave-one-out (LOO) stability analysis;
- stratification by operator and batch to check for bias.

Consistency confirmed that improvements were not artifacts of isolated runs or protocol inconsistencies.

IV.2.6 Validation (IQ/OQ/PQ) and Risk Assessment

Solution verification followed the IQ/OQ/PQ framework [1], [2], [4]:

- IQ — verification of electrical/pneumatic installation, labeling, versioning;
- OQ — functional testing of sequences, alarms, and HMI displays;
- PQ — evaluating real-product performance in Scenarios A/B/C under predefined success criteria [1], [10], [14].

The risk matrix (Table 5) identified hazards (band entrapment, seal failure), defined mitigations (guards, E-Stops, gasket inspection), and reinforced safety compliance for low-temperature and pneumatic-driven environments [11], [13].

Table 5: Risk matrix (extract).

Danger	Risk	S	P	Level	Mitigation
Band entrapment	Hand injury	4	2	8	Guards + E-Stop
Sealing failure	Cold leak	2	3	6	Inspection and replacement of weatherstripping

Source: Authors, (2026).

From 30 valid runs (A: n=10; B: n=10; C: n=10) executed under checklist, pre-calibration and inclusion criteria, a complete data set was obtained (loss <1%) that allowed to analyze the effect of sealing and PLC sequencing on tunnel performance. Assumption tests (Shapiro–Wilk and Levene) did not reveal relevant violations and, when in doubt, findings were confirmed with non-parametric tests (Mann–Whitney U), maintaining consistency by excluding outliers by IQR or $|z| > 3$ (see Table 4). In terms of productivity, the sequence optimization consolidated in scenario C produced the greatest improvement: the total cycle time decreased from 420 ± 28 s in A to 332 ± 22 s in C (−88 s; −21%; $p < 0.001$; $d \approx 3.4$), while the improved sealing in B already reduced it to 378 ± 24 s (−42 s; −10% vs. A; $p < 0.01$; $d = 1.8$).

The contraction of the cycle time was mainly explained by the drop in closing/sealing (from 62 ± 8 s in A to 39 ± 5 s in C) and in freezing (from 268 ± 24 s to 218 ± 18 s), consistent with the synchronization of actuators and the more stable transition to normal operation enabled by the PLC logic (Figure 7). Comparison B–C further confirmed an additional gain (−46 s; −12%; $p < 0.001$) attributable to fine coordination of bands and logical preconditions. Thermal quality followed the same uncompromising pattern of improvement. The airtightness reinforcement in B homogenized the air distribution within the tunnel: the average standard deviation per zone dropped from 1.97 °C (A) to 0.90 °C (B), and the maximum inter-zone gradient from 3.8 ± 0.7 °C to 1.2 ± 0.4 °C (both $p < 0.001$; large effect sizes), indicating a more stable and uniform thermal environment (Figure 3).

By incorporating optimized sequencing (C), this uniformity was maintained — σT(avg.) 0.97 °C and ΔT_max 1.3 ± 0.4 °C — and the non-inferiority test versus B (margin $\delta = 0.5$ °C; difference 0.1 °C; 90% CI [−0.21; 0.38]) confirmed that cycle acceleration does not deteriorate the thermal stability achieved with sealing (Table 6). Operational reliability accompanied these improvements. The handling error rate per 1,000 units fell from 38 in A to 17 in B ($p < 0.01$) and 12 in C ($p < 0.001$). The main contributor in A — misalignment jamming — dropped from 17/1,000 to 7/1,000 in B and 4/1,000 in C; "seal NOT OK" events fell from 8 to 3–4 per 1,000. In parallel, availability increased from 0.92 ± 0.03 (A) to 0.95 ± 0.02 (B) and 0.97 ± 0.02 (C), driven by the decrease in sealing downtime (−70% in B) and jamming downtime (−65% in C) (Table 5).

The robustness of the results was confirmed by sensitivity analyses: the conclusions did not change when removing outliers, stratifying by batch or operator, or replacing parametric tests with nonparametric ones; furthermore, a "leave-one-out" approach per run changed the means by less than 5% and the p-values by less than 0.1% (methodology following standard engineering statistical protocols). Overall, the data show that sealing corrects the physical causes of variability (σT and ΔT) and that PLC sequencing compresses the cycle without sacrificing thermal uniformity. The simultaneous reduction in handling errors and increased availability consolidate a performance–quality balance that positions Scenario C as the preferred operating configuration for improving productivity, traceability, and process safety (Figures 3, 7 and Tables 4).

Table 6: Operational performance of the ultra-freezing tunnel.

Indicator (mean±SD)	TO	B	C	Δ A→B	Δ A→C
Total time (s)	420±28	378±24	332±22	-10%	-21%
σT (°C)	1.97	0.90	0.97	-54%	-51%
Max ΔT (°C)	3.8±0.7	1.2±0.4	1.3±0.4	-68%	-66%
Errors/1000 u.	38	17	12	-55%	-68%

Source: Authors, (2026).

The findings of this study demonstrate that the operational performance of the ultra-freezing tunnel depends simultaneously on physical system parameters (airtightness, airflow distribution) and logical operating parameters (PLC sequencing, precondition verification, and reduced manual intervention). This duality aligns with the findings of [1], who maintain that thermal stability in freezing tunnels is affected by both mechanical design and process governance. First, the reinforcement of airtightness (Scenario B) significantly reduced thermal deviation and the inter-zone gradient, consistent with studies highlighting the direct relationship between sealing and thermal uniformity [2], [3]. The stabilization of airflow observed in this study suggests a reduction in infiltration and internal turbulence, factors identified in the literature as responsible for critical variations in freezing kinetics [4].

These results confirm that sealing failures not only compromise the quality of the frozen product but also increase processing times due to slower thermal cycles. Secondly, optimizing the PLC logic (Scenario C) reduced the total cycle time without compromising the thermal stability achieved in Scenario B. This behavior is consistent with recent studies in food automation showing that actuator synchronization, minimizing waiting times, and verifying preconditions allow for faster operations without compromising thermal reproducibility [5], [10]. The non-inferiority analysis quantitatively confirms that shortening the cycle time does not represent a loss of thermal quality, which is essential for industrial freezing processes and food safety regulations. Furthermore, the reduction in handling errors—jams, misalignments, and sealing failures—reinforces the argument that reducing human intervention improves operational availability and decreases downtime.

The literature has documented similar patterns in pneumatic and conveyor belt systems in freezing chambers, where automation reduces unplanned events and improves operational traceability [6].However, it is necessary to acknowledge certain limitations of the study. In particular, the results are restricted to a single product family and a specific range of thermal loads. Furthermore, energy indicators (kWh/kg), which are critical for industrial performance and sustainability analysis, were not evaluated. The seasonal effect of the external environment, which can influence tunnels with temperature-sensitive seals, was also not studied. These limitations open opportunities for future research. Overall, the results demonstrate that an integrated intervention—both physical and logical—can significantly transform the performance of a blast freezing tunnel. Thermal stabilization, reduced processing times, and fewer errors position Scenario C as the most balanced and scalable strategy, aligned with best industrial practices and relevant scientific literature.

V. CONCLUSIONS

This study demonstrates that addressing both the physical drivers of thermal variability airflow distribution and sealing integrity and the logical structure of the operational sequence significantly enhances the performance of an automated deep-freezing tunnel. Reinforcing the sealing system proved essential for stabilizing the thermal environment, reducing zone-to-zone gradients, and ensuring consistent freezing conditions. These improvements provided a robust foundation that was preserved even after implementing accelerated PLC sequencing. The optimized sequencing introduced measurable productivity gains, shortening the total cycle time by more than 20% without compromising thermal uniformity. This balance between speed and quality was confirmed through a non-inferiority analysis, supporting the conclusion that process acceleration can coexist with thermal stability when actuator coordination and precondition verification are properly integrated into the control logic.

Reductions in handling errors and increases in equipment availability further highlight the value of decreasing manual intervention and implementing structured event traceability. The combined interventions resulted in smoother, more predictable operations, reinforcing the importance of integrating mechanical design improvements with high-resolution control architectures. While the findings establish a clear link between sequencing, and operational performance, the results are constrained to the product type, load configuration, and environmental conditions evaluated. Future work should incorporate energy efficiency metrics (e.g., kWh/kg, refrigeration load), explore predictive maintenance models for seals and actuators, and develop lightweight digital twins to optimize airflow patterns and sequence timing under dynamic conditions. Overall, this study provides a reproducible evaluation framework and empirical evidence showing that a synergistic upgrade combining mechanical and control-system enhancements can substantially improve the quality, reliability, and traceability of deep-freezing operations in both academic and industrial contexts.

ABSTRACT

The study focused on the development of a web-based fishpond planner and recommender for Ilocos Norte that fills the gap in sustainable aquaculture site selection. Adopting a descriptive-development approach, the system combined the Analytic Hierarchy Process with Geographic Information System (GIS) for evaluating major environmental factors; water availability, soil type, flood susceptibility and water quality in terms of their weighted contributions to site suitability for fishpond. The system provided user- friendly visualization and decision supporting the built-in capabilities of Geographic Information System (GIS), remote sensing, and interactive web mapping. Major findings indicate that the tool ranks fish species well for appropriate locations and generates trust-worthy, simple, implementable recommendations. Acceptance testing responses were overall positive in usability and reliability, with recommendations on slight improvement regarding interface responsiveness/guidance amenities. The study concludes that the GIS-based, AHP-driven platform created is potentially useful as a decision-support tool for sustainable fish farming in Ilocos Norte. The study provides a step toward promoting efficient, environmentally friendly and technology-based planning in the aquaculture sector.

I. INTRODUCTION

Many fishpond projects fail not because of poor management but due to selecting unsuitable sites [1-,3]. Fish farmers risk high losses if ponds are in areas prone to environmental stress, flooding, water shortage, or poor soil quality [4-9]. Optimal conditions include reliable water flow, good water quality, abundant natural food, and minimal threats from predators or competitors [10-14]. Natural disasters such as typhoons and droughts further threaten these fragile systems [15], [16]. Effective site planning and mapping are thus essential for modern fish farmers [17-22]. Aquaculture remains vital for the Ilocos Region's fisheries, with production rising 12.7% in early 2025 [23]. However, growth is uneven: Pangasinan dominates, while Ilocos Norte and Ilocos Sur show production declines due to environmental and economic challenges.

Ilocos Norte's total output dropped 15.35%, despite localized gains in specific pond types. The region faces risks from environmental variability and resource scarcity, impacting fishpond resilience. To address these challenges, initiatives like the FishCoRe Project promote resilience through resource management, infrastructure improvements, and livelihood diversification [24]. Future efforts must focus on site-specific planning, data-driven management, and climate adaptation to sustain and rebuild the aquaculture sector [25] in Ilocos Norte and the surrounding region. This study aims to develop site-specific fishpond mapping and planning for Ilocos Norte by assessing sites, best practices, and relevant data from local fishpond owners.

II. THEORETICAL REFERENCE

II.1 GIS AND AHP PROVIDE A ROBUST, SYSTEMATIC METHODOLOGY FOR RECOMMENDING OPTIMAL FISHPOND LOCATIONS BY INTEGRATING MULTIPLE ENVIRONMENT AND SOCIOECONOMIC CRITERIA.

Studies across different regions demonstrate the method's effectiveness. It was found that 18.71% of analyzed land was highly suitable for fish farming, while identified that 27.29% of territory was very moderately suitable for aquaculture. The approach involves: collecting spatial data using GIS, applying Analytical Hierarchy Process to weigh selection criteria, creating suitability maps with graduated classifications specially highlighted that this combined method provides a better database for planners, enabling more informed decision-making in aquaculture site selection [26-30].

III. MATERIALS AND METHODS

This study used a descriptive-developmental design to create and validate a web application integrating the Analytic Hierarchy Process (AHP) [26], [27] with geospatial data visualization for recommending suitable domesticated fish species for cultivation. The methodology encompassed phases from data collection to application deployment. Phase 1 involved gathering primary field data and secondary environmental datasets from official agencies. In Phase 2, key site suitability parameters were identified, standardized into GeoJSON format, and organized for system use. Phase 3 prepared fish species data in JSON format, distinguishing domesticated from non-domesticated species.

The AHP decision model was developed in Phase 4 to weigh environmental parameters, ensuring consistency [28-30]. Phase 5 covered application setup using Laravel, Bootstrap, and Leaflet for interactive mapping. User interactions, data processing, and suitability calculations using AHP were implemented in Phase 6. Phase 7 involved filtering fish species based on suitability scores. Phase 8 enhanced user experience with results display, adjustable parameters, filtering options, and report export features. Finally, Phase 9 deployed the application on a web server and provided documentation and training materials.

IV. RESULTS AND DISCUSSIONS

Table 1: Key factors determining the suitability of sites for sustainable fish farming in the region.

Key Suitability Factor	**Description**	**Weight (w)**
Inland Water	Distance to freshwater sources (rivers/lakes). i.e., 5 = near, 1 = far	0.46
Underground Water	Depth to water table. i.e., 5 = shallow, 1 = deep	0.28
Flood Zones	Flood susceptibility. i.e., 5 = low flood risk, 1 = high flood risk	0.17
Soil Type	Soil permeability / water retention. i.e., 5 = clay loam (good), 1 = sandy (poor)	0.09

Source: Authors, (2026).

Table 1 presents the key factors that determine the suitability of a fishpond site and assigns a weight to each based on its importance. Inland water has the highest weight because the distance to freshwater sources like rivers or lakes is critical. Sites closer to these sources are much more suitable for fishponds. Underground water is also important, with the depth to the water table indicating how easy it is to access groundwater. Shallower water tables lead to higher suitability. Flood zones receive a smaller weight but are still significant because flood susceptibility affects the safety and stability of the pond. Sites with low flood risk are preferred. Lastly, soil type has the lowest weight among these factors but remains important.

Soils with good water retention, like clay loam, enhance pond water dynamics, whereas sandy soils are less suitable. The weights show the relative importance, with inland water availability being nearly half the decision weight, emphasizing water supply as the key suitability driver. Meanwhile, flood risk and soil properties contribute to the pond's resilience and management potential. The scoring scale of 1 to 5 for each factor allows evaluators to quantify site conditions in a consistent way, which supports multi-criteria analysis techniques such as the Analytic Hierarchy Process (AHP) to identify optimal fishpond locations. This approach aligns well with standard fishpond site selection guidelines and best practices from aquaculture literature.

Table 2: Appropriate Geospatial and Information Technologies for Optimizing Aquaculture Site Recommendation.

Technology	Role
Geographic Information System (GIS)	Spatial Data Platform
Remote Sensing (RS)	Environmental Data Source
Global Navigation Satellite System (GNSS)	Precise Geolocation
Multi-Criteria Decision Analysis (MCDA) / Analytic Hierarchy Process (AHP)	Decision Support Framework
Web-based Mapping Tools (Leaflet, OpenLayers)	Interactive Mapping Interface
Standardized Spatial Data Formats (GeoJSON)	Data Interoperability and Visualization
Backend Framework (Laravel 10)	Server-side Web Application Development
Frontend Framework (Bootstrap)	Responsive UI Design
JavaScript	Client-side Interactivity and Data Handling
Leaflet.js and Plugins (Leaflet-PIP)	Web Mapping and Spatial Querying
Decision Analysis Algorithms (AHP)	Analytical Modeling

Source: Authors, (2026).

GIS is the core platform for site suitability assessment, enabling storage, analysis, and visualization of environmental and spatial data such as soil, water bodies, elevation, and flood zones. Remote Sensing complements GIS by providing updated satellite or drone data, ensuring current site conditions. Accurate location referencing is achieved via GNSS for geospatial validation. AHP within GIS serves as a decision-support tool, weighting multiple environmental and socioeconomic criteria to rank site suitability and recommend fish species. Web tools like Leaflet provide user-friendly access, while standardized data formats like GeoJSON ensure interoperability. Backend systems built with Laravel and frontend frameworks like Bootstrap and JavaScript enable efficient data processing and interactive user experiences. Together, these technologies form an integrated, data-driven platform that facilitates informed, sustainable fishpond site selection through advanced spatial analysis and accessible web interfaces.

Fishpond site suitability evaluation using weighted environmental criteria.

The study applied the Analytic Hierarchy Process (AHP) with spatial data to evaluate fishpond sites based on four key environmental criteria: inland water proximity, underground water depth, flood risk, and soil type.

Table 3: Pairwise comparison matrix showing the relative influence of environmental factors on aquaculture site suitability.

Criteria	Inland Water	Underground Water	Flood-Prone	Soil Type
Inland Water	1	2	3	4
Underground Water	1/2	1	2	3
Flood-Prone	1/3	1/2	1	2
Soil Type	1/4	1/3	1/2	1

Source: Authors, (2026).

Expert judgment assigned the highest weight to inland water availability (0.46), followed by underground water (0.28), flood risk (0.17), and soil type (0.09). The consistency ratio of 0.044 confirmed reliable weighting.

Table 4: Inputs extracted from a sample site used in AHP computation for fishpond suitability assessment, showing scaled environmental criteria values.

Criterion	Value	Scaled (1–5)
Inland Water	1.2 km	4
Groundwater Depth	6 m	5
Flood Risk	Moderate	3
Soil Type	Clay loam	5

Source: Authors, (2026).

At a sample site in Batac, Ilocos Norte, scaled scores were inland water 4, groundwater 5, flood risk 3, and soil type 5, resulting in a high overall suitability score.

Table 5: Consistency ratio check for AHP: calculation of λmax, consistency index (CI), and consistency ratio (CR) demonstrating matrix consistency (CR < 0.10).

Criterion	(A×W)_i	λ_i = (A×W)_i / W_i
Inland Water	1×0.465 + 2×0.277 + 3×0.160 + 4×0.098 = 1.982	1.982 / 0.465 = 4.26
Underground Water	0.5×0.465 + 1×0.277 + 2×0.160 + 3×0.098 = 0.986	0.986 / 0.277 = 3.56
Flood-Prone	0.333×0.465 + 0.5×0.277 + 1×0.160 + 2×0.098 = 0.574	0.574 / 0.160 = 3.59
Soil Type	0.25×0.465 + 0.333×0.277 + 0.5×0.160 + 1×0.098 = 0.341	0.341 / 0.098 = 3.48

Source: Authors, (2026).

Compute λmax, CI, CR:

$$CI = \frac{\lambda_{max} - n}{n - 1}, CR = \frac{CI}{RI}$$

Assume λmax ≈ 4.12, then
CI = (4.12−4)/3 = 0.04,
CR = 0.04 / 0.90 = 0.044 < 0.10 ✅ Consistent.

The weighted sum calculations for each criterion demonstrate the relative influence of environmental factors in the AHP analysis. Inland Water, with the highest weight, yields a principal eigenvalue estimate of 4.26. Underground Water, Flood-Prone areas, and Soil Type follow with eigenvalues of 3.56, 3.59, and 3.48, respectively. These values reflect each criterion's contribution to the overall decision hierarchy and help assess the consistency and reliability of the weighting scheme before final suitability ranking.

Table 6: Species environmental preference ratings used for suitability assessment of Tilapia, Bangus, and Catfish common in the Philippines.

Fish	Inland Water	Groundwater	Flood-Prone	Soil Type
Tilapia	5	4	4	5
Bangus	4	3	3	4
Catfish	3	4	5	3

Source: Authors, (2026).

Table 7: Calculation of weighted suitability scores per location by combining criterion weights with scaled environmental ratings.

Fish	(0.46×IW)	(0.28×GW)	(0.17×Flood)	(0.09×Soil)	Total (S)
Tilapia	0.46×5=2.30	0.28×4=1.12	0.17×4=0.68	0.09×5=0.45	**4.55**
Bangus	0.46×4=1.84	0.28×3=0.84	0.17×3=0.51	0.09×4=0.36	**3.55**
Catfish	0.46×3=1.38	0.28×4=1.12	0.17×5=0.85	0.09×3=0.27	**3.62**

Legend:

IW – Inland Water
GW – Ground Water

Using the formula (Compute Weighted Suitability Score per location):

$$S_i = \sum(w_j \times r_{ij})$$

Species-specific suitability showed tilapia with the highest score of 4.55, highlighting the site's potential for tilapia farming. A suitability map integrating these weighted criteria identified optimal pond zones, demonstrating that the spatial AHP method effectively distinguishes suitable sites based on critical environmental factors.

Sample outputs demonstrating the application of Multi-Criteria Decision Analysis and AHP for fish farming site suitability.

Figures 1 to 4 show the effectiveness of Multi-Criteria Decision Analysis (MCDA) using the Analytic Hierarchy Process (AHP) to identify suitable fish farming sites based on critical environmental factors. AHP integrates inputs like soil type, nutrient levels, water availability, and flood risk by assigning weights to each, creating a reliable suitability index. The results rank fish species such as tilapia and catfish by environmental suitability, with maps confirming zones favorable to each species' requirements. The system also highlights which environmental factors positively or negatively influence suitability, aiding understanding.

Table 8: Summary of User Acceptance Test Results for Fish Farming Suitability System.

Test Aspect	Frequency	Percentage	Remarks
Map Interaction	50	100%	Smooth interaction, intuitive
GeoJSON Data Loading	50	100%	Fast loading, slight delay rare
Environmental Data Display	50	100%	Clear and accurate display
AHP Calculation	50	100%	Consistent and reliable results
Fish Recommendation Display	50	100%	Clear species info, visuals good
User Interface Usability	48	96%	Minor responsiveness issues
Help and Guidance	40	80%	Improvement needed

Source: Authors, (2026).

The user acceptance testing conducted with 50 respondents showed positive and very good results for the fish farming suitability system, with minor areas for improvement. Users found the map interaction intuitive, environmental data display clear, and the Automated Hierarchy Process (AHP) computations effective in recommending fish species based on multiple environmental factors. The GeoJSON spatial data loaded smoothly, and the suitability results were well visualized on the map. Some users reported minor UI responsiveness issues during data fetching and occasional slight delays when loading large spatial datasets. Additionally, respondents suggested enhancing the help and guidance features by adding more detailed explanations or tooltips for factors influencing recommendations to improve overall user experience.

V. CONCLUSIONS

This study successfully designed and developed a web-based fishpond planning and recommendation system tailored for Ilocos Norte that integrates environmental suitability factors with geospatial technologies. The key site suitability factors—water availability, soil type, and flood zones—were accurately identified and weighted using the Analytic Hierarchy Process, supporting effective fish species recommendations. The system utilized appropriate geospatial tools such as GIS, Remote Sensing, and web mapping frameworks to provide an accessible, interactive platform for users to explore aquaculture site suitability. The deployment of the system with a user-centered interface met its intended objective of facilitating informed decision-making among stakeholders. User acceptance testing demonstrated that the system is highly usable and reliable, though minor enhancements in responsiveness and guidance would further improve user experience. The study confirms the effectiveness and utility of a GIS-based, AHP-driven platform in supporting sustainable fishpond site selection and planning in Ilocos Norte, thereby achieving the research objectives.

It is recommended to continuously enhance and promote the use of the web-based fishpond planning and recommendation system in Ilocos Norte, ensuring its accessibility and usability among fish farmers, local government units, and other stakeholders. To improve system effectiveness, it is advisable to incorporate additional environmental and socioeconomic factors—such as natural calamity risks, and market access considerations—in future system updates. Strengthening cooperative efforts with government agencies like BFAR and DA will ensure updated datasets and institutional support, fostering integrated regional aquaculture development.

grid-to-vehicle (G2V).

ABSTRACT

The widespread deployment of electric vehicles (EVs) has significantly heightened the need for more efficient and intelligent charging technologies. Bidirectional wireless power transfer (BD-WPT) systems enable both grid-to-vehicle (G2V) and vehicle-to-grid (V2G) operation, supporting applications such as renewable energy integration, demand peak mitigation, and system frequency stabilization. However, existing control strategies face challenges related to synchronization, communication delays, and robustness under detuning and misalignment. This paper investigates a PQ-based synchronization control technique for a 7.7 kW series–series compensated BD-WPT charger, designed in compliance with SAE J2954 standards. The adopted method relies solely on local measurements of active (P) and reactive (Q) power, eliminating the need for communication links while achieving decoupled control of power direction and magnitude. A voltage-controlled oscillator (VCO) ensures robust phase synchronization between the inverter and rectifier. Simulation results demonstrate that the PQ-based control achieves accurate bidirectional power transfer, seamless G2V/V2G transitions, effective power regulation, and resilience against detuning and coil misalignment. These findings underscore the promise of PQ-based synchronization in improving the efficiency, reliability, and scalability of BD-WPT systems for future smart grid integration.

I. INTRODUCTION

The growing penetration of EVs has intensified research efforts toward developing efficient and user-friendly charging infrastructures. Within this context, wireless power transfer (WPT) systems have been recognized as a viable and forward-looking approach, offering advantages in terms of convenience, safety, and compatibility with autonomous operation. While conventional unidirectional WPT systems are restricted to G2V energy transfer, BD-WPT systems provide the added capability of V2G operation, where energy stored in EV batteries can be returned to the grid. This bidirectional functionality is crucial for supporting peak load management, renewable energy integration, frequency regulation, and backup power supply, making BD-WPT a cornerstone technology for future smart grids [1], [2].

Recent advances in BD-WPT have significantly progressed the control of power flow direction and magnitude across various system architectures. A comprehensive review of constant current-constant voltage (CC-CV) charging strategies for resonant inductive power transfer (RIPT) systems classifies control methods into primary, secondary, and dual side approaches. However, these methods face challenges in accurately estimating load resistance and mutual inductance, as well as communication delays and losses, which can reduce control robustness and system efficiency [3]. To address misalignment issues, innovative compensation techniques based on inherent resonance frequency tracking have improved stability in bidirectional electrical coupling WPT (EC-WPT) systems.

Yet, these methods still require further validation for scalability and broader application scenarios, indicating current limitations in practical deployment [4]. In [5] the perturbation and observation technique was applied for dualside phase-shift control; however, discrepancies between the control clocks may cause the primary and secondary sides to operate at different switching frequencies. The study [6] introduces a communication-assisted strategy for managing BD-WPT systems, enabling inverter–rectifier synchronization without current sensing. However, this approach enables low-latency and efficient bidirectional power flow regulation via a specialized wireless communication link between the primary and secondary sides. Nonetheless, the need for additional hardware and software raises system cost and potentially compromises overall robustness. At the circuit level, integrated bidirectional microwave WPT systems employ combined power amplifier and rectifier modules to switch between transmission and reception modes efficiently.

Although this reduces system complexity, these designs are primarily constrained by moderate space transmission efficiency and limited range, limiting their flexibility in diverse environments [7]. Research into bidirectional capacitive power transfer (BCPT) systems highlights challenges in achieving consistent power flow regulation and efficiency, with practical implementation and electromagnetic compatibility issues remaining significant barriers to widespread adoption [8]. Integrated approaches combining wireless power and data transfer via magnetic fields have enhanced power flow control and communication reliability, particularly for electric vehicle applications. Nevertheless, maintaining magnetic alignment and mitigating noise interference in the power and data channels continue to pose operational risks [9]. Finally, developments in bidirectional DC/DC converter topologies for V2G integration have advanced active power flow control between electric vehicles and the grid.

Despite these advances, converter design complexity, control robustness under varying conditions, and scalability to higher power levels remain key limitations [10]. Collectively, these limitations underscore ongoing challenges in achieving precise, stable, scalable bidirectional power flow control in wireless systems, and maintaining synchronization between primary and secondary converters, regulating active and reactive power flow, and ensuring seamless transitions between G2V and V2G modes. These issues motivate the exploration of alternative control techniques, among the available approaches, the PQ-based synchronization control has gained attention for its ability to decouple power direction and magnitude regulation [11]. In this work we adopt and reapply the PQ-based control technique to a 7.7 kW SS-compensated BD-IPT charger, this adopted technique enables: (1) local-only measurement of active (P) and reactive (Q) power (eliminating communication links), (2) decoupled control of power magnitude and direction, and (3) robust synchronization using a VCO-based feedback loop, even amid detuning and misalignment.

The performance of the adopted control method is demonstrated via MATLAB/Simulink simulations aligned with SAE J2954 standards, which specifies operating frequencies (81.39–90 kHz) and power levels (3.7–22 kW) for interoperability [12]. The remainder of this paper is organized as follows: Section **II** presents the modeling of the BD-IPT system, including the fundamental harmonic approximation (FHA) and power flow analysis. Section **III** describes the adopted PQ-based synchronization and power regulation control strategy. Section **IV** provides simulation results and performance evaluation under different operating scenarios. Finally, Section V concludes the paper with key findings and perspectives for future research.

II. MODELING OF THE BIDIRECTIONAL WIRELESS CHARGERS

Figure 1 illustrates the structure of a typical BD-WPT system for EVs. The system begins with a Mains AC Source (50/60 Hz) that is first processed by a bidirectional AC/DC converter is employed to generate a stable DC bus voltage. This is followed by a highfrequency DC/AC converter that generates high frequency AC voltage needed for efficient wireless energy transfer. The AC voltage is then conditioned through a primary compensation network to match the resonant frequency of the loosely coupled transformer, which wirelessly transmits energy across an air gap to the secondary side. The secondary compensation network ensures efficient energy reception. These compensation networks can be classified into four basic topologies: Series-Series (SS), Series-Parallel (SP), Parallel-Parallel (PP), and Parallel-Series (PS), as well as several higher-order configurations like LCC and LCL [13].

In this study, the LC resonant topology was selected as a representative case to analyze the BD-WPT system, the high-frequency AC/DC Converter rectifies the received AC into DC for charging the EV battery. When studying unidirectional wireless chargers, The battery is generally modeled as an equivalent resistance; nevertheless, for bidirectional wireless charging systems, it is more appropriately represented as an equivalent voltage source [14]. In G2V mode, the transmitter side converter functions as a DC/AC inverter, while the receiver side converter acts as a controlled AC/DC rectifier. Conversely, in V2G mode, where the EV battery supplies power back to the grid, the operational roles of the converters are interchanged [15].

A detailed circuit schematic shows that the transmitter side consists of a full-bridge inverter formed by switches Q_{p1} to Q_{p4}, controlled by a primary side controller, and tuned by components C_p. The inverter outputs a high-frequency AC voltage derived from the DC bus voltage V_p, which excites the primary coil L_p. The secondary side mirrors this structure with a full-bridge rectifier formed by switches Q_{s1} to Q_{s4}, controlled by a secondary side controller, and tuned by C_s . The secondary coil L_s. after receiving the wireless power, generates an AC voltage that is rectified to produce the secondary DC bus voltage V_s, which is used for battery charging or to return power to the grid, according to the operation mode. R_p and R_s represent the ESRs of the two sides respectively. The energy transfer is based on mutual inductance M between the transmitter and receiver coils. Compensation networks on both the primary and secondary sides are typically tuned to resonate with the switching frequency. For the SS compensation topology, this implies that [16]:

$$\omega_o = 2\pi f_o = \frac{1}{\sqrt{L_p C_p}} = \frac{1}{\sqrt{L_s C_s}} \tag{1}$$

Where f_o is the switching frequency and ω_o is the angular switching frequency.

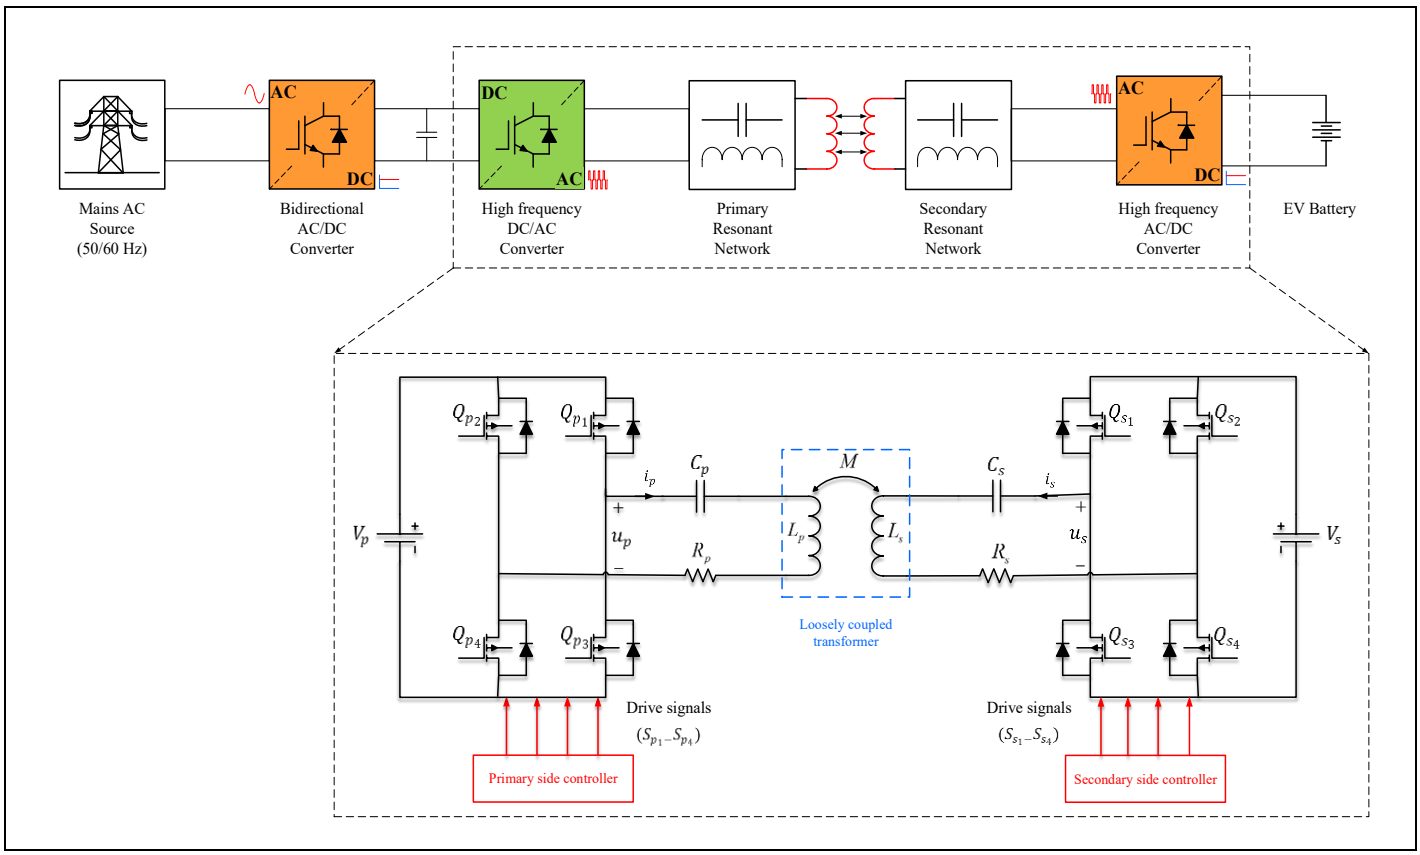

Figure 1: Schematic diagram of the BD-IPT system.
Source: Authors, (2026).

The amount and direction of power exchanged between the two ends of the BD-WPT system can be regulated by managing the magnitudes of the voltages u_p and u_s and the phase angle between them. These voltages are produced using full-bridge converters, both functioning at the switching frequency f_o while maintaining a 50% duty cycle .By introducing phase shifts φ_p on the primary side and φ_s on the secondary side between the two legs of each full-bridge, the converters generate output voltages whose magnitudes can be modulated.

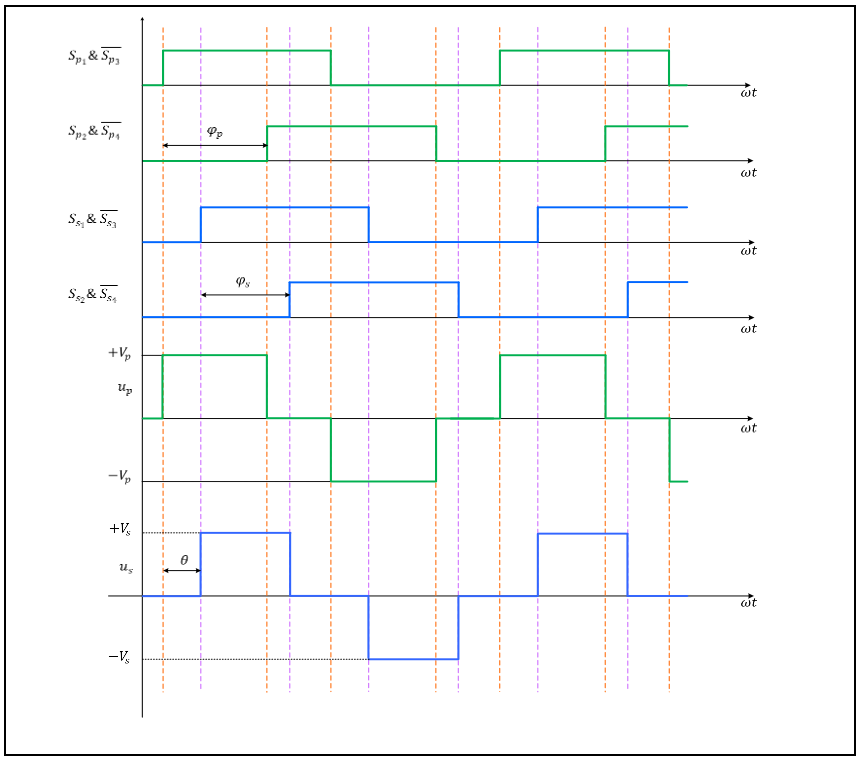

Figure 2: Voltage waveforms of primary and pickup converters.
Source: Authors, (2026).

The direction of power transfer is governed by the relative phase angle θ between primary and secondary voltages: a $+90°$ shift enables charging (grid to EV), while $-90°$ enables discharging (EV to grid), assuming resonant conditions. Figure 2 illustrates typical switching sequences employed to implement this control strategy [11]. Considering one period of the voltage u_p(Figure 3) and applying a phase shift of θ to obtain u_s, both signals can be represented through their Fourier series representation as follows:

$$u_p(t) = \frac{4}{\pi} V_p \sum_{n=1,3,5,\ldots}^{\infty} \frac{1}{n} cos\left(n\omega t + \frac{n\varphi_p}{2}\right) sin\left(\frac{n\varphi_p}{2}\right) \tag{2}$$

$$u_s(t) = \frac{4}{\pi} V_s \sum_{n=1,3,5,\ldots}^{\infty} \frac{1}{n} cos\left(n\omega t + n\theta + \frac{n\varphi_s}{2}\right) sin\left(\frac{n\varphi_s}{2}\right) \tag{3}$$

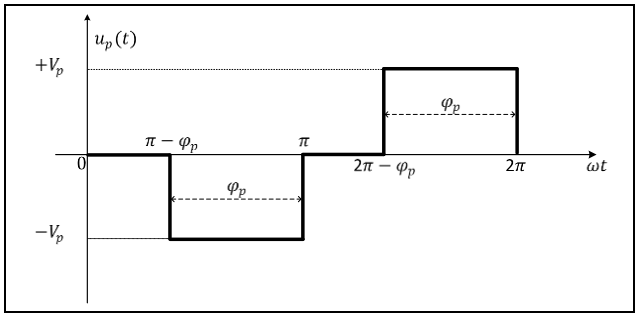

Figure 3: Primary converter output voltage (u_p) waveform over a single switching period.
Source: Authors, (2026).

Since the resonant network exhibits band-pass characteristics, the higher order harmonics can be disregarded, allowing the analysis to focus solely on the fundamental components [17], and the schematic diagram in Figure 1 may be reduced to an equivalent model comprising two voltage sources, and an impedance network, as shown in Figure 4:

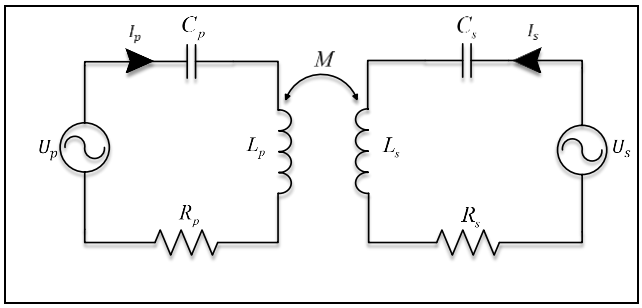

Figure 4: The equivalent circuit of the BD-IPT system.
Source: Authors, (2026).

By adopting the FHA, the steady-state model of the SS-compensated system is obtained as:

$$\begin{cases} \tilde{U}_p = R_p \tilde{I}_p + j\omega M \tilde{I}_s \\ \tilde{U}_s = j\omega M \tilde{I}_p + R_s \tilde{I}_s \end{cases} \tag{4}$$

Where $\tilde{U}_p$ and $\tilde{U}_s$ denote the phasors of the fundamental output voltages of the H-bridge converters on the primary and secondary sides, respectively, The phasor $\tilde{U}_p$ is taken as the reference ($\tilde{U}_p = U_p \angle 0°$) , while the phase angle of $\tilde{U}_s$ is θ, that is, $\tilde{U}_s = U_s \angle \theta$. Moreover, $\tilde{I}_p$ and $\tilde{I}_s$ represent the current phasor on the primary and secondary sides, separately:

$$\tilde{U}_p = \frac{2}{\pi\sqrt{2}} V_p \sin\left(\frac{\alpha}{2}\right) \angle 0° \tag{5}$$

$$\tilde{U}_s = \frac{2}{\pi\sqrt{2}} V_s \sin\left(\frac{\beta}{2}\right) \angle \theta° \tag{6}$$

Solving Equation (4), the primary and secondary currents are:

$$\tilde{I}_p = \frac{R_s \tilde{U}_p - j\omega M \tilde{U}_s}{R_p R_s + (\omega M)^2} \tag{7}$$

$$\tilde{I}_s = \frac{R_p \tilde{U}_s - j\omega M \tilde{U}_p}{R_p R_s + (\omega M)^2} \tag{8}$$

The apparent power of the primary side converter is:

$$S_p = \tilde{U}_p \tilde{I}_p^* = P_p + jQ_p \tag{9}$$

Where P_p and Q_p are the active and reactive power generated by the primary converter and they are given by:

$$P_p = \mathrm{Re}(S_p) = \frac{R_s U_p^2 + \omega M U_p U_s sin(\theta)}{R_p R_s + (\omega M)^2} \tag{10}$$

$$Q_p = \mathrm{Im}(S_p) = \frac{\omega M U_p U_s \cos(\theta)}{\omega R_p R_s + (\omega M)^2} \tag{11}$$

The apparent power absorbed by the secondary side converter is expressed as:

$$S_s = \tilde{U}_s \tilde{I}_s^* = P_s + jQ_s \tag{12}$$

Where P_s and Q_s denote the active and reactive power produced by the secondary side converter and they are given by:

$$P_s = \mathrm{Re}(S_s) = \frac{R_p U_s^2 - \omega M U_p U_s sin(\theta)}{R_p R_s + (\omega M)^2} \tag{13}$$

$$Q_s = \mathrm{Im}(S_s) = -\frac{\omega M U_p U_s \cos(\theta)}{\omega R_p R_s + (\omega M)^2} \tag{14}$$

As such, substitution of Equation (5) and Equation (6) to Equations (9)-(14) and by neglecting resistive terms results in:

$$P_p = \frac{8}{\omega M \pi^2} V_p V_s \sin\left(\frac{\varphi_p}{2}\right) \sin\left(\frac{\varphi_s}{2}\right) \sin(\theta) \tag{15}$$

$$Q_p = \frac{8}{\omega M \pi^2} V_p V_s \sin\left(\frac{\varphi_p}{2}\right) \sin\left(\frac{\varphi_s}{2}\right) \cos(\theta) \tag{16}$$

$$P_s = -\frac{8}{\omega M \pi^2} V_p V_s \sin\left(\frac{\varphi_p}{2}\right) \sin\left(\frac{\varphi_s}{2}\right) \sin(\theta) \tag{17}$$

$$Q_s = -\frac{8}{\omega M \pi^2} V_p V_s \sin\left(\frac{\varphi_p}{2}\right) \sin\left(\frac{\varphi_s}{2}\right) \cos(\theta) \tag{18}$$

To describe the power flow at the pickup side, the power phase angle is expressed as:

$$\theta_{Power} = \arccos\left(\frac{P_s}{\sqrt{P_s^2 + Q_s^2}}\right) \tag{19}$$

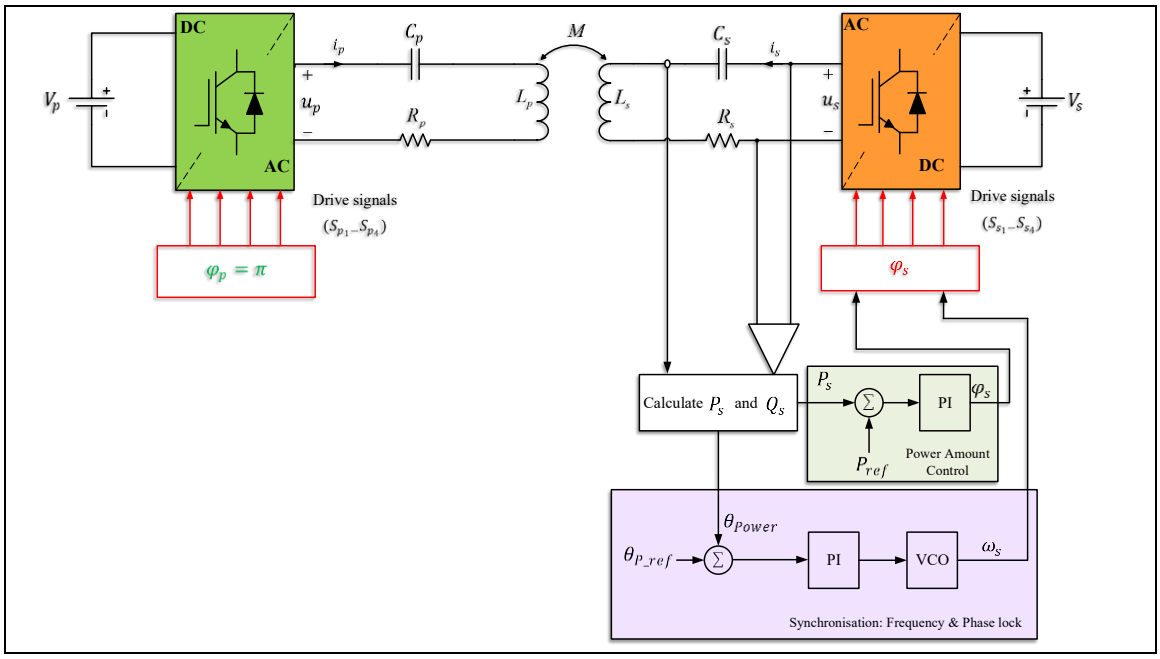
$$\theta_{Power} = \arccos[-\sin(\theta)] \tag{20}$$

From Equation (15) and Equation (17), it follows that when $\theta \in [-\pi, 0]$, with $P_p < 0$ and $P_s > 0$, the primary-side voltage lags the secondary-side voltage, thus enabling power flow from the secondary side back to the primary side.

Conversely, in cases where $\theta \in [0, \pi]$, with $P_s < 0$ and $P_p > 0$, the primary-side voltage leads the secondary-side voltage, and power flows from the primary to the secondary side. When $\theta = -/+ 90°$ (which is consistent with a power angle θ_{Power} of 0° or 180°, respectively), from Equation (16) and Equation (18), the output reactive power of the primary and secondary converters becomes zero, while the active power attains its maximum value.

III. THE SYNCHRONIZATION TECHNIQUE CONTROL

In the BD-WPT system, a PQ-based controller is adopted for the secondary side to regulate power transfer by processing the measured voltage and current to compute the power flow and the relative phase angle between the primary and secondary voltages $\widetilde{U}_p$ and $\widetilde{U}_s$ (Figure 5). The control scheme consists of two coordinated loops: one for synchronizing the converters and controlling the direction of power flow, and another for regulating the transferred active power. A VCO aligns the pickup switching frequency by minimizing the difference between the calculated power phase angle and its reference $\theta_{\text{P_ref}}$, with the error corrected through a PI controller to adjust the relative phase angle θ. In parallel, the measured active power is compared with its reference P_{ref}, and the error is processed by an independent PI regulator to generate a variable φ_s for amplitude modulation, enabling decoupled control of power direction and magnitude [11].



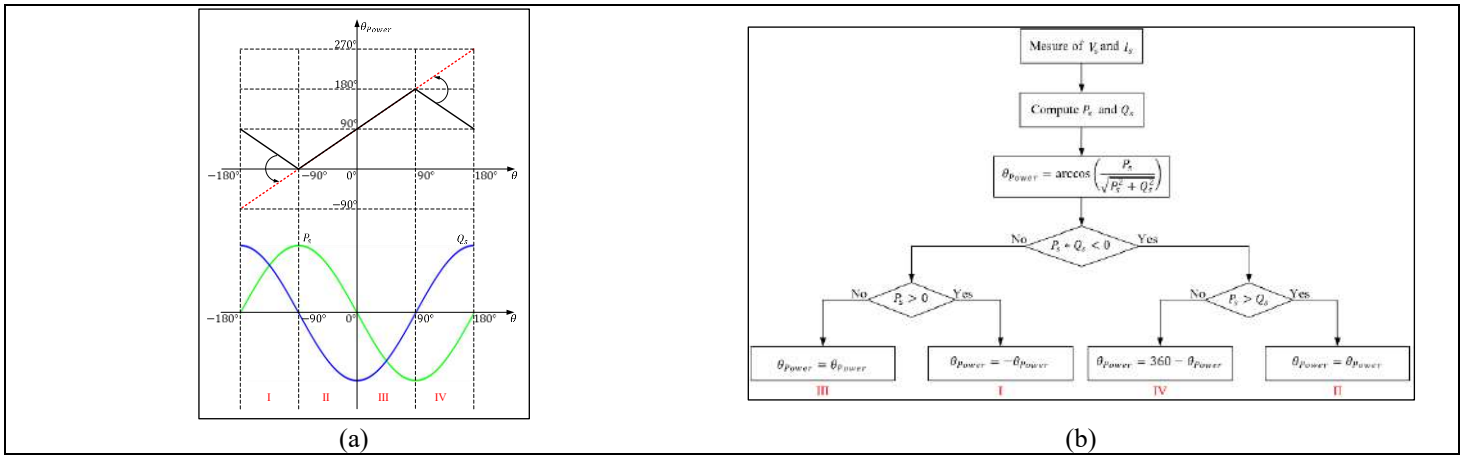


Figure 5: Synchronization and transferring power amount control technique.
Source: Authors, (2026).

Since the synchronization loop relies on the accuracy of the calculated power phase angle, a correction algorithm (Figure 6) is introduced to eliminate ambiguity caused by the non-monotonic behavior θ_{Power}, ensuring a continuous and robust mapping between the estimated and actual relative phase angle.

(a) (b)

Figure 6: (a) Power and phase angle characteristics. (b) Correction algorithm.
Source: Authors, (2026).

In Figure 6(a), the solid curves illustrate the active and reactive powers obtained from Equations (17)–(18), together with the power phase angle from Equation (19), plotted as functions of the relative phase angle θ under resonant operation. It can be observed that θ_{Power} increases monotonically in Regions II and III, but shows a decreasing trend in Regions I and IV as θ varies from $-180°$ to $180°$.

To eliminate this discontinuity, the correction procedure shown in Figure 6(b) is applied, which modifies the values of θ_{Power} in Regions III and IV to establish a continuous mapping between θ_{Power} and θ.

IV. SIMULATION RESULTS AND DISCUSSIONS

In order to validate the effectiveness of the adopted PQ-based control strategy for BD-WPT, different test scenarios were conducted to demonstrate both synchronization performance and power regulation capability using MATLAB software, considering the defined system parameters listed in Table 1. These parameters comply with the SAE J2954 standards. As specified in the SAE technical information report J2954, WPT systems should operate within the frequency range of 81.39–90 kHz. Furthermore, SAE J2954 categorizes wireless power transfer systems into four power levels: 3.7 kW, 7.7 kW, 11 kW, and 22 kW [12], [18]. The simulation setup adheres to the SAE J2954 WPT standards while remaining consistent with the lithium-ion battery voltage range (300–600 V) typically used in EVs.

Table 1: System parameters.

Parameter	Symbol	Nominal Value
Power output level	P_o	$7.7\ kW$
Input DC voltage	V_{in}	$240\ V$
Switching frequency	f_s	$85\ kHz$
Primary side compensation capacitance	C_p	$93.045\ nF$
Primary side self-inductance	L_p	$37.68\ \mu H$
Primary side ESR	R_p	$0.01\ \Omega$
Secondary side compensation capacitance	C_s	$64.87\ nF$
Secondary side self-inductance	L_s	$54.04\ \mu H$
Secondary side ESR	R_s	$0.01\ \Omega$
Mutual inductance of the coupled coils	M	$9.025\ \mu H$
Output Filter capacitor	C_o	$220\ \mu F$
Load resistance	R_o	$20.78\ \Omega$

Figure 7(a) illustrates the time-domain waveforms during maximum power transfer from the transmitter to the receiver side. The synchronization system operates by detecting the active and reactive powers, followed by adjusting the delay and duty cycle of the pickup control signals. By means of a VCO controller, the power phase is tracked to maintain a fixed 90° phase difference between the primary and secondary voltages. Consequently, the transferred power initially oscillates but eventually stabilizes at the reference value, while the pickup voltage locks in phase with the primary voltage and both active and reactive powers reach steady-state conditions.

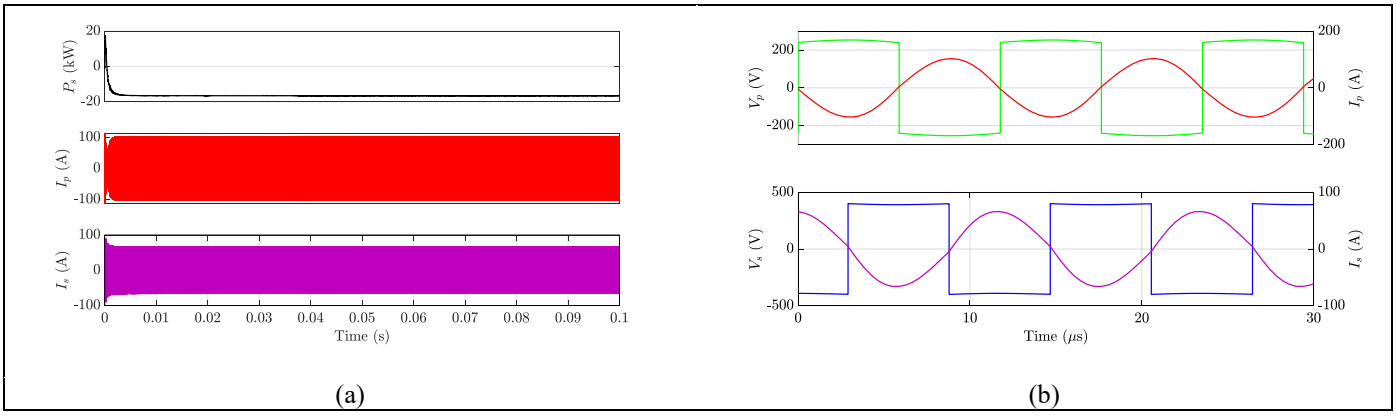

Figure 7: Waveforms under forward maximum power transfer: (a) active power and current profiles.
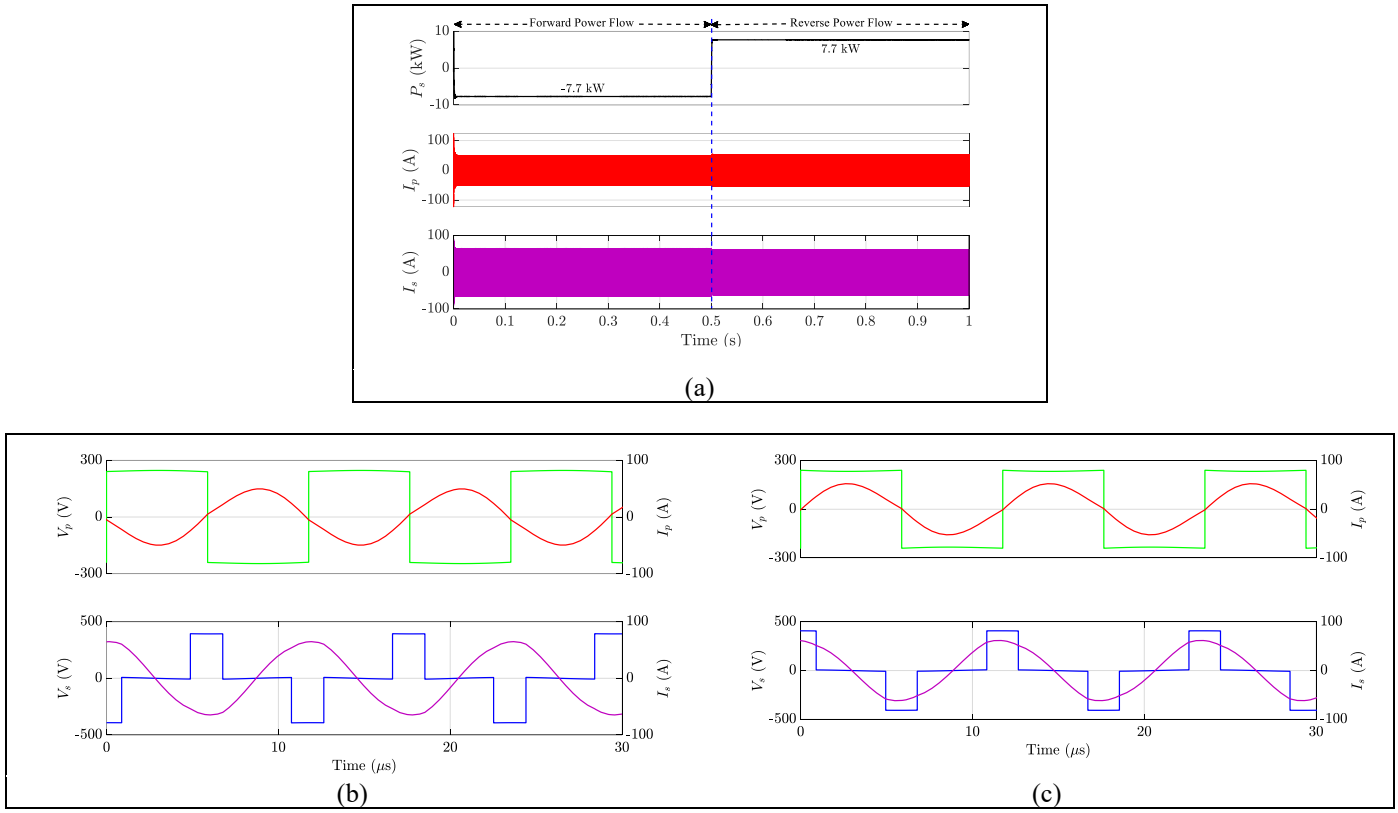
Source: Authors, (2026).

From Figure 7(b) the primary inverter voltage u_p (fixed square wave) leads the secondary inverter voltage u_s (which also exhibits a square shape under maximum power transfer conditions, where the secondary phase modulation φ_s reaches its maximum value of 180°) by 90°, this corresponds to maximum forward power transfer under resonant conditions, validating the PQ-based controller in achieving synchronization and stable operation in G2V mode. Figure 8(a) shows the transient response of active power and current profiles during the reversal of power transfer from forward (G2V) to reverse (V2G).

Furthermore, Figure 8(b)-(c) illustrates the voltage and current waveforms when 7.7 kW is delivered to the secondary side and when it is delivered back to the primary side. The transition is achieved by adjusting the relative phase angle between the primary and secondary voltages from $+90°$ to $-90°$. During this process, the controller successfully regulates synchronization, and the current profiles

adapt without significant distortion. In forward power flow (Figure 8(b)), V_p leads V_s by 90°, while in reverse power flow (Figure 8(c)), V_s leads V_p by 90°, confirming bidirectional capability.

Importantly, the magnitude of the voltages and currents remains similar in both directions, showing that the controller maintains symmetrical performance for G2V and V2G operation. This result demonstrates the PQ-based controller's effectiveness in enabling smooth bidirectional transitions without destabilizing the system.



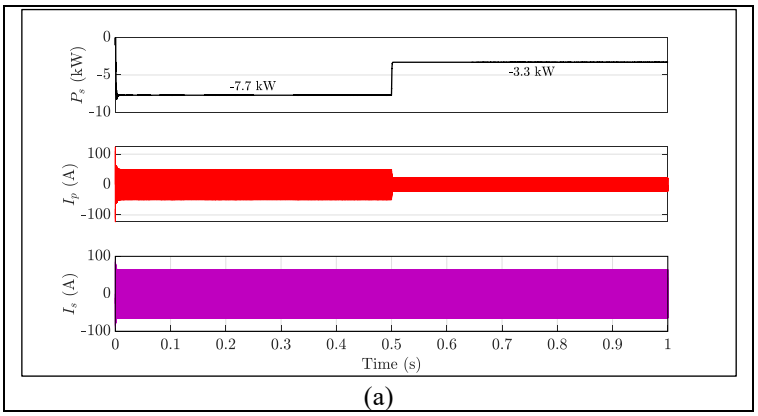


Figure 8: Waveforms during reversal of power transfer direction: (a) active power and current profiles, enlarged view of voltage and current waveforms: (b) under forward flow (c) under reverse flow.
Source: Authors, (2026).

Figure 9(a) shows the active power and current profiles when the reference power is reduced from –7.7 kW to –3.3 kW at 0.5 s. Figure 9(b) and 9(c) illustrate the corresponding voltage and current waveforms for each operating point. The controller adjusts the duty cycle of the secondary voltage V_s to match the new power reference. The results confirm that the PQ-based strategy can decouple power regulation from synchronization, since synchronization remains locked while the amplitude of transferred power is varied. The transient is smooth, and the system quickly stabilizes at the new reference power level, demonstrating the controller's robustness. These results indicate that the PQ-based approach enables accurate power regulation while maintaining phase synchronization.

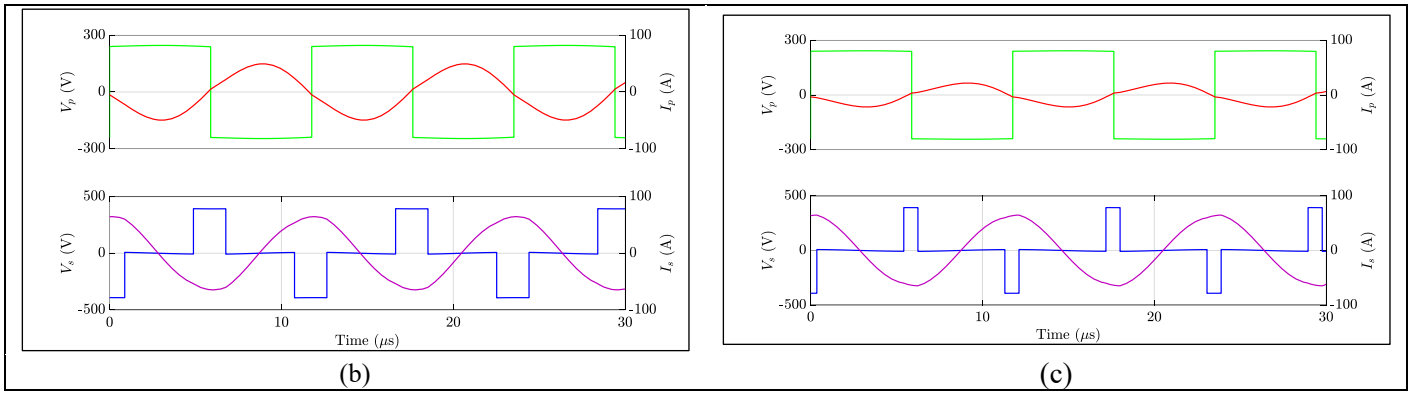

Figure 9: Waveforms during the power transition from $-7.7\ kW$ to $-3.3\ kW$: (a) active power and current profiles, enlarged view of voltage and current waveforms: (b) when transmitting $-7.7\ kW$ (c) when transmitting $-3.3\ kW$.
Source: Authors, (2026).

When the secondary resonant capacitor C_s is increased from its designed value of $64.87\ nF$ to $74.67\ nF$, the system operates under a detuned condition that alters the resonance balance between the primary and secondary circuits, and the resonance condition is no longer satisfied at the operating frequency of $85\ kHz$.

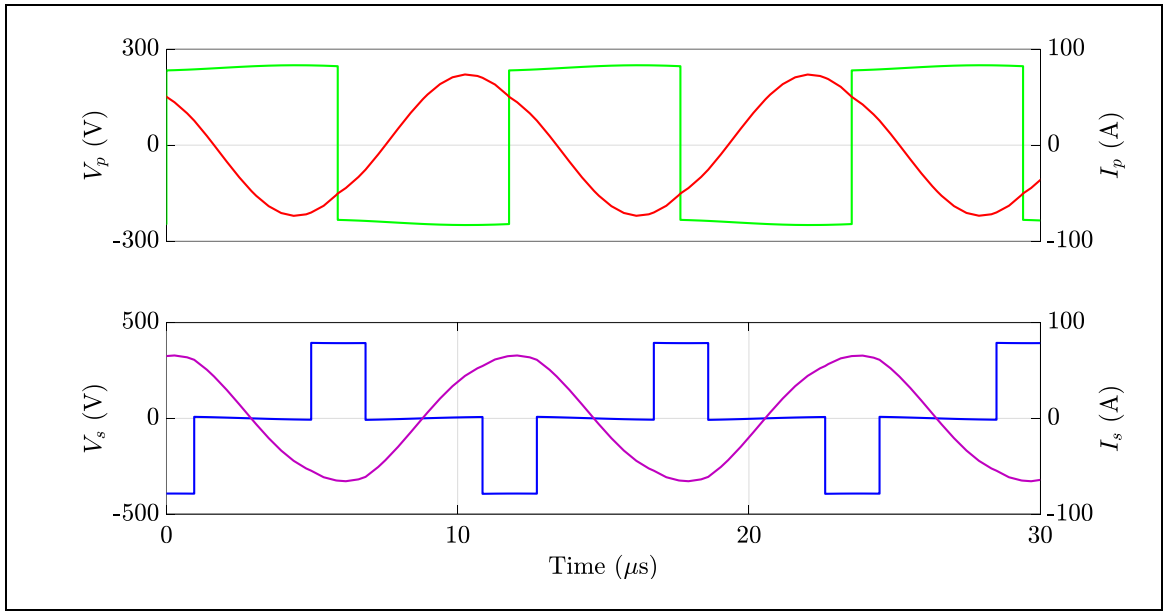

Figure 10: Voltage and current characteristics under detuned resonance.
Source: Authors, (2026).

As shown in Figure 10, this detuning mainly manifests on the primary side: the primary current I_p exhibits a clear phase displacement relative to the primary voltage V_p. In contrast, the secondary current I_s remains aligned with the secondary voltage V_s (but with negative polarity), indicating that the local resonance on the secondary side is preserved with respect to its driving voltage. This phenomenon occurs because variations in C_s modify the reflected impedance seen by the primary, thereby shifting the phase relationship between V_p and I_p and influencing the overall power flow.

Such detuning conditions emphasize the importance of the PQ-based synchronization control strategy, which decouples active and reactive power regulation. By accurately synchronizing the converter operation and controlling the power components, the PQ method enables the system to deliver the desired active power while keeping the reactive power at a minimum, even when parameter mismatches or resonance deviations occur.

To evaluate the robustness of the proposed PQ-based synchronization control, Figure 11 presents the primary and secondary voltage and current waveforms under a misalignment condition. The lateral displacement between the transmitting and receiving coils is modeled as a reduction in the coupling coefficient from 0.2 to 0.1, while maintaining a transferred power of 7.7 kW to the secondary side. Despite the weakened magnetic coupling, the controller successfully regulates active and reactive power by reducing the magnitude of the secondary voltage V_s. This confirms the capability of the PQ-based control strategy to sustain reliable power transfer and minimize reactive components even under significant coupling variations.

V. CONCLUSIONS

This work presented a PQ-based synchronization and control strategy for BD-WPT systems, applied to a 7.7 kW SS-compensated charger. By utilizing only local measurements of active and reactive power, the method eliminates communication requirements, thereby reducing system cost and complexity. The adoption of a VCO-based feedback loop ensures robust synchronization while enabling independent regulation of power direction and magnitude. Simulation results verified the controller's effectiveness under various scenarios, including forward and reverse power transfer, dynamic reference tracking, resonance detuning, and coil misalignment. The results confirm that the proposed PQ-based approach provides accurate, stable, and symmetric performance in both G2V and V2G modes. Future work will focus on experimental validation and extending the method to higher power levels and multi-vehicle charging scenarios, further advancing the deployment of BD-WPT systems in smart grid applications.

ABSTRACT

Numerical investigations on the thermal performance of microchannel heat sinks featuring pin-fin surface modifications have been performed using Computational Fluid Dynamics (CFD) simulations. The simulations have been carried out to assess the flow and heat transfer behavior across 55 distinct microchannel configurations with varying pin fin heights with water as the coolant medium. The performance of pin-fin-enabled microchannels was compared against conventional flat microchannel to quantify the enhancement effects. Two fin heights (40 µm and 60 µm) were examined in laminar flow regime across Reynolds numbers ranging from 500 to 2000. Results indicate that the integration of pin fins significantly improves thermal response by amplifying heat transfer surface area and inducing localized flow disturbances. The channel configuration with 60 µm fin height demonstrated optimal performance, achieving a notable increase in the Nusselt number and overall heat transfer efficiency. These findings suggest that surface modifications through pin fins, even with water as a base fluid, can substantially enhance the thermal capability of microchannel heat exchangers and are suitable for compact, high-performance cooling applications.

I. INTRODUCTION

The electronic industry has witnessed a progressive rise in the demand of portable electronic systems and MEMS in the recent decades. The ancient cooling systems lack in high performance and effective thermal management solutions become incapable to meet such surging demands. Accordingly, Microchannel Heat Sinks (MCHs) has evolved as a potential solution for high heat flux dissipation with a compact size scale advantage. The MCHs basically creates higher surface area to volume ratio and possibly produced fluid mixing inside the channels. There has been constant research to improve the heat transfer enhancement of MCHs. The addition of pin fins in the heat transferring surface of MCHs has been one of the attractive modifications in this direction.

Pin fins serve to increase the surface-to-volume ratio, hinder the thermal and velocity boundary layers and elevate fluid mixing. In the early phase of microchannel research, Tuckerman and Pease introduced MCHs as a promising technique for dissipating heat from microelectromechanical systems (MEMS). In the subsequent years researchers explored various MCHs geometries to optimize heat transfer performance to improve cooling efficiency [1]. Jyoti Singh and R.P. Sugavaneshwar studied the effectiveness of pin fins in MCHs and reported that optimal fin configurations can achieve up to 50% higher Nusselt numbers compared to conventional designs. This study provides critical insights design of pin fin enabled micro channels [2].

Compared the thermal performance of mini- and microchannels under identical working conditions and demonstrated that pin-fin microchannels (PF-MCs) exhibit superior hydrothermal performance relative to conventional microchannels (CMCs). Their findings emphasized the need for optimizing geometric configurations to balance heat transfer enhancement and flow resistance [3]. Haridas, D. and C.B. Sobhan investigated convective heat transfer in mini-channels using digital interferometric techniques and reported localized thermal gradients across the channel. Their results showed that flow conditions and channel dimensions significantly influence heat transfer performance [4].

Demonstrated that an increase in the number of channels, cross-sectional area and hydraulic diameter in microchannel heat sinks significantly enhances thermal performance. Surface temperature dropped from 361 K in a basic rectangular model to 324 K in the 11-channel design configuration marking a 188% improvement over the basic configuration [5]. Further experimental work by Haridas et al. on wavy microchannels revealed that surface modifications could enhance thermal transfer due to surface area and secondary flow effects under laminar conditions [6]. Numerical Simulations performed by N.B. Sukhor et al. on micro-pin fin heat sinks using water as the base fluid confirmed the effectiveness of structural modifications in boosting thermal performance [7].

Hasan and Muter numerically heat sinks with different fin geometries and coolants. The results emphasized significant heat transfer enhancements can achieved using conventional coolants like water with optimized geometries [8]. |Used CFD and machine learning to analyze flow behaviour and heat transfer in MCHs with pin fins embedded in the channel. The simulations predicts improved heat transfer with increasing flow speed while wider spacing between fins reduces both heat transfer and pressure drop. This study also emphasized the potential of Neural Network algorithms combined with CFD for better channel optimization [9]. Introduces an adaptive pin-fin microchannel (A-MCHS) with phase-change fins that shrink above 313.15 K enabling intelligent flow regulation at hotspot regions.

Compared to fixed pin-fin designs, A-MCHS improves local heat transfer by 37.9%, and enhances average Nusselt number by 7.4%. It also reduces pressure drop by 10.7% demonstrating efficient, self-regulating cooling and energy savings for high heat flux applications [10]. Showed that a V-shaped rib angle of 35° significantly enhances thermal performance with a Nusselt number of 13.81 at Re-300 compared to 8.12 at 90° [11]. Tomar, P., & Kumar, demonstrated that diamond-shaped pin fin with a height of 2.5 mm improve heat transfer 5 times and thermal performance by 340% compared to smooth channels. Optimal performance occurs at a fin height of 2.5 mm with Reynolds numbers ranging from 1500 to 4000 [12]. Inserted pillars into MCHs to stimulate heat transfer by four times with the highest Nusselt number achieved in configuration P75 configuration [13].

Found that smaller taper angles (15°) is very efficient at low Re while large taper angles (30°) excel at higher Re for enhancing heat transfer. The optimal taper angle of 30° achieved the highest THPP of 1.77 underscoring the need to balance thermal and hydraulic efficiency for MHS designs [14]. Proposed adaptive pin-fins microchannel (A-MCHS) to improve thermal performance by 37.9% in hotspot regions. The configuration increases average Nusselt number by 7.4%, and reduces the maximum chip surface temperature by 3.12 K. It also decreases pressure drop by 10.7% offering enhanced cooling and energy savings for high heat flux electronic chips [15]. Ali, N., et al., showed that semi-elliptical pin-fins (SEPFs) enhance heat transfer efficiency in MCHs with a maximum THPP of 1.41 for an aspect ratio of 1.0 at a Reynolds number of 300.

However, flow disturbances increase pressure drop and the minimum THPP value occurs for SEPF with $\Psi = 0.36$ at $Re = 900$ [16]. Alnaimat, F.,et al., found that incorporating square-shaped fins in microchannel heat sinks improves thermal performance by reducing thermal resistance. Optimizing fin size, space and channel size can enhance thermal efficiency with smaller fins, reduced spacing and certain channel configurations providing higher Figures of Merit (FOM) by balancing heat transfer enhancement with pressure drop [17]. Ehsani, H., et al., discovered that perforated pin fin systems (especially those with three square holes) enhance thermal efficiency by 16.63% compared to non-perforated pin fins. AIML enabled CFD analysis effectively predicts thermal performance with a low mean absolute error of 2.25%.

This study pay way for future of CFD simulations assisted by artificial intelligence and machine learning methods for improved accuracy and effective computational cost [18]. Lee, Y. J., & Kim, S. J., showed that the Manifold Microchannel (MMC) with fins improves thermal-hydraulic performance by reducing thermal resistance by 40% and consequently increasing the heat transfer coefficient by 20%. The system performs with a 5 fold increase in Coefficient of Performance (COP) at a flow rate of 300 ml/min for heat fluxes up to 1.2 kW/cm² [19]. Muhammad Anas Wazir., et al., revealed that the MC-Mixed pin fin configuration enhances convective heat transfer by 50% at $Re = 1000$ and achieves the highest TPF ($\eta = 1.4$) at $Re = 600$. Geometric optimization using Response Surface Methodology (RSM) provides optimal pin dimensions for both base wall and mixed configurations [20].

Fluid flow and heat dissipation were examined by A. Kumar., et al using the finite volume method in conjunction with computational fluid dynamics and heat transfer theory [21]. A. Fetuga., et al and O. T. Olakoyejo., et al examined the combined effects of advanced working fluids and optimised heat sink configurations can enhance heat transfer in thermal management systems, improving thermal-hydraulic performance and reducing entropy generation [22], [23]. Extending prior studies the authors analyze the impact of pin-fin height on velocity fields and its interaction with the thermal transport characteristics in a water-cooled microchannel heat exchanger. The study primarily focused on the role of physical geometry modifications on hydro-thermal performance of the system. Simulations are conducted across Reynolds numbers ranging from $Re = 500–2000$ all lies within the laminar flow regime.

The microchannel heat sinks were designed with copper walls and has dimensions of 600 µm in length, 265 in µm width and 62 in µm height concentrating to a hydraulic diameter of 100 µm. A constant heat flux of 100 W is applied to the heated surface with a coolant flow at constant inlet temperature of 300 K. The flow conditions are maintained under forward-biased. Pin fins are introduced to the microchannel to improve the performance and to create hindrance in the thermal boundary layers by forced convection. The analysis is performed for about four distinct Reynolds numbers from 500 to 2000 to study the laminar flow regimes and establish the correlations of velocity, temperature, pressure drop and convective heat transfer mechanism. By isolating the influence of geometric parameters, the study contributes to optimizing microchannel heat sink designs for reliable and efficient cooling applications. The findings of this study provide new insights into how pin-fin geometry and induced flow structures govern heat transfer enhancement in water-cooled microchannels.

These insights enable a systematic optimization of microchannel geometry and operating conditions to balance thermal efficiency and performance factors, offering practical design guidance for MEMS-based thermal management systems. By enhancing the thermal efficiency and design innovation of microchannel heat exchangers, this work aligns with SDG 7 (Affordable and Clean Energy) and SDG 9 (Industry, Innovation and Infrastructure).

II.1 COMPUTATIONAL MODELLING

II.1.1 Geometric Model:

The presented numerical simulation has been performed for two variations of microchannel heat sink geometries to investigate the functional ability of the pin fins on heat transfer and fluid flow behavior: The first geometry is a MCHs without any surface modifications (Fig 1 a) whereas the second geometry has been designed as a MCHs with pin fin enabled heating surface (Fig 1 c). The MCHs without pin fins is considered as the reference channel for comparison of thermal efficiency. Both the MCHs are constructed with a rectangular cross section as depicted in Figure 1 a.

Figure 1a: Computational Domain.
Source: Authors, (2026).

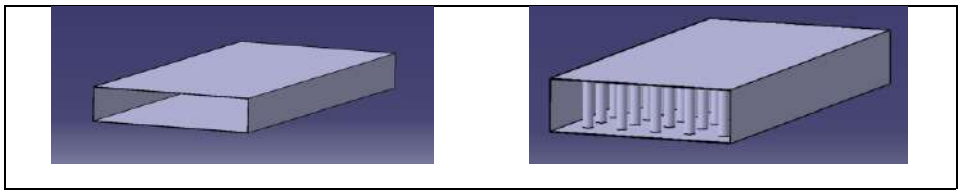

Figure 1b: Plain Channel.
Source: Authors, (2026)

Figure 1c: Channel with Pinfins.
Source: Authors, (2026)

The MCHs with pin fins has designed with 55 uniformly placed circular fins on the bottom heated plate of the channel. Pin fins are indulged in the geometry to promote fluid mixing and to enhance heat dissipation. Moreover, fin heights are altered to check the difference in the resulting heat transport. These geometrical design parameters will allow to establish the correlation with design parameter and flow mixing with in the channel. The design dimensions of the channel and the boundary conditions adopted for the simulation are summarized in Table 1.

Table 1: Geometrical Specifications of the Microchannel.

Symbols	Dimensional values (µm)
L_{ch}	600
W_{ch}	265
H_{ch}	62
d_p	15
S_p	50
h_p	60, 40
N_p	55
Heat Flux q	100 W/m2
Inlet Temperature	300K
Outlet Pressure	0 Pas

Source: Authors, (2026).

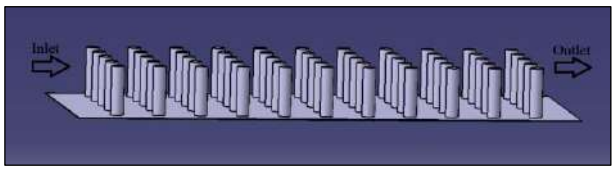

Figure 2: Pin fin arrangement on Heat Plate.
Source: Authors, (2026)

The total heat plate area is approximately 55 mm^2. The spacing between the fins (Sp), the diameter of the fins (dp) remains constant throughout the simulation. The height of the fin (hp) is varied for two different fin heights. The geometry and the entire simulation is performed with the use of a commercial software ANSYS Fluent. Figure 2 shows the top view of the pin fin arrangement.

II.1.2 Computational Modelling:

The simulation has been performed for steady state conditions by using pressure-based analysis. The entire analysis is performed in laminar regime. This model allows to predict the flow characteristics and omit the complications caused in the turbulence regime. The boundary conditions for this analysis are framed with the velocity as inlet and the pressure as outlet. The post processing part consists of the solver settings which are set to the Finite Volume Method, SIMPLEC method and the second order upwind methods. The fundamental equations are solved to the residual range below 10-6 .

This means that the Navier-Stokes equations are solved till they reach a stable value. The boundary layer is assumed with no slip condition and a heat flux of about 100 W/m2 is subjected to the bottom plate of the channel. The inlet temperature is set to 300K and the pressure at the outlet is 0 Pascal. Water is chosen as a working fluid with a density of 1000 kg/m3. To ensure differentiation between the channel walls and the heat plate behavior based on its thermal properties, the materials are differentiated. The channel walls are made of Aluminium and the heat plate is of Copper. The physical properties of the materials used in the computation has been mentioned in the Table 2.

Table 2: Properties of the Materials.

Material Properties	Copper	Water
Density [ρ] (kg/m3)	8978	998
Dynamic Viscosity [μ] (kg/ m/ sec)	-	0.00103
Specific Heat Capacity [Cp] (J/ Kg/ K)	386	4184
Thermal Conductivity [K] (W/ m/ K)	387.6	0.6

II.1.3 Mesh Independence Study

The mesh independence study is the crucial section of the CFD simulation process which entails in finding the most favorable mesh size for the efficient heat transfer analysis. The mesh size has been characterized by analyzing three different meshes: Course, Reference and Fine mesh. The mesh quality straightforwardly influences the fundamental equations and mostly around the inflated regions of the pins. The study is made to frame out the precise results and simultaneously constrain the computational time and cost. The study parametric are same for all the three comparative mesh sizes (Fig 3a-c).

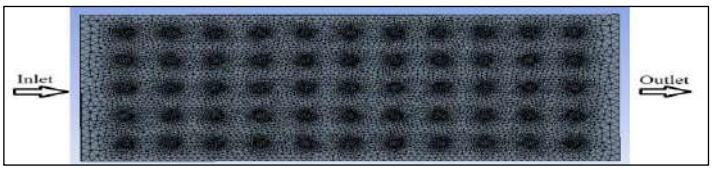

Figure 3a: Reference Mesh.
Source: Authors, (2026)

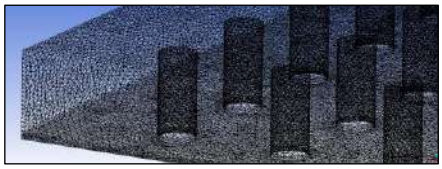

Figure 3b: Fine Mesh.
Source: Authors, (2026)

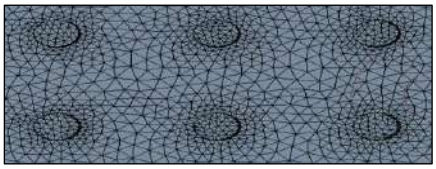

Figure 3c: Coarse Mesh.
Source: Authors, (2026)

These illustrations give the utmost reliable mesh value which compromises all the requirements of an effective heat transfer system. The reference mesh is chosen for the next stage simulations as it accommodates both accuracy and computational benefits. The fine mesh gives more accuracy however fails in the computational aspect. The coarse mesh satisfies the computational time and cost but the accuracy of the results is been compromised. So the reference mesh is taken as the optimal mesh size for this study (refer Table 3)

Table 3: Mesh types and Its findings.

S.No	Type of Grid	No: of elements	Computational time (hrs.)	Friction factor deviation (Δf)
1	Reference	2.625 x 106	3.80	2.25%
2	Fine	3.167 x 106	5.35	1.825%
3	Coarse	1.889 x 106	1.46	4.35%

Source: Authors, (2026).

The table also gives the reason for choosing the reference mesh, as it takes the convergence factor as the friction factor for additional calculation of the mesh size. The deviation in the friction factor, the computational time, the number of elements is the criteria taken into consideration.

III. METHODOLOGY

III.1 COMPUTATIONAL METHODOLOGY

This study employs ANSYS Fluent 2022 R2 for all the simulations performed . The software enables the detailed analysis of solid–fluid interaction through a three-dimensional conjugate heat transfer model. This coupling allows for an accurate representation of heat conduction within the solid domain (channel walls and pin fins) and convection in the fluid domain (flowing water), thereby providing an in-depth note of the thermal behavior within the microchannel. The simulation is carried out under steady-state conditions, assuming a fully developed and laminar flow regime throughout the computational domain. The subsequent conditions are formed to simplify and accurately represent the conjugate heat transfer problem:

- The fluid (water) is considered incompressible and Newtonian, implying that its viscosity remains constant and density does not change significantly with pressure or temperature.
- The flow is steady, meaning that all physical properties such as velocity, temperature, and pressure are independent of time.
- As the heat transfer is driven by forced convection, the effects of natural convection, radiation, and gravitational forces are considered negligible and excluded from the analysis.
- The flow is assumed to be laminar across all Reynolds numbers investigated (500 to 2000), ensuring a smooth and orderly fluid motion throughout the channel.

These assumptions align with typical microchannel flow characteristics and ensure numerical stability while maintaining a high degree of physical accuracy.

III.2 MATHEMATICAL MODEL

The fundamental equations are:

Continuity Equation

To effectively ensure that mass is conserved in the fluid domain, Continuity equation is employed. This equation shows that mass within a certain volume remains constant and also implies that the minute changes in mass will directly relate to the boundary flows.

$$\nabla . \vec{u} = 0 \tag{1}$$

In the case of incompressible flows, when the density is constant, this equation relates the mass flow rate with velocity and the flow boundaries. This equation changes the approach towards the fluid behaviour and enhances the analysis.

Momentum Equation

This equation is basically rooted from the Newton's second law and it describes the relation and balance between pressure and viscous forces acting on the fluid.

$$\rho_l \, (\vec{u} \cdot \nabla \vec{u}) = -\nabla p + \mu_l \, \nabla^2 \vec{u} \tag{2}$$

This inertial term denotes the change in velocity with space due to the movement of the fluid. As a result, this equation describes the fluid dynamics under varying conditions.

Energy Equation (Liquid)

The energy equation plays an important role in governing both the convective and conductive heat transfer within the fluid domain.

$$\rho_l \, C_{pl} \, (\vec{u} \cdot \nabla \, T_l) = k_l \cdot \nabla^2 T \tag{3}$$

By this we can analyse the thermal energy of the fluid which is essential in optimizing the thermal behaviour

Energy Equation (Solid)

The energy equation in the solid region denotes the heat flow in the channel walls and the pin fins.

$$\nabla (k_s \cdot \nabla T_s) = 0 \tag{4}$$

In this region, the convective heat transfer is absent and it is completely governed by conduction.

III.3 PARAMETER EVALUATIONS

Hydraulic Diameter D_h:

In microscale systems like microchannel heat sinks, the hydraulic diameter replaces the conventional diameter to determine the flow behaviour, especially in non-circular cross sections.

$$D_h = \frac{4A}{2P}$$

$$D_h = \frac{4(W_{ch} \times H_{ch})}{2(W_{ch} + H_{ch})} \quad (5)$$

Reynolds Number Re:

The dimensionless number which determines the flow phase. It is the ratio of inertial and viscous forces.

$$Re = \frac{\rho_l u_l D_h}{\mu_l} \quad (6)$$

Heat Transfer Rate:

The rate of heat transfer between the walls of the channel and the fluid is calculated subsequently,

$$h = \frac{q}{T_w - T_f} \quad (7)$$

Nusselt Number Nu:

A dimensionless quantity which influences the thermal performance factor directly is the Nusselt number.

$$Nu = \frac{hD_h}{k} \quad (8)$$

Friction Factor f:

The friction factor is calculated due to the presence of the pin fins which cause resistance to the flow.

$$f = \frac{2D_h \Delta p}{L \rho u_{in}^2} \quad (9)$$

Thermal Performance Factor TPF:

TPF is the balance in the heat transport and Δp of the system.

$$TPF = \frac{Nu/Nu_o}{(f/f_o)^{1/3}} \quad (10)$$

If the TPF is > 1, then the system has a good heat transfer enhancement.

IV. RESULTS AND DISCUSSIONS

The following sessions presents a detailed discussion of the observations from the numerical simulations performed on a microchannel with pin fin enabled heated walls. The results are presented in the form of velocity and temperature variations along the channel's axial length, heat transport rates and Δp. The results discussed the possible explanations of the velocity streamline and thermal streamline distributions and the corresponding thermal characteristics.

IV.1 VELOCITY STREAMLINES

The evaluation of the velocity streamlines in the micro pin fin enabled channels offers significant insights into fluid flow and heat transfer performance in these surface modified MCHS. In the steady-state simulation carried out in this manuscript, the velocity appears uniform throughout the process and stays constant over time. A key factor in the velocity distribution is the channel's structural model; even with the same Reynolds number (Re), narrower passages produce higher velocities while wider sections display lower velocities. Furthermore, pin fins enhance heat transfer coefficients by changing the local velocity profile and positively contributing to the velocity range (Fig. 4a,b & 5a,b). Furthermore, the flow behaviour and flow rearrangements are strongly influenced by the pin height.

The simulations were conducted for two distinct fin heights, to investigate the flow manipulation over pin height (60 µm at Re 500 (Fig 4 a); Re 2000 (Fig 5 a) and 40 µm at Re 500 (Fig 4 b); Re 2000 (Fig 5 b)). Velocity vortices form around the pin fins due to the varying local velocities change the streamline nature of the inlet velocity. The flow separates across the fins, mainly affecting the surface flow towards the middle of the channel. Increased velocity occurs mostly around the fins due to redirection, and flow detachment happens near the fins, which operate as obstruction to the flow pattern. As the fin height rises, the SA available for fluid contact also increases, which instinctively improves heat transfer efficiency. Variations in fin height alter the flow pattern, creating vortices and splashes and promoting fluid mixing.

Enhanced fluid mixing leads to higher heat transfer rates, thereby increasing thermal performance. By positioning the ideal channel, the overall efficiency and TPF can be increased even though a higher fin height does cause a greater pressure drop (Fig. 4a). Higher fins are clearly correlated with higher velocity at the centre of the channel, as shown by the cross-sectional planar view. When the pin height is 60 µm instead of 40 µm, streamlines exhibit more vortices and reach higher velocities (Fig. 4) (Fig. 5). Additionally, it is observed that flow detachment and reattachment are more noticeable at the inlet section and drastically decrease as the flow approaches the outlet section. This phenomenon is common in both the pin heights. Thus, the evolution of velocity streamlines with different pin heights concludes that when the Re is high and the fin height is at maximum, the VBL redistribution also increases. This condition stimulates fluid mixing, resulting in enhanced heat transfer and better thermal performance along with pressure drop.

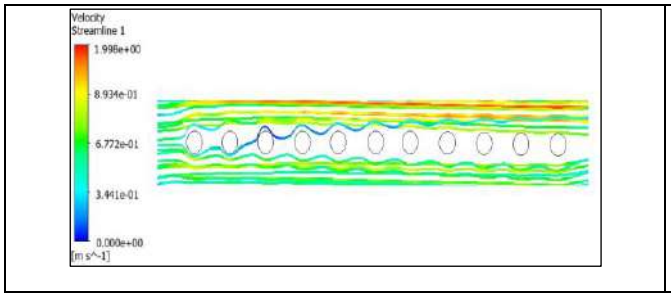

Figure 4a: Velocity streamlines on the microchannel with fin height of 60 µm at Re 500.
Source: Authors, (2026).

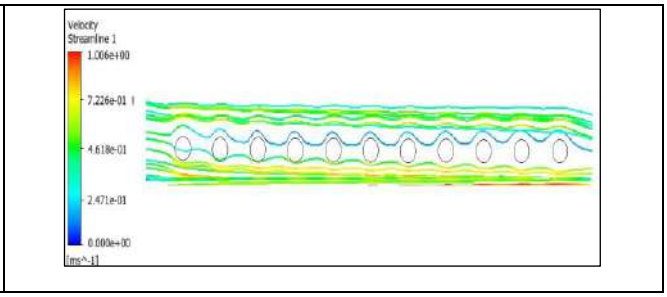

Figure 4b: Velocity streamlines on the channel with fin height of 40 µm at Re 500.
Source: Authors, (2026).

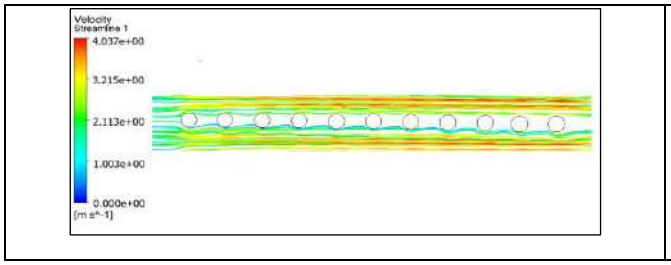

Figure 5a: Velocity streamlines on the microchannel with fin height of 60 µm at Re 2000.
Source: Authors, (2026).

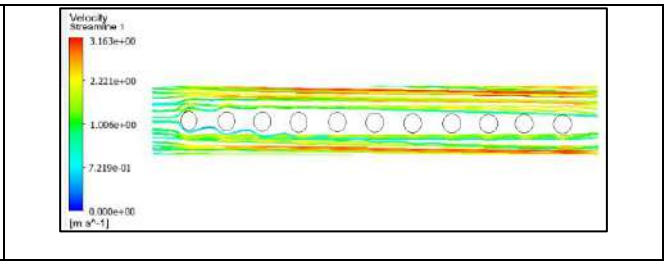

Figure 5b: Velocity streamlines on the microchannel with fin height of 40 µm at Re 2000.
Source: Authors, (2026).

At a Reynolds number of 2000, the velocity streamlines become more intense and complex due to increased inertial forces. With the 60 µm pin fins, the flow exhibits significant detachment and reattachment around the fins, creating flow mixing and high-velocity in the narrow gaps (Fig 5 a, b). The greater height of the fins increases blockage and enhances interaction with the fluid , leading to accelerated flow around the fins and improved fluid mixing, which contributes to better thermal performance. Instead, produces high pressure drop and makes it inefficient for a thermal system. In contrast, the 40 µm pin fins display relatively less intense streamline patterns when compared to fin 60 µm. The flow remains neither aligned nor distracted with the direction of the channel, and the disturbance caused by the fins is less pronounced. While this results in considerably high pressure drop, it also leads to reduced mixing and thermal enhancement. In both scenarios, flow disturbances are more prominent near the inlet and gradually stabilize toward the outlet. However, the taller fins (60 µm) with low Re (Fig 4a) induce stronger streamline evolution and create better heat transfer conditions.

IV.2 TEMPERATURE CONTOURS

The integration of fins within MCHS significantly enhances heat transportation productivity, as indicated in the higher temperature gradients observed along the channel length near the surface of the channel. The presence of fins not only modifies the flow dynamics but also directly contributes to improved thermal performance by increasing the efficient heat exchange surface area. Among the various fin design parameters, fin height serve a critical part in determining the thermal characteristics of the system. By increasing the surface area available for fluid contact, taller fins promote a steeper temperature gradient across the channel. This increase in the surface area-to-volume ratio is particularly beneficial in microchannel applications, where maximizing heat exchange within a limited space is essential.

Fin height variation has a direct impact on fluid flow behaviour, improving mixing and, as a result, thermal boundary layer distribution. This effect is particularly apparent at the outlet, where taller fins are associated with higher outlet temperatures (Fig. 7 & 9). The temperature contours make it easy to see how the TBL changes as the fluid travels downstream close to the outlet. The temperature gradients that have been observed, verify that the addition of fins considerably modifies the flow and temperature fields by encouraging the expansion of the TBL and increasing the total heat transfer rate. Furthermore, the height and arrangement of the fin have a significant effect on the thermal-fluidic performance of the system. A constant inlet fluid temperature of about 300 K is used at the start of the simulation.

As the working fluid travels through the channel, it absorbs heat from the heated base plate, causing a progressive temperature rise along the channel length. The interaction between the fluid and the pin fins facilitates greater heat absorption, resulting in noticeable temperature increases downstream. This interaction also leads to flow separation and detachment, which improves the temperature gradient due to induced mixing. As a result, the temperature distribution across the channel becomes more uniform, indicating effective convective heat transfer. A comparison between fins of 60 µm and 40 µm in height reveals that the taller fins (60 µm) disrupt and redirect the flow more effectively, leading to superior thermal performance (Fig 7 & 9).

These taller fins create more pronounced flow disturbances, contributing to a more uniform temperature field and enhancing overall heat dissipation. In contrast, the shorter fins (40 µm) allow the fluid to pass through with minimal disruption, resulting in reduced interaction and lower heat transfer rates (Fig 6 & 7). The findings of this study demonstrate that fins with an optimal height of 60 µm strike a balance sufficiently disturbing the flow constructively without causing excessive temperature peaks (Fig 7). This configuration creates a more uniform thermal field and efficient heat dissipation, making it a promising design for high-performance microchannel heat sinks.

IV.3 EFFECT OF PIN FINS ON BOUNDARY LAYER DISTRIBUTION

The incorporation of pin fins within microchannel configurations is essential for elevation of thermal performance of the system. One primary advantage of using fins is that significant improvement in the SA:V ratio available for heat exchange. By extending the solid-fluid interface, pin fins create additional pathways for heat to transfer from the channel walls to the working fluid. Furthermore, the presence of pin fins disrupts the smooth flow of fluid through the channel. This disruption alters the growth of the TBL, promoting greater convective heat transfer. As the fluid interacts with the fins, localized flow separation and reattachment occur, enhancing fluid agitation and mixing.

These changes in flow behavior contribute to improved thermal interaction between the fluid and the channel surfaces. Pin fins also play a critical role in achieving temperature uniformity within the channel. By enhancing fluid mixing, they help distribute the absorbed heat more evenly by reducing the formation of localized hot spots. This results in a more uniform temperature field along the channel, which is beneficial for both thermal management and the structural integrity of heat-sensitive systems. However, it is important to note that pin fins introduce resistance to flow. The obstruction they create leads to an increased pressure drop across the channel. While this can be seen as a drawback, it is usually accompanied by a simultaneous increase in heat transfer capability.

The greater the resistance and fluid interaction, the more heat is transferred to the fluid, resulting in improved thermal performance (Fig 10). It has also been seen from Fig 10 that the fins placed in the inlet section has better heat dissipation capacity as compared to the outlet section of the channel. There is a significantly temperature variation along the fin surface along the height of the pin as more fluid is in touch with the upper surface of the fin. In conclusion, pin fins positively contribute to the operation of microchannel heat sinks by increasing surface area, disrupting flow to enhance convective heat transfer, and promoting uniform temperature distribution. Despite the higher pressure drop they cause; the trade-off is justified by the significant improvement in heat dissipation.

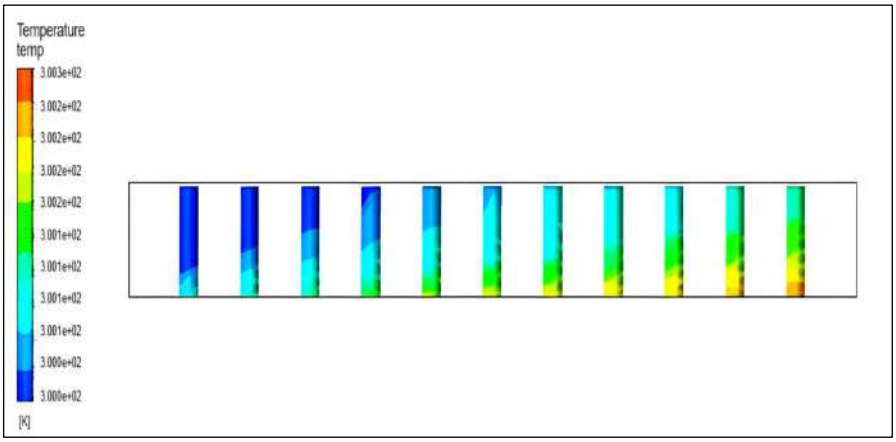

Figure 10: Effect of Temperature Distribution along the Fins.
Source: Authors, (2026).

Figure 11: Wall Shear-Induced Flow Diversion Around a Single Pin Fin at Varying Reynolds Numbers (a) 60 µm Re 2000; (b) 40µm Re-2000; (c) 60µm Re 500; (d) 40µm Re500.
Source: Authors, (2026).

The impact of wall shear forces on the flow diversion behaviour around a single pin fin under various geometric and flow conditions is shown in Figure 11. The intensity of the streamline colors highlights how changes in pin height and Reynolds number impact fluid deviation by revealing shear related velocity gradients. The flow is clearly strongly diverted and the pin fin is surrounded by dense streamlines that curve sharply. The obvious bending indicates a strong fluid to fin surface interaction and a high shear influence (Fig. 11 (a)). Despite a high Reynolds number, the reduced pin height leads to less pronounced deviation of the streamlines. The flow bypasses the shorter pin more easily, resulting in a comparatively weaker shear-induced diversion (Fig 11 (b)). At a lower Reynolds number, the bending of streamlines around the taller pin is still observable, but the overall flow energy is reduced. As a result, diversion patterns become less intense and more fluid (Fig. 11 (c)). Because of the negligible wall shear effects caused by the lower velocity and pin height, there is very little flow deflection in this case (Fig 11 (d)). In conclusion, flow behaviour is greatly influenced by both pin height and Reynolds number. While lower Reynolds numbers reduce the energy available for such diversion, a higher pin height increases wall shear-induced flow diversion.

IV.4 NUSSELT NUMBER

The Nusselt number (Nu) is a critical non-dimensional parameter for assessing flow induced heat transfer in relation to contact induced fluid-solid interface. (Fig 12) illustrates a comparative analysis of Nu values as a function of Re for three configurations: a plain microchannel without fins, a finned channel with a pin height of 40 µm, and a finned channel with a pin height of 60 µm. The results clearly show that the inclusion of pin fins elevates the convective heat transfer rate across all Reynolds numbers simulated. This improvement is due to the stimulated SA provided by the fins which intensifies the thermal interplay amidst the fluid and solid. Additionally, the fins help disrupt the boundary layer and promote localized mixing, thereby improving the mechanisms of convective heat transfer.

As demonstrated in (Fig 12) the Nu augments steadily with Re for all cases, which is consistent with the expected behavior of forced convection in laminar and transitional flow regimes. However, channels equipped with pin fins exhibit significantly higher Nusselt numbers compared to the baseline configuration without fins. Among the finned options, the design with a pin height of 60 µm consistently shows the highest Nu, indicating superior thermal performance. This enhancement is particularly noticeable at lower Reynolds numbers (i.e., Re = 500) where the effects of increased surface area and induced mixing are more pronounced due to weaker inertial forces. Although the relative improvement decreases slightly as the Re increases, the performance advantage of the taller fins (60 µm) remains evident across the range.

Overall, the findings confirm that increasing fin height improves the convective heat transfer rate (approx.. 60%) leading to higher Nusselt numbers. The configuration with a pin height of 60 µm offers the most effective thermal enhancement and is therefore ideal for microchannel heat sink applications that require better heat dissipation performance. The variation of the heat Transfer Gain Ratio (Nu/Nu_0) with Reynolds number for channels incorporating pin fins of 40 µm and 60 µm heights are shown in Fig 13. Nusselt number denoted by Nu for finned configurations, while Nu_0 denotes the value for a plain channel without fins. This ratio yields a normalized measure of heat transfer gain due to the inclusion of fins, independent of baseline performance.

The graph shows that, particularly at low Reynolds numbers, both finned configurations significantly outperform the plain channel in terms of heat transfer. Interestingly, the 60 µm fin consistently outperforms its 40 µm counterpart in terms of gain ratio, with the biggest improvement seen at Re = 500. This suggests that in lower flow regimes, the advantages of increased surface area and improved convective mechanisms are more potent. The relative gain from pin fins, however, slightly decreases as the Reynolds number rises, indicating the diminished impact of structural improvements under higher inertial forces. The findings show that although both fin heights improve thermal performance, the 60µm configuration is more efficient, especially when convective improvements are most advantageous.

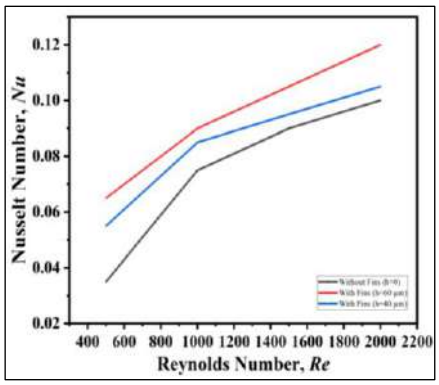

Figure 12: Variation of Nusselt number along various Reynolds numbers
Source: Authors, (2026).

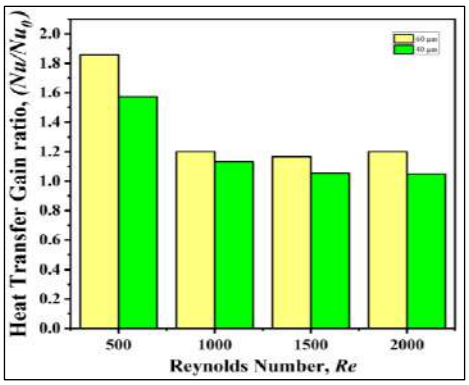

Figure 13: Heat Transfer Gain Ratio (Nu/Nu_0) vs Reynolds Number
Source: Authors, (2026).

IV.5 FRICTION FACTOR F

The friction factor is a non-dimensional parameter that quantifies the resistance a fluid encounters due to wall shear and geometric constraints within a channel. Figure 14 illustrates the deviation of friction factor with Re for three cases: a smooth channel without fins, and channels with pin fins of heights 40 µm and 60 µm. The presence of pin fins introduces additional obstacles within the channel which increases flow resistance and contributes to a higher pressure drop. These structural intrusions increase viscous drag as Figure 14 illustrates, channels with fins consistently show higher friction factors when compared to the smooth channel. The channel with 40 µm fins exhibits the highest friction factor across all Reynolds numbers among the tested configurations. This is explained by the development of recirculation zones, which increase wall shear stresses, and a stronger blockage effect. Despite having taller fins, the 60 µm fin configuration exhibits lower friction factors. This may be due to more efficient flow redirection and reduced wake interference at higher Reynolds numbers. For all cases, the frictional factor drops steadily with rise in Re, due to reduced influence of viscous forces in higher flow regimes.

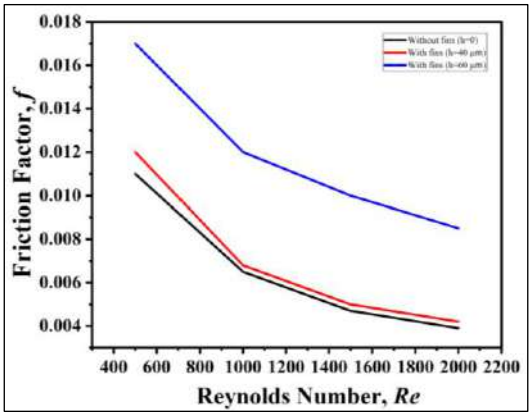

Figure 14: Friction factor vs Reynolds number.
Source: Authors, (2026).

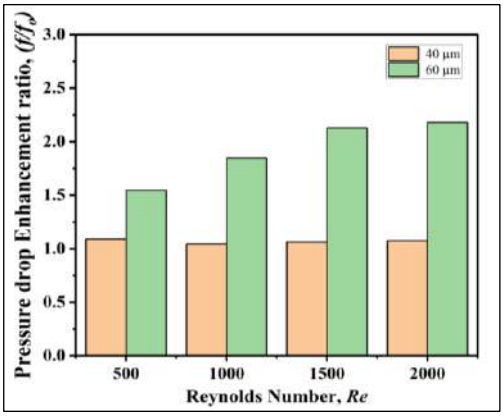

Figure 15: Pressure drop enhancement ratio vs Re for pin fins of 40 µm and 60 µm heights.
Source: Authors, (2026).

However, Finned channels exhibit higher resistance than the smooth configuration, but the relative differences between configurations are still consistent. These results highlight the fact that integrating fins can cause heat transfer, but it also raises the pressure drop. Therefore, choosing fin geometries for microchannel heat sinks requires striking a balance between hydraulic performance and thermal enhancement. The relationship between the pressure drop enhancement ratio (f/f_0) and the Reynolds number for pin fins of heights 40 µm and 60 µm (Fig 15). f_0 represents the friction factor of a plane channel while f denotes the friction factor for the pin fin configurations. The enhancement ratio increases with the Reynolds number for both fin heights, indicating that the pressure resistance rises due to the flow obstruction caused by the fins.

The 60 µm fins shows higher pressure drop across all Reynolds numbers, which can be attributed to greater blockage and surface area. Although this leads to increased flow resistance, it notably improves convective heat transfer. In contrast, the 40 µm fins exhibit a more moderate increase in pressure, achieving a balance between thermal performance and pumping power. These findings emphasize that integrating pin fins enhances heat transfer but also increases Δp which made it crucial to balance thermal performance with hydraulic efficiency when selecting fin geometries for microchannel heat sinks. Achieving this balance ensures optimal system performance without excessive pumping power requirements.

IV.6 THERMAL RESISTANCE:

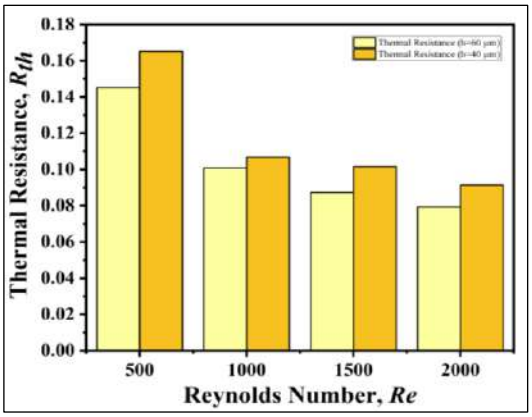

Figure 16: Pressure drop enhancement ratio vs Re for pin fins of 40 µm and 60 µm heights.
Source: Authors, (2026).

The relationship between thermal resistance (Rth) and Reynolds number (Re) for pin fin heights of 40 µm and 60 µm is clearly demonstrated in (Fig 16). The Thermal resistance lowers as Re rises for both fin heights, denoting a significant improvement in heat dissipation at higher flow rates.

Among all Reynolds numbers, the 60 µm fin configuration consistently exhibits lower thermal resistance than the 40 µm fin. This distinctively indicates superior thermal performance which in turn attributed to the expanded surface area. The most substantial reduction in thermal resistance occurs between Reynolds numbers of 500 and 1000, after which the decrease slows down, but the trend remains evident. This data confirms that taller fins (60 µm), in conjunction with higher flow rates, enhance convective heat transfer and make the system significantly more thermally efficient.

IV.7 THERMAL PERFORMANCE FACTOR:

The thermal performance factor (TPF) is a key metric employed to assess the balance between heat transfer enhancement and the resulting flow resistance. It is typically derived from the ratio of the Nu to f which allows for a comprehensive assessment of both thermal and hydraulic performance in a single criterion. The TPF varies with Re for three different channel configurations: a smooth channel, a channel with pin fins of height 40 µm, and a channel with pin fins of height 60 µm (Figure 17). The results clearly demonstrate the positive impact of incorporating pin fins on overall thermal performance. The reference channel without fins consistently shows the lowest thermal performance across all Reynolds numbers.

This is primarily due to its limited surface area and lack of mechanisms to disrupt flow. In contrast, adding pin fins significantly enhances thermal performance through improved convective heat transfer and better fluid mixing. Notably the configuration featuring 60 µm fins achieves the highest thermal performance factor among the tested setups. This improvement can be attributed to the larger SA in connection with the fluid, which allows for higher heat transfer rates without a surplus hike in Δp. The taller fin geometry promotes greater flow disturbance and thinning of the TPF, thus optimizing the balance between heat transfer and flow resistance.

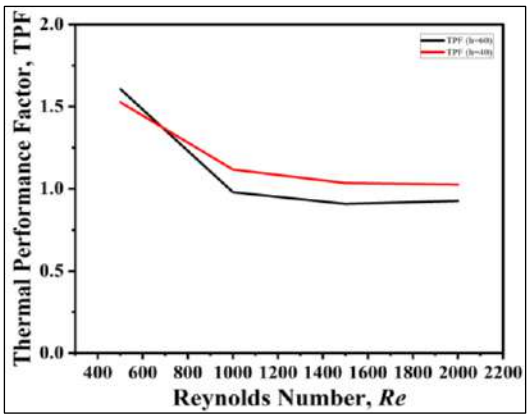

Figure 17: Thermal Performance Factor vs Reynolds number.
Source: Authors, (2026).

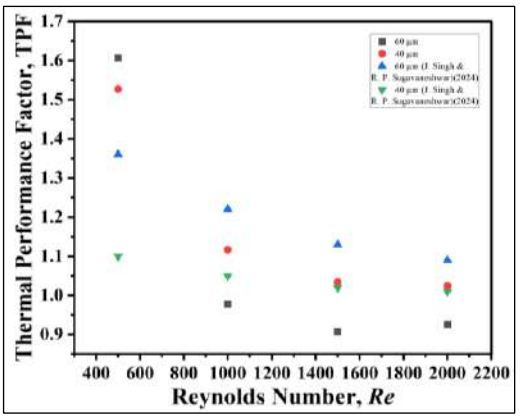

Figure 18: Thermal Performance Factor vs Reynolds number.
Source: Authors, (2026).

The configuration of 40 µm fins shows a moderate improvement over the non fin configuration but is still less effective than the 60 µm fins. This highlights the importance of fin geometry, specifically the height in determining overall system efficiency. The trends observed in Figure 17 reinforce the idea that optimal fin design is crucial for maximizing thermal performance in microchannel applications. The validation of the Thermal Performance Factor (TPF) for two fin heights (40 µm and 60 µm) in comparison to published results by J. Singh & R. P. Sugavaneshwar [3] (Fig 18). The validation clearly shows the comparison made on both the works. The following points states the comparison performed:

- The TPF values from this study closely correspond with the results reported by J. Singh & R. P. Sugavaneshwar confirming the accuracy and credibility of the numerical model.
- For both fin heights, the deviations are minimal at higher Reynolds numbers, which validates the thermal behavior captured in the simulation.
- The TPF consistently decreases with increasing Re in both datasets by reaffirming the trend that higher flow rates reduce the thermal enhancement relative to frictional losses.
- The strong alignment in performance trends supports the reliability and consistency of the simulation setup, meshing, and boundary conditions with previously established results.

IV.8 INTERNAL EFFICIENCY OF THE SYSTEM

The variation of internal efficiency is expressed as the ratio of Nusselt number to friction factor (Nu/f), with Re for three channel configurations: a smooth channel (0 µm), and channels with pin fins of 40 µm and 60 µm heights (Fig 19). Internal efficiency is a critical performance indicator as it balances heat transfer enhancement (Nu) against the pressure drop penalty (f) by offering insight into overall thermal-hydraulic effectiveness.

The internal efficiency increases with Reynolds number for all configurations, indicating improved convective heat transfer performance at higher flow rates. Among the three cases, the channel with 60 µm fins consistently demonstrates the highest internal efficiency followed by the 40 µm fin configuration, while the smooth channel perform least efficiently. The superior performance of the 60 µm fins can be attributed to their larger surface area and enhanced flow disruption which intensify thermal mixing without a proportionally high increase in pressure drop.

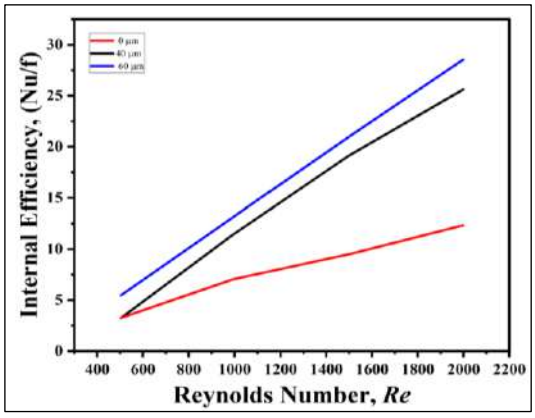

Figure 19: Internal Efficiency vs Reynolds number.
Source: Authors, (2026).

These results highlight that increasing fin height not only boosts heat transfer but also maintains a favorable balance with the associated pressure loss, making it a promising design choice for high-performance microchannel heat sinks. Notably at Re - 500, the 60 µm pin fin configuration achieves a desirable combination of moderate pressure drop and elevated thermal performance establishing it as an efficient and balanced solution for microchannel heat transfer systems.

V. CONCLUSIONS

This study presents a detailed numerical investigation into the augmentation of heat transfer in microchannels with the use of pin fins. The research employed computational fluid dynamics (CFD) simulations to analyze over 55 different heat sink configurations. Two distinct fin heights, both with identical diameters, were evaluated under consistent boundary conditions to assess their thermal performance. The results indicate that the fin height matching the full channel height (60 µm) delivers optimal thermal performance. Among the various flow conditions examined, a Re of 500 combined with the 60 µm fin height exhibited the most efficient thermal behavior, achieving substantial heat transport enhancement while upholding manageable flow resistance.

The introduction of pin fins significantly increased the Nusselt number and improved the overall thermal characteristics compared to conventional channel geometries without fins. This optimal configuration not only produced a higher Nusselt number but also resulted in a greater friction factor, highlighting the trade-off between thermal enhancement and pressure drop. Despite the increased pressure loss, the configuration with 60 µm pin fins achieved up to 60% higher thermal performance compared to the baseline case without fins, demonstrating its considerable advantage in thermal efficiency. Overall, the findings confirm that a fin height of 60 µm at a Reynolds number of 500 provides robust and consistent performance across varying operating conditions, making it highly suitable for high-efficiency thermal management applications.

ABSTRACT

Aeronautical structures commonly use perforated skin panels and wing ribs to reduce weight while maintaining satisfactory mechanical performance. However, the combined influence of aperture size, material anisotropy, and fiber orientation on global and net stress concentration factors in orthotropic composites remains insufficiently quantified. This work aims to analyze the stress concentration behavior of perforated panels made of isotropic and orthotropic composites. A uniaxial tensile load is modeled using the finite element method (Abaqus) and classical analytical models (Heywood, Lekhnitskii, and Green-Zerna), supplemented by parametric calculations in MATLAB for glass/epoxy and carbon/epoxy plates. The results show a maximum stress concentration factor of $K_{tg} \approx 6.6$ for a geometric ratio d/W = 0.5 under an applied stress of 10 MPa, with a maximum error of 5% between the analytical and numerical models. A reduction of approximately 60% in the concentration factor is observed for a fiber orientation of 0° . Finally, the study proposes global and local stress concentration maps that incorporate fiber geometry/orientation compatibility limits, enabling the optimization of composite wing ribs while preserving the advantages of lightness, stiffness, and control of local stress amplifications, and opening up prospects for the study of damage and fatigue.

I. INTRODUCTION

During their operational life, aircraft are mainly made up of thin metal or composite structures designed to withstand fundamental structural loads (tension, compression, and shear) as well as aerodynamic stresses. In order to maintain aerodynamic performance, it is essential that the chord geometry and wing profile are maintained with minimal elastic and plastic deformation. Wing ribs are essential internal structural components that support the wing surface, maintain the aerodynamic profile configuration, and transfer internal stresses. They play a key role in distributing and readjusting shear forces, which helps to reduce the effective span of the spars and reinforce the overall rigidity of the structure. In the 21st century, the use of metal and composite ribs has become essential due to their ability to improve mechanical properties, reduce structural weight, and enhance corrosion resistance.

Materials such as aluminum, steel, titanium, and their alloys are frequently used, along with an increasing proportion of sophisticated composite materials. In the aerospace, marine, and automotive industries, it is common to use panels and shells with various cutouts for functionality and weight reduction purposes. However, these geometric discontinuities such as holes, notches, or abrupt changes in cross-section represent potential points where stresses can concentrate, leading to cracking and premature failure. In reality, virtually all aeronautical structures have such geometric irregularities or microstructural anomalies, making it essential to examine in detail their impact on the strength and longevity of structures. Much previous work has been devoted to modeling and analyzing the stress concentrations induced by these discontinuities.

By [1] used the finite element method in Abaqus to study the stress fields in ribs pierced with circular, elliptical, and rectangular cutouts, showing that optimizing the geometry of the openings improved the mechanical strength of light aircraft ribs. Similarly [2] analyzed the behavior of composite ribs subjected to different types of loading and fiber orientations using numerical tools, evaluating the stress tensor and critical displacements. Furthermore, classical analytical work carried out by [3-7] has provided reference solutions for stress concentration in perforated isotropic plates, particularly in the presence of circular holes. More recently, several studies have examined the influence of the diameter/width ratio, the stress concentration factor (SCF), and deformations in isotropic and orthotropic plates subjected to static tensile and shear stresses [8-10].

In this context, the present work takes a comparative approach to the mechanical behavior of perforated rectangular plates, representative of wing ribs with and without circular cutouts. The finite element technique is used to determine the stress concentration factors around a central circular hole in isotropic and orthotropic plates exposed to a unidirectional tensile load. The key parameters examined include the diameter/width ratio d/W, the fiber direction, and the length/width geometric proportions. Various materials are involved in the numerical simulations performed in Abaqus: Al 2024-T3 aluminum, glass/epoxy composite, and carbon/epoxy composite. The primary goal of this research is to examine and compare the global and net stress concentration factors in isotropic and composite plates with holes, in order to deepen our understanding of the combined effect of the geometry of the openings and the direction of the fibers. To this end, the following research questions are posed:

- RQ1: How does the d/W ratio influence the global and net stress concentration factors in isotropic and composite plates?
- RQ2: To what extent does fiber orientation modify the intensity and distribution of stresses around a circular hole?
- RQ3: What is the level of agreement between analytical predictions and results obtained using the finite element method for different geometric and material configurations?

This work makes several original contributions. First, it provides an in-depth parametric analysis of global and net stress concentration factors as a function of the d/W ratio, fiber orientation, and material type (Al 2024-T3, glass/epoxy, and carbon/epoxy). Second, it implements cross-validation between numerical simulations in Abaqus and analytical calculations implemented in MATLAB, making it possible to identify the areas of validity and limitations of simplified analytical models. Third, it highlights the particular effect of fiber alignment on stress concentration in composite wing ribs, including for configurations with multiple openings. Finally, the numerical results are verified using analytical calculations performed in MATLAB, ensuring the overall consistency of the various methods while highlighting the limitations of analytical models in certain complex configurations. This research is distinguished by its in-depth examination of the impact of fiber alignment on stress density in composite wing ribs, specifically with regard to plates with two circular holes. It thus contributes to improving the structural behavior of aeronautical composite structures.

II. MATERIALS, METHODS, AND THEORETICAL MODELING

In this study, there are two complementary steps involved in examining the mechanical behavior of wing structures and the problem of stress concentrations. First, using a profile of NACA-2414 to model and simulate an aircraft wing, with or without skin, depending on whether the ribs are cut out or not. By using the finite element method, it is possible to model and simulate the distribution of stresses at the ribs and wing section. Pre-processing includes generating the geometric model imported from a Python program, extracting the geometry and mesh, assigning material properties, and defining boundary conditions and loads to determine stress intensities and concentrations. The second stage, which is theoretical in nature, involves analyzing the geometric discontinuities responsible for stress concentrations using orthotropic perforated rectangular test specimens (Glass/Epoxy and Carbon/Epoxy) measuring 100 × 50 × 1 mm, cut from the wing rib. These specimens were studied numerically using the finite element method in Abaqus [11] to evaluate the global and net stress concentration factors around the circular openings. The influence of fiber orientation $\theta=[0°,90°]et[0°,-90°]$ was examined using MATLAB [12] , as was the effect of the geometric ratio (d/W), which varies between 0.1 and 0.5, on the stress concentration factor values. The stress concentration factor (SCF) is defined, as stated by Peterson in 1974, as the ratio of the maximum local stress to the nominal applied stress: $\theta=[0°,90°]et[0°,-90°]$

$$K_t = \frac{\sigma_{max}}{\sigma_{nom}} \quad (1)$$

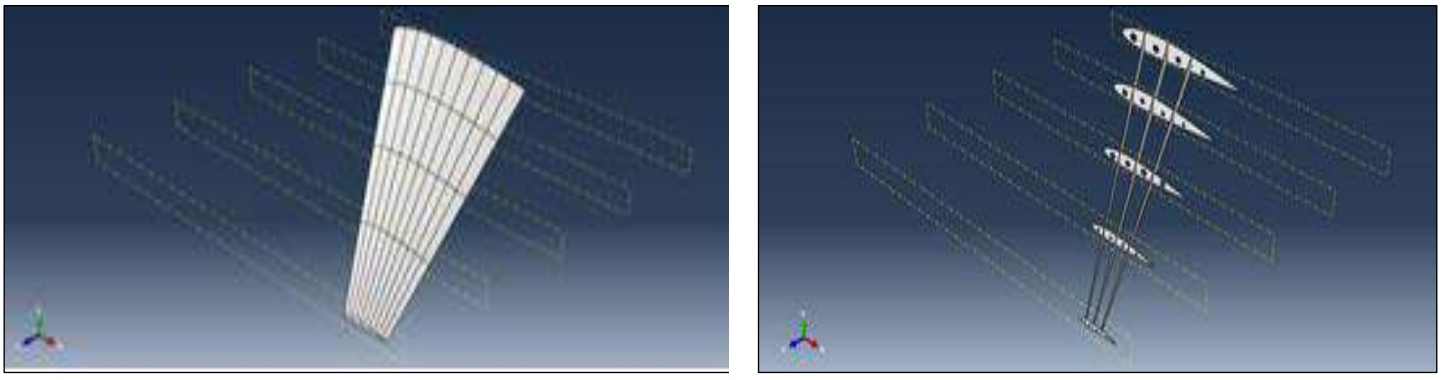

Figure 1: Aircraft wing with/without coating with hole.
Source: Authors, (2026).

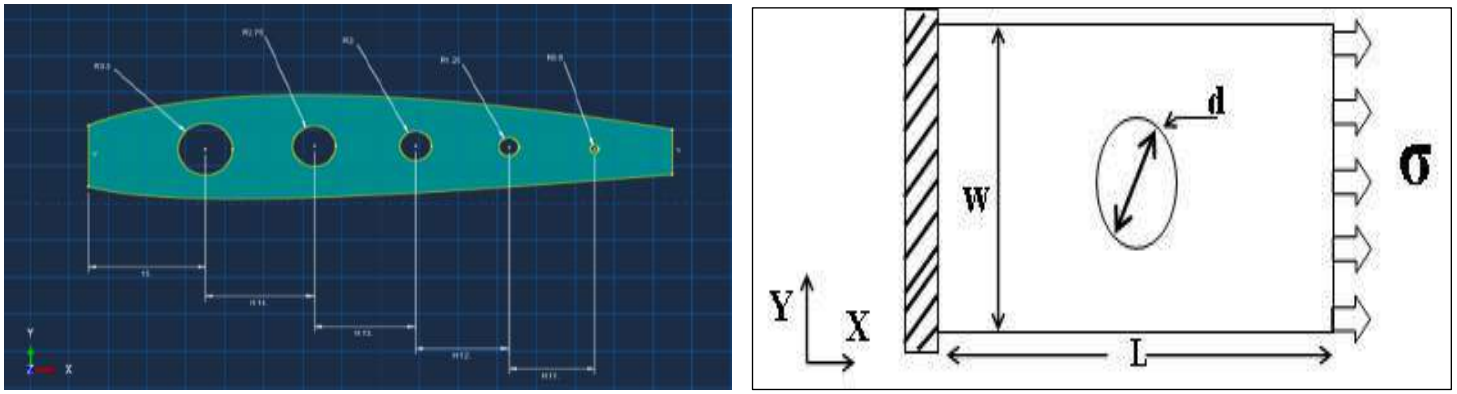

Figure 2: Plate with central hole subjected to uniaxial tension.
Source: Authors, (2026).

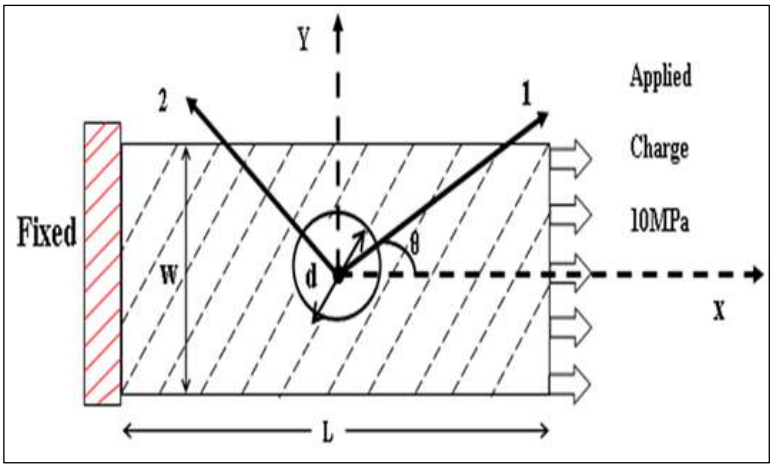

Figure 3: Laminated composite plate with circular hole.
Source: Authors, (2026).

For a rectangular orthotropic plate that has a central circular hole, Heywood (1952) proposed the following expression:

$$\frac{K_{Tg}^{\alpha}}{K_{tg}} = \frac{3\left(1-\frac{d}{w}\right)}{2+\left(1-\frac{d}{w}\right)^{3}} + \frac{1}{2}\left(\frac{d}{w}M\right)^{8}\left(K_{T}^{\alpha}-3\right)\left(1-\left(\frac{d}{w}M\right)^{3}\right) \quad (2)$$

Where K_{Tg}^{α} and K_{Tg} represent the stress concentration factors for an infinite and a finite plate, respectively. The magnification factor (M) is solely dependent on the geometric ratio (d/W).

$$M^{2} = \sqrt{1-8\left(\frac{3\left(1-\frac{d}{w}\right)}{2+\left(1-\frac{d}{w}\right)^{3}}-1\right)}\Big/2\left(\frac{d}{w}\right)^{2} \quad (3)$$

Lekhnitskii (1963) [13] introduced an alternative formulation of the SCF for orthotropic plates :

$$K_{T}^{\alpha} = 1+\sqrt{2\left(\left(\sqrt{\frac{E_{11}}{E_{22}}}\right)-\nu_{12}\right)+\frac{E_{11}}{G_{12}}} \quad (4)$$

Where:

E_{11} and E_{22} are the moduli of elasticity in the main directions.
G_{12} = is the in-plane shear modulus.
ν_{12} = is the Poisson's ratio.

An infinite SCF equal to 3 for an isotropic plate with a circular hole By simplifying the equation (2) we have:

$$\frac{K_{Tg}^{\alpha}}{K_{tg}} = \frac{3\left(1-\frac{d}{w}\right)}{2+\left(1-\frac{d}{w}\right)^{3}} \tag{5}$$

$$\sigma_{avg} = \frac{\sigma_{nom}}{1-\frac{d}{w}} \tag{6}$$

The SCF using Heywood's formulation will then be:

$$K_{Heywood} = K_{Tg}\left(1-\frac{d}{w}\right) \tag{7}$$

Lekhnitskii's (1963) theory is chosen to analyze the stress distribution in an orthotropic plate, the expression of the SCF corresponding to Lekhnitskii's theory is :

$$\begin{aligned} K_t = \frac{\sigma_\alpha}{\sigma^\infty} = \frac{E_\alpha}{E_1}\Big[-(\cos\varphi)^2 + (m+n)(\sin\varphi)^2\Big] m(\cos\alpha)^2 + \\ \Big[(1+n)(\cos\varphi)^2 - m(\sin\varphi)^2\Big](\sin\alpha)^2 - \\ n(1+m+n)\sin\varphi\cos\varphi\sin\alpha\cos\alpha \end{aligned} \tag{8}$$

Where:

E_α = modulus of elasticity in the direction defined by the angle α given by the following relationship :

$$\frac{E_\alpha}{E_1} = \frac{1}{(\sin\alpha)^4 + \frac{E_1}{E_2}(\cos\alpha)^4 + \frac{1}{4}\left(\frac{E_1}{G_{12}} - 2\nu_{12}\right)(\sin 2\alpha)^2} \tag{9}$$

φ = Angle of application of the tensile force relative to the main elastic axis.

α = Location angle of stress concentration factor.

The values of m and n are defined by :

$$m = \sqrt{\frac{E_x}{E_y}} \qquad n = \sqrt{2\left(\left(\sqrt{\frac{E_x}{E_y}}\right) - \nu_{xy}\right) + \frac{E_x}{G_{xy}}} \tag{10}$$

The elastic characteristics $\{E_x, E_y, G_{xy}, \nu_{xy}, \nu_{yx}\}$ in the reference frame (x, y) are linked to the material elasticity characteristics $\{E_1, E_2, G_{12}, \nu_{12}, \nu_{21}\}$ by equations: (13), (14), (15), (16):

$$\begin{aligned} \frac{1}{E_x} &= \frac{C^4}{E_1} + \frac{S^4}{E_2} + \left(\frac{1}{G_{12}} + \frac{2\nu_{21}}{E_1}\right)C^2S^2 \\ \frac{1}{E_y} &= \frac{S^4}{E_1} + \frac{C^4}{E_2} + \left(\frac{1}{G_{12}} + \frac{2\nu_{21}}{E_1}\right)C^2S^2 \\ \frac{\nu_{xy}}{E_y} &= \frac{\nu_{yx}}{E_x} = \frac{\nu_{21}}{E_1} - \left(\frac{1}{E_1} + \frac{1}{E_2} + \frac{2\nu_{21}}{E_1} - \frac{1}{G_{12}}\right)C^2S^2 \\ \frac{1}{G_{xy}} &= \left(\frac{1}{E_1} + \frac{1}{E_2} + \frac{2\nu_{21}}{E_1}\right)C^2S^2 + \frac{1}{G_{12}}\left(C^2+S^2\right)^2 \end{aligned} \tag{11}$$

In equations (13), (14), (15) and (16), the parameters C and S are the cosine and sine of the angle between the fibers and the x-axis. To determine the stress distribution around the circular hole in a composite plate. According to the theory of Green and Zerna (1654) [14] , the FCC can be expressed by the following formula:

$$K_t = \frac{\sigma_\alpha}{\sigma^\infty} = \frac{N_1 + N_2 + N_3}{\left(1+\gamma_1^2 - 2\gamma_1\cos 2(\alpha-\theta)\right)\left(1+\gamma_2^2 - 2\gamma_2\cos 2(\alpha-\theta)\right)} \tag{12}$$

The expressions for γ_1 and γ_2 are :

$$\gamma_1 = \frac{\sqrt{\left(\frac{E_2}{2G_{12}} - \gamma_{21} + \sqrt{\left[\left(\frac{E_2}{2G_{12}} - \gamma_{21}\right)^2 - \frac{E_2}{E_1}\right]}\right)} - 1}{\sqrt{\left(\frac{E_2}{2G_{12}} - \gamma_{21} + \sqrt{\left[\left(\frac{E_2}{2G_{12}} - \gamma_{21}\right)^2 - \frac{E_2}{E_1}\right]}\right)} + 1}$$

$$\gamma_2 = \frac{\sqrt{\left(\frac{E_2}{2G_{12}} - \gamma_{21} - \sqrt{\left[\left(\frac{E_2}{2G_{12}} - \gamma_{21}\right)^2 - \frac{E_2}{E_1}\right]}\right)} - 1}{\sqrt{\left(\frac{E_2}{2G_{12}} - \gamma_{21} - \sqrt{\left[\left(\frac{E_2}{2G_{12}} - \gamma_{21}\right)^2 - \frac{E_2}{E_1}\right]}\right)} + 1} \tag{13}$$

$$\begin{cases} N_1 = (1+\gamma_1)(1+\gamma_2)\left(1+\gamma_1+\gamma_2+\gamma_1\gamma_2 - \cos(\alpha-\theta)\right) \\ N_2 = -4\left[\gamma_1+\gamma_2-(1+\gamma_1\gamma_2)\cos 2(\alpha-\theta)(\sin\alpha)^2\right] \\ N_1 = -4(\gamma_1\gamma_2-1)\sin 2(\alpha-\theta)\sin\alpha\cos\alpha \end{cases} \tag{14}$$

Table 1: Results of mesh refinement.

Hole	Global stress concentration factor (analytic)	Global stress concentration factor (FEM)	
d/w	Heywood	Element Shape	Triangular
		Elements Number	Mesh type : STRI65
d/w=0.04	6.57	1134	4.296
	6.57	1341	5.159
	6.57	1461	5.298
	6.57	1572	6.915
	6.57	1632	6.080
	6.57	1676	6.099

To minimize computational costs, a coarse mesh was modeled in the region far from the critical areas, while local mesh refinement was conducted in the region around the openings. The triangular mesh used in the present analysis, consisting of STRI65 elements with six nodes, was shown to be efficient in the region with large stress concentrations. To validate the accuracy of the FEM simulation in the commercial code Abaqus, the mesh convergence study was conducted using the diameter-to-width ratio of d/W = 0.04 and comparing FEM data with Heywood's exact solution. It can be concluded that, using a coarse mesh with a smaller number of elements (total of 1134), the global stress concentration factor (K_t = 4.296) was lower than its exact value (K_t = 6.57), implying an error in the underestimation of stresses attributable to inadequate modeling of the stress gradient in the vicinity of the hole.

As the mesh was successively refined, the stress concentration factor gradually increased to 6.599 with a total of 1742 elements, being in excellent agreement with the exact results. This simulation results in excellent convergence of the FEM solution, thereby ascertaining the effectiveness of the triangular mesh in simulating accurately the localized stress pattern. The adopted strategy in mesh generation, thus, has proved to be most optimum in terms of computational accuracy and costs.

III. RESULTS AND DISCUSSIONS

III.1 STRESS VARIATION AND FIBER ORIENTATION IN THE DIRECTION OF TENSILE LOADING

Composite plates with a circular hole were subjected to tensile loading. The graphs show the variation of the stress concentration factor in the direction of uni-axial loading of the orthotropic plate fitted with circular hole of diameter (10, 16 , 22, 28, 30, 34).The different curves correspond to different fiber orientations θ (- 90°,- 60°,- 45, 0°,45°, 60°, 90°). The elastic characteristics of orthotropic materials given in table.

(a) (b)

Figure 5: variation in stress at edge of circular hole for (a) carbon/epoxy and (b) glass/epoxy.
Source: Authors, (2026).

The graph of a1 shows the variation in normal stress σ_{xx} as a function of the angle θ for orthotropic perforated plates (circular hole) made of composite materials of Carbon / Epoxy and Glass / Epoxy with three hole diameters of 10 mm, 16 mm, and 22 mm. It may be seen that, for both materials, the value of stresses attains a peak at around ± 45°. This indicates a critical zone of stress concentration generally associated with the effects of the hole's edge. Globally, for the same diameter, the levels of stresses in the Glass / Epoxy plates are greater than those in the Carbon / Epoxy plates, reflecting a lower capability to distribute charges around the discontinuity. Moreover, with the increase in diameter, there is a significant rise in maximum stress, particularly for the material Verre/Époxy.

This trend accentuates the greater sensitivity of this material to opening size, hence a susceptibility to strain concentration effects. On the other hand, the Carbon/Époxy plate shows a less abrupt increase in stresses with the increase of diameter, showing better ability to bear geometrical discontinuity. Finally, the symmetry of the curves with respect to the vertical axis (θ = 0°) translates to a symmetrical behavior of the stress distribution around the hole, which is typical of homogeneous loading of an orthotropic plate. These results highlight the importance of correctly choosing the material and the geometry of cutouts during the design stage, when composite structures are subjected to complex mechanical loading conditions.

Graph (b1) presents the normal stresses distribution, σ_{xx}, within an orthotropic plate with a circular hole as a function of the angle, θ, corresponding to three hole diameters, namely 28 mm, 30 mm, and 34 mm for two types of composite materials: Carbon/Epoxy and Glass/Epoxy. It can be noticed that for each curve, the maximum value appears at θ=0°, which indicates the loading direction; after that, these values decrease symmetrically towards ±90°. In addition, for the same diameter, the maximum stress value registered in carbon/epoxy material is far greater than that in the glass/epoxy ones, which implies higher rigidity.

Furthermore, increasing the hole diameter causes a significant rise in the maximum stress, which is due to the increasing concentration of loads around the opening. Hence, such a trend reflects the coupled effect of material and geometry on the distribution of stresses, a factor that plays a crucial role in the optimization of holed composite structures.

III.2 NUMERICAL SIMULATION AND ANALYTICAL EVALUATION OF STRESS CONCENTRATION IN ORTHOTROPIC PLATES

A study was conducted on a single-layer orthotropic plate with rectangular stratification of the same size as in the previous case and subjected to a uniform tensile load of 10 MPa. The global and net stress concentration factors were calculated using Heywood's analytical formulation based on equations and and were then compared with the data obtained using finite elements.

The comparative analysis shows good agreement between the two approaches, confirming the reliability of Heywood's formulation for estimating stress concentrations in an orthotropic plate.

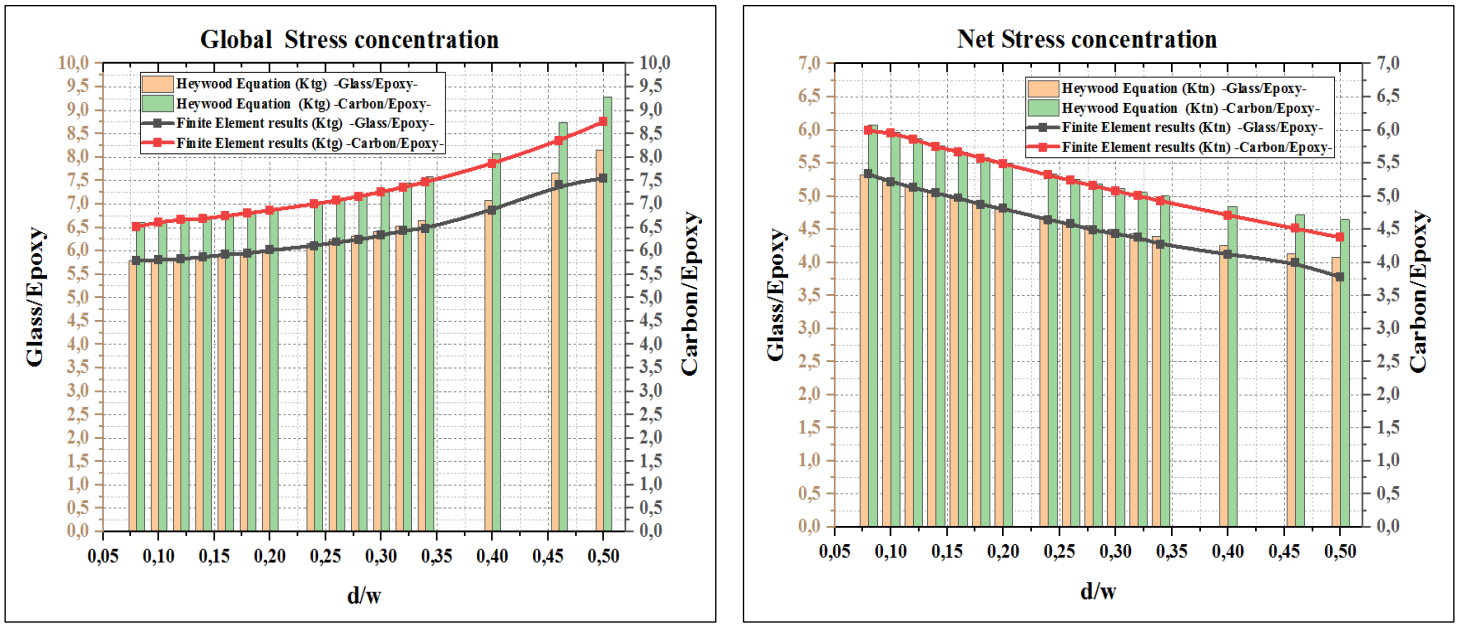

Figure 6: Comparison of stress concentration factors (Ktg and Ktn) for glass/epoxy and carbon/epoxy composites as a function of the ratio (d/w).
Source: Authors, (2026).

The above outcomes shown graphically reveal the development of global and net stress concentration factors with increasing values of (d/w), according to Heywood's analytical models and FEM computations, for flat orthotropic glass/epoxy and carbon/epoxy composite plates with holes. In general, the global stress concentration factor (K_{tg}) is observed to increase continuously with (d/w), while the net stress concentration factor (K_{tn}) is observed to decrease with the values of (d/w), due to the corresponding decrease in the cross-sectional area, with higher values registered by carbon/epoxy composites compared to glass/epoxy composites, reflecting higher stress sensitivity due to the presence of holes.

The present results show that there is an excellent fit between the values predicted by the analytical models and FEM computations, except slightly at higher values of (d/w), which can be better evaluated by the FEM method due to local stress adjustments around the hole that cannot be predicted by analytical models. These above outcomes show that, although the analytical models proposed by Heywood still provide useful estimates for moderate values, there is a need for FEM analysis, especially when dealing with extreme values of (d/w), and the difference between glass/epoxy and carbon/epoxy is due to the unique elastic properties of these composites.

III.3 ANALYSIS OF THE INFLUENCE OF THE FIBER ORIENTATION ANGLE θ° ON STRESS CONCENTRATION

Dans le cadre de l'étude de l'influence de la géométrie sur les facteurs de concentration des contraintes dans des stratifiés orthotropes, les équations constitutives (2) à (5) ont été implémentées sous MATLAB afin de calculer les facteurs de concentration globaux (K_{tg}) et nets (K_{tn}) en fonction du rapport entre le diamètre du trou circulaire et la largeur du stratifié (d/W). Les figures 19 et 20 présentent l'évolution de ces paramètres pour des stratifiés verre/époxy et carbone/époxy percés d'un trou circulaire, et ce pour différents rapports (d/W). Les facteurs de concentration (K_t) ont été déterminés pour plusieurs orientations de fibres (30°,45°,60°et 90°), à partir des équations analytiques sous MATLAB et des simulations numériques réalisées par éléments finis à l'aide du logiciel Abaqus.

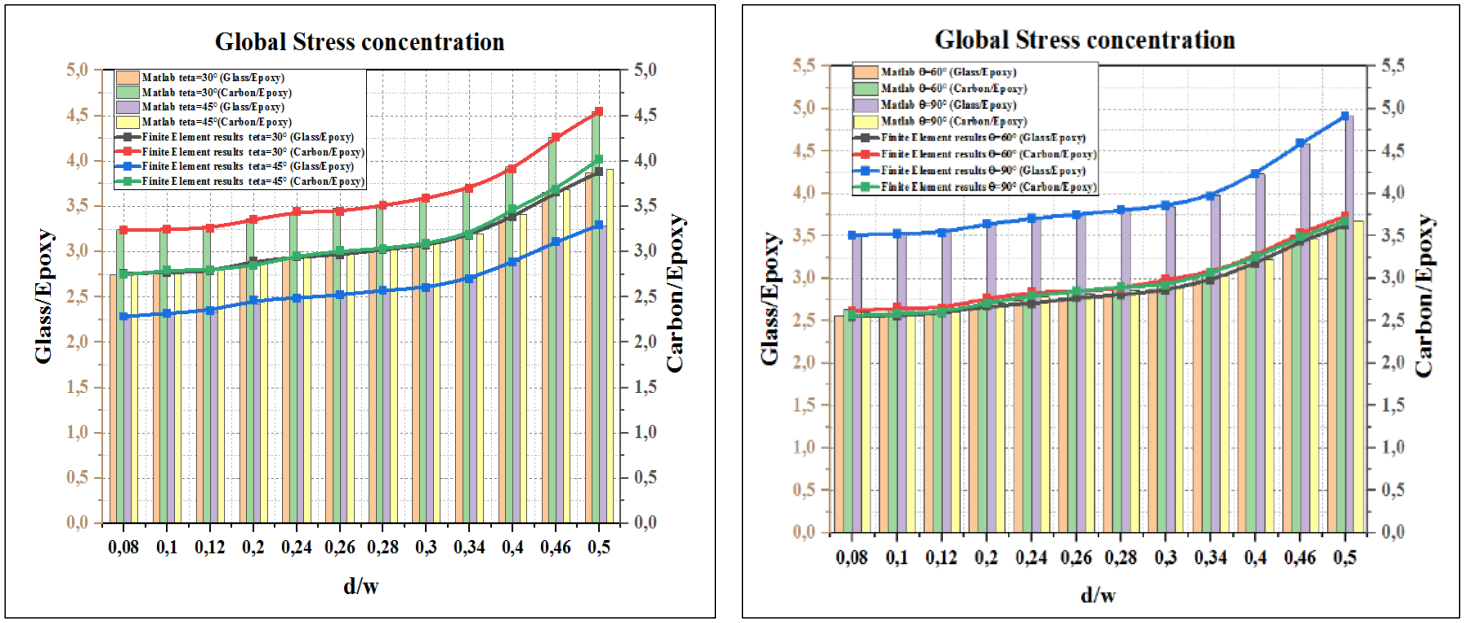

Figure 7: Evolution of the stress concentration factor K_{tg} for different fiber orientation angles (30°, 45°, 60°, 90°).
Source: Authors, (2026).

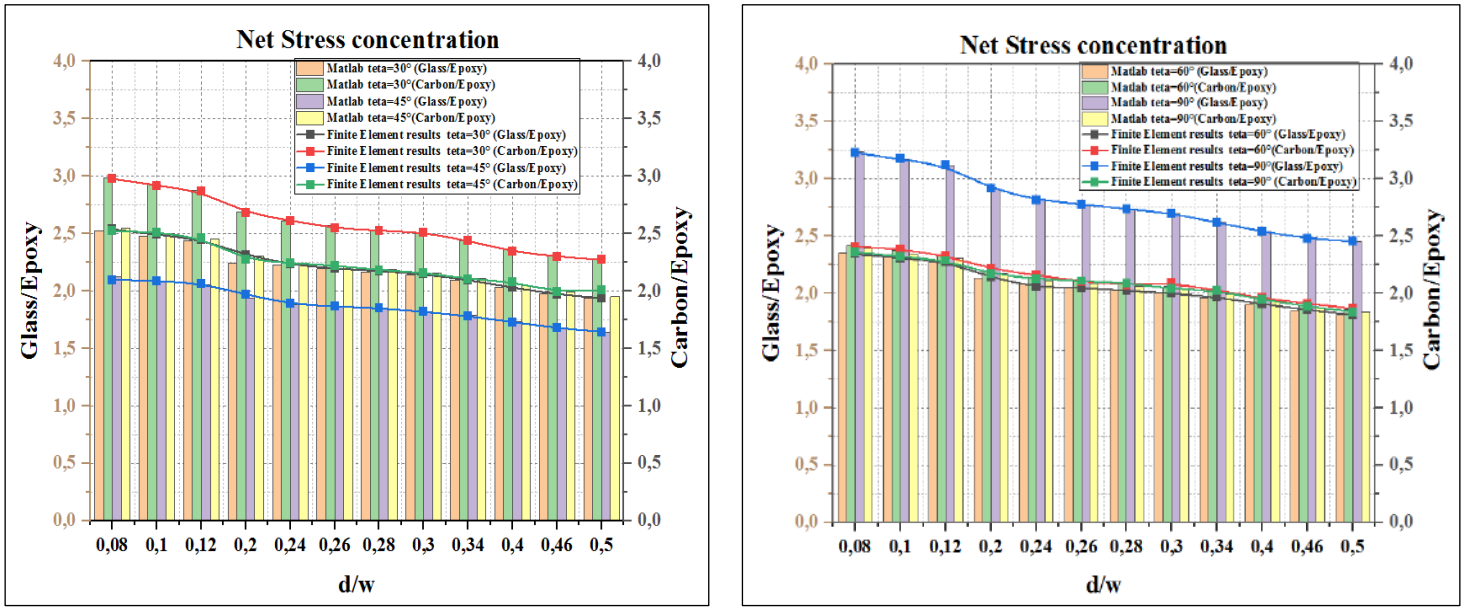

Figure 8: Evolution of the stress concentration factor K_{tn} for different fiber orientation angles (30°, 45°, 60°, 90°).
Source: Authors, (2026).

The deformations of stress concentration factors relative to the geometric ratio are presented for the four figures, regardless of their gross or total trend. These techniques are applied to glass/epoxy and carbon/epoxy composite laminates, viewed at various degrees in the fiber orientation space. The analytical findings solved using MATLAB are presented for the sake of clarity and are compared with their debatable numerical versions developed by finite elements. The results show that the net concentration factor follows a downward trend as the scale distributor competition in d/w increases, implying a more uniform redistribution of stresses as the relative aperture increases. On the other hand, the overall concentration factor increases sharply in proportion to for each value, reflecting an increase in local stiffness and stress amplification effects. In addition, the values for glass/epoxy composites are generally smaller than those for carbon/epoxy composites, indicating that glass/epoxy composites are less sensitive to stress concentration.

The discrepancy observed between analytical predictions and finite element results remains limited overall, but increases for high angles (θ =90°) and large ratios (d/w), reflecting the limitations of simplified analytical models in the face of local nonlinearities captured by numerical simulation. These observations confirm that fiber orientation and reinforcement type play a decisive role in controlling stress concentrations, and that hybrid modeling is necessary to reliably predict the mechanical behavior of laminated composites.

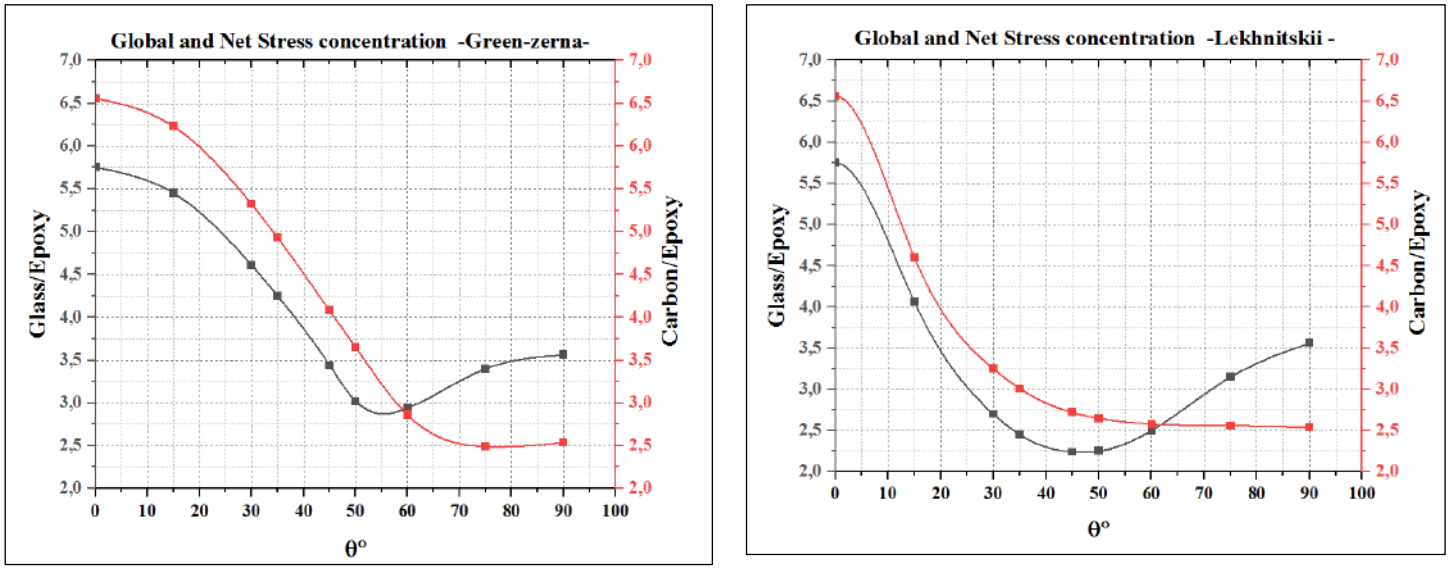

Figure 9: Influence of fiber angle θ on stress concentration for both theories: Glass/Epoxy and Carbon/Epoxy comparison.
Source: Authors, (2026).

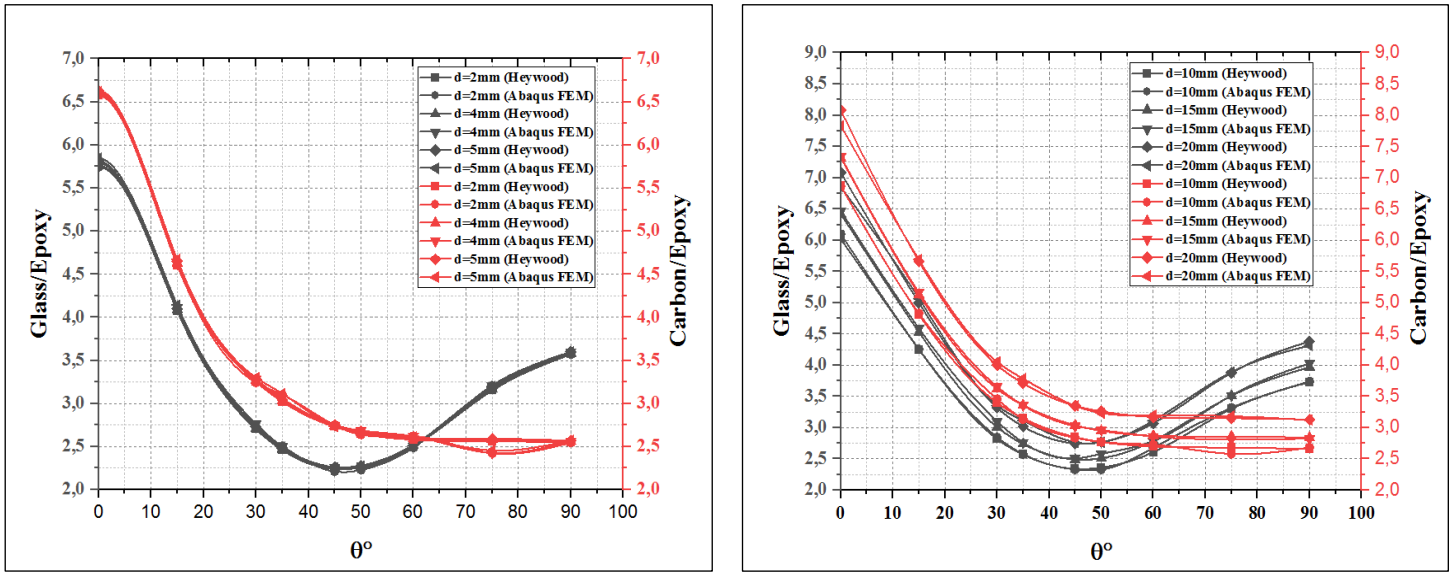

Figure 10: Variation of the stress concentration factor as a function of the inclination angle θ for Glass/Epoxy and Carbon/Epoxy materials as a function of the ratio (d).
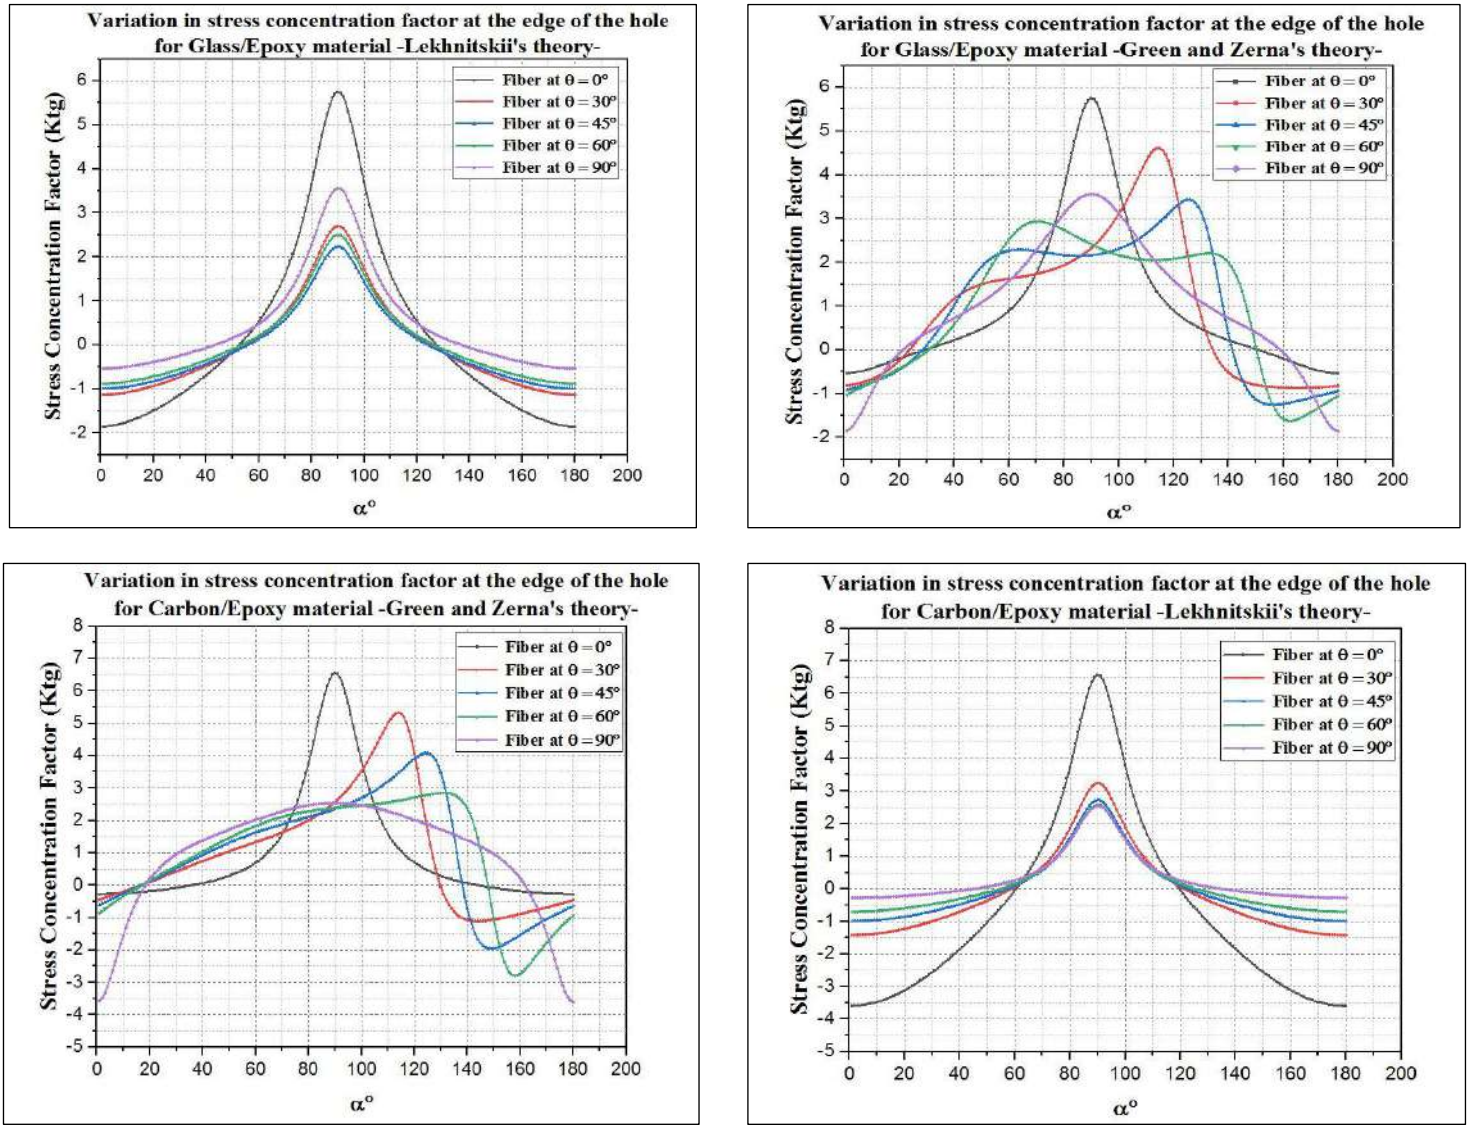
Source: Authors, (2026).

The analytical and numerical results clearly demonstrate that fiber orientation, denoted as, has a dominant effect on stress concentrations around a hole in composite plates. As changes from 0° to 90°, there is a substantial reduction (about 60%) in stress concentrations, as measured by stress concentration factor K_t, because of a more efficient stress field with increasing deviation from loading in the fiber orientation direction. These results are observed for Glass/Epoxy and Carbon/Epoxy composite materials, for which lower Kt values are expected for Carbon/Epoxy, because of increased specific stiffness and efficient stress transfer from fibers to matrices. Variations in Kt with respect to different theoretical models (Green-Zerna, Lekhnitskii, Heywood) are dominated by coupling effects due to shear/extension and anisotropy, for which Green-Zerna models show a steeper non-linear variation, while for Lekhnitskii, a smoother variation is observed.

Also, hole diameters show a significant effect, for which larger holes at small orientations lead to higher K_t, while at small diameters, a more homogenous stress field with less orientation dependence is observed. Usually, a minimum for K_t is observed for orientations near (= 45°-60°), at which optimal mix of longitudinal and transverse stiffness is achieved. In practice, orientation of layers near 90° decreases stress overconcentration with potential reduction in plate stiffness, increasing susceptibility to shear damage. These observations, supported by a good fit of analytical results with FE data from Abaqus, establish that this modeling study, through non-linear analysis and validation, assesses optimal fiber orientation of layers around holes in composite laminates.

III.4 EFFECT OF FIBER ORIENTATION ON THE VALUES AND LOCATION OF THE STRESS CONCENTRATION FACTOR



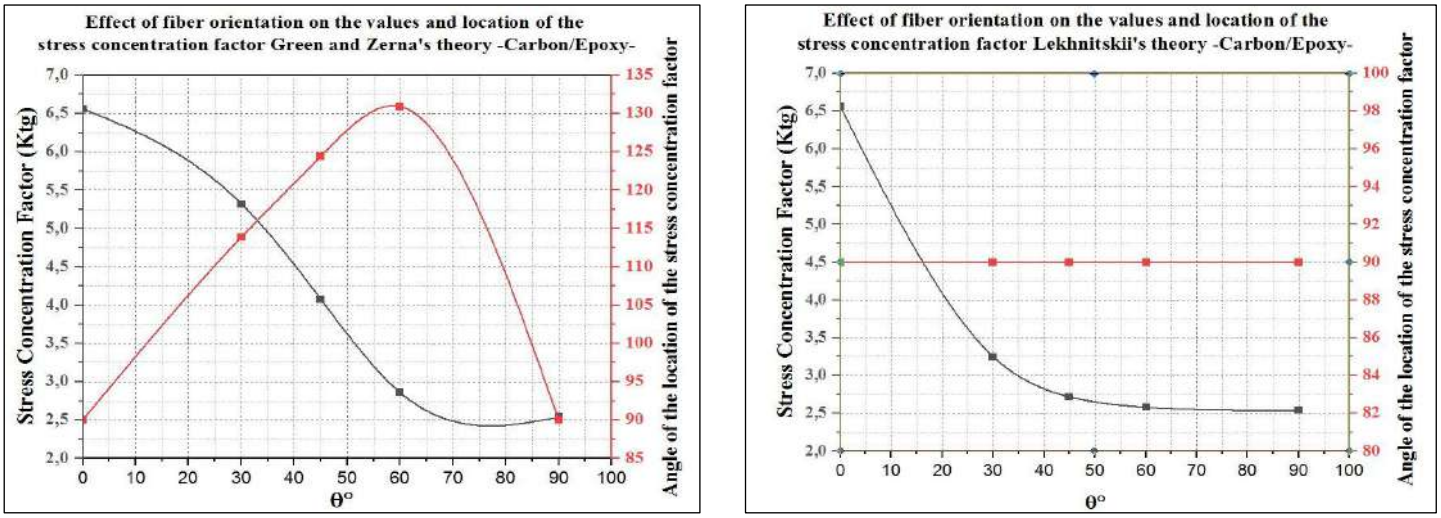


Figure 11: Influence of fiber orientation on the distribution of the stress concentration factor at the edge of a hole in a glass/epoxy and carbon/epoxy composite (Green and Zerna/Lekhnistskii theory).
Source: Authors, (2026).

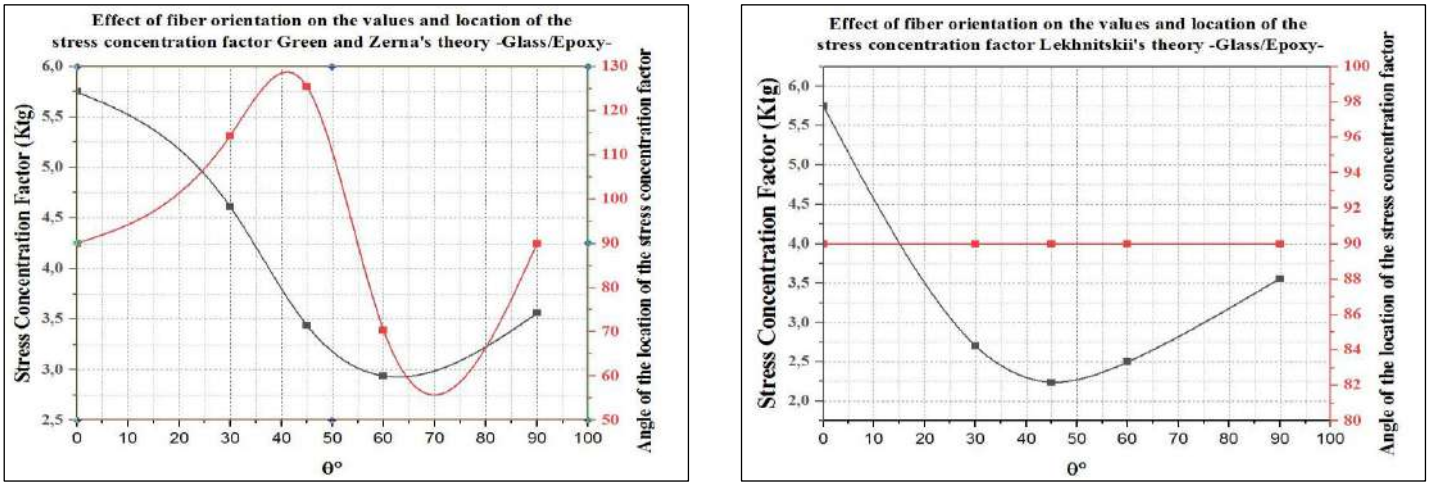

Figure 12: Effect of fiber orientation on the value and position of the stress concentration factor in glass/epoxy and carbon/epoxy composites (Green and Zerna/Lekhnistskii theory).
Source: Authors, (2026).

The figures clearly show the sensitivity of the fiber orientation, θ, to amplitude, as predicted by theory, at the central position of maximum stress around a hole. In both contexts, the stacking density, K_t, decreases sharply as the orientation approaches 90° while θ varies from 0° to a maximum of 90°, corresponding to 2.5, i.e., 60% attenuation. However, there are differences concerning the angle of location of the maximum; Green & Zerna predict a non-monotonic shift of this angle, which increases from θ = 0° to as far as 130° around θ = 50°-60°, finally returning to 90° as a function of θ, while it reaches 90°.

Lekhnitskii's solution has long attributed an almost constant angle of 90° to it. Expression: The angular variation predicted by Green & Zerna describes the anisotropic superposition in terms of shear fields and axial fields. On the other hand, in the method used by Lekhnitskii, critical localization does not take into account this transition of the stress field. In terms of practical prediction, it appears that the selection of material orientation not only reduces the level of critical stress localization (which is beneficial in terms of resistance to drilling and cracking), but can also cause it to vary.

IV.CONCLUSIONS

This research aimed at improving the comprehension and mathematical evaluation of the combined effect of opening geometry characteristics, material properties of elasticity, and orientation angles on stress concentration phenomena in isotropic and orthotropic plates resembling aircraft wings. By choosing a research approach that applies comprehensive mathematical modeling, numerical simulations using finite elements, and parametric calculations, many important results were obtained. It was found that the value of the general stress concentration factor K_{tg} systematically increased with the value of the geometric ratio d/W, thus expressing the effect of relative hole size on the local stress concentration. At a constant uniaxial stress of 10 MPa, the greatest value of $K_{tg} \approx 6.6$ was found at d/W = 0.5, in agreement with Heywood's classical mathematical calculations for thin perforated plates.

In fact, a mesh convergence test was performed in order to establish the validity of the finite-element numerical model, as differences between numerical and mathematical computations stayed below the limit of ±5% for representative hole sizes. Apart from geometric effects, other outcomes emphasized the importance of material anisotropy and orientation angles for composite plates. Both computational and analytical results clearly indicated that by varying the orientation angle from 0° to 90°, there is a remarkable decrease in the value of stress concentration factor, approximately 60% for glass/epoxy and carbon/epoxy materials. The minimum value for this concentration factor occurs for intermediate angles lying between 45° and 60° because of an optimized balance between longitudinal and transverse stiffness.

In general, materials with higher stiffness, such as carbon/epoxy, are expected to display higher values of stress concentration for given values of d/W comparison than glass/epoxy materials. Additionally, this comparison between global and net stress concentration factors highlighted interesting trends: K_{tg} is expected to increase with increasing values of d/W, but there is a concurrent decrease in K_{tn} because of the reduction in net cross-section. In fact, both parameters should be considered simultaneously for designing perforated structures. What makes these findings important is their direct relevance to the design and optimization of composite materials in the field of aerospace. These findings show that in managing stress concentrations in the vicinity of holes, effective design cannot be achieved in a purely geometrical manner, focusing solely on minimizing hole size, but that material selection and orientation also have to be carefully modeled.

The parametric maps obtained from this research activity can assist in design optimization, especially in wing ribs, where weight minimization has to be combined with limitations imposed by ultimate stresses that may cause material failure. In addition, their validation, obtained here relying on comparisons among Hood, Lekhnitskii, and Green-Zerna theories, Finite Element methods, confirms that the adoption of these models in the initial design phases makes sense but also that, in certain cases, Finite Element computations are required, namely when dealing with highly anisotropic materials. However, these results are to be viewed in consideration of the above-mentioned limitations. The analyses were carried out in the context of the linear-elastic model, static load, and the absence of phenomena of initial damage and progressive damage. The role of material nonlinearity, damage, delamination, and cyclic loads has not been accounted for, although they are crucial for the lifetime of the aerospace structure.

Therefore, further research needs to focus on the integration of the above-mentioned fields, such as progressive damage analysis, fatigue analysis, crack initiation around openings, and the validation of the results on perforated composite samples.

ABSTRACT

The aim of this work is to explore sentiment analysis in the Algerian dialect through the adaptation of pre-trained linguistic models. We focus on DziriBERT, a model specifically developed for the Algerian dialect and derived from the BERT (Bidirectional Encoder Representations from Transformers) model, recognised for its performance in various natural language processing tasks. Three fine-tuning approaches were studied: full fine-tuning, freeze tuning, and LoRA tuning (Low-Rank Adaptation). Experiments were conducted on two separate corpora: ADArabic and the corpus introduced by Adouane, to evaluate the robustness and generalisation of DziriBERT model. The results show that the LoRA method achieved the best performances, on the ADArabic corpus, it achieved 83.26% in terms of accuracy and 80.94% for F1-score. On the Adouane corpus, LoRA reached the highest performance, with an accuracy of 85.28% and an F1-score of 82.52%. These results confirm the relevance of using DziriBERT for sentiment analysis in the Algerian dialect and highlight the effectiveness of LoRA tuning as a lightweight and efficient alternative to full fine-tuning, with significantly reducing the number of adjustable parameters.

I. INTRODUCTION

Sentiment analysis (SA) is regarded as one of the most active research areas in Natural Language Processing (NLP). Sentiment analysis aims to identify and classify the polarity, the emotions and opinions expressed in texts [1]. It has become a major area of research with the rise of social networks, with millions of users sharing their opinions on products, events or personalities on a daily life [2], [3], financial domain [4] and even in the health sector [5]. In this paper, we focus on sentiment analysis for the Algerian dialect. Currently, the Algerian dialect (AlgD) occupies an important place in the Maghreb region dialects and developing effective sentiment analysis methods for AlgD is crucial to better understand users' opinions on social media. AlgD is based on the Arabic language [6], [7], it is used extensively in everyday conversations, informal exchanges and online communication. It is characterised by a mixture of Arabic, French, Tamazight, and sometimes Spanish and Turkish. This linguistic diversity makes it particularly difficult to process automatically, as it has no standardized orthography and varies from one region of the country to another [8-10].

Initially, sentiment analysis was based on sentiment lexicon techniques [11]. Later, Artificial Intelligence took up the challenge through machine learning (ML) [12-15], or through deep learning (DL) as in [10], [16], [17]. Although DL is recognised for its remarkable performance in various NLP tasks, its effectiveness remains limited when datasets are small or when text representations are based on traditional approaches (such as binary representation). Indeed, in the study by [18] on SA for the Algerian dialect, the results obtained using traditional ML models such as Support Vector Machines (SVM) and Naive Bayes (NB) were superior to those produced by deep models such as Convolutional Neural Network (CNN) and Recurrent Neural Network (RNN). The emergence of Transformers and large language models has improved the field of NLP by enabling models to understand context better, handle long sequences of text and achieve higher performance for a variety of NLP tasks. For example, BERT models [19] achieved state of the art results on numerous NLP tasks including sentiment analysis [19]. However, their performance depends on the data they were trained on which makes fine-tuning [20] essential for adapting them to specific tasks and different linguistic contexts. The Algerian dialect remains a particularly challenging case due to the lack of large annotated datasets, which makes it difficult for pre-trained models to work effectively.

This limitation is illustrated in the work of [10] where the performance of the BERT model proved to be inferior to that obtained using deep learning with CNN and Long Short-Term Memory (LSTM) and also traditional machine learning like SVM. This gap can be explained by the fact that the BERT model [19] was trained on a large English-language corpus and is therefore not adapted to the linguistic particularities of the Algerian dialect. Abdaoui et al. [21] developed DziriBERT, a model derived from BERT and refined from approximately 15 MB of texts. This model makes it possible to generate contextual representations adapted to AlgD. The pre-trained model DziriBERT was then refined to create the DziriBERT-Sentiment classifier, trained on the TWIFIL corpus [10].

The results obtained by DziriBERT-Sentiment surpassed those reported for the CNN, LSTM and BERT models used by previous studies [10] on the same corpus (TWIFIL). In this work, we investigate the DziriBERT-Sentiment model. We want to take advantage of fine-tuning techniques in order to adapt the model for use on other corpora. Additionally, we explore a novel fine-tuning method, LoRA tuning [22], which trains a reduced number of parameters thereby contributing to green AI applications. Furthermore, [23] showed that a moderately sized corpus (4 GB) could offer performance close to that obtained with a much larger corpus (130 GB). We therefore want to examine this finding in Algerian dialect sentiment analysis. This work is structured around the following research questions:

(I) To what extent does the DziriBERT-Sentiment classifier exhibit robustness when applied to new corpora?

(II) Is additional fine-tuning necessary to further improve the performance of the DziriBERT model for sentiment analysis in Algerian dialect when applied to new corpora?

(III) Which fine-tuning strategy (full fine-tuning, freeze tuning, or LoRA) achieves the most reliable performance gains?

(IV) How does the size of the training dataset affect the classifier's effectiveness, and what is the data volume required to obtain satisfactory performance levels?

The rest of this paper is organized as follows: Section 2 provides the background, offering a brief description of the key concepts discussed in this paper and review related works addressing sentiment analysis of AlgD. Section 3 presents our proposed method and data used in this research. Section 4 presents the whole set of results obtained. Finally, section 5 concludes the paper.

II. THEORETICAL REFERENCE

II.1 FUNDAMENTAL CONCEPTS

This section provides a brief overview of the important concepts underlying this work. These include sentiment analysis, the linguistic characteristics of the Algerian dialect, Transformer description, and strategies for fine-tuning pre-trained language models.

II.1.1 Sentiment Analysis

Sentiment analysis is one field of NLP. Its applications cover several sectors: marketing decision support, political intelligence, analysis of social trends and even the detection of hate speech [1]. SA is interested in studying the polarity of a text, whether it is negative or positive, this task is therefore a binary classification [24]. Other researches add a neutral class [10], [25], meaning that there are three classes to study.

II.1.2 Algerian Dialect

Algeria is one of 22 Arabic countries that speak Arabic. Modern Standard Arabic (MSA) is used in books, newspapers, official documents, etc. For oral communication in the daily life, people speak Arabic dialects. These dialects differ from country to other, from region to region in the same country. In Algeria, this dialect is called Algerian Dialect (AlgD). MSA is normalized and standardized but dialects are not. AlgD is characterized by: informal language, agglutinated negation, code switching (words from several languages in the same text), different writing script (Arabic, Latin or Arabizi) [6], [16], [26]. The Arabizi is recognised by the use of Latin letters and some numbers to designate some letters that do not exist in Latin. The letter "ع" in Arabic does not exist in Latin script, the internet users replace "ع" by a digit "3" ("ح" by "7", "ق" by "9", …).

II.1.3 BERT: Bidirectional Encoder Representations from Transformers

Bidirectional Encoder Representations from Transformers (BERT) developed by Google Research in 2018, is a powerful NLP model. BERT was trained using Books Corpus (800 million words) and Wikipedia (2.5 billion words) [19], [27]. BERT is based on a transformer architecture, using self-attention mechanisms to comprehensively understand the contextual meaning of words in sentences. Two main phases are followed by the model: pre-training and fine-tuning [19], [20]:

1. Pre-training: BERT learns from unlabelled data.
2. Fine-tuning: adjusting BERT's pre-trained parameters using labelled data.

Given the success of transformers, other models have been developed for multi-languages mBERT [19] or dedicated to specific languages such as CamemBERT [23] for French language. For Arabic language, AraBERT [28] was pre-trained using 23 GB of MSA text extracted from Wikipedia.

II.1.4 Fine-Tuning

Fine-tuning is a learning transfer technique which involves adapting a model that has been pre-trained on a large collection of data to a specific task by continuing training on a target dataset. It allows the reuse of previously learned representations and reduces the need for large quantities of annotated data [19], [29]. There are various variants:

Full tuning: all the parameters of the pre-trained model are updated during training. This allows better specialization, but it is expensive in terms of computation and memory [29].

Freeze tuning: some layers (often the lower ones) are frozen (their weights do not change). Only the top layers (often the classification head or a few top layers) are adjusted. This reduces the computational cost [30].

LoRA tuning: In Low-Rank Adaptation (LoRA) [22], all the pre-trained model weights are frozen and trainable rank decomposition matrices are injected. This approach significantly reduces the number of parameters that need to be trained. LoRA freezes the original weights and applies low-rank correction to the critical linear layers. Let W be the original weight matrix; the updated matrix W′ is defined as,

$$W'=W+\Delta W \text{ (with } \Delta W=AB) \quad (1)$$

If W has dimension d × k, then the dimension of A will be: d × r and the dimension of B will be: r x k. The parameter r is a hyperparameter to be defined (e.g. 4, 8, 16, etc.). When r=1, then A is a column vector and B is a row vector.

II.2 RELATED WORKS

Sentiment analysis in the Algerian dialect is getting more attention in recent years. Researchers at the beginning used classical methods like lexicon-based approaches and machine learning techniques. Currently, deep learning and transformer-based models are becoming popular. In this section, we provide an overview of key works by highlighting the methods and aspects that have been of particular interest to the research community and focusing on works using fine-tuning in the case of AlgD sentiment analysis. The paper of Moudjari et al. [10] addressed the lack of resources in the Algerian dialect by presenting TWIFIL (TWItter proFILing), a collaborative crowdsourcing platform for sentiment and emotion. The sentiment dataset of TWIFIL contains 9437 tweets annotated on 3 classes (negative, positive and neutral).To validate the corpus, several machine learning and deep learning models were evaluated, including SVM, MLP, CNN, LSTM, and multilingual BERT, using different feature representations. Experimental results showed that deep learning models outperformed classical approaches, the CNN model achieved the best performance (76% in terms of accuracy and F1-score).

By [16] focused their sentiment analysis study on only AlgD code-switching comments. They collected more than 36000 YouTube comments, organized into 4 classes (negative, positive, neutral and mixed). The texts are cleaned and normalized. The authors experimented several algorithms: SVM, CNN, LSTM and BiLSTM. In terms of accuracy, the best results were obtained by BiLSTM, it achieved 66.78%, and 60.17% for F1-score by CNN. To remediate the problem of an unbalanced corpus, the authors explored the inclusion of a sentiment lexicon and data augmentation. The insertion of lexicons improved the results for the negative and neutral classes. Abdaoui et al. [21] constructed a corpus of 1.1 million of tweets (15Mo of text) to create DziriBERT, a first pre-trained language model for the AlgD, using the same architecture as BERT base (12 encoders, 12 attention heads and a hidden dimension of 768). The model was trained using the Masked Language Modeling (MLM) task and a WordPiece tokenizer. The overall training time was 10 days. To deploy this pre-trained model, the authors further fine-tuned DziriBERT on an existing AlgD corpus: TWIFIL [10]; as described above. DziriBERT-sentiment achieved 80.3% for accuracy and 79.7% for F1 score.

According to the authors' tests, these results were better than the ones obtained using multilingual models such as mBERT, XLM-R, or Arabic models like AraBERT, QARiB, CamelBERT, and MARBERT. By [25] collected and manually annotated a dataset extracted from YouTube. The corpus contains 45000 texts organized into 3 classes (negative, positive and neutral). The authors initially used a deep learning model LSTM, then experimented FT of various architectures of BERT (base/large) and BERT Arabic (mini/medium/base/large). The results varied from 74.37% to ~81% in terms of accuracy and from 69.76% to ~78% for F1-Score. The results obtained by Bert Arabic (medium/base/large) surpassed those obtained by LSTM or BERT. The best result was obtained by Bert Arabic large (accuracy= 81.74 and F1-score= 78.38). For the best model, parameter's number is 336.7 million with a training time of about 2 hours. The authors tested 11 separate and combined pre-processing operations including classical operations such as stop word deletion and normalization. Some techniques help to increase performance and others reduce it. In contrast, the separation of emojis helped to increase model performance.

By [31] developed a system called AlgBERT, based on new version of Arabic BERT (AraBERT V2- Twitter) for the automatic generation of an annotated corpus. AraBERT Base V2-Twitter has had emoji added to their vocabulary. The AlgBERT model is fine-tuned using a corpus of approximately 54000 texts in Arabic and AlgD (the authors used existing dataset plus data annotated by authors). The classification is of binary polarity (the neutral class is eliminated from dataset). The number of parameters to train is 136 million. The authors use classical text pre-processing, plus the recognition of the polarity of the emoji to improve model performance. After splitting the dataset into train and test, AlgBERT obtained an accuracy of 92.62% and 92.26% of F-measure.The authors [32] collected and normalized two existing datasets of comments in AlgD from Facebook, Instagram, Twitter (now X), and YouTube. The combined corpus contains 12364 comments, annotated into three classes (negative, neutral and positive). The authors applied a complete pre-processing pipeline (with translation of emoji into positive/negative tokens) before training different models: SVM, NB, LR, and Decision Tree, achieving performances between 65% and 74% for accuracy.

They then proceeded to fully fine-tune the pre-trained DziriBERT model. After optimising the hyperparameters, the best result obtained was 82.01% in terms of accuracy using cross-validation, significantly surpassing traditional models. According to. [24] created DZDialect, a large dataset containing 117569 texts from existing datasets augmented by other YouTube comments. The data is organized on 3 classes but the authors used only 2 classes (positive and negative). After text cleaning, they employed various classifiers ML (SVM, KNN, NBM), DL (CNN, LSTM) and transformer models (DistilBERT, AraBERT Base/Mini/Medium, AraGPT-2). In general, transformer-based models gave good results compared with ML and DL except AraGPT-2. AraBERT Base attained an accuracy of 87.96% and 87.95% for F1, in the internal evaluation case. But for the external evaluation, the best results were achieved by AraBERT Mini, with an accuracy of 78.89% and 78.82% for F1 on the Narabizi dataset corpus [33]. To further enhance performance, ensemble learning techniques such as stacking and major voting were employed, specifically with DistilBERT, AraBERT Base, and AraGPT-2.

The results achieved 91% (accuracy and F1 score) using Stacking Ensemble with Logistic Regression on DZDialect. On the Narabizi dataset, using both ensemble methods showed the same performances, with 81.24% accuracy, and 80.57% F1-score. In table 1, we summarise the previous works based on FT, indicating the original model, the number of trained parameters, the volume of data used and their sources (we note, Tw for Twitter, YT: YouTube, Fb: Facebook, In: Instagram), the type of classification; i.e. number of classes; and the best results in term of accuracy (Ac) and F1-score (F1).

Table 1: Summary of works on AlgD sentiment analysis based on fine-tuning.

Model/Ref	model source	time	Ac and F1 score results	# param (million)	classes	Dataset/volume used	Source

Source: Authors, (2026).

After analysing Table 1, it can be seen that the best results were obtained in the case of binary classification. AlgBert [31] reached approximately 92% in both accuracy and F1-score , while a Stacking Ensemble of 3 models fine-tuned by [24] gave around 91%. For a ternary classification, DziriBERT-Sentiment [21] achieved an accuracy of around 80%. Fine-tuning BERT Arabic (Base and Large) [25] gave an accuracy of 81.74%. The best result was obtained by fine-tuning the pre-trained DziriBERT model achieving 82.01% accuracy [32].

III. MATERIALS AND METHODS

The experiments used DziriBERT model and its tokenizer available on Hugging Face[iii] platform. Corpora descriptions will be given below (Table 2). All experiments were conducted on the Google Colab platform, primarily using a T4 GPU, and an A100 GPU or L4 GPU when explicitly mentioned.

The training hyperparameters were fixed at a learning rate of (2×10^{-5}), a batch size of 8, and 5 epochs. For LoRA setting we added the following parameters: $r = 8$, $\alpha = 16$, dropout = 0.1, with targeted application on the Query, Key, and Value modules.

III.1 METHODOLOGY

DziriBERT [21] stands out for its compactness, with approximately 124 million parameters and a vocabulary of 50000 entries, making it one of the smallest models dedicated to AlgD. In this paper, we aim to study the application of DziriBERT to new datasets and to analyse the impact of different fine-tuning strategies on its performance. In this context, two areas of experimentation are possible:

A. DziriBERT[iv], the pre-trained model for the Algerian dialect.
B. DziriBERT-Sentiment[v], the classifier model for AlgD sentiment analysis.

For this study, we chose to work on the DziriBERT-Sentiment model. In the remainder of this paper, we will refer to it simply as DziriBERT. Above all, the dataset must be split into training (Train), validation (Valid) and test (Test) sets. The training and validation sets will be used to train and adjust the model while the test set will be used for model evaluation. We follow the approach illustrated in Figure 1.

1. Firstly, we apply original DziriBERT (without fine-tuning) on the Test portion of the dataset and record the results as baseline performance.
2. Then, we use the training and validation sets (Train and Valid) to fine-tune the DziriBERT model, using three different methods :
   - Full tuning (Full) : all the parameters of the model will be updated during training
   - Freeze tuning (Freeze) : only the parameters of the last layer will be updated during training
   - LoRA tuning (LoRA): all the model weights will be freeze, but we calculate the new matrix ΔW (with ΔW=AB) see section 2.4 for more details.
3. We evaluate the fine-tuned models on the same test set.
4. Next, we extract subsets Sub_Train and Sub_Valid from the training and validation sets, respectively, we then repeat the same process as in step 2 and 3 to fine tune the initial DziriBERT model using these subsets.
5. Finally, we compare the results obtained from the different experiments.

The application of the DziriBERT model explores two experiments: one without pre-processing and one with pre-processing texts from the corpus. The pre-processing step follows the same light pre-processing as described in [21]:

1. replacing all user mentions with @user;
2. replacing all email addresses with mail@email.com;
3. replacing all hyperlinks with https://anonymizedlink.com.

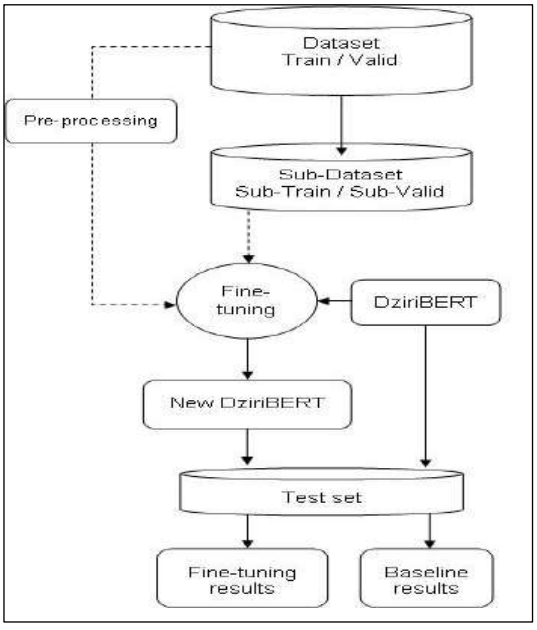

Figure 1: The diagram of the proposed model.

III.2 DATA DESCRIPTION

To evaluate our approach, we use one of the largest public corpora, ADArabic[vi] dataset created by [25], which is dedicated to AlgD SA. To strengthen our study, we also use another corpus collected by [16], referred to here as the Adouane corpus.

III.2.1 ADArabic Dataset

The corpus consists of 45000 annotated comments from YouTube, with five classes of sentiments, from very negative to very positive. We grouped the negative classes (very negative and negative) and the positive classes, to obtain three classes: negative (NEG), neutral (NEU), and positive (POS). First the dataset was split into a training set (80%) and a testing set (20%), and the training set was further divided into Train (80%) and Validation (Valid) (20%). Table 2 presents the basic statistics of resulting dataset.

Table 2: ADArabic corpus description, after regrouping.

Train			**Valid**			**Test**			**Total**
28800			7200			9000			
NEG	NEU	POS	NEG	NEU	POS	NEG	NEU	POS	45000
10213	6459	12128	2553	1615	3032	3191	2019	3790	

Source: Authors, (2026).

III.2.2 Adouane Dataset

Adouane corpus [16] contains 36120 comments from YouTube. The corpus is organized into three parts: Train, Validation (Valid) and Test. Each part includes four classes (positive, negative, neutral and mix). To maintain consistency with the ternary classification setting, the Mix class was removed, leaving a total of 24,384 comments. A description of the resulting corpus is provided in Table 3.

Table 3: Adouane corpus description, after Mix class removing.

Train			**Valid**			**Test**			**Total**
17304			714			6366			
NEG	NEU	POS	NEG	NEU	POS	NEG	NEU	POS	24384
4849	5524	6931	167	154	393	1408	1584	3374	

Source: Authors, (2026).

IV. RESULTS AND DISCUSSIONS

To present the results clearly, they have been organised into sections. For all experiments we measured accuracy (Ac) and macro F1-score (F1) on Test set.

IV.1 BASELINE RESULTS

Table 4 presents the obtained results. Without pre-processing, DziriBERT obtained 76.22% in terms of accuracy and 74.36% for F1-score on the ADArabic corpus, and 73.66% accuracy and 68.34% F1-score on the Adouane corpus. Contrary to our expectations, we have the same finding with or without pre-processing results (see table 4). For that reason, following experiments were performed without pre-processing.

Table 4: DziriBERT result before fine-tuning on 02 datasets.

Dataset	**Without pre-processing**		**With pre-processing**	
	Ac	F1	Ac	F1
ADArabic corpus	76.22%	70.45%	76.22%	70.45%
Adouane corpus	73.66%	68.34%	73.66%	68.34%

Source: Authors, (2026).

IV.2 FINE-TUNING DZIRIBERT ON ADARABIC CORPUS

Regarding the fine-tuning strategies, Full fine-tuning requires training all parameters (+124 million). With freeze tuning, only 2307 parameters need to be trained, which is less than 0.2% of the total DziriBERT parameters. LoRA, on the other hand, trains 444675 parameters, which is equivalent to 0.36% compared to full fine-tuning parameters number. This is valid for all the following experiments.

IV.2.1 DziriBERT Fine-Tuning Results on ADArabic (Full Corpus)

Table 5 shows the DziriBERT FT results, on the whole ADArabic corpus. The experiments were running using L4 GPU. We can see that all three FT techniques (Full, Freeze and LoRA) improved the baseline results in terms of both accuracy and F1 scores. Full FT achieved 82.57% accuracy and 79.48% F1-score after 1 hour (hr) and 42 minutes (mn) of training, while Freeze achieved 79.51% accuracy and 75.54% F1-score in 1 hour and 35 minutes. LoRA achieved the best performance with 83.26% accuracy and 80.94% F1-score in the shortest training time of 1 hour and 24 minutes. When analysing the confusion matrix (see Figure 2), it is obvious that it is always the neutral class that is wrongly predicted, this is probably due to the imbalanced data.

Table 5: FT results on ADArabic corpus using GPU L4.

	# params	**Time of training**	**Ac**	**F1**
Full	124 443 651	1hr 42mn	82.57%	79.48%
Freeze	2 307	1hr 35mn	79.51%	75.54%
LoRA	444 675	1hr 24mn	83.26%	80.94%

IV.2.2 Impact of Dataset Size on Fine-Tuning Performance

To explore the final objective of this paper, we examined the results obtained by fine-tuning DziriBERT using subsets of the training (Train) and validation (Valid) sets. For each experiment, we tested several values of $N1$ and $N2$ representing the sizes of Train and Valid subsets respectively. The choice of N1 was almost arbitrary while N2 was generally set to 20% of N1. We started with N1=1000 and a step size of 500. If the variations in the results did not exceed 1 point, we moved on to larger step size such as: 2500 or 5000.

Table 6 summarises the results of all the experiments on the Test set. The last row represents the results obtained using the complete dataset. The best values for each technique are highlighted in bold, and the best values for each subset are underlined. The results of all experiments outperform the baseline in terms of both accuracy and F1-Score. In general, the best results are achieved using the full dataset.

Table 6: Impact of dataset size on performance of FT on ADArabic corpus.

		Full		**Freeze**		**LoRA**	
N1	N2	Ac	F1	Ac	F1	Ac	F1
1000	200	80.39%	76.82%	76.66%	71.54%	80.62%	77.49%
1500	300	80.41%	77.79%	76.81%	71.91%	79.20%	75.58%
2000	400	81.23%	78.34%	76.86%	72.06%	81.23%	78.40%
2500	500	80.87%	77.38%	76.94%	72.30%	80.89%	77.91%
3000	600	80.86%	77.43%	77.04%	72.43%	81.42%	78.67%
5000	1000	80.07%	78.27%	77.47%	73.13%	78.96%	75.27%
10000	2000	81.29%	78.37%	78.16%	73.91%	80.99%	77.92%
15000	3000	82.01%	79.29%	78.66%	74.42%	82.31%	80.02%
20000	4000	82.34%	78.92%	79.03%	74.92%	82.72%	80.30%
25000	5000	**82.63%**	**80.16%**	79.32%	75.36%	82.82%	80.36%
28800	7200	82.57%	79.49%	**79.51%**	**75.54%**	**83.26%**	**80.94%**

Source: Authors, (2026).

For Full fine-tuning (Full), when N1 = 1000, accuracy reached 80.39% and F1-score 76.82%, corresponding to improvements of 4.17 and 6.37 points respectively, compared to the baseline. Full reached its maximum at N1 = 25000, where accuracy reached 82.63% (an improvement of 6.41 points) and F1 reached 80.16% (an improvement of 9.71 points). With Freeze tuning, accuracy increased from 76.66% to 79.51% and F1 from 71.54% to 75.54%, showing maximum improvement of 3.29 points for accuracy and 5.09 points for the F1-score when using the complete dataset. Using LoRA at N1 = 1000, accuracy reached 80.62% and F1 77.49%, corresponding to improvements of 4.40 and 7.04 points respectively. LoRA reached its maximum performance with the whole dataset, achieving 83.26% accuracy (an improvement of 7.04 points) and 80.94% F1 (an improvement of 10.49 points). The results for Freeze are the lowest, its best results using the whole dataset are still lower than those obtained by Full or LoRA using only 1200 texts (N1=1000 and N2=200). The latter achieved around 80% for accuracy and 77% for F1. Using a subset of 2400 texts, Full and LoRA techniques achieved a local maximum of Accuracy ≈81% and F1≈78, which means an improvement of baseline results by 5 points in terms of accuracy and around 8 points for F1. In most cases, LoRA's performance are better than Full ones (see Table 6 and Figure 3).

IV.3 DZIRIBERT FINE-TUNING ON ADOUANE CORPUS

On the Adouane corpus, we explored the same experiments as in the previous section, and we summarized all the results in Table 7. The last row corresponds to the whole-dataset results. The number of parameters for each experiment does not change. For this run, we started with N1 = 1000 with a step size of 1000. After N1 = 4000, we jump directly to the whole dataset because the validation set contains only 714 texts. This is due to the removal of the Mix class (see the Data description section). We have almost the same findings as in the previous section. The three FT techniques improved the baseline results (see Table 7). Using Full technique, accuracy started from 81.95% to 84.70%, F1 from 78.98% to 81.56%. Therefore, compared to baseline, the improvements can reach 11.04 and 13.22 points for accuracy and F1, respectively, using the whole dataset, in the training time of 20 minutes using an A100 GPU.

Regarding Freeze, accuracy started from 75.12% to 79.89%, F1 from 70.71% to 76.61%. Therefore, the improvements can reach 6.23 and 8.27 points. Processing the whole dataset took only 8 minutes using an A100 GPU. LoRA strategy achieved the best results, an accuracy of 85.28% and 82.52% for F1, in the training time of 15 minutes and 59.49 seconds using an A100 GPU. The enhancements started from 8.53 points to 11.62 for accuracy and F1 from 10.76 points to 14.18 points. In this corpus, we found that using subset of 1200 texts (N1=1000 and N2=200) gives results close to the original results reported by [21] the creator of DziriBERT when using Full or LoRA fine-tuning techniques. On the other hand, using a subset of N1 equal to 2000 or 3000, Full or LoRA fine-tuning can achieve results close to the best performance obtained so far by [32] based on the fine-tuning of the pre-trained DziriBERT model (see Table1).

Table 7: Impact of dataset size on FT performance on the Adouane corpus.

Technique		**Full**		**Freeze**		**LoRA**	
# params		124 443 651		2307		444 675	
N1	N2	Ac	F1	Ac	F1	Ac	F1
1000	200	81.95%	78.98%	75.12%	70.71%	82.19%	79.10%
2000	400	82.42%	78.84%	75.79%	71.67%	82.50%	79.31%
3000	600	82.08%	79.21%	76.81%	73.03%	83.95%	80.96%
4000	714	83.62%	80.28%	77.18%	73.45%	83.98%	81.04%
17304	714	**84.70%**	**81.56%**	**79.89%**	**76.61%**	**85.28%**	**82.52%**

Source: Authors, (2026).

IV.4 DISCUSSION

DziriBERT model gave moderate results (baseline), around 75% on ADArabic corpus and a little less on Adouane Corpus. For both datasets, looking at the accuracy and F1-score graphs (see figure 4, where O.W is used to designate Original Work and B.L baseline), Freeze FT improved baseline results in an increasing and monotonic manner in relation to N1. Full FT and LoRA FT had results close to each other. They alternated between growth and decline. They increased baseline by 6-14 points (around 10 points) when using the whole dataset. Sometimes LoRA slightly outperformed Full FT, while requiring significantly fewer parameters and time.

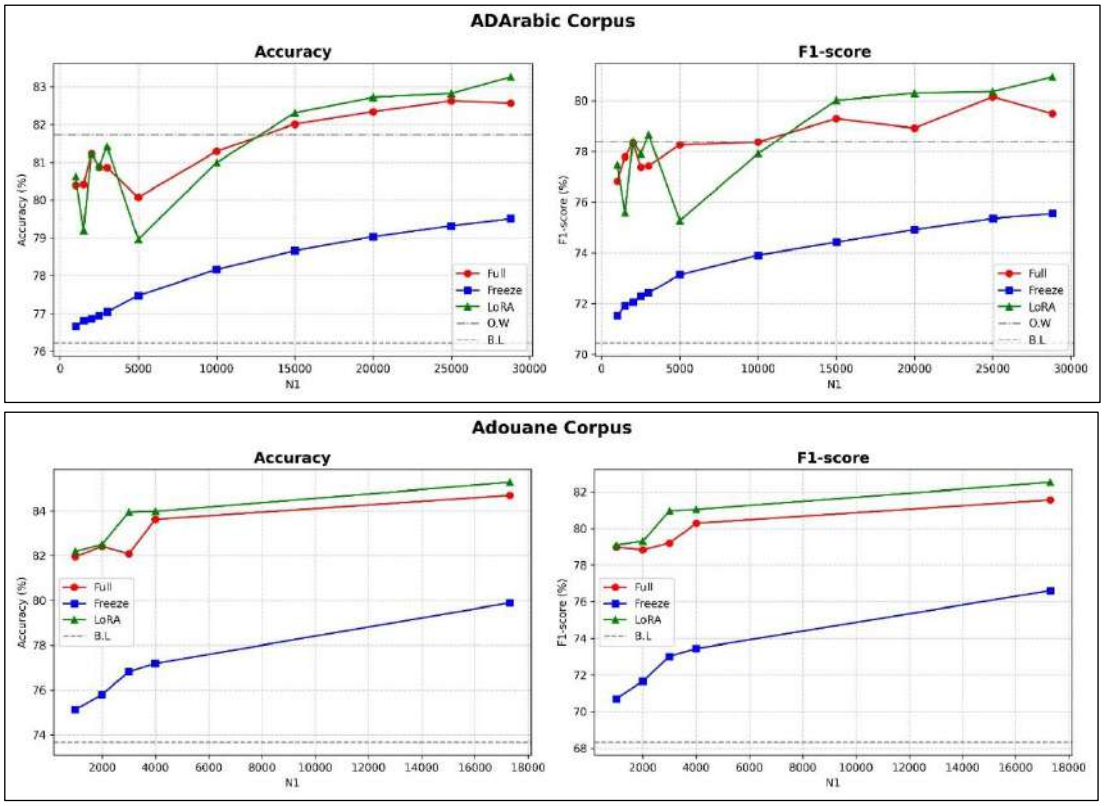

Figure 3: Accuracy and F1-score variation according to N1 using Full, Freeze and LoRA fine-tuning. (O.W:original work and B.L: baseline).

Source: Authors, (2026).

Certainly, with Freeze FT, we had a very small number of parameters to train, and although it improve the baseline results, but they are still very limited and inferior to those given by Full or LoRA FT. Here, Freeze retrained only the last layer (the layer responsible for classification). Even if we use the whole dataset, the Freeze results remain lower than those obtained by retraining all parameters with subset of 1200 texts, which means that the word embedding weights of AlgD in DziriBERT must be readjusted, maybe by other words from different social networks. Noting that DziriBert was trained on one million Twitter texts. The latter is not the most widely used network by Algerians (see Figure 4) but it ranks last [34].

For a ternary classification using the DziriBERT model: [21] achieved an accuracy of 80.3% using a dataset of 9437 Twitter texts, [32] achieved 82.01% using FT of DziriBERT with 12364 texts from Twitter, YouTube, Facebook and Instagram. Our work achieved 83.26% on ADArabic corpus that contains 45000 texts from YouTube, thus exceeding the results of the authors of the original work, who based their research on FT several BERT models.-On ADArabic corpus, the original work by [25] achieved 81.74% accuracy and 78.38% F1-score, based on fine-tuning six BERT models variants with multiple pre-processing treatments. On the same corpus, our approach reached 83.26% accuracy and 80.94% F1-score using only DziriBERT fine-tuning without any pre-processing.

We achieved also 85.28% accuracy on Adouane corpus (24384 texts from YouTube), this result represents the best performance obtained for AlgD SA in ternary classification. This finding indicates that DziriBERT is well adapted to Algerian sentiment analysis and probably other NLP tasks. On both datasets, we found that Full FT and LoRA FT significantly improved the models, by using the complete dataset or sub-dataset. But LoRA combines the advantages of both Full and Freeze techniques, providing significant performance improvements like Full while requiring a very small number of parameters to be retrained similar to Freeze. In addition, LoRA results usually outperforms those of Full FT, so we can adopt LoRA as the best FT strategy. On the other hand, LoRA also reduces energy consumption. This helps to preserve the environment.

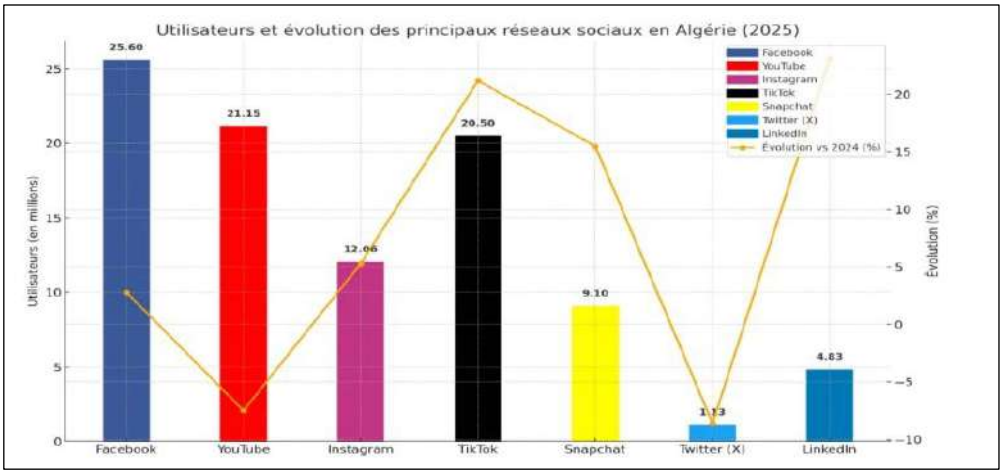

Figure 4: Users and the evolution of social networks in Algeria.
Source: [34].

The experiments conducted in this research suggest that using a small dataset for FT can produce satisfactory results. This emphasises that data quality can sometimes take precedence over quantity. Small data means fewer instructions need to be run in less time, which also helps to preserve the environment. As future work, we plan to: (i) Test DziriBZRT on other corpora. (ii) Fine tune the pre-trained DziriBERT model with texts from others sources such as Facebook and Instagram (in addition to Twitter). (iii) Deal with others Sentiment Analysis challenges such as: sarcasm or negation treatment.

V. CONCLUSIONS

In this paper, we have explored the sentiment analysis of Algerian dialect using three techniques of fine-tuning (Full, Freeze and LoRA tuning) on DziriBERT. The study is conducted on two existing datasets; ADArabic and Adouane corpus. The results of all experiments are better than the baseline, i.e. when using DziriBERT without FT. On both datasets, we found that Full and LoRA significantly improved the models, by using the complete dataset or sub-dataset. But LoRA combines the advantages of both Full and Freeze techniques, i.e. significant performance improvements like Full and a very small number of parameters to be retrained like Freeze. In addition, LoRA results usually outperforms Full ones, so we can adopt LoRA as the best FT strategy. On the other hand, LoRA has an impact on energy consumption. This helps to preserve the environment.

ABSTRACT

The complex structure of brain tumors and the need for prompt and accurate detection present a major challenge to the medical community. This paper suggests an improved CNN framework for classifying brain cancers in the big data healthcare arena, addressing the shortcomings of current diagnostic techniques. The CNN model was enhanced by integrating transfer learning methods and data augmentation using Magnetic Resonance (MR) images. The model's predictive performance was further improved by adding more training parameters in pre-trained deep learning models like ResNet-50, VGG-16, Inception V3, DenseNet201, Xception, and MobileNet. According to experimental results, the suggested model performs better than baseline models and achieves a 99.40% classification accuracy rate. According to this study, a more precise and effective way to diagnose brain tumors could be achieved in clinical settings by using the suggested model. The future direction suggested enhancing the dataset and further refining the model to improve its generalization capabilities in diverse clinical scenarios.

I. INTRODUCTION

An abnormal growth of tissues in the human brain is called a brain tumor, which is a dangerous medical condition that affects the majority of people worldwide. It disrupts regular brain activity [1]. According to risk factors, the category of benign brain tumors grows gradually and does not pose a threat. On the other hand, malignant brain tumors are made up of cancer cells that start small, proliferate, and spread to other areas of the brain [2]. Early detection and diagnosis are essential for successful treatment and recovery. In this sense, scientists and medical professionals in the big data healthcare industries have invented a variety of advanced non-invasive techniques to identify and classify these tumors [3]. Recently, deep learning models have been frequently used in the process of creating automated systems for screening of tumor regions [4].

In recent times, the diagnosis of tumors using image data with the help of neural networks is becoming popular and is frequently employed for the categorization and examination of medical images. CNN models can extract more associated characteristics from the image dataset [5]. In addition, in the big data healthcare domain, recently developed sophisticated approaches, such as transfer learning, also enhance the prediction accuracy of advanced machine learning frameworks to accurately diagnose and classify brain cancers [6]. In this proposed work, we have analyzed an enhanced CNN model to diagnose brain cancer in the big data healthcare domain by classifying MR images of brain tumors.

The CNN model picks out additional detailed features from the picture data for the overall classification, making it more appropriate for the various types of tumor categorizing utilizing the tumor picture collection. Apart from boosting the model's capacity for prediction due to an insufficient image data set, we have included a transfer learning technique to ensure that the CNN model is properly aligned [7]. To smooth the implementation of the transfer learning technique, we incorporated the six popular pre-trained frameworks in this research, such as ResNet-50 [8], VGG-16 [9], Inception V3 [10], DenseNet201 [11], Xception [12], and MobileNet [13]. The training parameters generated by these frameworks are separately transferred to the CNN model to train it effectively.

The model was trained using a series of MR images of brain tumors to fine-tune it [14]. The fine-tuning process is very useful because it decreases the time complexity and does not require training deep learning frameworks from scratch. To overcome the limitations of the data size, the popular technique of data augmentation is also included in the training process [15]. At the end of the study, we compared our recommended model's performance with some baseline models, which are also equally important. The findings of the experiment verified that the recommended model accomplished more precise predictions and could be effectively implemented in the big data healthcare domain. The achievements of this proposed work are in the following order:

- In the big data healthcare domain, an enhanced CNN framework that uses advanced techniques like transfer learning for categorising and diagnosing tumors using an MRI data set is recommended.
- Some trendy frameworks, which are already trained on a huge amount of ImageNet data collection, are employed for creating training parameters or weights. The training parameters of these frameworks are separately transferred to CNN models for efficient training.
- To train models more effectively and optimise model accuracy, the advanced machine learning technique is employed to enhance the volume of the data collection.
- The estimation of the effectiveness of our suggested model is excellent when compared to baseline models.

The remaining components of this research are structured in the following sequence: In the literature review section, previous related work is explored. The suggested model approach and data collection have been explained in the "Materials and Methods" section. The proposed Experimental procedures are explained in the “experiments” section. We discussed the proposed work's relevance in the "Discussion" part. The "Conclusion" section suggests the concluding opinions and future areas for investigation.

II. LITERATURE REVIEW

Innovative techniques are applied in the scientific field of medical imaging, and various cutting-edge technologies work to make segmenting, classifying, and other diagnostic tools more user-friendly and functional. The following part provides a summary of the various successful research studies that have been performed in the field of modern AI technology, with the conclusions of their achievements.
The latest findings are encouraging and have a considerable effect on brain tumor diagnosis and treatment. By [16] classified brain cancers by applying a model of neural networks with a sophisticated architecture and high accuracy values, applying a dataset of 5,812 MRI pictures. According to [17] proposed a customized neural network framework for classifying brain tumors based on images collected from different sources.

They used advanced 10-fold cross-validation to record the results and achieved more than 96% accuracy. The model's fundamental structure makes it incapable of studying complicated patterns. In turn [18] employed a paired GAN (generative adversarial network) framework to categorise different kinds of glioma brain tumors and obtained a mean accuracy of 88.82%. To address the lack of images for classification, enhanced MRI images are provided. By [19] presented a sophisticated CNN model using the dataset. The network is constructed using graph techniques with an accuracy of 95.49%. Scatterplots and some other graphical tools are employed to display results effectively. In contrast to several CNN models, which obtained lower accuracy with the proposed model.

To classify gliomas into subtypes [20] investigated the use of the discrete wavelet transform in combination with an advanced deep neural network model. MRI scans of brain tumors were acquired via the online repository. The framework divides the medical images into four distinct stages according to the WHO guidelines, and with the right feature extraction and selection strategies, the architecture performed excellently with 96.15% accuracy. Using the feature extractors D-SURF and [21] suggested a novel categorization approach. A dataset of 3,064 photos is used in their study to provide training SVM for the classification procedure.

Even with the meticulous Extracting characteristics procedure, it performed well and achieved an accuracy of more than 90%, which indicates requirements for extra SVM fine-tuning. A comparative deep study of the various existing frameworks, like CNN, VGG 16, Inception-V3, and Resnet-50, was carried out by [22] using a collection including 3,264 MR pictures. The accuracy ranges of the models were 80% to 93.30%, respectively. The literature study indicates that current methods for diagnosing brain tumors still lack a strong predictive capacity, making it difficult to accurately diagnose brain tumors to get the right care and make a full recovery. To properly treat and recover from brain tumors in the Big Data healthcare arena, a novel, robust way of precisely detecting them is needed.

III. MATERIALS AND METHODS

III.1 DATA SET

We employed a data set of brain tumor MRI from the Kaggle web repository, which included 3064 different forms of images. [23].

III.2 INTRODUCTIONS TO CNN FRAMEWORK

The base architecture of deep learning contains a feed-forward neural network, which contains multiple hidden layers to optimize the model's performance. Deep learning consists of various types of frameworks, among them, CNN is one of the most famous and widely used frameworks for implementing deep learning techniques (Figure 1). It is widely employed in various image processing-related research areas. It is particularly used to handle grid-like structures, such as image collections. The backpropagation algorithm can be used to train CNNs. Some important layers, such as the input layer [24], convolutional layer [25], pooling layer [26], fully connected layer [27], and output layer [28], make up a convolutional neural network's main structure (Figure 1). These layers execute several tasks, including feature extraction, classification, and dimensionality reduction [29]. The filter or Kernel [30] is slid across the input shape during the convolution process, computing the feature map and the value of each output.

Designed a Sliding Kernel using a dot product expression for quick deployment, utilizing convolution as a linear operator. Let's consider y and z as input and kernel functions. We can mathematically represent the convolution process (x * y) (a) on time index t using Eq. (1).

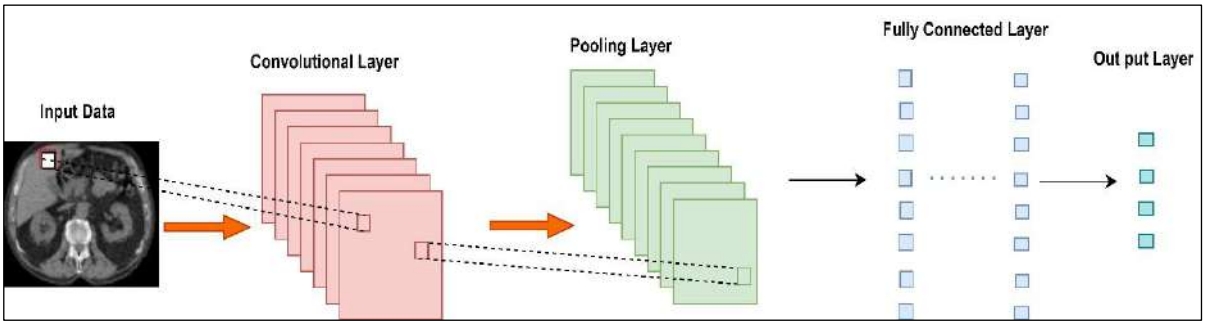

Figure 1: CNN framework for tumor classification.
Source: Authors, (2026).

$$(x * y)a = \int x(t)y(a-t)d\mathrm{a} \tag{1}$$

The CNN model typically uses 2 or 3-dimensional convolutions. Eq. (2) provides a mathematical expression for the convolution when a two-dimensional image I is used as the input and K as a 2D kernel.

$$(I * K)(i,j) = \sum_m \sum_n I(m,n)K(i-m, j-n) \tag{2}$$

Two activation functions, such as Sigmoid and ReLU, can be incorporated in addition to acquiring non-linearities. The sigmoid activation function [31] is expressed mathematically by Eq. (3):

$$\theta(x) = \frac{1}{1+\exp(-x)}, x \in R \tag{3}$$

When the output must fall within the range of binary [0,1], the sigmoid non-linear activation function is appropriate. Eq. (4) mathematically defines the second activation function ReLU [32]:

$$Relu(x) = \max(0, x), x \in R \tag{4}$$

Pooling layers are used to determine the dimensionality and provide a statistical summary of their inputs without affecting any important information. The final layer, referred to as a fully connected layer in a neural network, has input and output sizes of n and m, respectively. Weight matrices and other factors are used to express the output layer. The final layers are used for problem classification. After this layer, the output is flattened and appears as a single-dimensional vector [33].

III. 3 IMPORTANCE OF CNN FOR TUMOR CLASSIFICATION

CNN frameworks have produced noteworthy results recently in several fields, including image classification and diagnosis systems. CNNs are less complex and adapt more quickly than NLPs since they have fewer neurons and parameters. Medical image classification is a particular field in which the CNN model is quite beneficial. This study presents the design of the CNN network, which consists of four convolutional layers that contain alternate pooling layers, followed by an important dropout layer [34] presented after a regular pair of convolutional and pooling layers. To classify brain MR images into different categories (Meningioma, Glioma, and Pituitary), various components of convolutional neural networks, like a fully connected layer, pooling layer, sigmoid and ReLU activation function, and dropout layer, are used efficiently. Furthermore, we have employed the powerful optimistic algorithm, SGD [35], to train models efficiently.

III. 4 ENHANCED CNN FOR BRAIN TUMOR CLASSIFICATION

We have used advanced machine learning techniques like Data Augmentation (DA) and recently developed Transfer Learning technique to increase the projected accuracy of the proposed CNN framework. The issue of not having enough data for model training can be fixed via data augmentation. The modern transfer learning (TL) methods are frequently applied to image classification jobs. In the proposed research work, we included various frameworks that used transfer learning methods to increase the accuracy of the recommended CNN architecture.

III. 5 IMPORTANCE OF TRANSFER LEARNING TECHNIQUE(TL) IN IMAGE CLASSIFICATION

The concept of transfer learning [36] is breaking out from the isolated learning paradigm and applying knowledge gained from one task to another that is related (Figure 2).

The concept of transfer learning [36] is breaking out from the isolated learning paradigm and applying knowledge gained from one task to another that is related (Figure 2). Conventional learning is isolated, happening only based on certain tasks, datasets, and the training of distinct, isolated models on them. Nothing that is transferable from one model to another is retained. Through the use of features, weights, and other knowledge from previously trained models, transfer learning allows us to train fresh models. The ability to adapt knowledge from previously learned activities to more recent, related tasks is the goal of transfer learning.

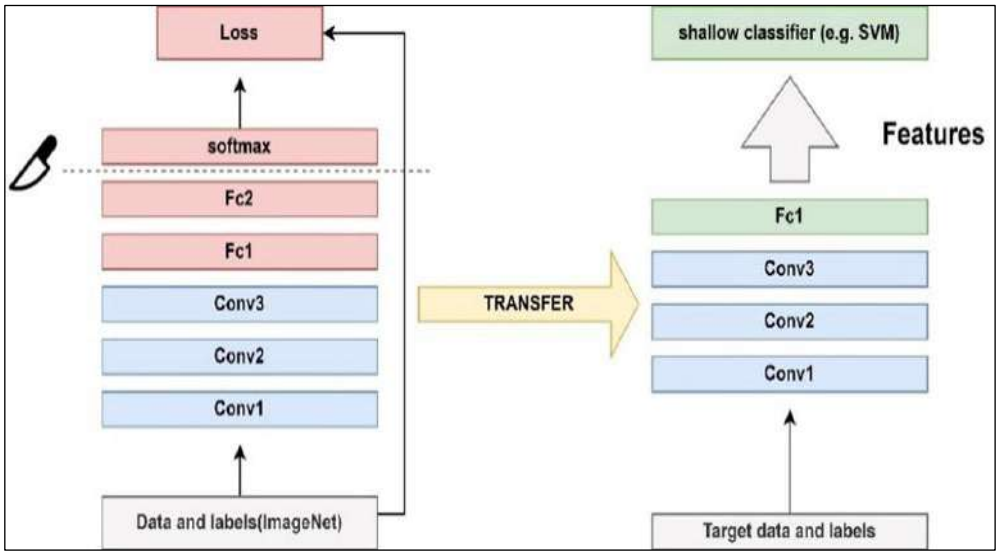

Figure 2: Transfer Learning Technique.
Source: Authors, (2026).

To increase the accuracy of the suggested CNN framework, we employed different pre-trained architectures, which have used transfer learning techniques as their core functionality. We used ResNet-50, Inception V3, VGG-16, Xception, DenseNet201, and MobileNet architectures in this research. The CNN framework was effectively trained using the training parameters provided by the above-mentioned frameworks. The CNN model was then finalized for the classification task, which is increased in volume using modern augmented technology. The distribution quantity of the data set plays an important role in the tumor classification task. The data set of tumour images used in this proposed work was split into a ratio of 70:30 for the training and testing data sets. The experimental performance is evaluated using the various performance metrics, like Matthews Correlation Coefficient (MCC), Sensitivity, Specificity, Accuracy, Precision, and F1-Score [37].

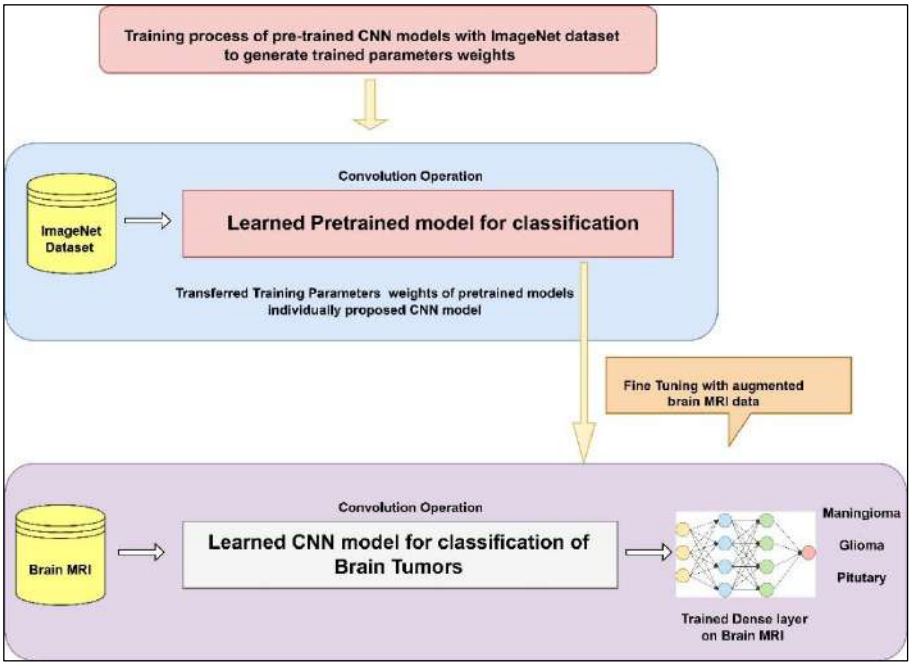

Figure 3: Functional flow chart of the proposed brain tumour classification model in a big data health care system.
Source: Authors, (2026).

CNN models are being widely used for medical image categorization issues. The CNN model can be trained more effectively with an extensive image data set because it can extract more relevant features for accurate picture categorization during the training phase. The CNN model performs worse when large picture data sets are not available, especially in the medical domain.

However, modern techniques are integrated to enhance the capacity of the recommended image classifier framework. In this work, some modern advanced techniques have been used to optimize the performance of the proposed model [38]. The previously mentioned pre-trained architecture was trained on a huge multidisciplinary ImageNet data repository, which has 10,000 object classes and 1.4 billion images. The trained parameters, which have been obtained from the above architectures, were passed to the CNN framework for efficient training on its own. The CNN architecture was improved, and its final classification in the big data healthcare system was determined with the support of MRI data collection.

Additionally, several MR images were used for training and testing work on the suggested deep-learning framework. After performing both activities, the results were compared among the transfer learning models. The suggested approach for training and testing models uses a holdout cross-validation mechanism. To enhance the proposed framework's capacity, the common method of zooming was employed in the data augmentation process to boost the original dataset. The incorporation of modern techniques significantly improved the CNN model's predicted accuracy [39]. Several assessment metrics have been utilized to determine the model's evaluation criteria. The functional flow chart of our proposed framework is presented in Figure 3, and the algorithm in Figure 4.

Algorithm : Proposed brain tumor classification model in Big data healthcare system

Input: E Number of epochs; w: Transfer learning model parameters; η: Learning rate; b : Batch size; X_{train} : Brain tumor training data set; X_{test}: Brain tumor test data set; X': ImageNet data set.

Output: P_{test} : The assessment metrics are computed on the test data Initialize transfer learning models parameters w

Transfer Learning :

IV. EXPERIMENTS

❖ **Experimental setup.**

We tested the feasibility of our suggested structure in the big data healthcare system through several evaluations. In the proposed research work, the brain tumour MRI collection was utilized to test the proposed model. To produce trained parameters (weights), we used six CNN frameworks that are already trained on large image data sets. For effective model training, we transferred the trained parameters to the CNN architecture separately. The CNN framework's prediction accuracy was enhanced as an output. The CNN model's final classification and fine-tuning were performed using MRI data collection. The various forms of MRI images (glioma, meningioma, and pituitary) represent 233 patients and 3064 slices in the data.

This data collection is far too small to train the CNN model efficiently. A modern data enhancement method augmentation has been utilized to address the issue of tiny brain tumours. The three types of photos are added to existing photographs using the data augmentation approach (zooming), which involves zooming both horizontally and vertically [40]. The SGD Optimization technique is used to optimize the model efficiently. Furthermore, in every experiment, some important parameters like learning rate (LR), batch size = 120, epochs = 50, SGD = 0.0001, and outer and inner activation function ReLu are employed. It is important to note that the softmax activation function was applied to our CNN model's final prediction layer. Evaluation indicators are integrated to assess the accuracy of the framework. The experimental results were graphed and tabulated.

V. RESULTS AND ANALYSIS

There are 233 participants and 3064 slices in the Brain Tumor data set. Of these, 82 subjects have meningioma (with sections 708), 91 have gliomas (with slices 1426), and 60 have pituitary tumours (with segments 930). As a result, there are 233 subjects in the data overall, and there are 3064 slices total. To effectively train the model, the dimension of 512 × 512 × 1 must be reduced to 224 × 224 × 1. The popular data augmentation approach was employed on the source dataset of brain tumour images by applying random zooming to address the imbalance issue in the dataset. Every slice is being magnified, and a new data collection has appeared, which contains 6128 image slices.

V.1 EXPERIMENTAL RESULT ANALYSIS OF THE CNN MODEL, WITH AUGMENTED AND ORIGINAL DATA COLLECTION

The source and enhanced tumour MRI data collection are employed to analyse the efficiency of the suggested CNN framework. The recommended CNN architecture is set up with the necessary hyperparameters. 70% of the image collection is utilized for model training, while 30% is used for testing the model. Various assessment matrices were employed to examine the accuracy of the architecture. Table 1 summarizes all these hyper-parameter values as well as the output of the experiments. Table 2 shows the results, based on the suggested CNN frameworks with original and augmented MRI data collection. The various forms of tumors (glioma, meningioma, and pituitary) are efficiently classified by our CNN design, as evidenced by the 97.30% accuracy rate.

The Proposed CNN model's 98.04% specificity demonstrates that it is an excellent detection model for identifying healthy patients, and its 96.15% sensitivity indicates that it detected the affected subjects with significant accuracy. Conversely, after being trained and assessed on an expanded image collection, the recommended architecture demonstrated exceptionally high efficiency. The suggested framework yielded 98.52% of training accuracy, 99.00% of specificity, 98.10% of sensitivity, and 98.40% of MCC. The framework's training accuracy increased from 97.30 to 98.52%, highlighting the significance of the data augmentation procedure. Additionally, it showed that additional data is needed for the recommended framework to be trained and work efficiently. Figure 5 represents the above analysis in chart format.

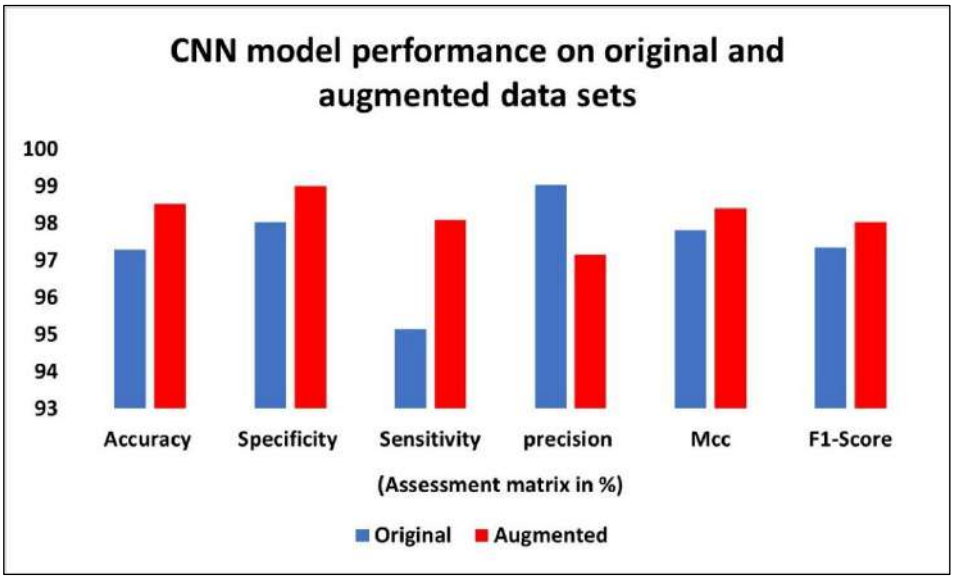

Figure 5: CNN framework efficiency chart based on original & augmented data collection.

Table 2: Comparative Analysis of Different Transfer Learning Frameworks' Efficiency Based on Original and Augmented Data Collection

Pre-trained frameworks	Proposed data set types	LR	Assessment metrics					
			Accuracy (%)	Specificity (%)	Sensitivity (%)	precision (%)	MCC(%)	F1-Score(%)
ResNet50	Original	0.0001	99.05	100.00	89.50	98.74	98.65	99.52
	Augmented	-	99.40	99.06	96.12	99.21	99.15	99.42
VGG-16	Original	-	96.76	99.21	95.00	96.98	98.92	97.97
	Augmented	-	97.87	98.01	100.00	96.97	98.78	99.01
Inception V3	Original	-	97.01	99.01	99.86	98.81	95.75	98.08
	Augmented	-	98.01	100.00	98.65	97.54	99.01	97.20
DenseNet201	Original	-	97.01	99.97	98.12	99.13	97.97	99.08
	Augmented	-	97.80	100.00	97.44	95.67	99.02	99.31
Xception	Original	-	98.10	98.86	97.30	99.01	99.12	98.64
	Augmented	-	98.87	99.01	98.50	97.23	97.98	99.20
MobileNet	Original	-	98.07	99.42	93.10	99.11	97.64	93.23
	Augmented	-	98.57	100.00	99.66	93.97	99.31	99.04

Source: Authors, (2026).

Based on the experimental findings, we deduced that the suggested convolutional neural network framework successfully categorized the different kinds of tumor MR images. Additionally, the augmentation procedure enhanced the CNN model's performance by providing additional data to extract more relevant attributes. The performance of various previously mentioned pre-trained frameworks has been measured on both the source and augmented MRI data collection. The experimental findings based on various pre-trained deep learning models and their hyperparameter values have been represented in Table 2, Figure 7 represents the above comparison in a pictorial format using the graphical chart method. After analysing the findings, we deduced that the method of augmenting data improved ResNet-50's training accuracy and that the model successfully identified the different kinds of brain tumours based on MRI.

V.2 ACCURACY COMPARISON OF THE PROPOSED (RESNET 50) FRAMEWORK WITH LEADING-EDGE ARCHITECTURES

In Table 3, we have contrasted the accuracy of our ResNet-50 model with cutting-edge techniques. The graphical representation of the accuracy comparison is depicted in Figure 6. The suggested model achieved 99.40% accuracy, which is the highest when compared to other cutting-edge methods. The suggested method's great performance showed that tumour images (gliomas, meningioma, and pituitary) are accurately classified by it and that it is a simple process to use in the big data health care domain.

Table 3: Performance Comparison with Previous Models.

Model	Accuracy (%)	Reference
ANN and KNN	97.98	[38]
GA-CNN	94.2	[39]
SVM and KNN	85.88	[40]
CNN-TF	94.82	[41]
Proposed method ResNet	99.40	2025

VI. DISCUSSION

The identification and classification of MR images are essential for the analysis of brain cancer in big data healthcare systems. In a big data healthcare system, computer-automated diagnostic systems (CAD) based on artificial intelligence (AI) can accurately diagnose many diseases. Deep learning methods, particularly CNNs, are extensively employed in CAD systems for the diagnosis of serious illnesses. The advanced machine learning-based deep learning framework is mostly employed for the detection and classification of medical pictures. Deep characteristics that are extracted from image data by the CNN model were crucial to the final classification of the images. Researchers have suggested several techniques for diagnosing brain cancer utilizing deep learning models and brain MR image data. Nevertheless, the accuracy of these current techniques is lacking.

To overcome this medical problem, which is related to MR images, an advanced and efficient approach is required for the precise and effective diagnosis of the illness in big data healthcare systems. In the proposed work, a CNN framework is recommended that categorizes different tumors from magnetic resonance imaging. For final classification, the recommended frameworks collect detailed attributes from the brain MRI collection. We have implemented a transfer learning approach to enhance the CNN model's predictive capacity [41]. In comparison to baseline approaches, the suggested method produced excellent results, as shown in Table 3, Figure 6, regarding meningioma, glioma, and pituitary categorization. Moreover, the suggested approach might be effortlessly used for the identification and categorization of tumor images in the big data healthcare domain.

VII. CONCLUSION

The CNN model is important for accurately classifying medical images, and it is utilized in the majority of CAD systems to analyze medical image data. We have presented an advanced diagnosis technique for classifying brain tumors in our proposed research work. In the suggested approach, we have employed brain tumor MR imaging data to perform training of various neural networks for the classification of tumor images which are related to the brain. We have included two modern and popular approaches to improve the recommended framework's prediction power.

Comparing the testing findings to baseline approaches, the recommended architecture(ResNet 50) achieved 99.40% enhanced accuracy, which is excellent in comparison to any other frameworks. The suggested method's good prediction results defined efficient data pre-processing and model parameter adjustments, including layer counts, optimizer, and activation functions. The suggested ResNet 50 model performs well, which makes it potentially useful for diagnosing brain cancer and classifying brain tumors in the context of a big data Healthcare system. To diagnose brain tumours in the future, we'll employ further deep-learning methods and datasets about brain tumors.

ABSTRACT

The global tire industry generates approximately 1.5 billion end-of-life tires annually, amplifying waste, emissions, and health risks. This review synthesises contemporary life cycle assessment (LCA) evidence and recycling innovations, including pyrolysis, microwave devulcanization, and hybrid thermochemical routes, to map credible pathways toward circularity. We identified four persistent gaps: heterogeneous LCA methods and data silos, misaligned policy incentives, scalability and profitability limits of advanced recycling, and fragmented adoption of sustainable materials. To address these issues, we propose an integrated framework that couples standardised, sector-specific, and dynamic LCAs with modular, upgraded pyrolysis for high-value recovery (carbon black substitutes, oils, and steel), design-for-circularity (renewable elastomers and sensor-enabled tires), and enabling instruments (extended producer responsibility, differentiated subsidies, and carbon crediting). The framework establishes feedback loops between tire design and end-of-life performance, supports regionally deployable solutions, and prioritises the use of interoperable data platforms, pilot deployments, and policy realignment. Collectively, these measures can accelerate the tire sector's transition from linear to circular models while minimising environmental burdens across the production, use, and end-of-life stages.

I. BACKGROUND AND MOTIVATION

The global tire industry, with a market size exceeding $250 billion, is indispensable to modern mobility and poses a formidable environmental challenge. This is due to the excessive demand in the automotive industry for the use of vehicles such as cars, motorcycles, and heavy vehicles such as lorries and buses, as well as the development and aerospace sectors such as airplanes. According to previous studies, as living standards rise and the number of automobile owners increases each year, an increasing number of people choose transportation as their major mode of mobility. [1] Approximately 1.5 billion tires reach end-of-life annually, contributing to a growing stockpile of waste and associated environmental hazards, such as fires, leachate, and microplastics.

Furthermore, incorrect disposal procedures have turned the growing number of waste tires into a severe environmental issue, as they can contaminate the air and soil, spread dangerous diseases, and offer habitats for rats. Therefore, finding an environmentally appropriate approach to dispose of these old tires is critical. Recycling materials from old tires is increasingly regarded as a sustainable method for disposing of unwanted tires owing to its numerous benefits. Recycling old tires can reduce CO2 emissions by approximately 1523 tonnes per year, according to a life cycle study that examined the environmental effects of textile fibres salvaged from discarded tires. [2] However, owing to continuous innovations in tire design and material science, the industry struggles to transition from a linear to a circular model.

These due to break from the linear model, a creative process of systemic reconfiguration and flexibility is necessary. As a result of the technological revolution of the previous 200 years, the modern world is a complex system of interconnected parts surrounded by extensive stakeholder networks, rules, and incentive systems. These reasons make systemic sustainability change more challenging, both individually and in tandem with globalisation and shifting social expectations. The current unsustainable system has become stable due to the linear model's intrinsic lock-in inertia, which includes sunk costs in infrastructure, skills, and established economies of scale. As a result, transitioning to the circular model demands consideration of complex relationships and structural changes. Because of the significant initial investment, transitioning to an incentive structure based on long-term sustainability principles typically results in poor, short-term financial performance. Governments must play an important role in internalising the externalities associated with resource exploitation and waste disposal to change the current fiscal, accounting, and regulatory frameworks. [3]

Circular economy (CE) principles offer a conceptual and operational framework for reducing waste, extending product lifecycles, and recovering materials for reuse. However, the translation of CE concepts into measurable and scalable industry practices, particularly within the tire lifecycle, remains underdeveloped. Life cycle assessments (LCA) and advanced recycling technologies are essential instruments in this transition but are unevenly adopted across sectors and geographies. [4] This is because the implementation of a CE may have a disproportionate impact on certain groups or individuals, and there is a risk that it will exacerbate existing imbalances. The shift to a CE raises social challenges, such as income distribution, employment patterns, and the effectiveness of existing political structures. It has been claimed that CE will alter employment patterns across several industries, necessitating a shift in labour costs rather than material pricing. Furthermore, the transition to a CE may increase competition for resources, raising raw material costs and making acquisition more difficult for small businesses and low-income individuals. [5]

I.1 STATE OF THE ART

Recent literature reflects the increasing momentum toward sustainability in the tire sector. Advances in LCA methodologies, including attributional and consequential models, allow for detailed comparisons of recycling, pyrolysis, retreading, and incineration pathways [6], [7]. For example, crumb rubber production, a widely used recycling method, performs moderately well in terms of environmental impact but is often constrained by market saturation and quality degradation issues. This is because tires consist of numerous finely developed elements, including treads, belts, inner liners, and sidewalls. When the performance characteristics of these parts are integrated, the resulting tires are strong, durable, dependable, and safe. These characteristics ensure the durability of the tyre materials and particles in the environment. Tires contain several chemicals and molecules, many of which are proprietary [8]. Tires are mostly constructed of rubber, with a framework consisting of textiles or metal mesh. Different tire brands, types, and components employ proprietary rubber formulas [9–13].

According to previous studies [12], tire rubber is typically composed of 40-60% synthetic and/or natural rubber, 20-25% fillers and reinforcing agents such as carbon black and silica, 12-15% process or extender oils, vulcanisation agents such as Zn and thiazoles, and additional additives such as preservatives and processing aids (5-10%). The ratio of natural to synthetic rubber in tires is approximately 50:50; trucks have more natural rubber, passenger cars have more synthetic rubber, and heavy-duty vehicles have little to no synthetic rubber [14]. Tires contain thousands of chemicals, including polycyclic aromatic hydrocarbons (PAHs), contaminants in manufacturing feedstocks, weathering or transformation products as tires age, and intentionally added chemicals such as N-(1,3-dimethylbutyl)-N′-phenyl-p-phenylenediamine (6PPD, DTXSID9025114; CAS 793-24-8) [15]. As a result, the chemical composition of the tyre wear particles varies.

Consequently, it is difficult to track and classify tire particles and tire-derived chemicals in environmental samples, anticipate the fate of tire microplastics, and assess their ecotoxicological impact. Research on the general and quantitative chemical composition of tyre rubber is still critically needed to produce new recycled types. Moreover, new materials research has led to the development of bio-based and smart elastomers, which may increase recyclability and reduce environmental burdens during use [16]. Simultaneously, integrated frameworks for tire lifecycle extension, such as predictive maintenance via AI and embedded tire sensors, suggest avenues for proactive waste minimisation. However, the systemic integration of these solutions remains rare. While a few smart city projects (e.g. in Europe and East Asia) incorporate tire recycling into urban sustainability plans, many regions still rely on landfilling or uncontrolled incineration [17], [18].

I.2 DEFINING THE RESEARCH GAP

The overarching gap lies in the absence of a unified operational framework that synthesises Life Cycle Assessment (LCA) results and innovative recycling methods into actionable circular business models. Several critical micro-gaps emerge within this broader challenge which are data silos and standardisation challenges in comparing LCA studies across tire types and regions [19]. In production and trading companies, life cycle evaluation can be used to address both general concerns and specific commodities issues. Waste management strategies, action plans, and design enhancements can be developed based on these findings and compared with those of other companies [20]. Environmentally friendly transportation must be designed using data from different sources. The increased use of cars has considerably influenced the natural environment. Multinational decision-makers must collaborate to change the current scenario [21].

To satisfy a specified vehicle tire recovery level, manufacturers and importers must follow regulations governing waste and product management constraints and deposit requirements. If they do not meet these conditions, they will face penalties [22]. Given the foregoing, the environment's ability to meet the demands of contemporary systems on natural resources is rapidly eroding. Concerns surrounding the assessment of the environmental impact of automotive tires must be addressed. A review of several studies on the environmental impact of commodities, such as vehicle tires, throughout their life cycle, shows that it is critical to identify specific sets of impacts and their sequence. Current and future costs should be considered. For example, a natural rubber tire has a different environmental impact than a regular automobile tire [23].

In addition, the insufficient scalability and profitability of newer pyrolysis-based systems despite their carbon offset potential [24]. The pyrolysis process can significantly benefit waste polymers that are typically difficult or impossible to recycle. This technique provides a realistic pyrolysis option for the economical and environmentally responsible reuse or disposal of these polymers, converting them into useful chemicals and fuels. Finally, pyrolysis can be beneficial to enterprises. However, in term of the scalability of system pyrolysis recycling is limited by the lack of usable space for expansion, scaling operations for viability, modularization, and quick turnaround time-speed to market. This is because the number of waste tires in this modernising environment has been a lot of increased significantly, and it is not sufficient to use the pyrolysis system.

The industrial sector still uses the old-school method of burying the remaining waste tires [25]. In addition, the fragmented adoption of sustainable materials is largely confined to research laboratories or niche commercial applications [26]. According to the European Tyre and Rubber Manufacturers' Association (ETRMA) statistics, the most commonly used technique among the various end-of-life tire recycling activities in 2018 was grinding or shredding used tires. This creates a significant challenge for researchers because it combines the material properties of one tire with another. The shredding process produces the so-called "chips," which are often used as alternative fuel (energy recovery). The ETRMA has released new, worrying numbers, revealing that 318 800 t of tires were wasted in 2018, a 12% rise over 2017. As evidenced by the statistics presented above, the disposal of worn tires is a major environmental concern that poses numerous challenges for researchers and corporate executives.

Thus, it is impossible to justify research on material recycling technologies for used tires [27]. Finally, Disjointed policy frameworks, where incentives for circular practices are either absent or misaligned with technical feasibility [28]. The existence of fragmented policy frameworks, where incentives for circular practices are either non-existent or not in line with technical feasibility, represents a major research gap in the tyre industry's efforts to advance a circular economy. Although the necessity of encouraging recycling, reuse, and resource efficiency in tire manufacturing and end-of-life management is becoming more widely acknowledged, current laws and policies sometimes fall short of offering cogent, helpful frameworks that are in line with what is both technically and financially feasible.

For example, subsidies or tax incentives might favour incineration over material recovery, even though, when considering life cycle assessments (LCA), the latter has a higher potential for environmental advantages. Furthermore, inconsistent policies across areas may stymie the development and deployment of novel recycling technologies by causing ambiguity and dispersion in market signals. These legislative misalignments might deter investment in sustainable design and enhanced recovery processes, as businesses may not see obvious benefits or returns under the present frameworks. Addressing this gap necessitates integrated policy approaches that not only incentivise circular innovations but are also informed by strong LCA data, ensuring that environmental objectives are achieved in ways that are both technically possible and commercially appealing [29].

I.3 OBJECTIVES OF THIS REVIEW

This study aims to map the transition of the tire industry toward circularity through an integrated review of life cycle assessments and recycling innovations. Specifically, the review will revealed about analyzes the strengths and limitations of LCA as a decision-making tool for tire recycling. In addition, the current and emerging recycling technologies, including pyrolysis, DE vulcanisation, and AI-enhanced separation, are evaluated. Second, identify the policy and industrial barriers that hinder circularity. Finally, a synthesised framework is proposed for advancing circular strategies in tire production, use, and end-of-life treatment.

II. HYPOTHETICAL SOLUTIONS FOR SEVERAL POSSIBLE BEST METHODS TO CLOSE THE GAP

Researchers have estimated various viable but inconsistently implemented approaches for bridging the systemic and technological gaps in the circular transformation of the tyre industry. These initiatives are divided into four main areas: materials science, policy integration, LCA standardisation, and technical innovation. These are explained in detail in each category below.

II.1 LIFE CYCLE ASSESSMENT (LCA) HARMONIZATION AND EXPANSION

LCA has become the cornerstone of environmental impact analysis; however, inconsistencies in methodologies and assumptions often limit comparability. A unified LCA framework tailored for the tire industry that accounts for regional, material, and use-phase variability could provide more actionable insights across the value chain. One proposed solution is a sector-specific LCA toolkit based on ISO 14040/44 but enriched with tire-specific inventory data, material degradation profiles, and recyclability indices [30]. Standardising LCA categories, such as global warming potential (GWP), acidification, and resource depletion, would foster comparability between tire brands and recycling strategies. Moreover, dynamic LCA models that integrate real-time data (e.g. wear sensors and GPS-based usage) could move the field beyond static cradle-to-grave snapshots toward adaptive cradle-to-cradle loops. Figure 2 shows an illustration of the LCA.

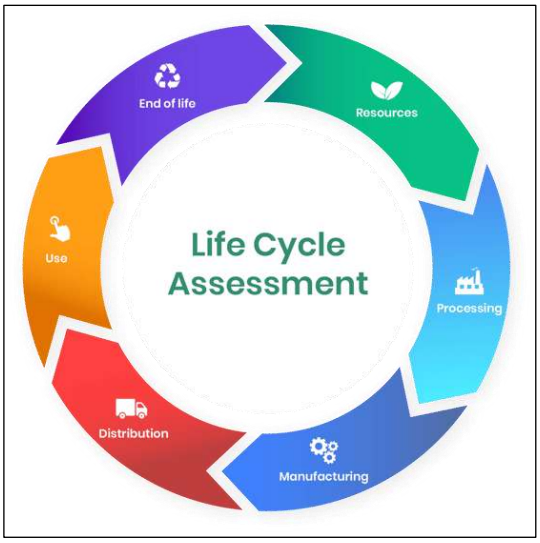

Figure 2: Life Cycle Assessment (LCA).
Source: [31].

II.2 ADVANCING TIRE RECYCLING TECHNOLOGIES

Pyrolysis, microwave devulcanization, and supercritical fluid extraction are increasingly recognised as next-generation recycling pathways. These technologies enable the recovery of high-value materials, such as carbon black, steel, and oil. Therefore, it is necessary to upgrade pyrolysis systems with continuous feed reactors, and gas cleaning units are being tested to improve the yield and reduce emissions [32]. The intention is to build a waste tyre (WT) pyrolysis and upgrading factory with an annual capacity of 100,000 tonnes, which will be allowed. Figure 3 depicts the pyrolysis of WT to produce high-value pyrolytic materials and the construction of new tires using M-CBp. Following the pre-stripping of the steel wire, the WTs were cracked in a revolving kiln to generate three-phase products. Subsequently, TPO and CBp were improved independently.

The pyrolytic gas served as the fuel for pyrolysis. The TPO components were separated into light, medium, and heavy oils based on their boiling points using a three-stage atmospheric and vacuum distillation tower set. The light and medium fractions completed sulphur removal to produce low-sulfur petrol and diesel. In terms of CBp, M-CBp created through various modification processes might be used to replace various proportions of commercial carbon black used in new tire production. Waste heat from pyrolytic gas combustion and TPO refining was recycled to generate steam (400 °C, 0.5 MPa) and low-quality steam (200 °C, 0.5 MPa) as byproducts of circulation.

In addition, microwave devulcanization allows for the selective cleavage of sulfur crosslinks, preserving the rubber backbone, which is a major advantage over mechanical shredding [33]. Devulcanization procedures vary according to the reaction mechanisms, which are physical, chemical, and biological. In the physical process, waste rubbers are devulcanized using external energies such as thermal, cryo, mechanical, microwave, or ultrasonic. To recuperate waste rubbers, a chemical process generates phenol sulphide and disulphides. Furthermore, in biotechnological processes, bacteria such as chemolithotrophic microorganisms and Nocardia species have been used to devulcanize scrap rubber. Among these approaches, microwave devulcanization has been extensively explored because of its high efficiency and superior control over the ultimate temperature, which plays an important role in devulcanization.

In addition, hybrid approaches that couple mechanical pre-processing with thermochemical recovery optimise throughput and energy efficiency. This type of process can be classified based on the target product, such as gas, liquid, or solid, the oxidation environment (partial or anaerobic), and the type of feedstock (wet or dry). Thermochemical conversion methods hold significant promise for producing renewable electricity through waste and coal co-combustion in power plants and for decentralised generation in underdeveloped nations. Additionally, using thermochemical processes to generate electricity from waste can contribute to meeting renewable portfolio standards in certain US states [34]. This type of transformative but underexplored option is modular recycling systems embedded within urban environments, allowing for decentralised, demand-responsive treatment, especially in smart cities pursuing circularity.

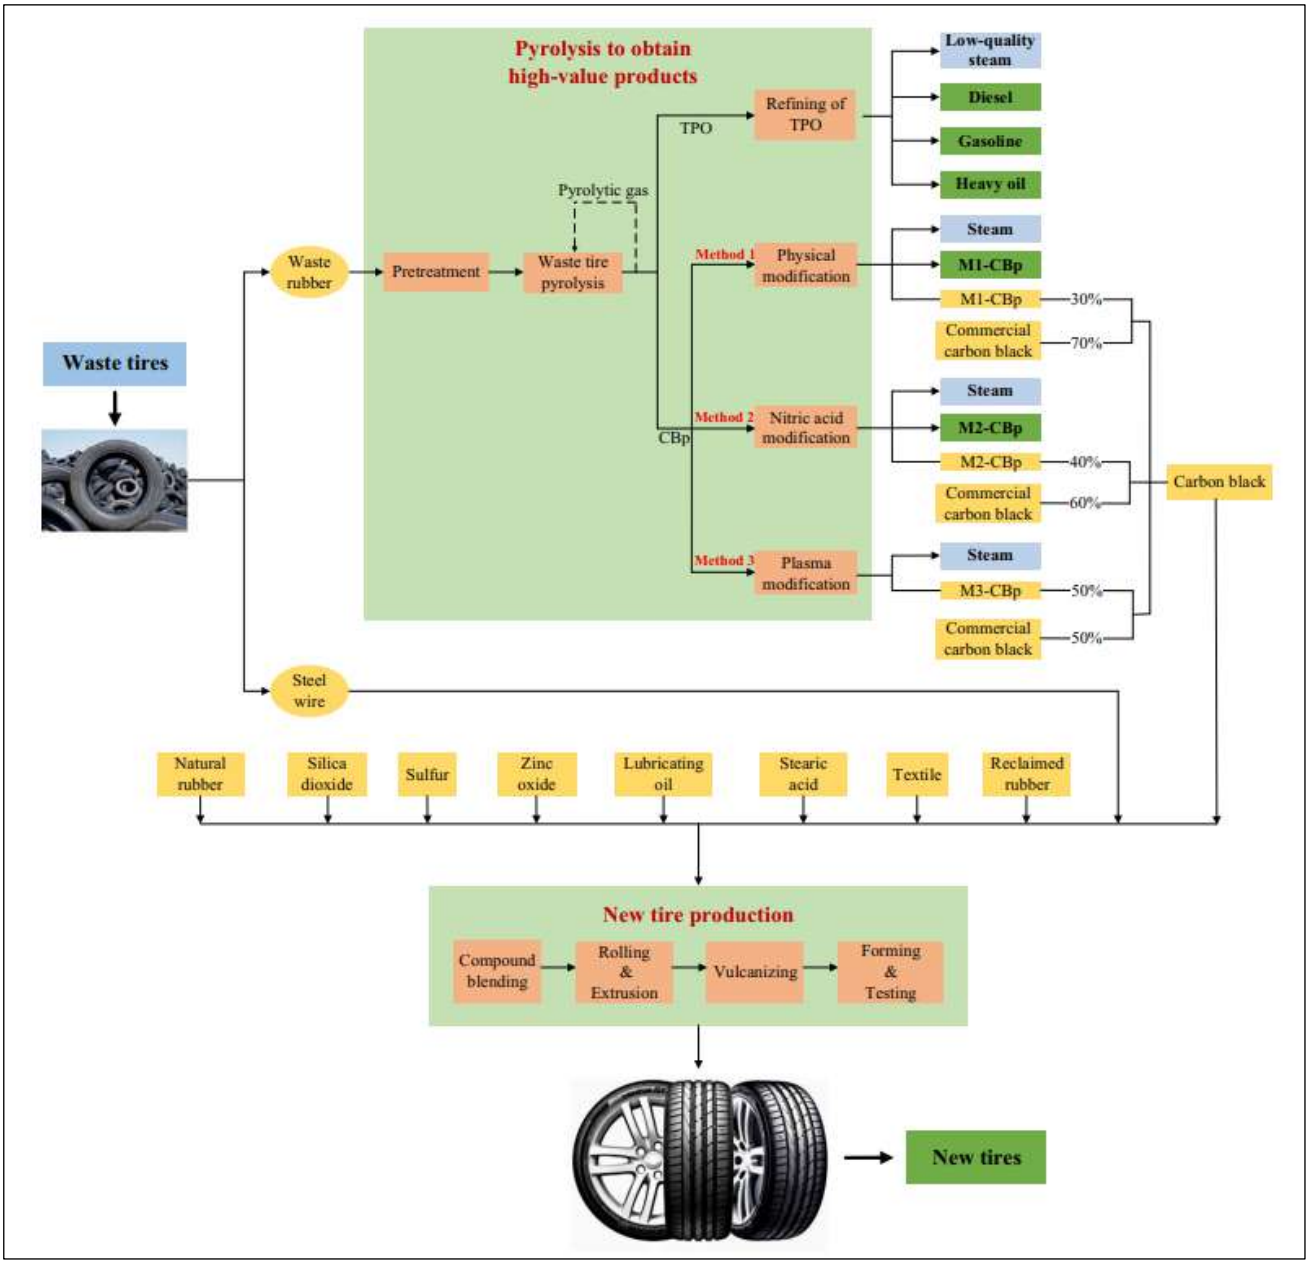

Figure 3: Flowchart of the closed loop of waste tire pyrolysis and new tire production.
Source: [32].

II.3 SUSTAINABLE AND CIRCULAR TIRE DESIGN

To achieve true circularity, tire design must anticipate end-of-life (EOL) processing. Several innovations show promise, such as dandelion rubber (Taraxacum kok-saghyz) and guayule as renewable elastomer sources, which reduce fossil dependency and potentially simplify devulcanization [35]. In addition, modular tire architectures that separate the tread from the carcase via mechanical fasteners could enable selective reuse and recycling. In addition, the provided sensor enabled smart tires to track wear and performance, potentially informing dynamic LCA models and enhancing product stewardship [16]. However, these solutions require compatibility with existing manufacturing lines and standardisation across different suppliers. This means that it is necessary to know each region and country that supplies the particular types of tires that match the environment.

II.4 POLICY, ECONOMIC INSTRUMENTS, AND INDUSTRIAL SYNERGIES

Public policy remains a significant bottleneck. Despite mandates in the EU and extended producer responsibility (EPR) laws in some countries, enforcement remains uneven. So to link with the policy and EPR laws. The proposed strategies include differentiated subsidies or tax incentives for tires that meet recyclability and life cycle performance thresholds. EPR frameworks internalise the cost of post-consumer waste and promote closed-loop models [36]. In addition, industrial symbiosis, where tire waste is co-processed with other industrial byproducts (e.g. in cement kilns), optimises material flows and emissions profiles [37]. Finally, emerging carbon credit markets could monetise the environmental benefits of high-efficiency tire recycling, providing additional incentives for early adopters [19].

II.5 INTEGRATIVE PLATFORMS AND CROSS-SECTORAL COLLABORATION

These can give the complexity of tire circularity; no single actor or intervention can succeed alone. Interdisciplinary platforms that bring together material scientists, LCA practitioners, policymakers, and industry stakeholders are essential. Emerging digital twins and collaborative LCA databases can catalyse such integration, enabling data transparency, interoperability, and benchmarking.

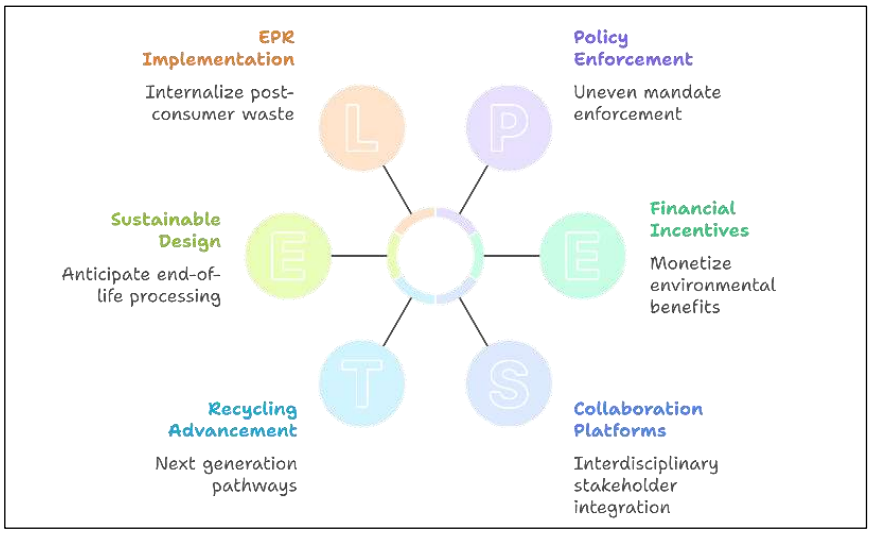

Figure 4: Tire Industry Circular Transformation.

III. THE BEST METHOD AMONG THEM AND HOW IT CAN CLOSE AND SOLVE THE GAP

Although numerous solutions have been proposed to address the linearity of the tire industry, not all offer equal potential in terms of scalability, system integration, and environmental efficacy. After a critical assessment of the approaches outlined in Chapter 2, one method emerges as the most promising: Integrated Life Cycle–Informed Modular Pyrolysis within a Circular Policy Framework. This hybrid strategy unifies real-time LCA modelling, advanced modular pyrolysis, and policy-supported circularity incentives to create a closed-loop system. This section defends its selection and details how it addresses the key structural and environmental gaps in the industry.

III.1 SUPERIOR MATERIAL RECOVERY

Among all the reviewed recycling technologies, advanced pyrolysis offers the broadest material recovery profile, yielding carbon black substitutes (CBp), oils, and steel. When enhanced with modular scalability and upgraded reactor design, pyrolysis provides both high throughput and regional flexibility [38]. Critically, pyrolysis does not require prior sorting by material type and can handle mixed, contaminated, or aged tires, which often overwhelm mechanical or devulcanization-based methods [33].

III.2 INDUSTRIAL INTEGRATION POTENTIAL

The pyrolysis byproducts can reenter the supply chain, making this method uniquely compatible with circular manufacturing. Carbon black recovered via pyrolysis has shown near-commercial-grade performance when upgraded chemically or physically. This allows for partial substitution in new tire manufacturing, thereby reducing raw material demand and production emissions [26].

III.3 THE ROLE OF DYNAMIC, DIGITAL LCA

Static LCAs fail to capture the real-time variability in tire performance and end-of-life impacts. Embedding IoT sensors in tires and using cloud-based LCA platforms enable "living LCAs" that adjust impact predictions based on wear, driving behaviour, and regional recycling options. These LCAs are not only descriptive but also prescriptive; they can recommend optimal end-of-life treatment routes, for example, prioritising pyrolysis if a tire has high embedded energy or directing mechanical recovery if treads are intact. When integrated with digital twins, these models can simulate various circular scenarios, allowing manufacturers and policymakers to select strategies that minimise ecological and economic costs.

III.4 POLICY SCAFFOLDING AND INCENTIVIZATION

Even the most advanced technologies require policy scaffolding to thrive. Integrated modular pyrolysis succeeds when supported by differentiated recycling subsidies favoring high-yield, low-emission technologies. Besides that, EPR regulations that mandate material traceability and minimum recycled content in new tires [39] and digital certification of carbon savings, enabling manufacturers to monetize their environmental performance through carbon credits or product ecolabels [19]. Such measures close the economic loop and create systemic incentives to adopt and sustain circular practices across the tire lifecycle.

III.5 FEEDBACK LOOP BETWEEN MATERIAL DESIGN AND END-OF-LIFE PATHWAYS

The most critical function of this integrated strategy is that it enables a continuous feedback loop between tire design and end-of-life recovery. If a certain compound in a tire hinders pyrolysis efficiency, that information can be fed back into material R&D. If a modular pyrolysis unit reports higher yields from tires made with renewable elastomers (e.g. dandelion rubber), this can drive design innovation [35]. In this way, the system evolves organically, aligning product innovation with recyclability, market dynamics and environmental performance.

III.6 ANTICIPATED CHALLENGES AND COUNTERARGUMENTS

Despite its strengths, integrated modular pyrolysis faces challenges such as non-trivial energy input requirements that must be offset with renewable sources or recovered heat loops or public perception and investor uncertainty around pyrolysis persist, often due to legacy associations with incineration and digital infrastructure costs for LCA standardisation and sensor integration may limit adoption in low-resource contexts. These challenges are not insurmountable but must be acknowledged in any realistic deployment. Hybrid approaches, including phased rollouts, public-private partnerships, and open data sharing, can reduce systemic resistance and upfront costs.

IV. SUMMARY AND FUTURE DIRECTIONS

This review examines the intersection of life cycle assessments (LCA) and recycling innovations in guiding the tire industry's transition toward a circular economy. The investigation revealed the following core findings: current LCA frameworks offer critical environmental diagnostics but lack standardisation and real-time adaptability. A shift toward dynamic, digital LCAs is essential. Pyrolysis and its modular variants have emerged as the most promising recycling pathways for tires because of their capacity for material recovery, compatibility with mixed waste, and integration potential within existing supply chains.

Design for circularity, especially innovations in sustainable elastomers and sensor-enabled tires, can amplify both reuse and recovery potential but requires coordinated standardisation and investment. Finally, policy frameworks such as extended producer responsibility (EPR), subsidies for high-efficiency recycling, and carbon credit mechanisms are essential scaffolds that translate technical promises into systemic impacts. By integrating modular pyrolysis, digital LCAs, recyclable design, and supportive policy, a tire economy is envisioned that not only minimises waste but also transforms it into a valuable input for new cycles of production.

IV.1 CONTRIBUTIONS TO THE FIELD

This study contributes to the growing dialogue on circularity in the tire industry by offering a synthesised roadmap that integrates technological, environmental, and policy dimensions. Unlike earlier studies that focused on isolated solutions, this study presents a comprehensive framework in which LCA acts as the analytical engine, pyrolysis as the material recovery mechanism, and policy as the market enabler. Furthermore, by acknowledging the nuances and trade-offs in each domain, this study provides a balanced and realistic foundation for both academic enquiry and industrial action.

IV.2 RESEARCH LIMITATIONS

This study has several limitations. First, comparative LCA data across geographies are inconsistent, which restricts generalisability. Second, while pyrolysis holds immense potential, much of the data are based on pilot-scale or regional deployments, limiting insights into global scalability. Third, social dimensions, such as labour conditions in recycling sectors or public acceptance of new materials, are underexplored in this review but are vital to the circular transition.

IV.3 FUTURE RESEARCH DIRECTIONS

To close the remaining gaps and deepen the operational feasibility of circular tire systems, future studies should prioritise real-world pilot projects combining IoT-enhanced tires, dynamic LCAs, and localised pyrolysis units in both urban and rural contexts. Cross-sector LCA platforms enable data sharing among tire manufacturers, recyclers, and policymakers. Materials science research has focused on easily recoverable compounds and alternative fillers (e.g. lignin and silica) to replace carbon black. Policy modelling to simulate the environmental and economic impacts of various EPR designs, recycling credits, and trade regulations. Additionally, a critical frontier will be the integration of behavioural sciences into the circular economy model to understand how consumer use patterns, industry incentives, and regulatory cultures influence the success or failure of recycling strategies.

IV.4 FINAL REFLECTIONS

The transformation of the tire industry from a predominantly linear model to a circular one is not purely a technical challenge. It is a systems problem interlacing materials science, environmental modelling, economics, and governance. The convergence of modular and scalable technologies with smart and transparent analytics is the key to accelerating this transition. However, most crucially, it demands collaboration across silos. Manufacturers must align with regulators, researchers with recyclers, and policymakers with data scientists. Only through such integrative action can the vision of a zero-waste, resource-efficient tire industry become a tangible reality.

ABSTRACT

Wireless Sensor Networks (WSN) contain sensor nodes that transmit with each other using only wireless channels. They are deployed in unreachable regions to gather information about the circumstances. Nonetheless, sensor nodes have limited energy, which poses a significant challenge to expanding Network Lifetime (NL). Therefore, the most crucial issue is to reduce nodes' energy consumption and increase the NL. To cope with these problems, this research uses the Ford Distributing Shortest Routing Protocol (FDSRP) with Spotted Hyena Bio-inspired Optimization (SHBiO) technique for efficient data transmission in WSN. Initially, the proposed forms Cluster Members (CMs) using the Reliable Congestion Free Node Selection (RCFNS) method. Based on the CMs, the optimal Cluster Head (CH) picks using the SHBiO method. Subsequently, the proposed FDSRP protocol finds the shortest path between CH and the Base Station (BS). This proposed protocol works based on a proactive process to transmit packets. The proposed simulation experiment is conducted in a Network Simulator version 2 (NS2) environment. Analysis shows the proposed method produces significantly better throughput, packet transmission, and drop rate while consuming less energy than other methods.

I. INTRODUCTION

WSN comprises numerous small nodes with sensing, computing, and data transmission capabilities [1]. It is prevalent in various applications, such as green agriculture, medical care, military, and environmental monitoring, because they are convenient to deploy, easy to self-organize, and capable of real-time tracking [2]. It consists of several fully connected and wirelessly connected sensor nodes. Each sensor node collects incoming possibilities, grabs data, and transmits it back to the Base Station (BS) [3]. However, since most sensor nodes are battery-powered, replacing or recharging the battery is challenging.

Nonetheless, the energy of WSN nodes is still restricted, and it should be designing energy-efficient routing protocols to decrease energy consumption [4], [5]. By grouping the WSN nodes, the nodes' Energy Consumption (EC) can be virtually reduced, and the network's life cycle can be prolonged [6]. Behind the WSN nodes, usually, a cluster forms, with a CH node elected in each cluster [7]. Thus, cluster quality and CH selection significantly impact network performance and lifetime [8]. In clustering, nodes are grouped to construct clusters, as presented in Figure 1. The cluster consists of members called CMs, and each cluster selects a CH to collect and transmit the packets (data) to the BS.

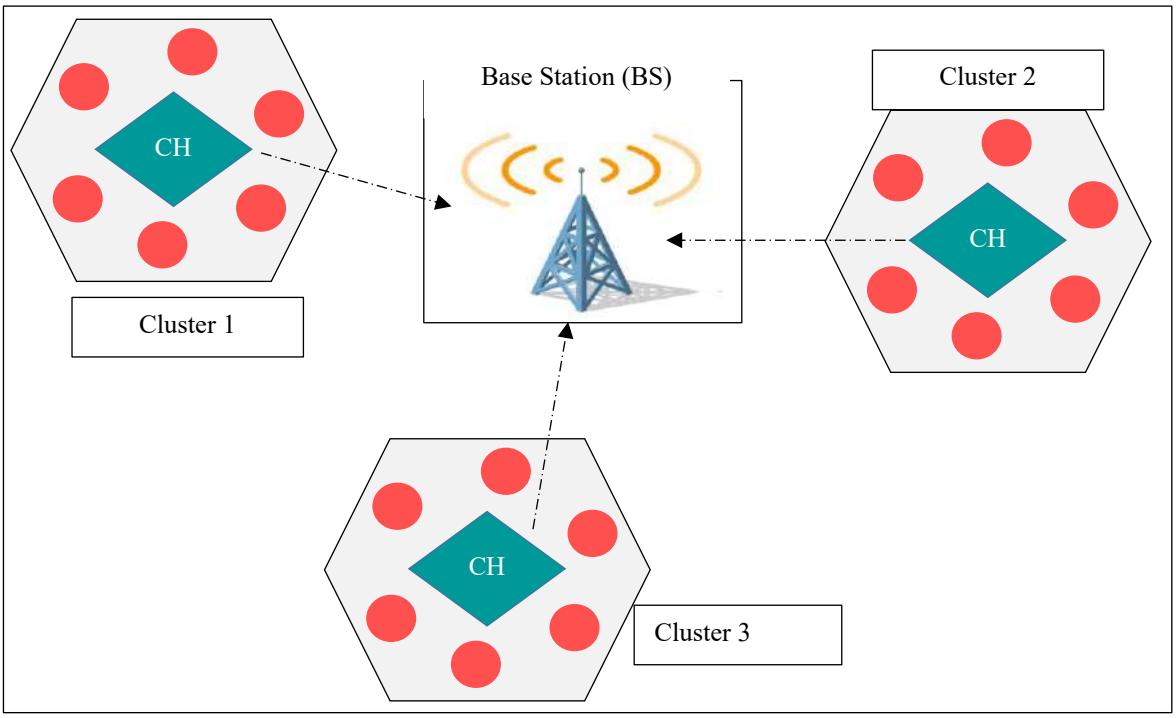

Figure 1: Structure of Cluster formation.
Source: Authors, (2026).

Therefore, different approaches were required for CH decision-making. However, if the CH is selected incorrectly, the packet transmission between the cluster members and the sink nodes will consume more energy than other sensor nodes. An outline of research issues related to WSN energy optimization follows:

- Network durability and data transfer efficiency are challenged as energy resources are limited within WSN nodes.
- Traditional methods had a high delay during data communication in the network.
- It isn't easy to design an effective leadership election technique.

This research introduces FDSRP with the SHBO methods for WSN based on the research issues. The foremost goal of this research is to use the shortest path to enhance Energy Efficiency (EE) and data communication performance in WSNs. This study's significant contribution is outlined as follows:

- We devise an RCFNS method to form a cluster of members for data communication.
- The SHBiO method quickly finds solutions in WSNs and determines the better CH from CMs.
- To design, a proposed FDSRP protocol is employed to find the shortest path between CH and BS.
- Efficacy CH preference and the creation of appropriate data communication aid increase the network's average lifetime.
- Additionally, the BS will acquire more packets because nodes utilize less energy to transmit packets.

Table 1: Nomenclature.

Notations	Description
$\mathcal{L}_N$	List of nodes
n	node
$\mathbb{M}_{Tr}$	Traffic mass
$\mathcal{P}_{size}$	Packet size
$\mathcal{T}_{\mathfrak{B}q}$	Total buffer queue
$\mathcal{M}_q$	Maximum buffer queue
$\mathcal{C}_{level}$	Congestion level
$\mathbb{T}_{Energy}$	Transmit energy
$\mathbb{R}_{Energy}$	Received energy
$\mathbb{J}$	Constant
Avg_{Energy}	Average energy
$\vec{g}$,$\vec{k}$	Coefficient vector
$\vec{\mathfrak{D}}_{\mathcal{H}}$	Hyena distance
$MinN_{count}$	Minimum node count
PR_I	Previous route information
N_{count}	Hop count

Table 1 describes the nomenclature used in this paper.

I.1 ORGANIZATION OF THIS PAPER

Section 2: Review of existing works
It examines the recent methods of packet communication in the WSN environment.

Section 3: Proposed design
Detailed proposed design methodologies, architecture diagram, and flowcharts are illustrated.

Section 4: Experiment result analysis
Simulation results setup and comparison performance analysis are described.

Section 5: Conclusion of the work
It presents the summary of the proposed work findings and the results obtained from the proposed work.

II. BACKGROUND STUDYaveley

The author [9], concentrated on EE communication in 5G WSNs with an IoT environment. This study involved the Deep Belief Network (DBN) technique for a routing protocol and the Mantaray Foraging Optimization (MRFO) algorithm to elect the CH for data communication. Thus, the methods offered increased the PDR and NL while reducing energy consumption. By 10] the study deals with the efficient WSN using the MOFAC-GA-PSO method. In turn [11] focused on the QoS improvement routing in WSN. This study used the Elite Niche Clonal Evolutionary Computing (ESQRA-ENCEC) method to minimize the latency and energy consumption in the network. However, multi-hop communication is a challenging task for data transmission.

By [12] have designed an Emperor Penguin Colony (RPC) method for EE data gathering in WSN. The suggested method analyses the intrusions and ignores the malicious nodes in the network. Yet, nodes are generally powered by batteries, which have restricted power and are challenging to replace, [13], [14] have concentrated on link quality in WSNs with IoT. The study employed the Link Quality-based Energy-Efficient Routing (LQEER) protocol to calculate the connection rate during communication. This method decreased the packet loss in the network. According to [15] novel focused on enhancing the NL in the IoT network using an Improved Energy-Efficient Clustering Protocol (IEECP).

This method contained the CH selection using the fuzzy method to reduce the node's energy consumption. However, the offered protocol suffered the CH selection because it didn't analyses adequate energy for data communication. By [16] developed Meta-inspired Hawks Fragment Optimization (MIHFO) with Energy Efficient Engroove Leach Clustering Protocol (EELCP) to resolve the previous issue. Then, they introduced a protocol to create a group for communication. Then, the Heuristic Wing Antfly Optimization (HWAFO) approach is used for path selection for data communication. However, it fails to attain efficient PDR throughput performance.

Table 2: Summary of extant approaches for WSN.

Author's name	Published year	Method used	Features	Issues
[17]	2021	BSO–MTLBO	Minimize the energy draining.	It is a complicated task.
[18]	2022	CVX-DV-hop	Resolve optimization issues.	High cost.
[19]	2024	Angle-Based Asymmetric Sorting Method	Minimize the computation overhead	Didn't provide QoS performance.
[20]	2024	MinMax-DV-hop	Address optimization problems.	Failed to achieve high PDR.
[21]	2024	RANP-PSO	To improve the localization accuracy.	Higher energy consumption.
[22]	2021	MACO-QCR	Less delay and high energy efficient.	High traffic.
[23]	2024	HDASCII-AE	Improved energy efficient.	Data transmission is an arduous task.

Source: Authors, (2026).

Table 2 illustrates the summary of extant approaches for WSN. By [24] Study has presented a shuffled ARSH-FATI method for lifetime maximization in the network. Another study [25] used a Salp Swarm Algorithm (SSA) technique for NL maximization in the network. This method enhanced the energy efficiency performance. Likewise [26] the novel employed cooperative WPT-based multihop communication for NL maximization.

III. PROPOSED DESIGN

This section illustrates the details of the proposed SHBiO-FDSRP approaches and explains how the optimal CH selection process can extend the network lifetime. The proposed workflow is presented in Figure 2. The proposed system involves vital stages: i) Node deployment, ii) Forms a cluster of members, iii) CH selection and iv) Shortest path identification.

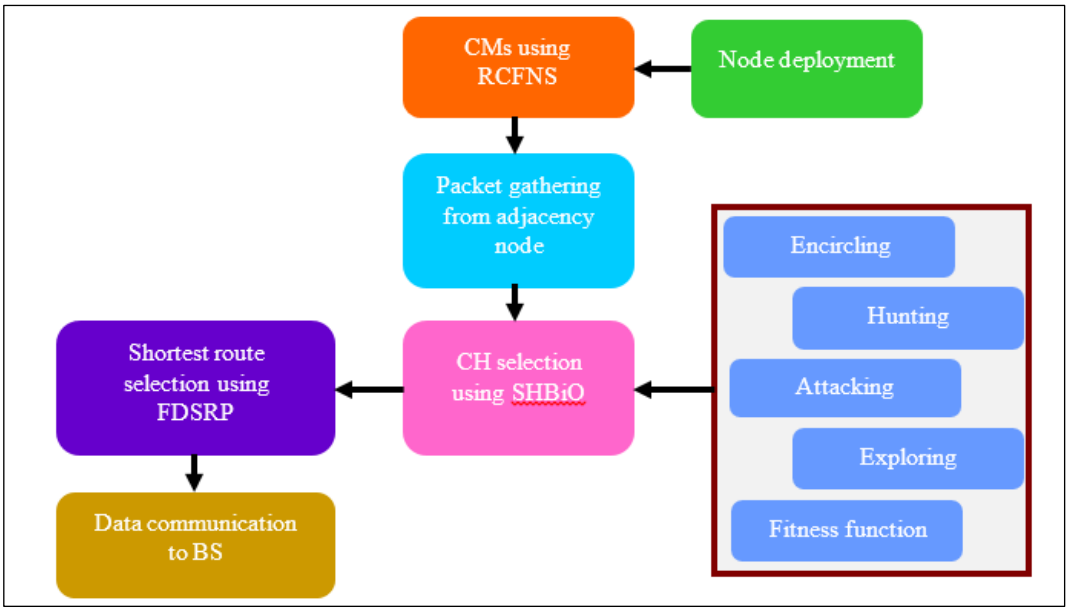

Figure 2: Proposed overview of the packet communication.
Source: Authors, (2026).

Firstly, nodes are generated randomly in the network, and then energy-efficient nodes form a group. Following that, the proposed SHBiO method is utilized for efficient CH selection for data transmission to BS. Finally, the shortest path is identified using the FDSRP protocol.

III.1 NODE DEPLOYMENT

The node deployment phase is crucial to the success of data transmission. At this stage, approximately 100 nodes are used in the network. The nodes are distributed at various positions from top to base over a 1000*1000m area. Every node has a distinct identity, energy, etc., which is maintained in the route table. Figure 3 describes the node deployment in WSN. Let assume, list of nodes$\mathcal{L}_N = \{n_1, n_2, n_3 \ldots n_N\}$, where, n lies the nodes in the network and N denotes total number of nodes.

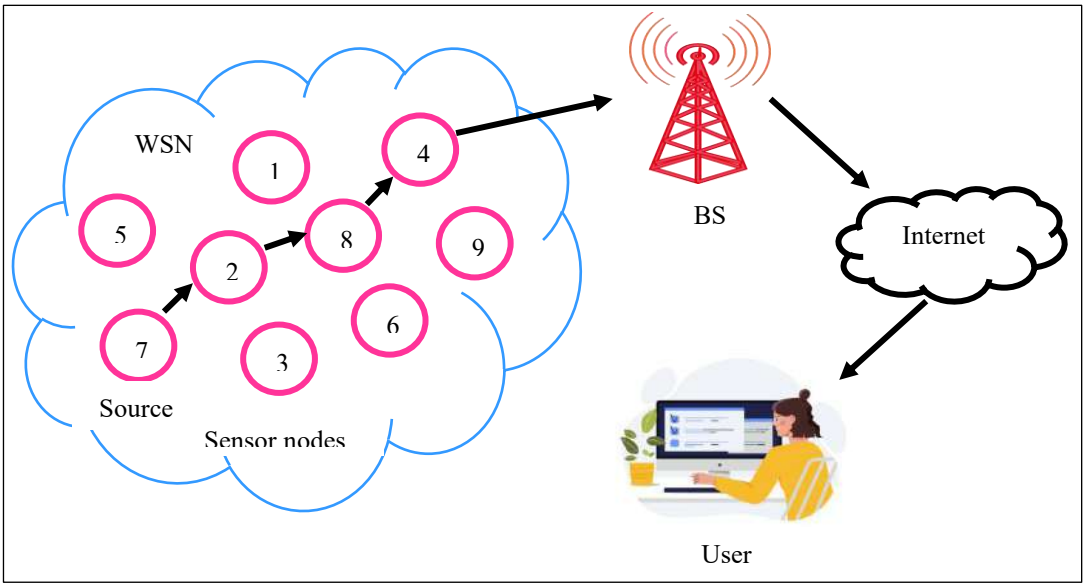

Figure 3: Architecture for distribution of node in WSN.
Source: Authors, (2026).

III.2 RELIABLE CONGESTION FREE NODE SELECTION (RCFNS)

In this phase, the Reliable Congestion Free Node Selection (RCFNS) approach is employed to form cluster members in the network. This method identifies the traffic less with reliable nodes for data gathering. When traffic volume increases, some data may not be sent or sent at the lowest transfer rate, resulting in data congestion without complete transfer. Overloading the node buffer queue can cause data deletion. To make the routing process more accessible, routes with less traffic must be chosen. All neighboring nodes adjust their queue lengths continually and send this information to the source. Traffic mass ($\mathbb{M}_{Tr}$) is estimated as the buffer queue size for all neighboring nodes, as described in equation 1.

$$\mathbb{M}_{Tr} = \frac{\sum \mathcal{P}_{size}}{\mathcal{T}_{\mathfrak{B}q}} \tag{1}$$

Here, $\mathcal{P}_{size}$ lies the packet size, and $\mathcal{T}_{\mathfrak{B}q}$ denotes the total buffer queue.

$$Tr_{\mathcal{L}} = \frac{\mathbb{M}_{Tr}}{\mathcal{M}_{\mathfrak{B}q}} \tag{2}$$

From equation 2 describes the maximum buffer based traffic congestion level$Tr_{\mathcal{L}}$. Here, $\mathcal{M}_q$ denotes the maximum buffer queue.

$$\mathcal{C}_{level} = 1 - Tr_{\mathcal{L}} \tag{3}$$

Equation 3 estimates the congestion level of each node in the network. The value of congestion level must be between 0 and 1. Greater than 1 indicates heavy traffic, which may result in high packet loss. Do not select this node as a forwarding node.

$$CM_{dis} = \sqrt{(a_1 - a_2)^2 + (b_1 - b_2)^2} \tag{4}$$

Equation 4 evaluate the two node distance based Euclidean process [27]. Accordingly, the energy needed to send or acquire a data over distance CM_{dis} can be expressed as:

$$\mathbb{T}_{Energy} = \mathbb{J} * CM_{dis} \tag{5}$$

The transmit energy $\left(\mathbb{T}_{Energy}\right)$ node consumes energy to send data over a certain distance, and the energy is boosted based on the distance from the receiver. Below equation is used to estimate the received energy $\mathbb{R}_{Energy}$can be expressed as:

$$\mathbb{R}_{Energy} = \mathbb{J} * CM_{dis} \tag{6}$$

One node consumes receiver energy $\left(\mathbb{R}_{Energy}\right)$to obtain data from other nodes. Like the transmitter, receiver energy relies on the distance among the transmitter and receiver.

$$Avg_{Energy} = \frac{\sum_{i=1}^{N-1} C_{reE}^{i}}{N} \tag{7}$$

From equation 7 calculate the average energy the node in the network. Here, C_{reE}^{i} lies the current residual energy of node. In WSNs, the proposed RCFNS method of picking the optimal nodes accomplishes proper cluster formation and expands the NL.

III.3 SPOTTED HYENA BIO-INSPIRED OPTIMIZATION (SHBIO)

The SHBiO method is used for Cluster Head (CH) selection based on hyena bio inspired process. The algorithm's central conception is to emulate spotted hyenas' social behavior. This method involves only four steps: encircling, hunting, attacking, and exploring. Figure 4 describes hyenas' searching for prey and hunting process.

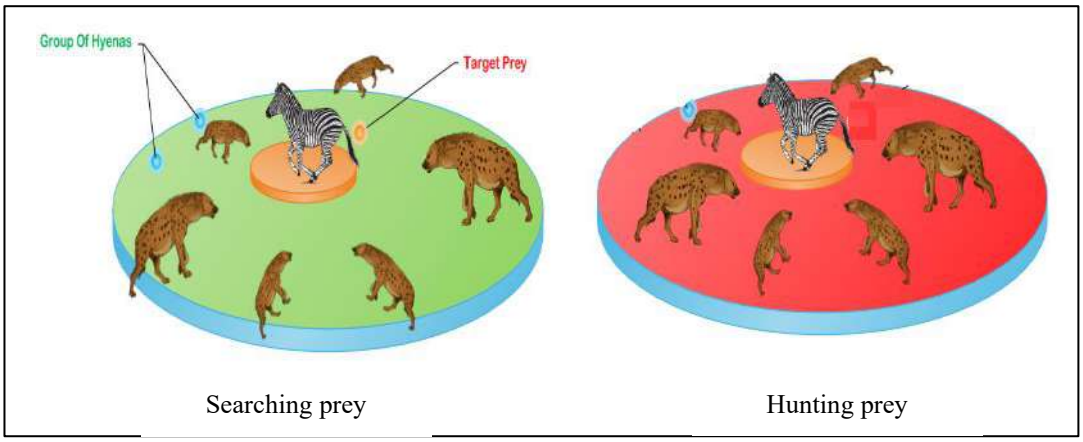

Figure 4: Graphical representation of SHBiO method.
Source: Authors, (2026).

In this method, a group of trusted friends directs hunting behavior to the optimal search agent and accumulates the optimal solution. The following expressions indicate spotted hyenas' encircling behavior.

$$\vec{\mathfrak{D}}_{\mathcal{H}} = \left|\vec{g}.\overrightarrow{\mathbb{P}_{py}}(\mathrm{t}) - \vec{\mathbb{P}}_{\mathcal{H}}\right| \tag{8}$$

$$\vec{\mathbb{P}}(\mathrm{t}+1) = \vec{\mathbb{P}}_{py}(\mathrm{t}) - \vec{k}.\vec{\mathfrak{D}}_{\mathcal{H}} \tag{9}$$

The above equation is find the prey and hyena distance$(\vec{\mathfrak{D}}_{\mathcal{H}})$. Let assume, t lies the current repetitions, and $\vec{g}$,$\vec{k}$ are the coefficient vectors. $\vec{\mathbb{P}}_{py}$ and $\vec{\mathbb{P}}_{\mathcal{H}}$ are the location vector of prey and hyena, correspondingly. || denotes the absolute values and . denotes the multiplication.
$\vec{g}$,$\vec{k}$, $\vec{\mathcal{H}}$ calculations as,

$$\vec{g} = 2 \cdot \overrightarrow{R_{v1}} \tag{10}$$

$$\vec{k} = 2\vec{\mathcal{H}} \cdot \overrightarrow{R_{v2}} - \vec{\mathcal{H}} \tag{11}$$

$$\vec{\mathcal{H}} = 5 - \left(\text{repetitions} \times \frac{5}{Maximum_{\text{repetitions}}}\right) \tag{12}$$

Herein,$\overrightarrow{R_{v1}}$, $\overrightarrow{R_{v2}}$ are the random vectors limit [0,1], repetitions =0, 1, 2, 3 ….$Maximum_{\text{repetitions}}$. The search agent updates their hyenas and prey locations. To mimic the hunting manners of spotted hyenas and identify promising space areas, the following equation is expressed:

$$\vec{\mathfrak{D}}_{\mathcal{H}} = \left|\vec{g} \cdot \overrightarrow{\mathbb{PB}}_{\mathcal{H}} - \vec{\mathbb{P}}_{\mathcal{H}}\right| \tag{13}$$

$$\vec{\mathbb{P}}_{\mathcal{H}} = \overrightarrow{\mathbb{PB}}_{\mathcal{H}} - \vec{k} \cdot \vec{\mathfrak{D}}_{\mathcal{H}} \tag{14}$$

$$\vec{\mathcal{G}}_{\mathcal{H}} = \vec{\mathbb{P}}_{\mathcal{H}} + \vec{\mathbb{P}}_{\mathcal{H}+1} + \cdots + \vec{\mathbb{P}}_{\mathcal{H}+i} \tag{15}$$

Where, $\overrightarrow{\mathbb{PB}}_{\mathcal{H}}$ lies the position of best hyenas and $\vec{\mathbb{P}}_{\mathcal{H}}$position of other hyenas. $\vec{\mathcal{G}}_{\mathcal{H}}$ Denotes cluster of hyenas. Based on the above process, the hyena strikes the prey, as denoted by the equation below.

$$\vec{\mathbb{P}}(\mathrm{t}+1) = \frac{\vec{\mathcal{G}}_{\mathcal{H}}}{i} \tag{16}$$

Algorithm steps:

Input: Hyenas$\mathcal{H}$, Avg_{Energy}
Output: Picking of Cluster Head (CH)
Start procedure
    Initialize the hyena's population $\mathcal{H}$
    Read nodes Avg_{Energy}
    Import parameters$g$, k
    $\overrightarrow{\mathbb{PB}}_{\mathcal{H}}$ is the position of best hyena
    $\vec{\mathcal{G}}_{\mathcal{H}}$ is the cluster of hyena
    $If\ (\mathrm{t} < i)$
        For each search
            Update the present location of hyena
        End for
        Update the parameters
        Estimate the fitness of each hyena
        Update the $\vec{\mathcal{G}}_{\mathcal{H}}$
        $\mathrm{t} = \mathrm{t} + 1$
    End if
    Return CH
End procedure

The above algorithm steps is used to select the CH based on hyena behavior. Therefore, this method elect CH based on fitness function and behavior of hyenas.

III.4 FORD DISTRIBUTING SHORTEST ROUTING PROTOCOL (FDSRP)

In this phase, after cluster formation, we use the FDSRP protocol to identify the path for data communication without loss with minimum latency. Nodes within the minimum hop count are appropriate for routing, considering the balance between nodes. This method identifies the neighbor node and selects the path for proficient communication in WSNs. Every node sends data to determine the different nodes within its communication range. The node keeps a separation line among successive nodes below a profundity threshold, allowing it to select the best forward node most suitable for data communication. When a node transmits the packet, it reveals a Route Request (RREQ) message to its adjacency node. Since the adjacency node may be the destination, it sends a Route Reply (RREP) message with other important information (source and destination addresses, hop count, RREQ ID sequence number, etc.). It records the value of R there in the route table.

$$\mathfrak{P}^{loss} = N_{v,u} Log_{10}(\mathrm{CH}) + p_c \tag{17}$$

From equation 17 describes the two node communication path loss$\mathfrak{P}^{loss}$. Here, v, u are the adjacency nodes and p_c denotes the positive constant values.

$$\mathcal{S}_{NR} = \frac{Sl_{power}}{Ns_{power}} \tag{18}$$

$$\mathcal{S}_{NR(db)} = 10log_{10}\mathcal{S}_{NR} \tag{19}$$

From equations 18 and 19 identify the signal to noise ratio($\mathcal{S}_{NR}$). Let us assume, Sl_{power} and Ns_{power}lies the power of signal and noise, correspondingly.

$$T_{RE} = \sum_{\mathcal{L}_{Ni}=1}^{N} \frac{\mathcal{E}_{drop}}{|R_{BS}|} \tag{20}$$

The above equation is used to identify the total residual energy-based energy drop $\mathcal{E}_{drop}$ and range of base stations in the network.

$$N_{count} = \left[\frac{\mathcal{L}_N(n_s, n_d)}{T_{RE}}\right] \tag{21}$$

The above equation finds the hop count (N_{count}) during the path discovery for data communication in the WSN.

Algorithm steps:
Input: Hop count(N_{count}), CH, $\mathcal{L}_N$ and routing information R_I
Output: Choose a route with minimum congestion $\mathbb{R}_{short}$
Start procedure
    Initialize the hop count(N_{count}), CH and$\mathcal{L}_N$
    For each $CH \in C_G$ do
        $For\ each\ nodes n_i = 1: \mathcal{L}_N$
            Node n send the RREQ
            $If(R_I < PR_I \& N_{count} < MinN_{count})$
                Node RREP
                Calculate distance CH to BS
                Select shortest route($\mathbb{R}_{short}$)with minimum congestion level.
            Else
                Ignore the node or path
            End if
        End for
    End for
End procedure

The above algorithm steps efficiently identify the routing for data communication in WSN. Here, PR_Ilies the route information, $MinN_{count}$ denotes the minimum node count, and C_G denotes cluster group. This method attains the proficient route selection minimum congestion level in the path.

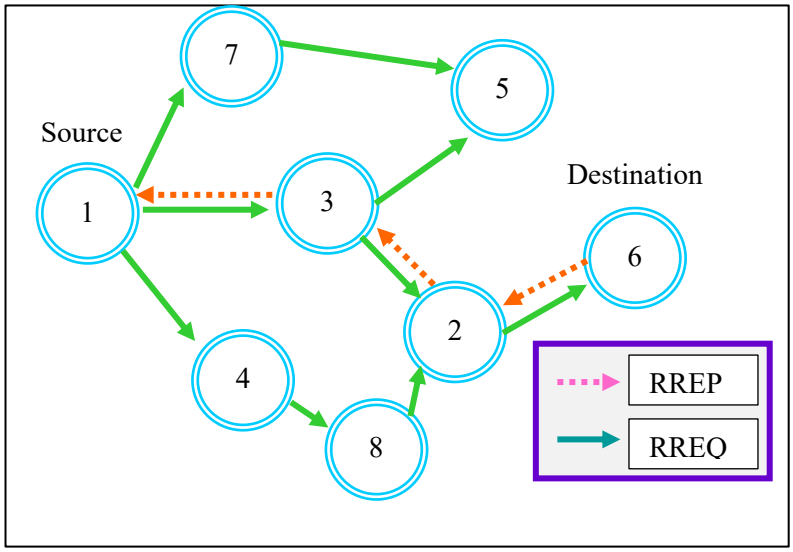

Figure 5: FDSRP protocol's shortest path identification.
Source: Authors, (2026).

Figure 5 illustrates the FDSRP protocol's shortest path identification process. Another process is data communication between the sender and receiver, as presented in the algorithm steps below.

Algorithm steps:
Input: Shortest route($\mathbb{R}_{short}$)
Output: Data transmission
Start procedure
For every $n_i = 1{:}\mathcal{L}_N$ do
If acknowledgement received ==true
Check node id, response with minimum congestion path
Estimate the total residual energy
$If\ (send\ packet == true)$ Then
Data transmission to the next node.
Else
Ignore route
End if
Else if acknowledgement received ==false
Packet drop or loss
End else if
End if
End for
End procedure

This stage constructs the following packet exchange and routing process efficiently and effectively data transmission. Figure 6 illustrates the data transmission process.

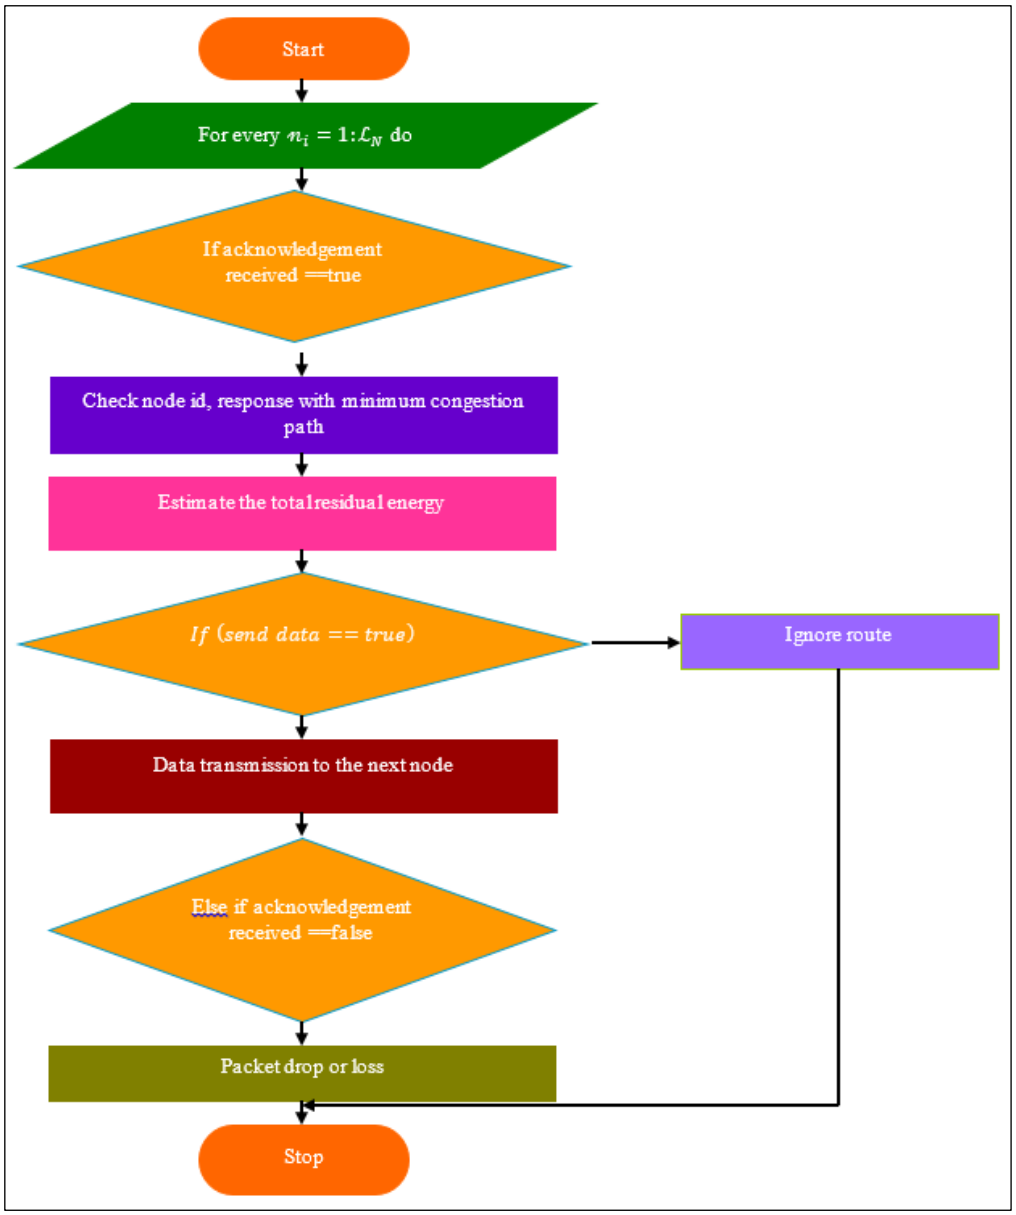

Figure 6: Flow diagram for data transmission.
Source: Authors, (2026).

IV. RESULT AND DISCUSSIONS

We strategically positioned 100 sensor nodes and monitored the environment using a Network Simulator (NS-2) to initiate the simulation process. Table 3 presents the simulation network configuration of this system. The experiment results are the proposed FDSRP-SHBiO compared with the Cooperative Sink Isolation-Multi-Hop Topology Driven Clustering Approach (CIS-MTDCA), LQEER [14], and IEECP [15] protocols.

Table 3: Network configurations and their values.

Parameters	Values
Network field	(1000, 1000) m^2
Network type	WSN
Initial energy	50J (or) 0.5J
Traffic type	Constant Bit Rate (CBR)
Number of nodes	20, 40, 60, 80 and 100
Deployment	Randomly
Packet size	512 bytes

Source: Authors, (2026).

IV.1 PERFORMANCE ANALYSIS

The proposed protocol efficiency analyzes vital performance parameters like PDR, throughput, NL, latency, and energy Consumption (EC).

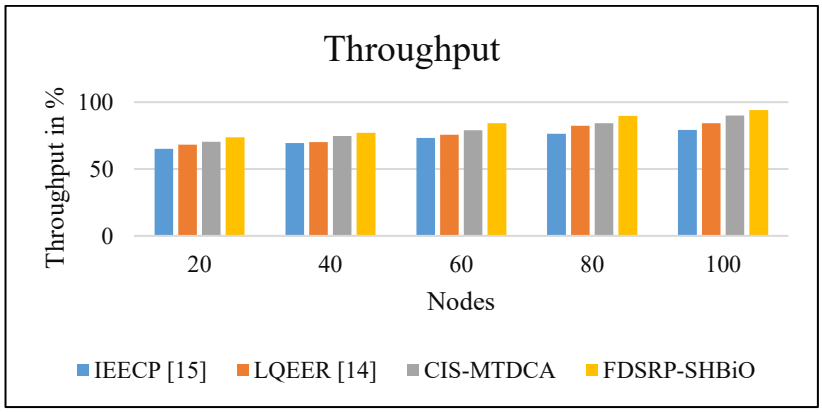

Figure 7: Performance analysis for throughput and its comparison.
Source: Authors, (2026).

Figure 7 shows the throughput results of different protocols, namely CIS-MTDCA, LQEER [14], IEECP [15], and the proposed FDSRP-SHBiO protocol. The throughput parameter is presented in percentage. The findings of the proposed attained average throughput is 94.09%. The existing methods' average throughput is 79.24%, 84.36%, and 90.11% for IEECP [15], LQEER [14], and CIS-MTDCA correspondingly.

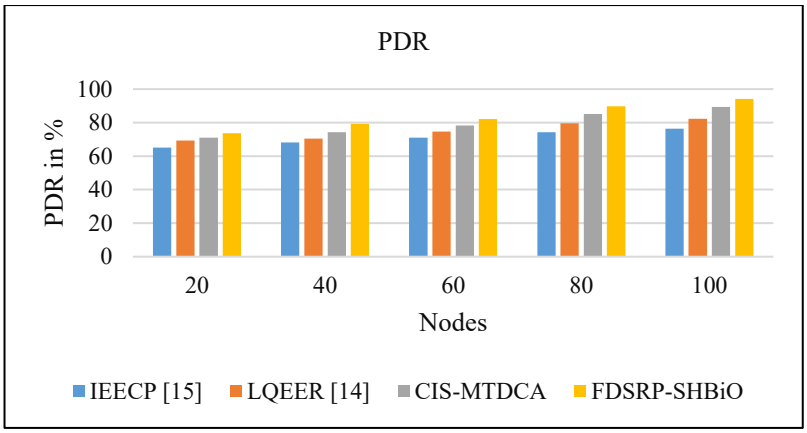

Figure 8: Performance analysis of PDR and its comparison.
Source: Authors, (2026).

Figure 8 presents the PDR results of diverse protocols, namely CIS-MTDCA, LQEER [14], IEECP [15], and the proposed FDSRP-SHBiO protocol. The PDR parameter performance is shown in percentage. The proposed protocol achieved 94.2%, while the CIS-MTDCA protocol attained 89.42%. The existing IEECP [15] and LQEER [14] protocols are 76.3%, and 82.36%, respectively.

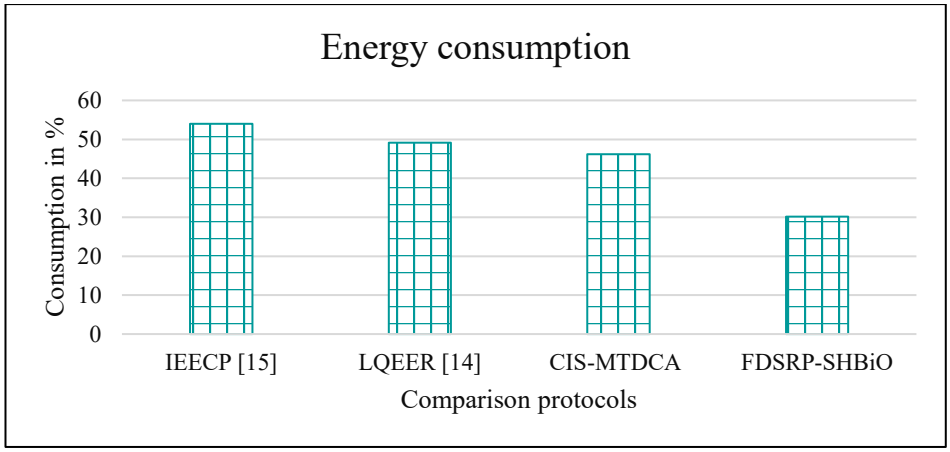

Figure 9: Performance analysis of energy consumption and its comparison.
Source: Authors, (2026).

Figure 9 illustrates the energy consumption results of diverse protocols, namely CIS-MTDCA, LQEER [14], IEECP [15], and the proposed FDSRP-SHBiO protocol. The energy consumption parameter performance is shown in percentage. The proposed protocol achieved 30.15%, while the CIS-MTDCA protocol attained 46.2%. The existing IEECP [15] and LQEER [14] protocols are 54.02%, and 49.17%, respectively.

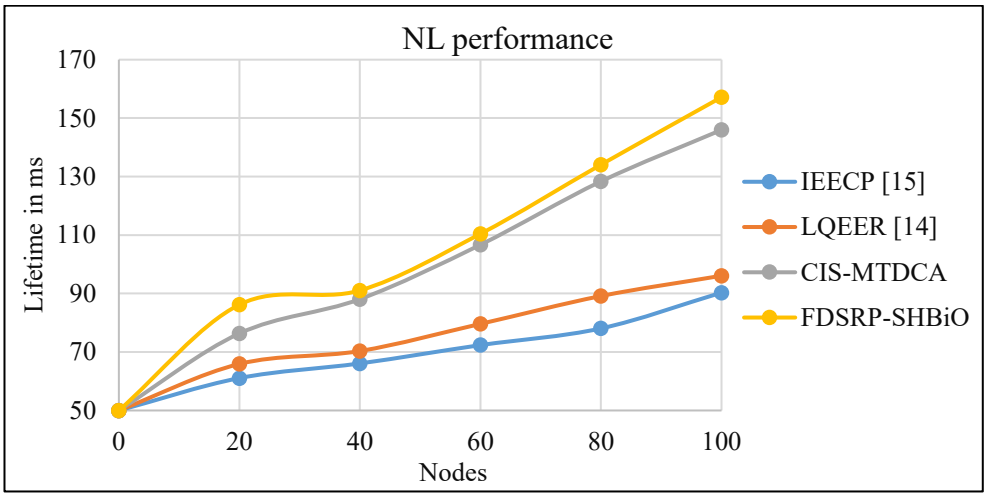

Figure 10: Performance analysis of network lifetime and its comparison.
Source: Authors, (2026).

Figure 10 illustrates the energy consumption results of diverse protocols, namely CIS-MTDCA, LQEER [14], IEECP [15], and the proposed FDSRP-SHBiO protocol. The proposed SHBiO method proficiently elected the CH has attained high network lifetime than other existing protocols. The proposed protocols attained results are 86.19ms, 91.07ms, 110.42ms, 134.08ms and 157.16ms for 20, 40, 60, 80 and 100 nodes.

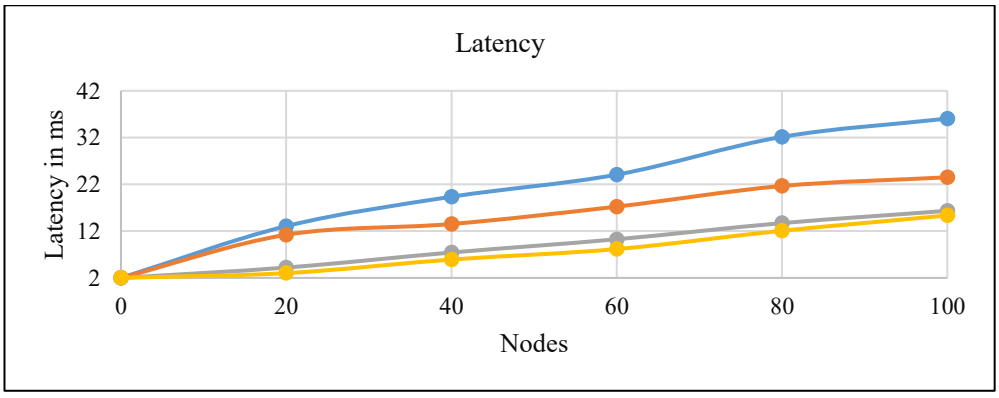

Figure 11: Performance analysis of latency and its comparison.
Source: Authors, (2026).

Figure 11 describes the time complexity of the proposed protocol compared to previous protocol outcomes. The proposed method attains latency at 3.02ms, 5.92ms, 8.16ms, 12.08ms, and 15.35ms for 20, 40, 60, 80, and 100 nodes. Yet, the existing protocols achieve a higher latency performance than other methods.

Table 4: Proposed and various previous protocols comparison performance.

Protocols	Total nodes	Throughput in %	PDR in %	NL in ms	Latency in ms
Proposed	20	73.62	73.62	86.19	3.02
	40	77.05	79.21	91.07	5.92
	60	84.31	82.05	110.42	8.16
	80	89.73	89.76	134.08	12.08
	100	94.09	94.2	157.16	15.35

Table 4 shows the overall performance of the proposed and previous protocols in terms of comparison outcomes for efficient communication in the network.

V. CONCLUSION

This novel introduced the proposed FDSRP-SHBiO protocol to improve network lifetime in WSN. The proposed RCFNS method is employed for groups of CMs without traffic and reliable nodes based on buffer length, received energy, and transmitted energy. In addition, based on efficient CMs, we selected energy-efficient CH using the SHBiO method for data communication between CH and BS. Finally, the FDSRP protocol finds the shortest path for communication in the network. An NS2 simulator is employed to test the proposed protocol using various parameters. The simulation results of the proposed compare CIS-MTDCA), LQEER, and IEECP protocols. These protocols were tested on multiple cases using nodes and CH. The level of PDR is 94.2%, throughput is 94.09%, and NL is 157.16ms for 100 nodes. The outcomes describe the proposed protocol obtains superior performance regarding PDR, throughput, and NL.

ABSTRACT

Power systems are becoming more complex because of large-scale integration of renewable energy, the widespread generation of electricity from various sources, electric vehicle charging networks, advanced power electronic converters, and significant automation through digital substations and smart grid technologies. These changes create new operational conditions with less system inertia, two-way power flows, and highly variable generation patterns. This leads to non-linear, rapidly changing, and data-heavy disturbances that are hard to detect and isolate using traditional relay-based protection methods. Conventional protection systems, which rely on preset thresholds, fixed setups, and basic network models, often have trouble with high levels of inverter-based resources, layout changes, and communication delays. In this context, artificial intelligence offers strong data-driven methods that can learn complex system behavior directly from data. It can uncover hidden traits, identify types and locations of faults, spot early and developing anomalies, and assist with smart, adaptable decision-making almost in real time. This review outlines key AI techniques, including machine learning, deep learning, fuzzy logic, and reinforcement learning. It examines how recent studies have used these methods for fault detection, diagnosis, classification, and anomaly monitoring in transmission, distribution, and microgrid environments. Additionally, this paper addresses practical issues such as data quality, limited labels, class imbalance, model generalization across different network setups, computational demands, and constraints for real-time use in digital relays and edge devices.

I. INTRODUCTION

Contemporary society relies on power systems that function safely, dependably, and consistently to sustain essential infrastructure, industry, transport, and communication services. Contemporary power systems face numerous disruptions such as equipment wear and tear, insulation breakdown, faults in lines and cables, unusual and fluctuating load conditions, switching and protective actions, sporadic renewable energy generation, failures of power-electronic converters, and more frequent cyber incidents. If faults and abnormal conditions go undetected or are recognized too late, they can lead to cascading failures, widespread blackouts, faster equipment deterioration, safety risks, and significant reliability and financial losses.

Traditional protection strategies predominantly depend on established thresholds, preset relay configurations, and simplified system hypotheses, which may fail to adequately reflect the highly dynamic, nonlinear, and data-driven characteristics of modern smart grids, marked by inverter-based resources, two-way power flows, and regular network reconfigurations. Moreover, conventional techniques frequently exhibit restricted sensitivity to emerging faults, sporadic anomalies, and slight variations in operational patterns, particularly in the presence of noisy data and communication lags.

Artificial intelligence offers robust data-driven instruments that can detect intricate patterns, learn system behavior from extensive measurement data, adjust to evolving operational conditions, and pinpoint early warning signals that may not be readily apparent via traditional analytical methods. This review outlines essential AI methods for detecting faults and anomalies in power systems, provides a summary of recent advancements in applications related to transmission, distribution, and microgrids, and addresses practical challenges in deployment like data accessibility and labeling, class imbalance, interpretability of models, constraints in real-time implementation, compatibility with existing protection systems, and resilience against measurement uncertainties and cyber-physical threats. Additionally, the document emphasizes new prospects for future advancement, such as adaptive and self-refreshing protection strategies, hybrid models that combine physics-informed and data-driven approaches, explainable and reliable AI for operator trust, and resilient frameworks that improve the reliability and security of next-generation intelligent protection systems.

II. LITERATURE REVIEW

By [1] developed a dynamic risk assessment model for cyber-physical power systems under cyber-attacks, emphasizing the integration of cyber vulnerabilities and physical consequences. The methodology involved assessing network security vulnerabilities in SCADA systems with substations, considering existing software vulnerabilities and defines mechanisms, corrected by propagation characteristics. Physical consequences were evaluated through minimum load shedding under N-I Consistency scenarios. According to [2] developed an intelligent fault diagnosis method for lithium-ion batteries in electric vehicles, focusing on timely fault state detection and degree identification. The method applied support vector machine to classify the symptom of fault, the discrete cosine method to remove the noise , and introduced the modified covariance Matrix to reduce effects of current variation of condition indicators. Grid search was used in order to optimize the SVM parameters. The test result showed that MCM-based model had good accuracy and timeliness, proved the feasibility of proposed method for future fault management strategies.

In turn [3] aimed to detect fraudulent behavior and malfunctions in smart meter data using a hybrid ML approach. The approach included using unsupervised ML on smart meter time series data to discover anomalous values. Spectral Residual-Convolutional Neural Network (SR-CNN) and a martingale-based anomaly detector were applied to data.. Based on the separated asymmetrical data, the two classes boosted decision tree and fisher linear discriminant analysis were utilized for classification. By [4] investigated to enhance the security of smart grid SCADA systems by developing a novel AI based framework to detect and prevent network intrusions. The methodology involved the preprocessing and normalization of benchmark datasets, applications of Zaira Ebola search optimization(ZESO) algorithm to achieve the feature extraction , and association of Deep Random Kernal Forest Classification (DRKFC)organized at the reliable attack detection procedure.

In turn [5] discusses both traditional and deep learning methods for anomaly detection and fault location in power grid datasets. The paper explains how deep networks (e.g., DNN,CNN,RNN) are employed to extract deep features from time-series grid data and improve detection and localization accuracy compared to conventional approaches. It also highlights challenges like data noise, spatiotemporal feature extraction, and the robustness of AI models in grid operations. According to [6] categorizes AI application in to fault data processing, modeling, and hyper parameter optimization (HPO). It demonstrate how AI technique such as GANs address class imbalance, how deep learning improves decision accuracy and how hybrid model can achieve near perfect detection accuracy . It also discusses optimization methods like evolutionary algorithms for enhancing AI performance .

By [7] provide a concise but informative overview of how artificial intelligence technique and transforming fault detection and diagnosis in power systems , with particular emphasize on distribution network where most faults occur. The authors explain the conventional protection and monitoring approaches , although reliable under well-defined operating condition, struggle when the grid becomes complex,variable,and saturated with distributed energy resources. Nature scientific report constructs an AI framework that merges cyber and physical grid data for anomaly detection using LSTM network and random forests for classification with very high accuracy. It also uses explainable AI for interpretability and adversarial training for robustness against attacks such as False data injection and DoS attacks [8].

Khan and colleagues examine AI based fault detection framework across transmission and distribution systems and compare them with classical techniques. Their study categorizes AI approaches into supervised learning, unsupervised learning and deep learning, providing examples of how each is applied in practice. Deep learning architecture such as CNNs and LSTMs are shown to capture nonlinear and time dependent fault behavior more effectively than traditional approaches. They conclude that future systems will likely integrate physics-based model with AI to improve accuracy, reliability and trustworthiness [9]. According to [10] suggested to enhance the reliability, safety, and security of smart hybrid renewable-based micro grids by developing novel control strategies for fault diagnosis and cyber -attack resilience. The methodology was based on design on fault tolerant control using optimal fuzzy gain-scheduling technique to counteract power loss faults and attack resilient control utilizing estimated sensor values fasting data integrity attacks.

III. RESEARCH CHALLENGES AND LIMITATIONS

Even with significant progress in AI- driven faults detection and cyber-physical security for modern power systems, many critical research challenges and practical limitations remain. These issues must be addressed before widespread implementation can take place. A major problem is that many cyber-physical risk evaluation and security analysis framework still rely on overly simplify threat assumptions, specific attack paths, and limited attacker capabilities. These modelling methods cannot fully capture the complex interactions between the dynamics of physical power networks and cyber communication systems. As a results, they struggle to represent coordinated, multi-phase, and adaptive cyber-physical attacks in real operational environments. Furthermore, most of the case studies are conducted on small or medium test setups, and validation with actual utility-scale infrastructure is rare, which greatly undermines trust in their relevance to larger interconnected networks [1], [20].

A significant limitation is the heavy dependence of data-driven fault diagnosis and intrusion detection methods on large, high-quality labelled datasets. Machine learning models, such as support vector machines, convolutional neural networks, and hybrid CNN-RNN architecture, require well-representative training data to perform consistently however, actual power system datasets are often very imbalanced, with normal operating conditions dominating and fault or attack incidents occurring infrequently, and inconsistent labelling across substations and utilities. These challenges severely hinder the models' learning abilities and can lead to biased decision boundaries and poor detection performance in new situations [2], [5], [6], [23].

While data augmentation techniques and generative models like GANs have aim to address data scarcity and imbalance, these methods add further complexity to both model design and training. The quality of samples generated synthetically relies heavily on careful architecture selection and hyper parameter tuning. . Poor tuning can lead to unrealistic fault patterns that harm classifier performance on real data. Additionally, methods for feature selection and model tuning that depend on optimization increase computational demands. This complicates their use in real-time protection and monitoring systems that have strict latency requirements [5], [16].This problem become even more significant for wide-area monitoring and protection applications that rely on high-resolution synchro phasor data and fast decision-making.

The interpretability and transparency of AI models are still major challenges for safety-critical power systems. Deep learning models often function as black boxes, providing little insight in to the reasons behind specific alarms, classification results, or control decisions. For protection engineers and system operators it is crucial to understand why a relay acted or why an anomaly triggered an alert. This knowledge is vital for maintaining system safety and avoiding unnecessary tripping or cascading failures. This lack of transparency make it essential to accept deep learning-based protection systems, especially in important areas like transmission line protection, generator safeguarding, and cyber-attack prevention methods [8], [12], [21].

New decentralized learning and security systems, such as federated learning and blockchain architectures, provide promising solutions for protecting privacy, enabling collaborative learning, and resisting data manipulation. However, implementing them in large energy systems comes with many ongoing challenges. Regular model updates and distributed consensus processes canlead to significant communication overhead. This result in high network traffic and great risk of communication failures. Additionally, latency and synchronization issues between control centers and substations in different areas can lower real-time performance. Scalability is a major concern because of the increasing number of participating nodes and data sources in today's smart grid environments. Making sure that distributed learning agents while meeting real-time operational constraints continues to be a tough research problem [13], [14], [19], [22].

From a methodological perspective, traditional statistical methods and control chart techniques struggle to adapt in rapidly changing operational conditions. These methods usually assume stable processes and clear statistical features. However this rarely happens in today's power systems, which are marked by variable renewable generation, flexible loads, and frequent topology changes. Their effectiveness dropped significantly during short production runs and rapidly changing conditions, where there is not enough historical data to accurately estimate statistical parameters accurately [11]. On the other hand, advanced AI-driven models, can adapt more easily but often overfit when trained on limited or specific data. Overfitted models may perform very well in controlled environments but have trouble when faced with unexpected disturbances, new protection parameters, or unfamiliar network setups [3], [25].

High-impedance fault detection is a long-standing challenge. These faults produce weak and very inconsistent signatures, which load fluctuations, switching transients, and background noise can easily hide. Monitoring wind turbines and renewable energy converters is also tough due to non-stationary operational characteristics, mechanical-electrical interactions, and environmental factors like temperature and wind speed. Classifying power quality events is getting more complicated as distributed energy resources, power electronic converters, and electric vehicle charging systems introduce new disturbance patterns and harmonic interactions. Current feature extraction and learning models often had a hard time staying reliable amid rapidly changing grid dynamics and significant renewable integration [17], [18], [24].

A major limitation is that most current studies primarily focus on detection and classification accuracy as the main performance metric. However, effective power system operation requires not only accurate detection but also synchronized and quick response plans. There is limited research on how outputs from AI-based detection can interact with adaptive protection settings, corrective action strategies, or wide-area control systems. The lack of closed-loop systems that manage detection, decision-making, and control at the same time limit the real-world effectiveness of many proposed approaches. Additionally, the connection between AI-based decision support systems and traditional protection devices, such as distance relays, differential relays, and overcurrent relays, is rarely explored in depth [4], [7], [9], [10].

Integrating AI models into current grid systems present significant implementation challenges. Older protection and supervisory control systems were not build to handle data-heavy learning algorithms or frequent model updates. Limited computing resources at substations, strict certification requirements for protection systems, and careful operational practices make adoption difficult. Additionally compatibility issues among various vendors, data formats, and communication protocols make large-scale implementation difficult. Without standard interfaces and validation methods, ensuring consistent performance across different platforms. Cyber-physical co-simulation environments and digital twins have been proposed to improve the testing and validation of advanced security and protection systems.

However, creating high-fidelity models that accurately represent both cyber infrastructures and the dynamics of physical power systems remains a complex task. Streamlining communication models, security logic, and human operator actions can lead to overly optimistic assessments of system robustness. Furthermore, maintaining and updating digital twins is necessary to reflect changing network configurations and operational methods, which increases development costs and complexity [1], [20]. Ultimately, future smart grids need hybrid and scalable systems that combine the benefits of physics-driven models, statistical approaches, and advanced machine learning techniques. Data-driven solutions rely heavily on data quality, concept drift, and vulnerabilities to adversarial manipulation, while model-based approaches struggle to capture the complex nonlinear dynamics and cyber interactions.

Therefore, there is an urgent need for resilient, understandable, and flexible hybrid architectures that incorporate system knowledge, security concepts, and network constraints into learning frameworks. These integrated solutions should enable adaptive protection, coordinated cyber-physical responses, and seamless integration with existing operational infrastructures to ensure the secure and reliable functioning of future power systems [4], [7], [9], [10].For Reference, Comparison Summary of AI based Anomaly detection techniques in Power systems is provided in Table 1 below.

IV. CONCLUSION

The reviewed literature shows that artificial intelligence is a strong tool for fault detection, anomaly monitoring and cyber resilience in modern power systems. This includes diagnosing problems at the component level, such as lithium-ion battery failures in electric vehicles and issues with converters and sensors. It also covers risk assessments, intrusion detection, and situational awareness in SCADA and energy management systems. Unlike traditional rule-based and signal-processing protection methods, AI techniques perform better in handling non-linear dynamics, complex data, and rapidly changing operational conditions. Deep learning models like convolutional neural networks (CNNs), recurrent neural networks (RNNs), and long short-term memory (LSTM) networks helps extract complex spatial and temporal relationships from synchro phasors, smart meter, and substation data. Standard analysis struggles to capture, especially during periods of high renewable energy integration and low system inertia. Furthermore hybrid learning models that combine unsupervised anomaly detection with supervised fault classification significantly improve detection accuracy and sensitivity to early faults.

They also provide better resilience against noise, missing data, and class imbalance. AI-powered optimization techniques, transfer learning, GAN-based data augmentation, and improved feature learning enhance model performance across different networks designs and scenarios. The growing connection between cyber security and the reliability of power systems is clear in the literature. Cyber-attacks, like false data injection, replay attacks, and coordinated intrusion strategies, can leads to serious physical consequences. These includes improper relay operations and decreased stability overall stability. Research shows that AI-driven systems improve detection speed, accuracy, and flexibility. They also support predictive and preventive measures, help operator's decisions and encourage strong, intelligence, and self-correcting power system operations. Also, emerging trends shows the need for explainable AI, physics-based learning, and edge-based deployment. These elements are vital for reliable, scalable, and real-time implementation of AI-powered protection and monitoring systems in future smart grids.

VI. ACKNOWLEDGMENTS

The authors sincerely thank Government College of Technology (GCT) for allowing access to advanced research facilities through the Research Centre of Excellence – Alternate Energy Research Laboratory. The Centre's laboratory facilities, technical support, and research environment greatly helped with the literature review, analysis, and critical assessment of recent advancements in AI-driven fault and anomaly detection in power systems. The authors appreciate the valuable academic discussions and help from the faculty members and researchers at GCT, which improved the technical quality, clarity, and organization of this review paper. The support and resources from the Research Centre of Excellence – Alternate Energy Research Laboratory were crucial for the successful completion of this review study.

VII. FUTURE SCOPE

Although, AI based methods shows promise, several important research areas till need attention before we can use them widely in real power system protection and monitoring, First, there is a strong need for real-time, scalable, and deployable AI systems that can operate reliably under rapidly changing load patterns, high uncertainity in renewable generation, increasing integration of inverter-based resources, and evolving cyber threats. Most current studies rely on offline simulations, lab tests, or publicity available benchmark datasets , which do not fully capture the practical challenges . Therfore, future research should focus on extensive field trails and utility grade implementations that consider realistic communication delays, data synchronization errors, packet losses, missing and corrupted measurements, varying sensor quality, and limitations of intelligent electronic devices(IEDs) digital relays, and edge-computing platforms.In addition, we need model compression, lightweight designs, and hardware-aware AI to ensure that advanced learning models can meet the strict latency and relaiablity need of protection applications.

Second, we should develop hybrid protection and monitoring frameworks that merge data-driven AI models with physics-based system models, power system dynamics, and traditional protection logic. This improvement will enhance model clarity , operational stability and operator confidence. Purely data-driven solution often lack physical consistency and may make decisions under new operating conditions, changes in topology, or rare Extreme events. Techniques like physics-informed learning, digital twin-assisted training, and co-simulation of protection and control systems can improve generalization and reduce on large labelled datasets. Additionally, explainable AI (XAI) techniques are difficult for understanding the internal process of complex models. This understanding helps protection engineers and system operators know why a specific fault classification, islanding decision, load – shedding command, or cyber-attack isolation action was taken. Such clarity is vital for compliance with regulations acceptance by operators, post-event analysis and safe collaboration between humans and machines in future control centers.

Third ,AI based monitoring and protection systems encounter challenges from sensor issues, measurement noise, model drift, and international data tampering. Adversarial attacks, data poisoning , replay attacks, and false data injection can mislead learning models, which might lead to incorrect relay operations, delayed fault isolation, or control actions. Future research should focus on secure learning methods, anomaly-aware training, adversarial and trust-aware decision- making across diverse data sources. Integrating cyber security analytics in to protection and monitoring processes will be vital for detecting coordinated cyber-physical attacks. This ensure that protection decisions stay reliable, even if communication and sensing systems are compromised.

Fourth, the absence of standardized, large-scale, and openly accessible datasets still makes it hard to benchmark and replicate research fairly. Most current datasets comes from specific test systems, simulation tools, and attack scenerios which complicate how Algorithms are compared. Creating standardized open datasets that encompass various operating conditions, fault types, levels of renewable integration, cyber-attack scenarios, and communication behaviors- while maintaining data privacy and utility confidentiality- will speed up methodological progress and objective evaluation of AI algorithms. Furthermore, we need to establish commom evaluation metrics, testing protocols, and validation frameworks to support clear and consistent performance assessments across different research efforts.

Fifth, future research should focus on continuous learning, online adaptation, and transfer learning techniques to handle changing system setups, seasonal load variations, equipment aging, and fluctuating market and operational conditions. AI models in real electric grids must be able to update themselves without needing frequent offline retraining or complete redeployment. Federated and distributed learning approaches can help multiple utilities to work together on modern development while keeping data private and reducing communication needs. These methods are especially attracted for large interconnected power systems and widely distributed microgrids.

Finally, future power systems will gain a lot from fully integrated cyber-physical monitoring and protection systems . These system will bring together fault and anomaly detection, cybersecurity analytics, predictive maintenance, stability assessment, and fault-tolerant control within one operational framework. A close integration of AI-driven situational awareness with wide-area measurement systems, digital substations, and energy management systems will help support proactive and coordinated decision-making across generation, transmission, and distribution levels. These systems can give early warnings of cascading failures, smart self-healing actions, coordinated protection setting, and resilient recovery strategies after major disturbances or cyber incidents. In the end, these improvement will create next generation smart grids and microgrids that are not only intelligent, but also secure, flexible, understanding , and highly reliable. This will ensure a sustainable and trustworthy operation of future power infrastructure

Pelican Optimization Algorithm (POA).

ABSTRACT

The rapid adoption of electric vehicles poses considerable challenges for the operation of radial distribution networks, due to the increased burden and voltage issues at electric vehicle charging stations (EVCS). This paper introduces the Pelican optimization algorithm (POA) for the optimization of distributed generators (DG) to alleviate the negative effects of EVCS loading on the distribution system. Five cases of DG are examined: Type-I (unity power factor), Type-II (reactive power only), Type-IIIA (power factor of 0.85), Type-IIIB (power factor of 0.9), and Type-IIIC (optimized power factor). The proposed methodology is validated by implementing it on two test systems, and the obtained POA results are compared with Particle Swarm Optimization (PSO) results. Type-IIIC DG provides the best overall performance, achieving an impressive 90.39% loss reduction for the IEEE-33-bus system and a remarkable 98.02% reduction for the 69-bus system, and also ensures excellent voltage stability. Type-II DG shows poor performance and is considered unsuitable for practical applications. POA has shown strong effectiveness in achieving the desired objectives, especially with multi-DG configurations

I. INTRODUCTION

The current electric power distribution system is grappling with significant challenges due to rising energy demands, environmental issues, and the need for improved system reliability. Traditional centralized power generation paradigms are gradually expanded by distributed generation (DG) technologies, which offer promising solutions to these complex challenges. Sustainable, economical, and dependable Distributed generation, characterized by small-scale power generation sources located near consumption points, has emerged as a pivotal component in modern power system architecture. These systems reduce power losses in addition to enhancing voltage profiles and improving overall system stability.

Electrification of the transportation sector is increasing worldwide. This transition, while environmentally beneficial, introduces an additional load on existing distribution networks. Electric vehicle charging stations (EVCS) represent a new category of load that is both substantial in magnitude and variable in nature. The higher penetration of EVs into the grid results in increased loads, higher energy losses, and worse voltage profiles. The authors in [1] discuss the impact of EVs on distribution systems, including the volatility of loads, peak demand, and strategies that transform challenges into grid support through real-time management.

The researchers in [2] review optimization techniques applied to EV planning in distribution networks, considering diverse objective functions and load models, including conventional, heuristic, and metaheuristic methods. Integrating distributed generators (DG) is emerging as one of the most effective strategies to address surging global electricity demand. Studies on optimal placement and sizing of DG have consistently shown its effectiveness in significantly enhancing voltage stability, reducing losses, and improving reliability of distribution systems. Reference [3] provides an extensive analysis of optimization frameworks for distribution systems integrating EV charging stations, in conjunction with renewable energy sources, energy storage systems, and distributed generation.

The simultaneous optimization of multiple DG units and EVCS locations transforms this into a complex, multi-objective optimization problem with numerous decision variables and constraints.The majority of the research demonstrates the effectiveness of metaheuristic optimization techniques[4] such as Particle Swarm Optimization (PSO), Genetic Algorithm (GA), Differential Evolution (DE), Ant Colony Optimization (ACO), and various hybrid approaches in addressing the highly non-linear and constrained nature of EV charging station planning problems.

Nevertheless, ongoing research continues to focus on the development of advanced optimization algorithms capable of more efficiently solving the integrated planning challenges associated with EV charging stations and distributed generation. In this context, the present study adopts a novel metaheuristic algorithm, namely the Pelican Optimization Algorithm (POA), to simultaneously optimize the placement and sizing of EV charging stations and distributed generators. Furthermore, different types of distributed generators [5]are considered to effectively mitigate the technical impacts of EV charging integration on distribution network performance.

This paper aims to optimize various types of multiple DGS with EVCS, considering two test systems: IEEE-33 and IEEE-69. A multi-objective function that minimizes active power losses, minimizes the average voltage deviation index (AVDI), and enhances the voltage stability index (VSI) is considered. Minimization of power losses directly impacts operational costs and system efficiency, making their reduction a primary economic objective. The AVDI ensures that voltage levels remain within acceptable bounds throughout the distribution system [6]. The VSI provides crucial information regarding the system's margin to voltage instability, thereby serving as a reliable indicator.

II. PROBLEM FORMULATION

II.1 OBJECTIVE FUNCTION AND ITS CONSTRAINTS

The objective function of the paper is to minimize power loss, AVDI, and enhance VSI.

II.1.1 Active Power Loss:

EVCSs impose substantial load demands, thereby increasing active power loss when they are placed at optimal nodes within the distribution network. Hence, the aim is to minimize the active power loss and is given as:

$$f_1(k) = \min \sum_{k=1}^{N_{br}} R_j * I_j^2 \quad (1)$$

Where R_j is the jth branch resistance, I_j is the current flowing in the jth branch, j is the branch number, and N_{br} is the total number of branches.

II.1.2 Average Voltage Deviation Index:

A node's voltage deviation index is the difference between the node's actual voltage and the reference voltage (1 p.u.) in a network. The AVDI represents the average VDI across all nodes in the network. A lower value signifies greater voltage stability, and it is given as

$$f_2(k) = \frac{1}{b} \sum_{k=1}^{b} |1 - V_k|^2 \quad (2)$$

Where b is the total number of buses, k is the bus number, and V_k is the voltage at the k^{th} bus,

II.1.3 Voltage Stability Index:

The maximum Voltage Stability Index (VSI) of the distribution system indicates that the bus can maintain its voltage profile within acceptable limits, even under varying loading conditions. It is important to keep the VSI of all buses in the distribution system close to unity to ensure the safe operation of the system, and is given as

$$VSI_{k+1} = |V_k|^4 - 4 * [P_{k+1}X_{j-} Q_{k+1} R_j]^2 - 4 * [P_{k+1}R_{j-} Q_{k+1} X_j] |V_k|^2 \quad (3)$$

Where, VSI_{k+1} represents the VSI of (k+1) th bus,P_{k+1} , Q_{k+1}, denotes the active and reactive powers at the (k+1)th bus, $R_j$and X_j represents the resistance and reactance of the j^{th} branch connecting the k^{th} and $(k + 1)^{th}$ bus. During operation, the voltage level of the entire network must be increased by maximizing the VSI of the bus with the lowest value. In this study, three different objective functions are developed to (i) reduce the real power loss, (ii) minimize the Average Voltage Deviation Index (AVDI), and (iii) enhance the Voltage Stability Index (VSI). This multi-objective optimization problem is formulated using a weighted-sum approach and is expressed as:

$$F(k) = \min [w_1(f_1(k) + w_2(f_2(k) + w_3 \frac{1}{f3(k)} \quad (4)$$

where w1 accounts for 50% of the impact on power losses, w2 represents 20% of the effect on AVDI, and w3 reflects 30% of the influence on VSI.

II.2 OPERATIONAL CONSTRAINTS

II.2.1 Equality Constraints

The active and reactive power supplied by the substation must balance the total active and reactive power demand of the system, including the additional load imposed by EV charging stations.

$$P^{substation} + \sum_{k=1}^{N_{bus}} P_{DG}(K) = \sum_{j=1}^{N_{br}} P_{loss}^{j}(k, k+1) + \sum_{k=1}^{N_{bus}} P_{D,k} + P_{EVCS}^{k} \quad (5)$$

$$Q^{substation} + \sum_{k=1}^{N_{bus}} Q_{DG}(K) = \sum_{j=1}^{N_{br}} Q_{loss}^{j}(k, k+1) + \sum_{k=1}^{N_{bus}} Q_{D,k} + Q_{EVCS}^{k} \quad (6)$$

Where N_{br} represents the number of branches, N_{bus} denotes the number of branches, $P^{substation}$, and $Q^{substation}$ are the real and reactive powers of the electric substation, respectively. $P_{DG}(K)$ and $Q_{DG}(K)$, are the k^{th} bus total real and reactive powers injected by DGs, P_{loss}^{j} and Q_{loss}^{j} represents the real and reactive power loss in the j^{th} branch, $P_{D,k}$ and $Q_{D,k}$ are the active and reactive power demand at the k^{th} bus, P_{EVCS}^{k} is the charging station load at $k^{th,}$

II.2.2Inequality Constraints

Voltage magnitude of each bus should lie between 0.95 and 1.05 p.u.

$$V_{min} \leq V_k \leq V_{max} \quad K=1,2,3, \ldots\ldots N_{bus} \quad (7)$$

The limit of line current is as given below

$$I_j \leq I_j^{max} \quad j=1,2,3\ldots\ldots\ldots N_{br} \quad (8)$$

The injected DG power should lie within certain limits

$$DG_{min} \leq DG_{Sizing} \leq DG_{max} \quad (9)$$

II.3 LOAD FLOW ANALYSIS

By [7] proposed a direct approach for load flow solutions, which yields better results, as conventional load flow studies, such as Gauss-Seidel, Newton-Raphson, and Fast Decoupled load flow methods, are not suitable due to the high R/X ratio of distribution networks. This load flow uses two matrices: bus injection to branch current matrix (BIBC) and bus current to bus voltage matrix (BCBV) matrices to calculate the power loss as explained below. The complex load Si in the distribution network is expressed as,

$$S_{i=} Pi+jQ_i \quad \text{for } i=1, 2\ldots\ldots\ldots, N \quad (10)$$

Where P_i, Qi are the real and the reactive powers at the ith bus, N is the total number of buses and the corresponding current injection is given as,

$$I_i = \left(\frac{Si}{V_i}\right)^* \quad (11)$$

Where I_i, V_i are the currents, and voltages at i^{th} bus, respectively the two formulated matrices, BIBC and BCBV, are interconnected as

$$[\Delta V] = [BIBC]\,[BCBV]\,[I] \quad (12)$$

$$[\Delta V] = [DLF]\,[I] \quad (13)$$

Where DLF is the direct load flow matrix. The iterative procedure is done as below

$$I_i^k = \left(\frac{Si}{v_i^k}\right)^* \quad (14)$$

$$[\Delta V^{k+1}] = [DLF]\,[I^k] \quad (15)$$

$$v^{k+1} = [v_o][\Delta V^{k+1}] \quad (16)$$

The power flow is computed as follows

$$P_{i+1} = P_{i-} P_{Li+1} - R_{Li+1} * \left(\frac{P_i^2 + Q_i^2}{|V_i^2|}\right) \quad (17)$$

$$Q_{i+1} = Q_{i-} Q_{Li+1} - X_{Li+1} * \left(\frac{P_i^2 + Q_i^2}{|V_i^2|}\right) \quad (18)$$

Where P_i and Q_i are the real and reactive powers flowing out of bus i, and P_{Li} and Q_{Li} are the real and reactive load powers at bus i. The resistance and reactance of the line section between buses i and i +1 are denoted by $R_{i,i+1}$, and $X_{i,i+1}$, respectively. The power loss of the line section connecting buses i and i +1 may be computed as:

$$P_{Loss}(i, i+1) = R_{Li+1} * \left(\frac{P_i^2 + Q_i^2}{|V_i^2|}\right) \quad (19)$$

$$Q_{Loss}(i, i+1) = X_{Li+1} * \left(\frac{P_i^2 + Q_i^2}{|V_i^2|}\right) \quad (20)$$

The total loss is calculated as

$$P_{T,Loss} = [BIBC] * P_{Loss}(i, i+1) \quad (21)$$

$$Q_{T,Loss} = [BIBC] * Q_{Loss}(i, i+1) \quad (22)$$

$$P_{Loss} = \sqrt{P_{T,Loss}^2 + Q_{T,Loss}^2} \quad (23)$$

III. OPTIMIZATION ALGORITHMS

III.1 PARTICLE SWARM OPTIMIZATION ALGORITHM (PSO)

Particle Swarm Optimization is a population-based stochastic optimization algorithm that addresses various search and optimization challenges by mimicking the collective intelligence observed in natural swarms such as bird flocks and fish schools. It workson a swarm of N particles in a search space with D dimensions. Each particle is a possible answer to an optimisation problem. Each particle progressively adjusts its position by incorporating its previous velocity vector, its individual optimal position (pbest), and the collective optimal position (gbest) disseminated throughout the swarm [8]. Two fundamental equations govern particle dynamics in PSO. For particle *i,* the velocity and position updates are formulated as:

Velocity Update Equation:

$$V_i^{k+1} = \omega^k \times V_i^{k+1} + C_1 \times rand_1 \times (P_{best,i}^k - X_i^k) + + C_2 \times rand_2 \times (G_{best,i}^k - X_i^k) \quad (24)$$

The inertia weight used is calculated using the equation

$$\omega^k = \omega_{max} - \left(\frac{\omega max - \omega min}{kmax}\right) \times k \quad (25)$$

Position Update Equation:

$$X_i^{k+1} = X_i^k + V_i^{k+1} \text{ for i=1, 2,,,,……,n} \quad (26)$$

Where n represents the number of particles in the search space

Algorithm for PSO:

1. Initialize data, EVCS, and DG numbers.
2. Set the number of iterations and other parameters of PSO along with EVCSs and DG lower and upper bound limits.
3. Initialize the velocities and positions of the particle's population in the swarms.
4. Set the iteration to one.
5. Perform the load flow analysis and evaluate the best particle's index, velocities, position, and power losses.
6. Determine the Global optimum and Local optimum
7. According to Equations (24) and (26), update the velocities and locations. The optimal value is assessed, and the optimal particle index for EVCS and DG is identified
8. Update the Gbest and Pbest of swarms.
9. Repeat steps 6–12, incrementing by 1, until the maximum number of iterations is attained.
10. Print the best solution and end.

III.2 PELICAN OPTIMIZATION ALGORITHM (POA)

The POA is based on the hunting methods of pelicans, which [9]. When pelicans are hunting, they work in groups in search of their prey and then dive strategically, extending their wings to direct the prey towards the water's surface and shallow areas, which makes it easier to catch. It initializes a population of pelicans that change their positions according to the optimal solutions to simulate prey pursuit. The algorithm guarantees global optimization through dynamic exploration of new regions. This leads to stable and efficient solutions for difficult problems. The initialization of the population is done by

$$X_{i,j} = l_j + \text{rand}.(u_j - l_j) \text{ , i=1, 2,……, N, j=1,2….m} \quad (27)$$

Where X_(i,j) denotes the value of the jth variable as defined by the ith candidate solution, lj signifies the jth lower bound, and uj denotes the jth upper limit of the problem variable, rand is a random number in the interval [0, 1], N represents the number of population members, and m indicates the number of problem variables in this POA, the population of pelican agents is represented by a population matrix. Each row corresponds to a candidate solution vector, while each column denotes the recommended values for the decision variables

$$X=\begin{bmatrix} X_1 \\ \vdots \\ X_i \\ \vdots \\ X_N \end{bmatrix}_{N\times m} = \begin{bmatrix} x_{1,1} & \dots & x_{1,j} & \cdots & x_{1,m} \\ \vdots & \vdots & \vdots & \vdots & \vdots \\ x_{i,1} & \dots & x_{i,j} & \dots & x_{i,m} \\ \vdots & \vdots & \vdots & \vdots & \vdots \\ x_{N,1} & \dots & x_{N,j} & \dots & x_{N,m} \end{bmatrix}_{N\times m} \quad (28)$$

Where X is the population matrix, and Xi represents the ith individual pelican. The above initial populations are used to determine the objective functions in the vector form, as shown below

$$F = \begin{bmatrix} F_1 \\ \vdots \\ F_i \\ \vdots \\ F_N \end{bmatrix}_{N\times 1} = \begin{bmatrix} F(X_1) \\ \vdots \\ F(X_i) \\ \vdots \\ F(X_N) \end{bmatrix}_{N\times 1} \quad (29)$$

The POA approach is represented in two phases based on pelicans' hunting behavior. The hunting behavior is simulated using two phases

(i) Moving towards prey

Exploration entails moving toward the prey, whereas exploitation necessitates gliding on the water's surface. During the initial phase, pelicans randomly identify and approach their prey within the search space, mathematically represented by the equation

$$x_{i,j}^{p_1} = \begin{cases} x_{i,j} + rand.(p_j - l.x_{i,j}), & F_p^1 < F_i \\ x_{i,j} + rand.(x_{i,j} - p_j), & else \end{cases} \quad (30)$$

Where Fp represents the prey objective function value. A pelican agent's new position is accepted only if it yields a better objective function value. This effective updating criterion steers the algorithm away from suboptimal regions, avoiding premature convergence to local optima. The position of the POA is updated using the equation below

$$X_i = \begin{cases} X_i^{P_1}, F_i^{P_1} < F_i ; \\ X_i , else , \end{cases} \quad (31)$$

(ii). Winging on the water surface

During this phase, pelicans use the surface of the water to push fish up by spreading their wings, thereby catching the fish in their throat bag. Pelicans capture a greater quantity of fish in the region targeted by this method. During this phase, the algorithm gets closer to finding better solutions in the hunting zone, which makes it easier to take advantage of POA. This pelican's hunting behaviour is written mathematically as

$$x_{i,j}^{p_1} = x_{i,j} + R.\left(1-\frac{t}{T}\right).(2.\,rand - 1).\,x_{i,j} \quad (32)$$

Effective updating has been used to decide whether to accept or reject the most recent pelican position, as shown in the equation below.

$$X_i = \begin{cases} X_i^{P_2}, F_i^{P_2} < F_i ; \\ X_i , else , \end{cases} \quad (33)$$

Algorithm Procedure

1. Initialize the bus and line data, EVCS, and DG numbers.
2. Initialize the number of iterations and other parameters of POA along with EVCSs and DG lower and upper bound limits.
3. Randomly initialise the places of the pelican population inside the defined search space limits for EVCS sites and DG capacity.
4. Set the iteration counter t = 1.
5. Evaluate the fitness of each pelican using load flow analysis and other performance indices for the current EVCS and DG placement configuration.
6. Identify the global best position (x_best) representing the optimal EVCS and DG configuration with minimum power losses.
7. Generate a random prey position within the search space bounds.
8. Update positions using equations (27)-(31)
9. Run load flow analysis for all updated pelican positions to evaluate new fitness values.
10. Update the global best position if any pelican achieves better performance (lower power losses) than the current global best.
11. Check boundary constraints for EVCS locations (valid bus numbers) and DG capacities (within specified limits). Apply corrections if positions violate bounds.
12. Increment iteration counter: t = t + 1 and repeat steps 7-13, till the maximum number of iterations is attained
13. Print the best solution and end.

IV. RESULTS AND DISCUSSIONS

IV.1 SYSTEM DESCRIPTION:

The initial test system is the IEEE-33 bus distribution network, with 33 nodes and 32 branches, with a total real power demand of 3715 kW and total reactive power loads of 2300 kVAr [10]. The second test system is the IEEE-69 bus distribution network, with 69 nodes and 68 branches, with a total real and reactive demand of 3803.9 kW and 2693.1 KVAR. Both systems operate at 100 MVA and 12.66 kV. Table 1 shows the electric vehicle (EV) models that are considered in this paper. These include the BMW i3, Tesla Model X, Chevrolet Volt, and Chang'an Yidong. Charging stations (CS) equipped with AC/DC level-2 charging ports (CPs) compliant with the SAE J1772 standard are also included. These ports are capable of charging both Battery Electric Vehicles (BEVs) and Plug-in Hybrid Electric Vehicles (PHEVs) with a maximum power output of 7 kW[6].

Table 1: EVCS Features for Simulation.

Tesla Model X	13	15	195
BMW i3	44	10	440
Chevrolet Volt	2.2	25	55
Chang An Yidong	3.75	20	75
SAE J1772 Standard	7	30	210
Total CS power rating (kW)		100	975

Three different scenarios are addressed in this work on two IEEE systems to validate the methodology

Scenario 1: Base case

Scenario 2: Optimal placement of three EVCSs

Scenario 3: Optimal placement of three EVCSs with three DGs of different types

IV.2 RESULTS OF THE IEEE-33 BUS SYSTEM

Scenario 1: Base case

With the load flow analysis on the first test system, the base case real power and reactive power losses are 202.66kW and 134.7 kVAr, respectively. The minimum voltage of 0.9131 p.u is obtained at bus 18, whereas the minimum VSI value is 0.6951 p.u, and the AVDI minimum is 0.0036 p.u

Scenario 2: Optimal placement of three EVCSs

When multiple EVCSs of 975 kW are optimally placed with the considered optimization algorithms, system performance improves, rather than random placement. Both PSO and POA identified the optimal locations for three EVCSs as 2,19,25. With the identified locations, the power loss becomes 287.1126 kW, VSI decreased to 0.678644 p.u., and AVDI increased to 0.004313 p.u. This result underscores the importance of optimization of DGS with EVCS in the distribution system.

Table 2: Results of the IEEE-33 bus system with and without EVCSs.

	Locations	**Ploss(kW)**	**AVDI (p.u)**	**VSI (p.u)**	**Vmin (p.u)**
Load Flow					
Base Case	-	202.66	0.00366	0.6951	0.9131
Three EVCSs (3*975kW)					
PSO	2,19,25	287.1126	0.004313	0.678644	0.9076
POA	2,19,25	287.1126	0.004313	0.678644	0.9076

Source: Authors, (2026).

Scenario 3: Optimal placement of three EVCSs with three DGs of different types

In this case, three DGs of different types are optimally placed in conjunction with three EVCS of 975 kw in the radial distribution system. Type-3 DGs with different power factors (0.85, 0.9) and an optimized power factor are considered in this study. With optimization algorithm PSO, the losses for Type-1, Type-2, Type-3A, Type-3B, Type-3C are reduced to 69.22 %,21.19%,87.86%,87.47 % and 89.66 %. The AVDI values have become 0.000459 p.u., 0.001507 p.u., 0.000019 p.u., 0.000031 p.u., and 0.000029 p.u.Also, the VSI values have increased to 0.813721 p.u.,0.873617 p.u., 0.968282 p.u., 0.950191 p.u.,0.957584 p.u., as shown in Table 3.

Source: Authors, (2026).

With POA the losses Type-1, Type-2, Type-3A, Type-3B, Type-3C DGs are reduced to 69.43 %,21.74%,87.92%,87.71 % and 90.40 %. The AVDI values have become 0.000438 p.u., 0.001431 p.u., 0.000022 p.u., 0.0000528 p.u., and 0.000027 p.u.Also, the VSI values have increased to 0.880739 p. u,0. 814559p.u, 0.967913p.u,0.954793 p.u, and 0.965020 respectively.

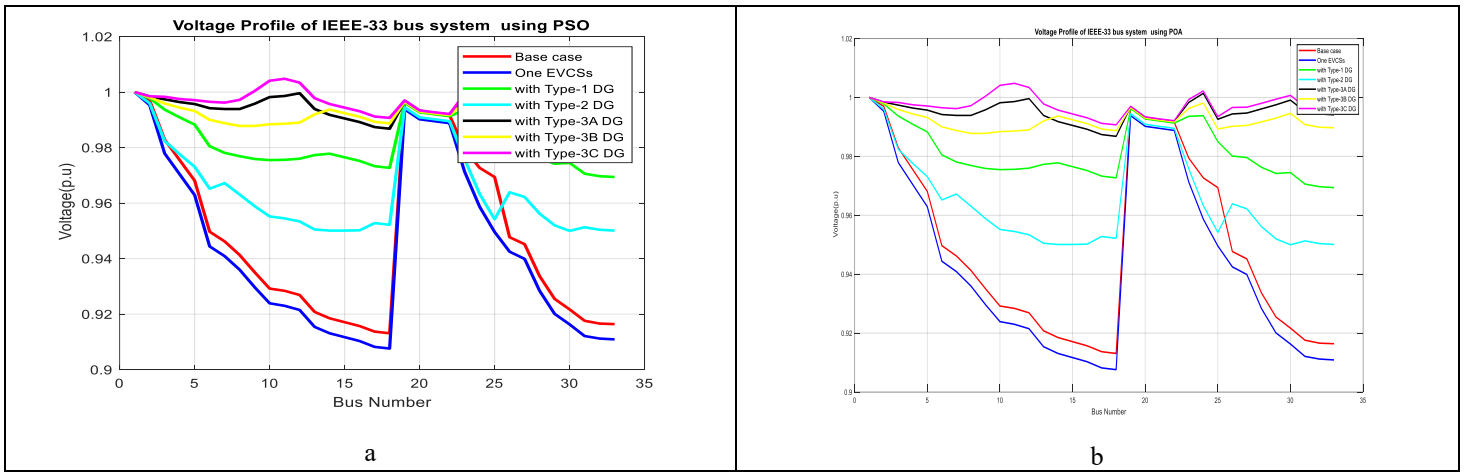

Figure 2: Comparison of the voltage profile within the IEEE-33 bus system, a) with PSO, b) with POA.
Source: Authors, (2026).

The results show that Type-3C with optimal power flow achieves the highest loss reduction, at 89.66% using PSO, followed closely by 90.40% with POA. The minimum voltage is better with POA, which is 0.9915 p.u., as shown in Figure 2. Fig. 1 also shows the convergence curve for three EVCSs with three different types of DGs. The final curves for POA and PSO are similar, but POA converges more smoothly.

IV.3 RESULTS OF THE IEEE-69 BUS SYSTEM

Scenario 1: Base case

With the load flow analysis on the IEEE-69 bus system, the base case real power and reactive power losses are 224.8807kW and 102.64393 kVAr, respectively. The minimum voltage of 0.9092 p.u is obtained at bus 65, whereas the minimum VSI value is 0.683325 p.u, and the AVDI minimum is 0.001460 p.u.

Scenario 2: Optimal placement of three EVCSs

Both the optimization algorithms PSO and POA identified the optimal locations for three EVCS as 2,28, and 47 for the IEEE-69 bus. The power loss increased to 225.2724 kW. Additionally, VSI is decreased to 0.683224 p.u. and AVDI is increased to 0.001462 p.u.

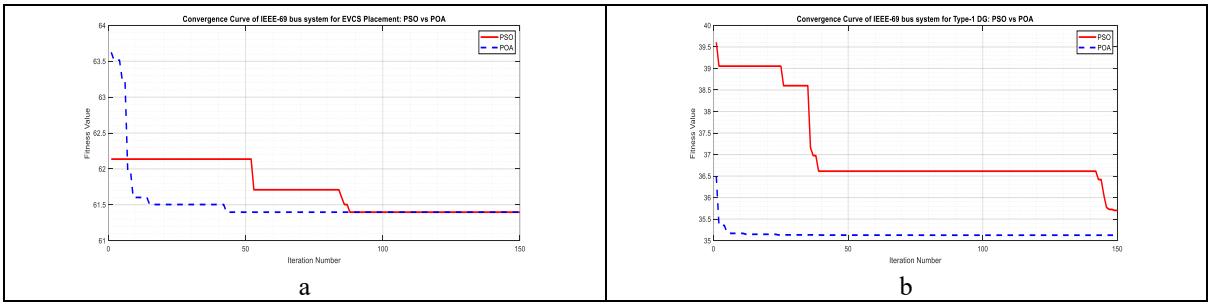

Table 4: IEEE-69 bus system performance before and after placement of EVCS.

	Locations	Ploss(kW)	AVDI(p.u)	VSImin (p.u)	Vmin(p.u)
Load Flow					
Base Case	-	224.8807	0.001460	0.683325	0.9091
Three EVCSs (3*975kW)					
PSO	2,28,47	225.2724	0.001462	0.683244	0.9092
POA	2,28,47	225.2724	0.001462	0.683244	0.9092

Source: Authors, (2026).

Scenario 3: Optimal placement of three EVCSs with Three Different Types of DGS

With the Type-I configuration (3 DGs integrated with 3 EVCS), the system achieved a power loss reduction of 69.10%. The minimum bus voltage improved to 0.9790 p.u. using POA and 0.9789 p.u. using PSO. The voltage stability index increased to 0.918686 p.u. and 0.918304 p.u., while the average voltage deviation index decreased to 0.000076 p.u. and 0.000077 p.u. for POA and PSO optimizations.

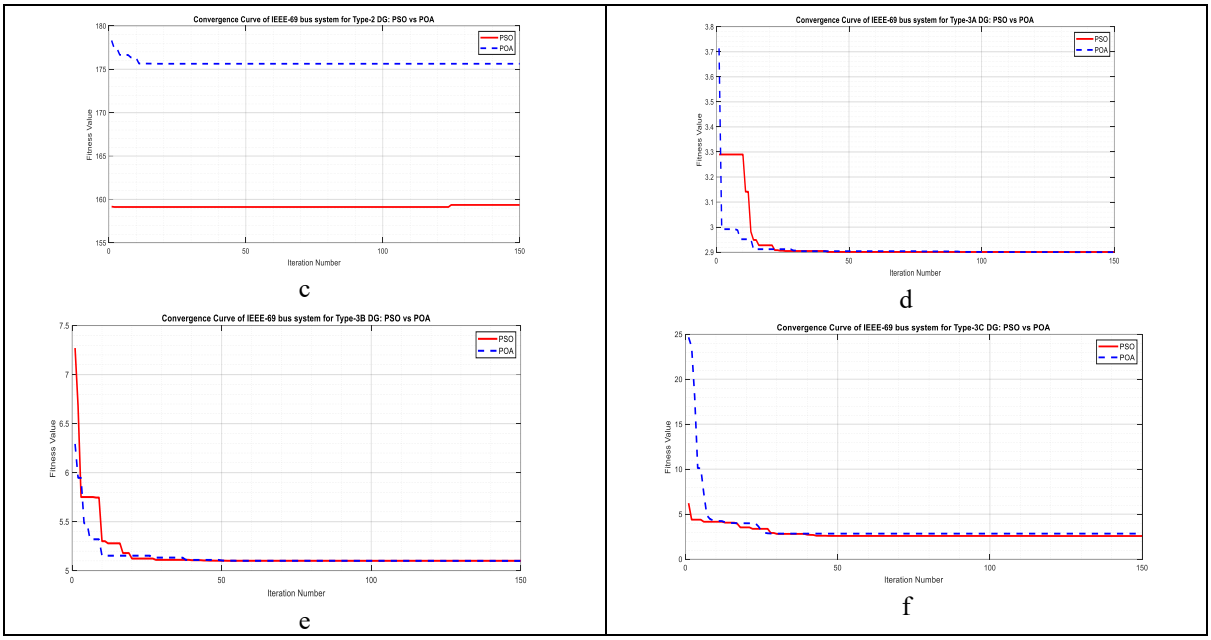

Figure 3: Convergence Curves of the IEEE-33 bus system with optimization algorithm a) With EVCSs only b). EVCSs with Type-1 DGs c). EVCSs with Type-2 DGs d). EVCSs with Type-3A DGs e). EVCSs with Type-3B DGs f). EVCSs with Type-3C DGs. Source: Authors, (2026).

With Type-2 DG, power losses decreased to 155.233kW and 155.22 kW. The voltage stability index (VSI) improved to approximately 0.7497 p.u., while the minimum bus voltage reached 0.9305 p.u. for both methods. The average voltage deviation index (AVDI) was measured at 0.000742 p.u. for both POA and PSO approaches. The results are tabulated in 5.

Table 5: Performance Indices of IEEE-69 bus system.

	Locations	**Sizes**	**Ploss (kW)**	**% Reduction in Loss**	**AVDI (p.u)**	**VSImin(p.u)**	**Vmi (p.u)**
Type-1 (kW)							
PSO	17,11,61	362,578,1712	69.6193	69.09	0.000077	0.918304	0.9789
POA	17,11,61	380,530,1720	69.5989	69.10	0.000076	0.918686	0.9790
Type-2 (kVAr)							
PSO	17,11,61	467,1000,1000	155.233	31.08	0.000742	0.749738	0.9305
POA	18,11,61	466,1000,957	155.22	31.09	0.000742	0.749736	0.9305
Type-3A (kVA)							
PSO	17,11,61	386+i239 517+i320 1746+i1082	5.1876	97.70	0.000002	0.977075	0.9942
POA	11,18,61	519+i32 387+i240 1745+i1082	5.186	97.70	0.000002	0.977075	0.9942
Type-3B (kVA)							
PSO	17,11,61	406+i196 543+i263 1829+i886	9.5878	97.44	0.000002	0.977038	0.9942
POA	11,18,61	544 +i264 405+i196 1829+i886	9.5863	95.74	0.000002	0.977038	0.9942
Type-3C (kVA)							
PSO	17,11,61	380+i251 494+i353 1676+i1195	4.4583	98.02	0.000002	0.977092	0.9942
POA	11,61,18	496+i354 1675+i1195 379+i251	4.4567	98.02	0.000002	0.977092	0.9942

Source: Authors, (2026).

Type-3A (3DGs) reduced power losses to 5.186 kW and 5.1786 kW, VSI increased to 0.977075 p.u, and AVDI decreased 0.000002 p.u, while Vmin reached 0.9942 p.u, for POA and PSO. Type-3B (3DGs) reduced power losses to 9.5878 kW and 9.586 kW, minimum voltage reached 0.9942 p.u, VSI increased to 0.977038 p.u, and AVDI decreased to 0.000002 p.u, for POA and PSO, respectively.

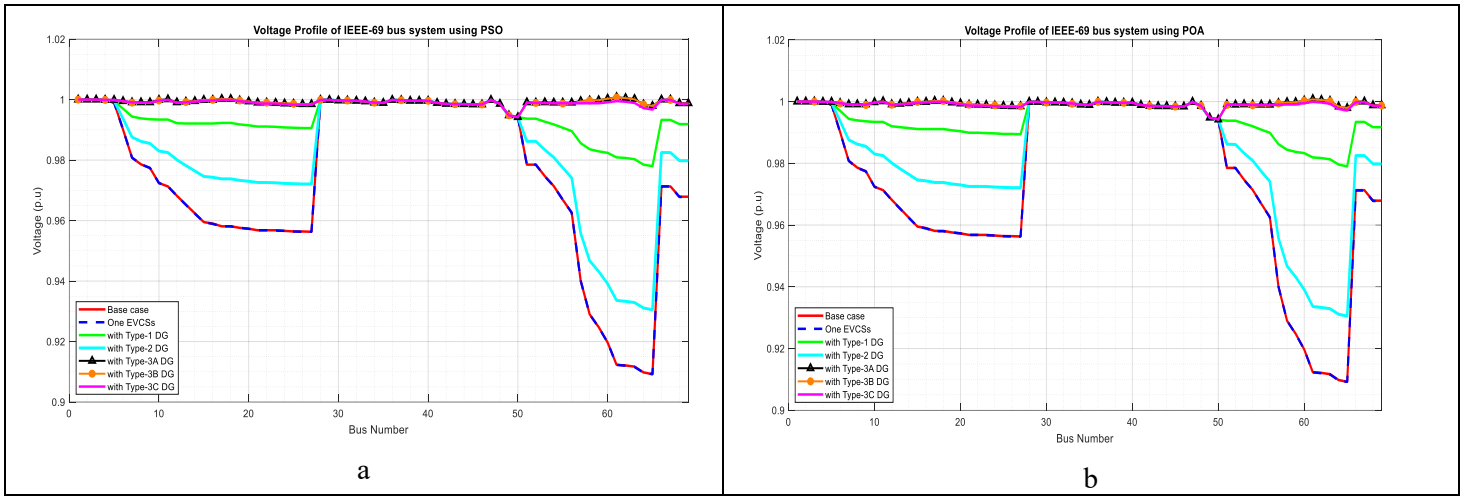

Figure 4: Comparison of the voltage profile within the IEEE-69 bus system, a) with PSO, b) with POA.
Source: Authors, (2026).

For type-3C, DGs with optimized power factors are determined with both optimization algorithms. This reduced power losses to 4.4567 kW and 4.4583 kW, and voltage profiles increased to 0.9942 p.u., VSI increases 0.977092 p.u and AVDI decreases 0.000002 p.u., for POA and PSO, respectively, as shown in Table 5. Type -3 C Dg achieved power loss reduction of 98.02 % with both theoptimization algorithms. The convergence curves shown in Figure 3 prove that the new algorithm, POA, outperforms the PSO in fitness value. Figure 4 illustrates the voltage profile of the IEEE-69 bus network, considering the impact of various distributed generation types in conjunction with EVCSs.

V. CONCLUSIONS

The incorporation of a significant number of electric vehicles (EVs) negatively impacts system performance, resulting in an increase in power losses, a rise in average voltage deviation index (AVDI), a reduction in voltage stability index (VSI), and a decline in the voltage profile. Consequently, different types of distributed generators (DGs) are incorporated with electric vehicle charging stations (EVCS), and it is observed that an increase in the number of DGs yields improved outcomes. This is performed by implementing a novel optimization algorithm, called the Pelican Optimization Algorithm. In here, the multi-objective function, i.e, reduction of power loss, minimization of Average Voltage Deviation Index, and enhancement of Voltage Stability Index, is formulated and optimized using Particle Swarm Optimization (PSO) and Particle Optimized Algorithm (POA), with POA yielding better results than PSO for both the IEEE-33 and IEEE-69 bus systems. From the results, we can conclude that the Type-IIIC DG outperformed the others. Although PSO performs better in certain cases, POA remains consistent across different performance measures

ABSTRACT

This research introduces a real-time framework for Personal Protective Equipment (WPE) identification utilizing YOLOv8, an advanced object detection model. The suggested system is intended for the ongoing surveillance of building sites and industrial settings to autonomously confirm worker adherence to obligatory safety equipment, including hardhats and highly visible safety vests. The system analyses input stream from a live camera or pre-existing picture datasets to execute real-time detection of WPE violations in video frames. Upon detecting non-compliance, automated alarm notifications are promptly created and dispatched over the Telegram instant messaging platform, facilitating swift safety intervention. The implementation is constructed with Python, utilizing OpenCV with video processing as well as the YOLOv8 system for object identification and inference. The suggested solution presents an effective scalable, and scalable safety compliance tracking system that can be effortlessly incorporated into current industrial safety overall surveillance infrastructures to improve worker security and workplace safety.

I. INTRODUCTION

Worksite Protective Equipment (WPE)—comprising hard hat, safety vests, safety masks, and associated protective equipment—serves a vital function in mitigating injuries and fatalities in hazardous situations including construction sites, production lines, and industrial plants [1]. Notwithstanding the implementation of rigorous workplace safety standards, adherence to WPE usage continues to be a chronic issue. Recent studies indicate that human variables, including fatigue, inattentiveness, restricted visibility [2], and the vastness of industrial workstations, substantially diminish the efficacy of manual safety oversight [3]. WPE infractions frequently remain unnoticed, so exposing workers to dangers including falling objects, machinery-related incidents, and chemical exposure [4].

Conventional manual monitoring methods are arduous, unreliable, and unsuitable for dynamic, large-scale settings. Supervisors cannot consistently oversee all employees in real time, resulting in delayed reactions and heightened risk. Contemporary literature progressively highlights the shortcomings of rule-based and human inspection systems, advocating towards automated safety monitoring systems powered with computer vision as well as artificial intelligence (AI). Progress in deep learning, especially convolutional neural network (CNN)-inspired object detection models, has shown considerable enhancements in accuracy, resilience, and inference performance for real-time safety applications.

In recent years, object identification systems including YOLO (You Only Look Once), the SSD, along with R-CNN with faster speeds have been extensively investigated for personal protective equipment detection [5-7]. The most recent version, YOLOv8, demonstrates enhanced performance regarding detection accuracy, minimal latency, and computing efficiency, rendering it appropriate for real-time implementation on edge devices. Recent research indicate that YOLO-based models attain almost real-time inference speeds while maintaining excellent accuracy in identifying WPE components, including helmets, face masks, and safety vests, across diverse illumination and occlusion scenarios.

This project presents an on-demand WPE compliance tracking system that utilizes YOLOv8 for automated identification of uses of WPE using live camera feeds or image datasets, motivated by recent breakthroughs [8]. The technology detects WPE breaches in real time and issues immediate notifications via Telegram alerts, allowing supervisors to react swiftly to safety infractions. The proposed system attains real-time performance, facilitating prompt diagnosis and intervention [9]. The system integrates intuitive features, including an overlay visual interface that presents live video feeds and compliance metrics, as well as a notification cooldown mechanism to avert alert saturation [10]. The technology is engineered for scalability, enabling deployment in various industrial settings and adaptation to differing safety standards. Moreover, by employing open-source technology and ensuring interoperability with inexpensive hardware, the system provides a cost-efficient and pragmatic solution for improving workplace safety. This project seeks to diminish industrial fatalities and injuries by automated WPE compliance monitoring, reducing dependence on manual inspections, and promoting a proactive security culture in highly hazardous sectors via sophisticated, real-time surveillance technologies.

II. LITERATURE REVIEW

The literature review distinctly demonstrates a progressive enhancement in WPE detection techniques, especially for the development of deep learning techniques -based models for object detection and real-time alarm systems are shown in Table 1. Initial research [11],[12] predominantly utilized YOLO (You Only Look Once) and SSD frameworks, attaining moderate identification accuracies (82–87%) in controlled environments. These studies revealed the viability of computer vision-based WPE identification; nevertheless, they were constrained by diminished resilience in intricate industrial settings and comparatively slower inference times. Subsequent studies [13] employed advanced detectors like Faster R-CNN and YOLOv5, resulting in enhanced accuracy in detection (up to 89%) and the implementation of automatic alarm systems via IoT and SMS. Nevertheless, these models frequently exhibited elevated computing cost, constraining real-time implementation in extensive environments.

Beginning in 2022, research increasingly emphasized continuous operation and system integration. According to [12] illustrated the efficacy of YOLOv6 and YOLOv7 integrated with Telegram-based alert systems, with detection accuracies nearing 90% and facilitating expedited reaction times. These studies emphasized the significance of amalgamating algorithms for detection with communication channels for prompt safety responses. Recent research [14] highlight the superiority of YOLOv8, which provides improved detection speed, diminished latency, and increased precision relative to earlier YOLO iterations. These methodologies routinely provide an accuracy or mean Average Precision (mAP) of 90–93%, accompanied by real-time alert notifications over Telegram and SMS.

The enhancements in YOLOv8's architecture render it especially apt for implementation in dynamic, high-risk settings. Upon reviewing the studies, numerous notable trends, technological innovations, and research deficiencies in YOLO-based WPE systems for detection, especially those employing YOLOv8, can be discerned. The progression of YOLO designs, spanning with YOLOv4 [14] through the latest YOLO technique variants, illustrates ongoing advancements in deep learning-based object recognition, particularly regarding detection precision, inference speed, overall model efficiency. Each subsequent version has architectural enhancements that improve extraction of features and real-time efficiency, rendering YOLOv8 especially appropriate for safety-critical applications like real-time WPE monitoring for compliance in construction and industrial settings.

Source: Authors, (2026).

The literature indicates a distinct trend towards real-time compliance with WPE monitoring systems based on YOLO, featuring integrated alarm mechanisms. YOLO offers an optimal mix between speed and accuracy compared to previous models, rendering it the most efficient solution for scaled, real-time industrial safety monitor. This substantiates the selection of YOLO but Telegram-based notifications in the suggested approach, establishing it as a technologically robust and modern methodology consistent with recent research developments.

II. PROPOSED METHODOLOGY

The dataset constitutes the fundamental basis of the presented WPE detection method and is essential for attaining dependable and resilient model performance. It consists of over 2,800 annotated photos and many hours of real-world recordings obtained from active building sites. The data encompasses a broad spectrum of operating circumstances, including various worker postures, differing intervals from the camera, several camera perspectives, and intricate backgrounds typically found in construction settings. The dataset comprises photos and video images of workers adhering to WPE requirements and breaching safety protocols, facilitating the model's ability to learn distinguishing features for precise categorization. The information encompasses types of worksite protective equipment, including hard helmets, safety face masks, and further pertinent protective equipment. The data also illustrates real-world issues such partial occlusions, congested environments, fluctuations in illumination, low-light settings, and blurry motion, which are essential for enhancing model generalization. The dataset was meticulously labeled with boundaries for each WPE category, utilizing standardized labelling formats suitable with YOLOv8 to facilitate deep learning-based object detection.

Furthermore, data pretreatment and augmentation methods—including scaling, normalization, vertical flipping, and luminance adjustments—were employed to improve dataset variety and mitigate overfitting. Learning the YOLOv8 model on this extensive and representative dataset enhances detection precision as well as resilience in real-time applications. The utilization of actual building site data guarantees that the model operates dependably under practical conditions, rendering it appropriate for scalable and ongoing WPE compliance tracking in high-risk industrial settings. The proposed methodology shown in Figure 1.

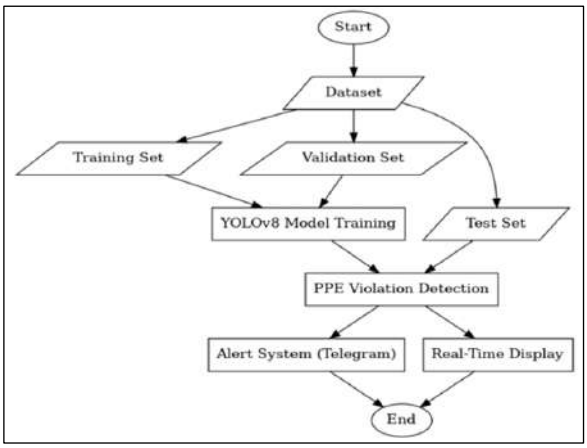

Figure 1: Methodology.
Source: Authors, (2026).

The dataset was methodically partitioned to guarantee comprehensive model learning and assessment. The training set, consisting of 70% of the data set (2,416 annotated photos), reflects authentic building site settings under various lighting scenarios: daytime (50%), poor lighting environments (30%), and difficult circumstances such as occlusions and intricate camera angles (20%). The dataset illustrates differences in WPE kinds, material choices, colors, and worker postures, allowing the algorithm to acquire distinguishing features efficiently. A stringent quality assurance procedure guaranteed a minimum of 95% classification accuracy, while systematic dataset organization reduced overfitting and enhanced generalization. Each photos were scaled to a uniform quality and normalized to enhance feature extraction efficacy. Data augmentation techniques, including as flipping, rotation, contrast or brightness modifications, were employed to enhance generalization, resulting in an approximate 60% increase in the validation dataset size.

Every image was meticulously annotated with box boundaries for worksite protective equipment components, including safety caps, vests, gloves, and protective goggles, while a multi-tiered verification method guaranteed 98% annotation accuracy, facilitating dependable performance evaluation during training. The test dataset, consisting of 10% of the entire data (100 pictures), was designated solely for final assessment on unobserved samples. This subset encompasses highly demanding cases, including severe fluctuations in illumination, occlusions, and intricate backdrops, to evaluate real-world robustness. The trained model attained a detection accuracy of 90% on the test data set, with 5% error rates and 8% negative results, demonstrating robust reliability while highlighting opportunities for small enhancements. The results illustrate the model's capacity for effective generalization and consistent performance in actual building site settings.

III. RESULT AND DISCUSSION

The YOLOv8 model undergoes a systematic training procedure that enhances diagnosis precision while maintaining computing economy. The model is optimized meticulously adjusting learning rate, size of batches, and the total amount of epochs, to achieve peak performance. During the training phase, the model attains a minimum Average Precision (mAP) around 85%, alongside a recall rate of 88% as well as precision of 90%, underscoring its proficiency in accurately detecting WPE. Iterative enhancements during training result in an 8% decrease in false positives along with a 12% increase in detection speed relative to YOLOv7. The model can effectively differentiate between WPE-compliant and non-compliant personnel in actual scenarios. Upon completion of training and testing, the model is deployed to identify WPE issues in real-time through the continuous analysis of pictures. The system analyzes frames at a rate of under 0.4 seconds per monitored image, ensuring instantaneous performance.

The detection accuracy differs according to the kind of WPE: helmets are recognized with 88% accuracy, vests with 94%, and masks with 93%. Upon the occurrence of a violation, the system autonomously categorizes the specific type of absent worksite protective equipment, such as an unidentified helmet or gloves, facilitating accurate monitoring of safety infractions. This real-time monitoring markedly improves workplace safety by assuring compliance with WPE rules among all people. The proposed method incorporates an automated alert system that dispatches alerts via Telegram upon detection of a WPE violation to ensure prompt safety enforcement. These warnings, dispatched within 2 seconds, encompass an image or video sample of the infraction, accompanied by specifics regarding the absent WPE.

The alert system achieves a 96% efficacy accompanied by an inaccurate alert rate of under 3%. This guarantees that safety officers obtain real-time updates, enabling them to implement corrective measures prior to an event transpiring. A real-time monitor is included into the system to facilitate ongoing tracking and visual insights. This dashboard provides a consolidated overview of WPE compliance, featuring a live video with marked detections, a record of previous breaches. The system upholds a system uptime of 96.5%, guaranteeing continuous monitoring of building sites. Monitoring data indicates a 13% enhancement in WPE compliance over a six-month period, attributable to ongoing supervision and real-time notifications. This dashboard facilitates the visualization of compliance trends and the identification, enabling safety inspectors to implement proactive steps to uphold elevated workplace safety standards.

Figure 2: Real time Feed.
Source: Authors, (2026).

The system incessantly analyzes real-time video streams from a webcam, employing the YOLO-V8 model to identify individuals and evaluate their adherence to WPE standards. Each identified individual is delineated with a boundary according to compliance status. The system recognizes an individual having a confidence score about 0.88. WPE compliance issues are identified, including the lack of a helmet had a confidence score for 0.77 and a vest for safety with a confidence value of 0.86. Simultaneously, the usage of compatible WPE, shown by an identified mask has a confidence value of 0.88, is documented. Figure 2 and 3 illustrates the continuous video feed employed for monitoring WPE compliance. Figure 4 shows for image dataset.

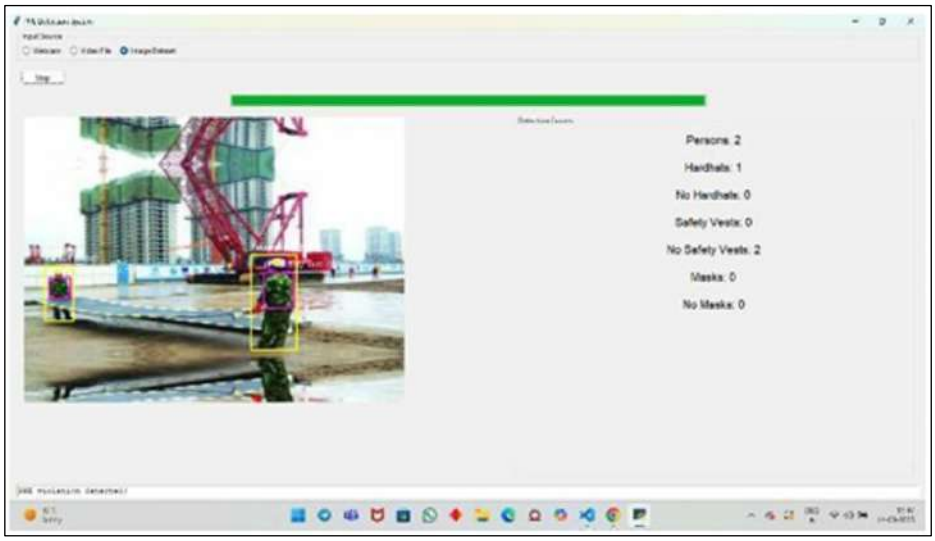

Figure 3: Real time Video Feed.
Source: Authors, (2026).

The monitoring summary provides a structured WPE compliance assessment:

• Total men detected in worksite: 3
• Hardhats Worn: 3
• Safety Vests Worn: 0
• No Masks: 0
⚠ WPE Violation Detected!
⚠ Immediate action is needed.

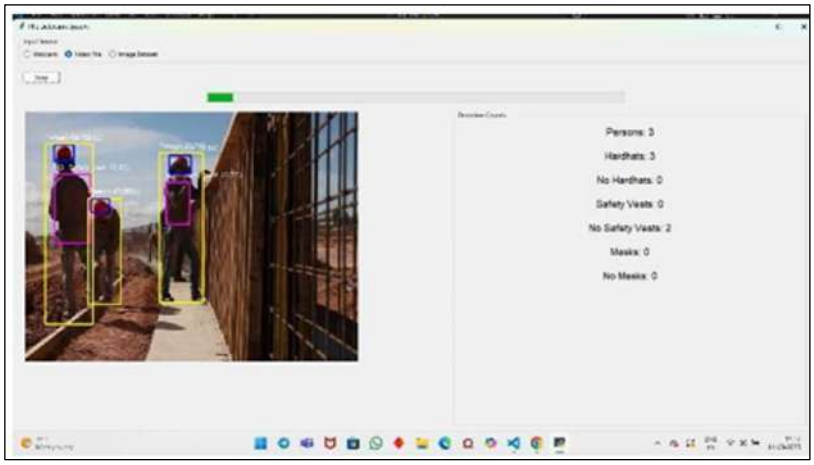

Figure 4: Image Dataset.
Source: Authors, (2026).

The WPE identification model encounters various problems that could affect its precision and dependability. Illumination and environmental factors, including inadequate illumination, glare, and severe weather, can diminish visibility, hence impacting detection efficacy. Obstruction and incomplete visibility may result in misrepresentation when personal protective equipment are concealed or workers avert their gaze. Challenges in small item detection occur when remote workers are rendered too diminutive for precise recognition. Class imbalance within the dataset may induce bias, particularly if specific WPE items are inadequately represented. False positives and false negatives might result in superfluous notifications or overlooked violations. Moreover, restricted variety in the color and design of WPE can diminish detection accuracy. Finally, real-time processing limitations caused by high-resolution photos and intricate sceneries may impede performance, underscoring the necessity for additional optimization.

IV. CONCLUSION

The assessment of the YOLOv8 recognition of objects model for WPE identification yields significant insights into its efficacy and practical applicability. The consistent enhancement in precision during training underscores the model's growing accuracy in detecting WPE, so guaranteeing a dependable approach for identifying violations and safety infractions. The model's capacity to distinguish between correctly utilized WPE and incidents of misuse illustrates its ability to offer accurate suggestions. The continual improvement in recall performance with increased training epochs signifies that the system is progressively enhancing its ability to recognize WPE-related concerns. These findings bolster the model's capacity to enhance safety compliance in construction and industrial settings. These findings collectively illustrate the YOLOv8 model's advancement towards enhanced accuracy and dependability, thereby establishing a solid platform for providing useful and practical suggestions about worksite protective equipment. The effective implementation of the YOLOv8 detection of objects paradigm further emphasizes its relevance.

ABSTRACT

This work presents an integrated renewable energy interfacing system that combines a Quadratic Boost Converter (QBC) with a Hybrid Active Filter (HAF) to enhance power quality and voltage regulation in photovoltaic (PV) and battery-supported hybrid energy sources. The coordinated operation of the converter–filter system is supervised by two closed-loop controllers: a classical Proportional–Integral (PI) controller and a Fractional-Order Proportional–Integral–Derivative (FOPID) controller. The controllers are designed to regulate the DC-link voltage of the QBC while ensuring harmonic suppression in the grid-side current. The Simulink-based evaluation demonstrates that the FOPID regulator delivers faster transient response, improved steady-state accuracy, and reduced harmonic distortion compared to the conventional PI scheme, making the topology suitable for power-quality enhancement in distributed renewable systems.

I. INTRODUCTION

The integration of renewable sources such as photovoltaic panels, and energy storage, requires converters that control voltages and can also compensate for nonlinear load effects expected in power- electronic environments [1], [2]. Hybrid Energy Storage Systems (HESS) that combine batteries and supercapacitors can achieve optimal energy and power density, but these systems will only operate successfully if the power-electronic interface satisfies performance expectations [3], [4]. To manage the harmonic distortion, voltage imbalance and dynamic load variations hybrid active power systems can be used. Their performance is highly dependent on the control scheme implemented. While PI-based filters are widely used for grid-interfacing applications, they may exhibit sluggish response under fast transients. Fractional-order controllers such as FOPID introduce adjustable dynamic behavior that better suits nonlinear compensation and converter coordination [5], [6], [7]. High-gain converters such as quadratic boost converters further support PV and hybrid storage applications by providing the required DC-link level with reduced component stress [8], [9]. When paired with active filtering and advanced control techniques, they enable robust PQ conditioning even under variable renewable input and nonlinear load conditions [10], [11]. This work focuses on a unified implementation that integrates a QBC, HAF, and PI/FOPID control to evaluate the improvements in voltage regulation, harmonic mitigation, and transient behavior.

II. SYSTEM DESCRIPTION

Figure 1 illustrates the proposed setup for the QBC-integrated hybrid active filter system. This system combines a photovoltaic (PV) source and a battery, each of which is processed through a QBC stage to convert DC power with high gain. The outputs are then combined at the DC link and sent to the hybrid active filter [12], [13]. This filter injects a compensating current into the transmission line, which helps to reduce the effects of nonlinear loads and provides reactive power support.

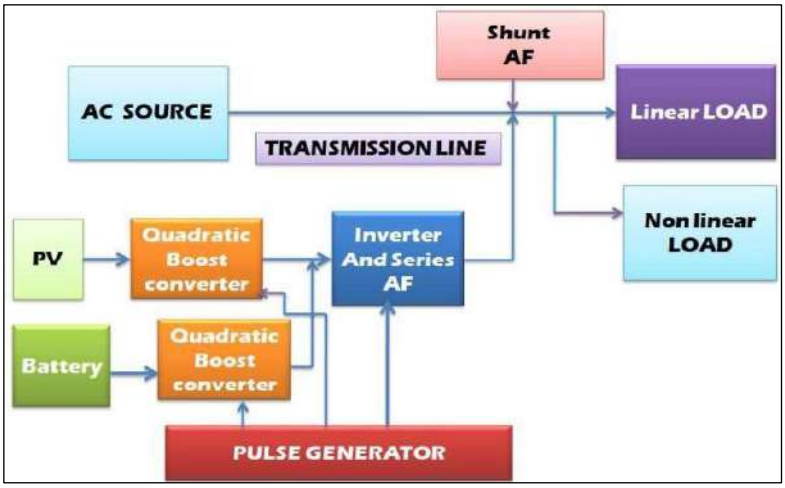

Figure 1: Proposed Block Diagram of QBC with the hybrid active filter system.
Source: Authors, (2026).

The above circuit configuration which is the QBC-based Hybrid Active Filter (HAF) system is presented in Figure 2. The HAF monitors the load-side current waveform in a constant manner [14], [15]. According to the identified harmonic and reactive components, it produces a suitable and compensating signal. This injection of current forces the source current to remain almost sinusoidal and phase-aligned with the voltage [16], [17]. The design supports both harmonic mitigation and reactive-power balancing.

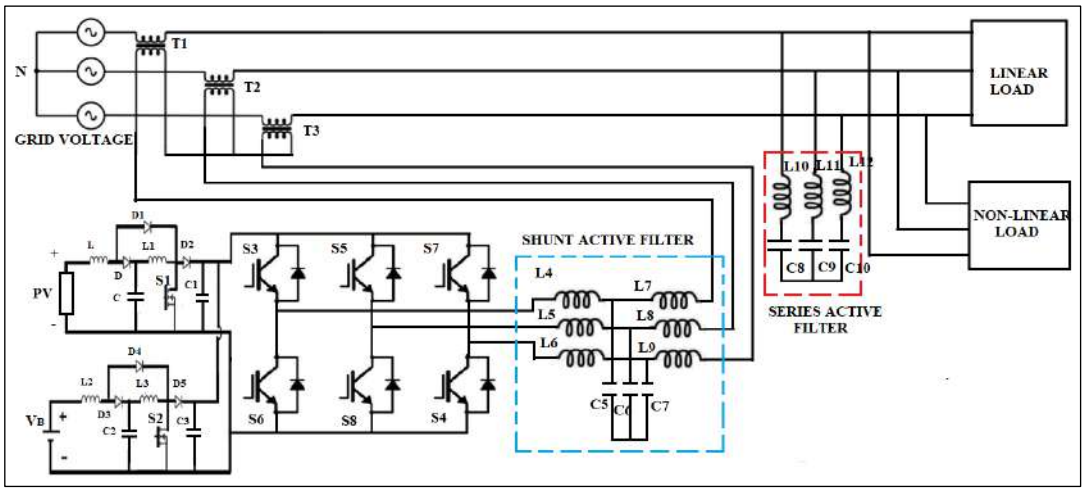

Figure 2: Proposed Circuit Diagram of QBC with Hybrid Active Filter.
Source: Authors, (2026).

The closed-loop simulation model of the QBC-fed Hybrid Active Filter (HAF) system using PI and FOPID controllers is shown in Fig. 3. A closed-loop controller regulates and controls the QBC output voltage [18], [19] [20]. The PI controller uses proportional and integral actions; whereas the FOPID controller uses an adjustable fractional-order terms that provide greater range in shaping transient the characteristics of the output. Both controllers utilize feedback from the DC-link voltage to determine and control the switching command for the converter.

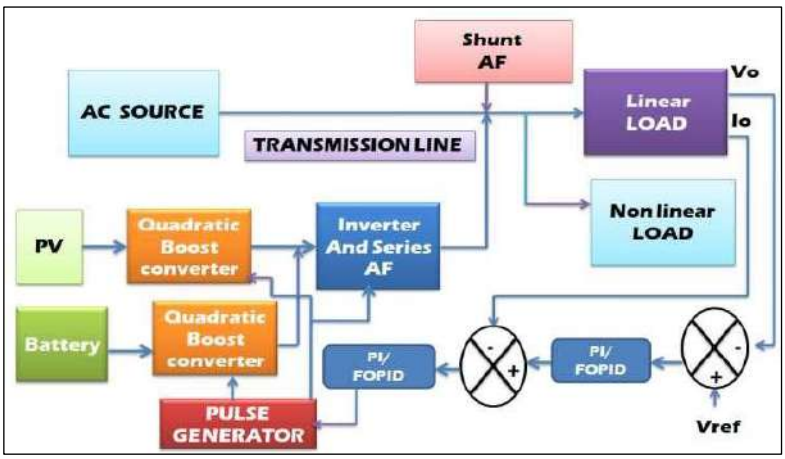

Figure 3: Closed Loop Simulation Block Diagram.
Source: Authors, (2026).

The Figure 4 shows the Closed-loop Circuit of PI/FOPID. In this configuration, the controller constantly monitors the difference between the reference input and the actual system response [21], [22]. According to this error, the controller tweaks the control signal to ensure the system output moves towards the pre-set value. This feedback mechanism helps maintain accuracy and stability in the overall system performance.

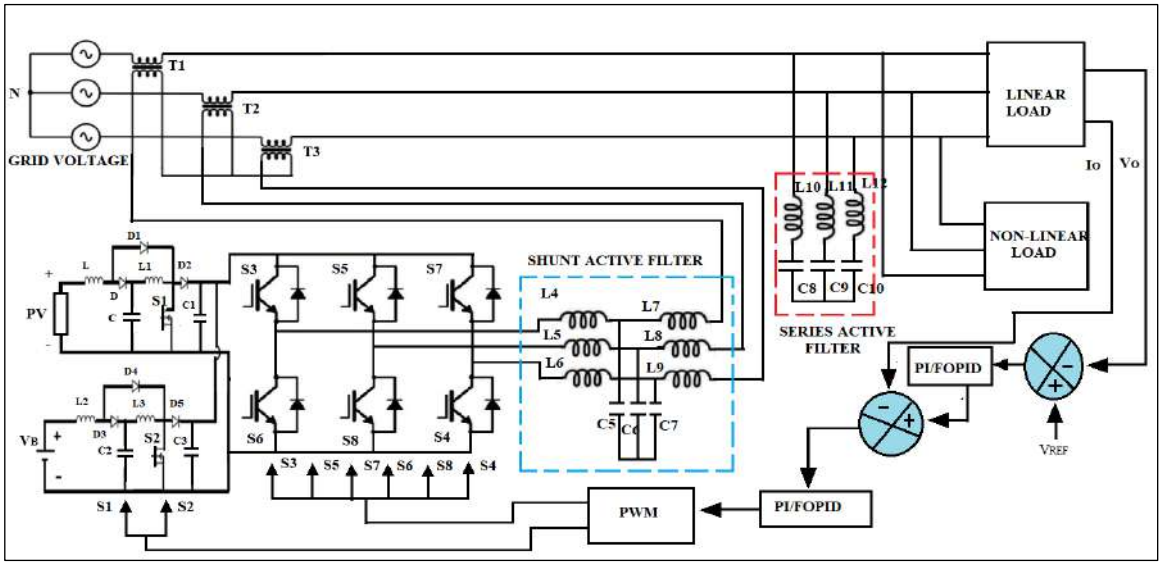

Figure 4: Closed Loop Circuit Diagram of PI/FOPID Controller.
Source: Authors, (2026).

The QBC uses a single MOSFET (M1) along with two inductors (L1, L2), two capacitors (C1, C2), and three diodes (D1, D2, D3). The duty cycle K determines the switch conduction duration. Operating in continuous conduction mode allows the converter to achieve a squared voltage conversion ratio, making it suitable for renewable sources requiring substantial step-up capability [23], [24]. The corresponding circuit layout is illustrated in Figure 5.

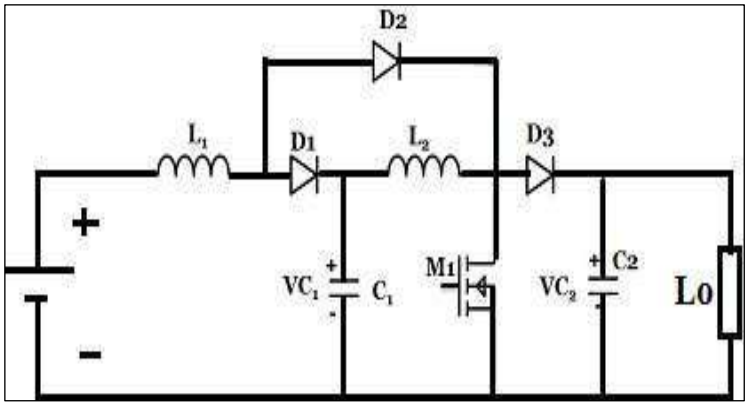

Figure 5: Circuit diagram of Quadratic Boost Converter
Source: Authors, (2026).

II.1. MODE 1 OPERATION

When M1 is turned on, D1 and D3 remain reverse-biased and D2 conducts. L1 stores energy from the input source, while L2 is energized through C1. Capacitor C2 supplies the load during this interval, causing its voltage to drop slightly.

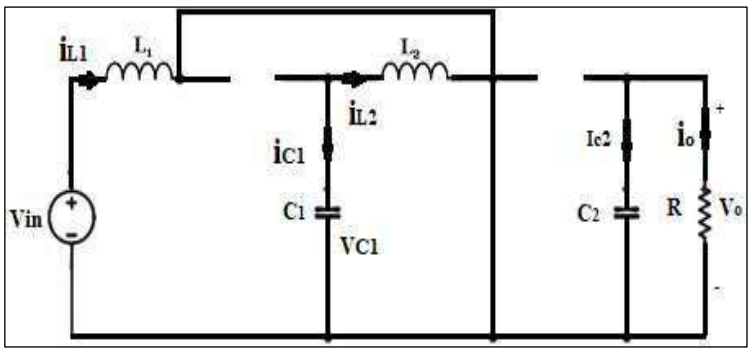

Figure 6: Quadratic Boost Converter: Topology when SW is tuned ON.
Source: Authors, (2026).

$$(\Delta I_{L1})_{On} = \frac{VsKT}{L1} \quad (1)$$

$$(\Delta I_{L2})_{On} = \frac{V_{SKT}}{L_1} \quad (2)$$

Meanwhile the capacitor currents are expressed by

$$(IC1)\ On = -\ IL2 \quad (3)$$

$$(IC2)\ On = -\ I0 \quad (4)$$

II.2. MODE 2 OPERATION

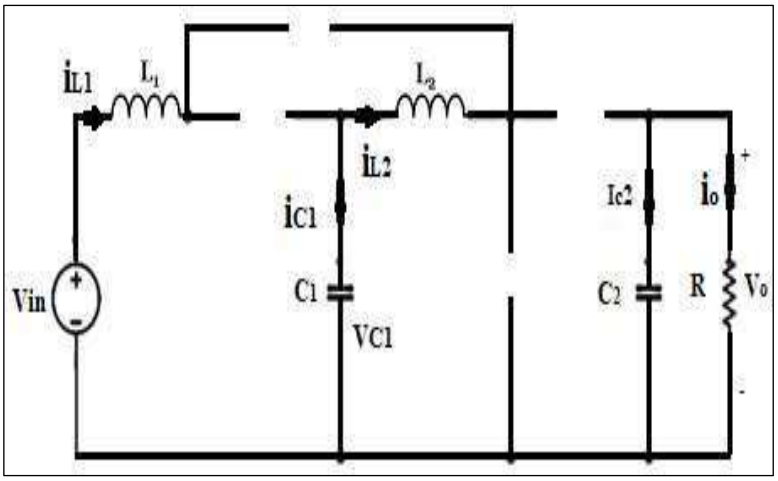

Figure 7: Quadratic Boost Converter: Topology when SW is turned off.
Source: Authors, (2026).

When M1 is switched off, D1 and D3 conduct, routing the inductors stored energy toward C1, C2, and the load. L1 transfers energy primarily into C1, whereas L2 supplies the load directly. Both C1 and C2 are charged during this period, and the inductor voltages reverse due to the decreasing current [25].

$$(\Delta I_{L1})_{Off} = \frac{Vs - VC1(1-K)T}{L1} \quad (5)$$

$$(\Delta I_{L2})_{Off} = \frac{VC1 - VO\ (1-K)T}{L2} \quad (6)$$

III. RESULTS AND DISCUSSIONS

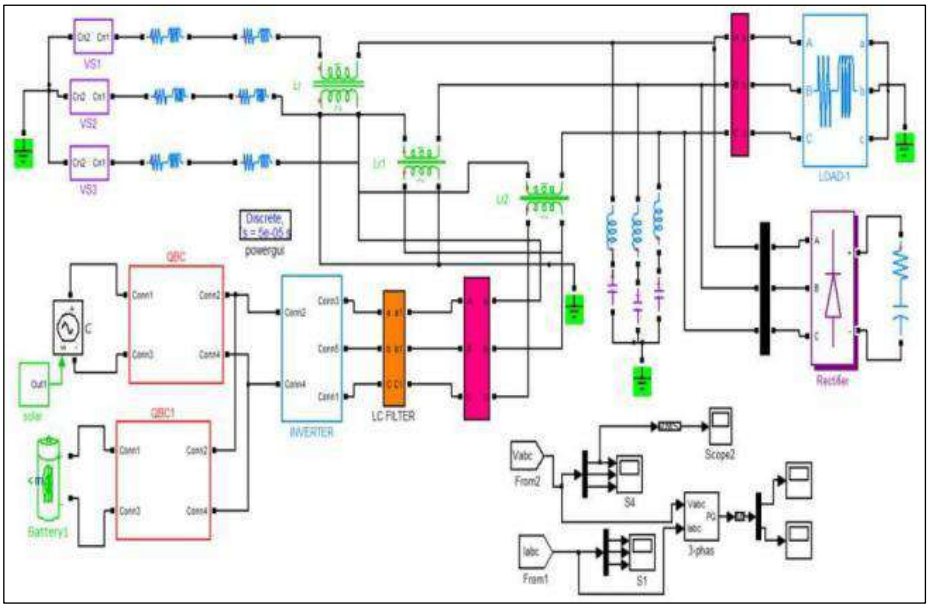

Figure 8: Circuit diagram of QBC with hybrid active Filter load disturbance.
Source: Authors, (2026).

Figure 8 illustrates the implementation of the QBC interfaced with a hybrid active filter under dynamic load-disturbance conditions.

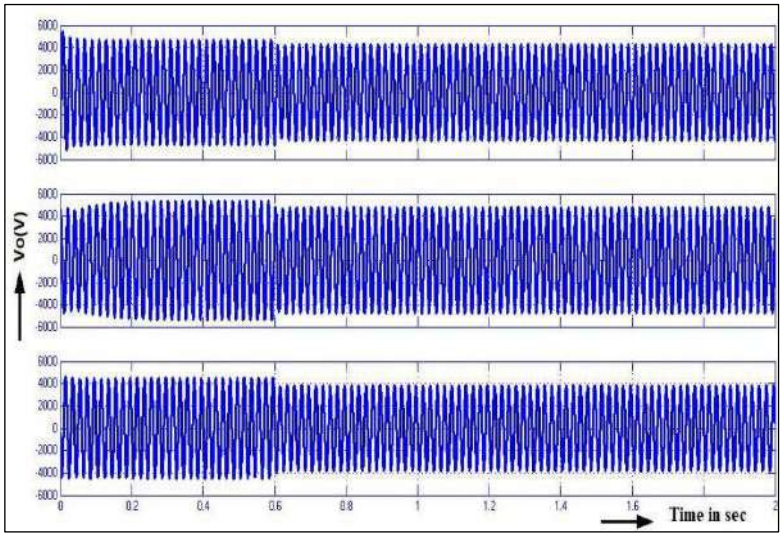

Figure 9: Output Voltage.
Source: Authors, (2026).

The instantaneous output-voltage profile, shown in Fig. 9, reaches a peak magnitude of nearly 4730 V. The corresponding RMS output voltage, presented in Figure 10, stabilizes around 3030 V.

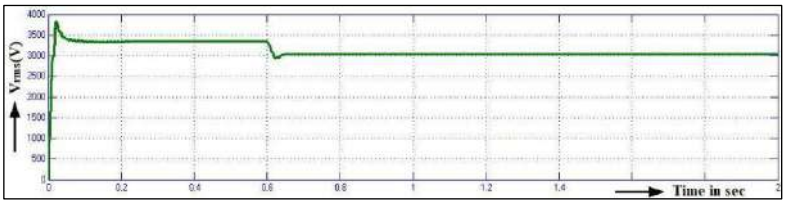

Figure 10: RMS Output Voltage.
Source: Authors, (2026).

The output current waveform, illustrated in Figure. 11, indicates that the converter delivers an average load current of approximately 13.4 A.

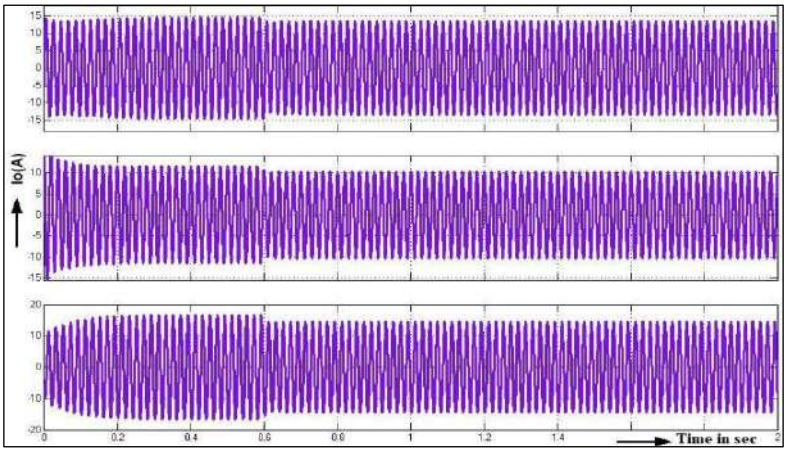

Figure 11: Output Current.
Source: Authors, (2026).

Figure 12: Real Power.w.
Source: Authors, (2026).

Figure 12 presents the real-power profile of the system, demonstrating an effective power transfer of about 7.34×104 W. The corresponding reactive-power characteristic, shown in Figure 13, is measured to be 3.56×104 VAR, reflecting the system's reactive component under the applied load conditions.

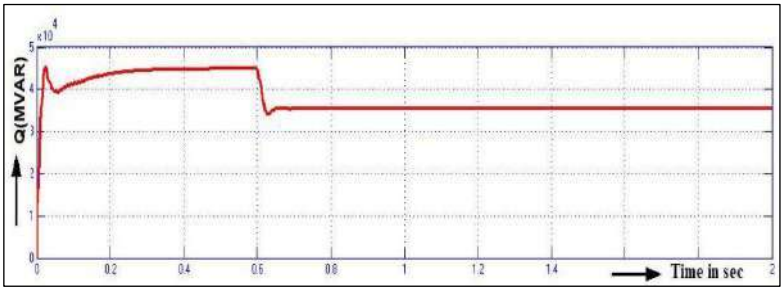

Figure 13: Reactive Power.
Source: Authors, (2026).

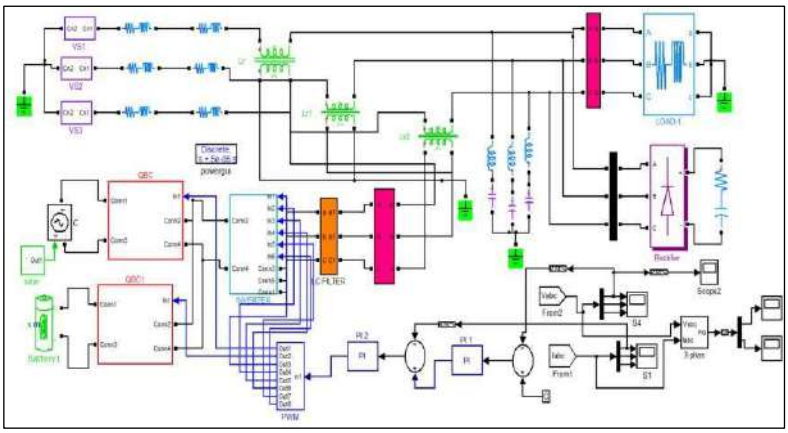

Figure 14: Circuit Diagram of QBC with Hybrid Active Filter PI controller.
Source: Authors, (2026).

The above Figure 14 shows the configuration of the quadratic boost converter (QBC) integrated with a hybrid active filter and governed by a closed-loop PI control scheme. This controller regulates the switching action to maintain a stable high-gain output even during load side or supply side variations.

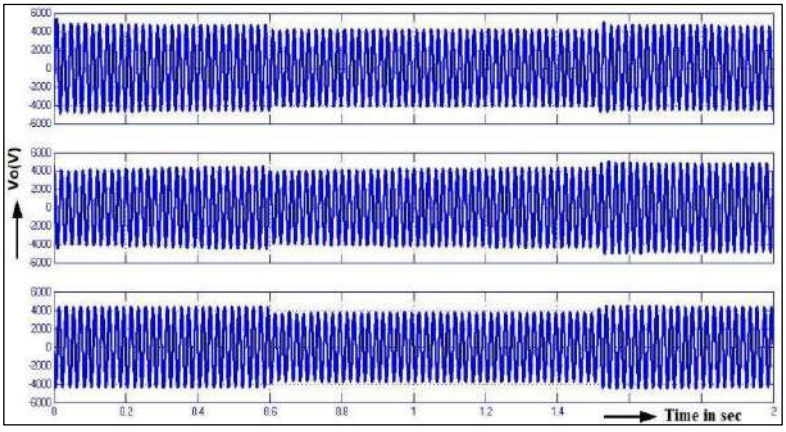

Figure 15: Output Voltage.
Source: Authors, (2026).

Figure 15 shows the instantaneous output voltage waveform witch reaches a peak value of approximately 4600 V. The corresponding RMS output voltage is plotted in Fig. 16, that is around 3250 V, indicating effective voltage stabilization under PI-controlled operation.

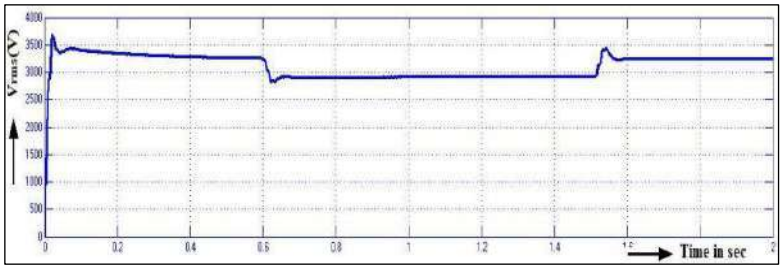

Figure 16: RMS Output Voltage.
Source: Authors, (2026).

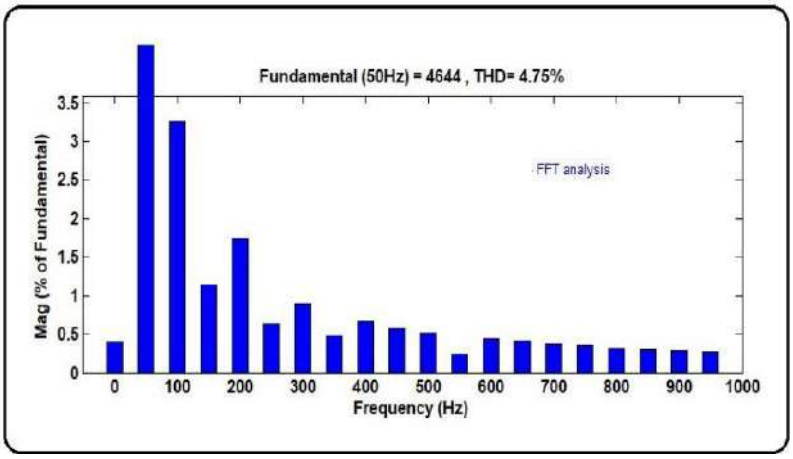

Figure 17: Output Voltage THD.
Source: Authors, (2026).

The output voltage THD, illustrated in Figure 17, is around 4.75%. The output current waveform, presented in Figure 18, shows that the system delivers an average load current of approximately 13.2 A under PI-controlled operation.

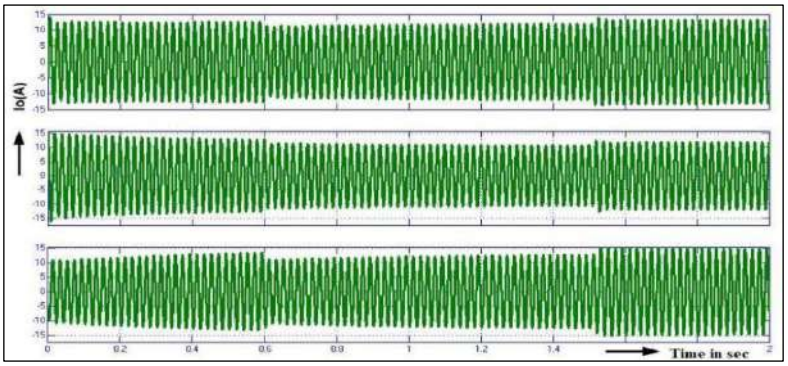

Figure 18: Output Current.
Source: Authors, (2026).

The total harmonic distortion (THD) of the output current, is illustrated in Figure 19 which is around 4.34%. This confirms the improved waveform quality achieved through the hybrid active filter.

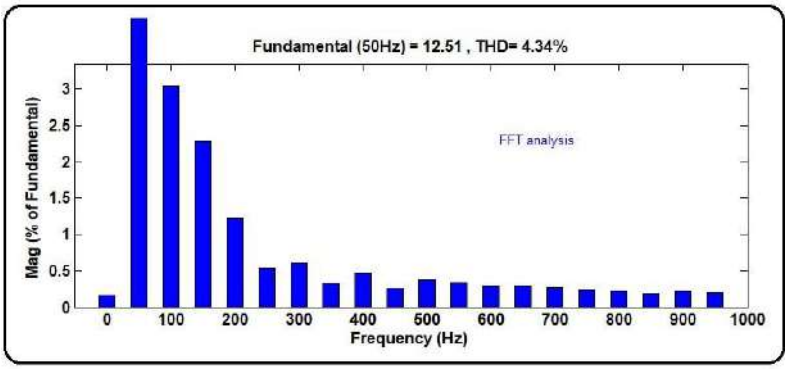

Figure 19: Output Current THD
Source: Authors, (2026).

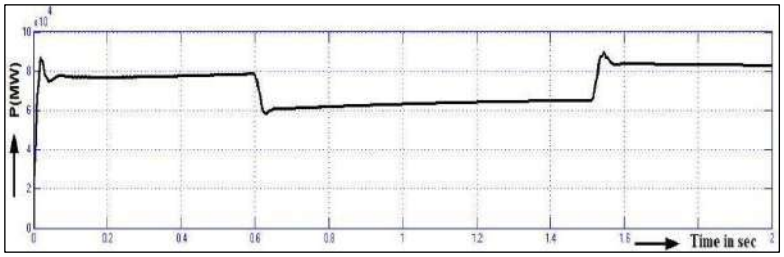

Figure 20: Real Power.
Source: Authors, (2026).

The real-power measurement which is depicted in Figure 20 indicates a delivered power of about 8.3×104 W, while the reactive-power profile shown in Figure 21 shows a corresponding value of approximately 3.98×104 VAR. These results signify the converter's capability to regulate current and maintain acceptable power-quality indices.

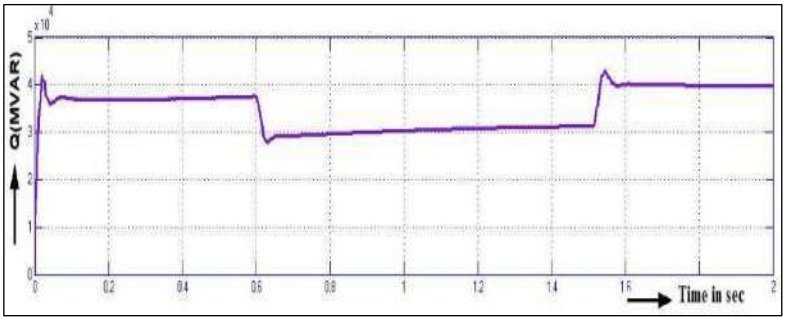

Figure 21: Reactive Power.
Source: Authors, (2026).

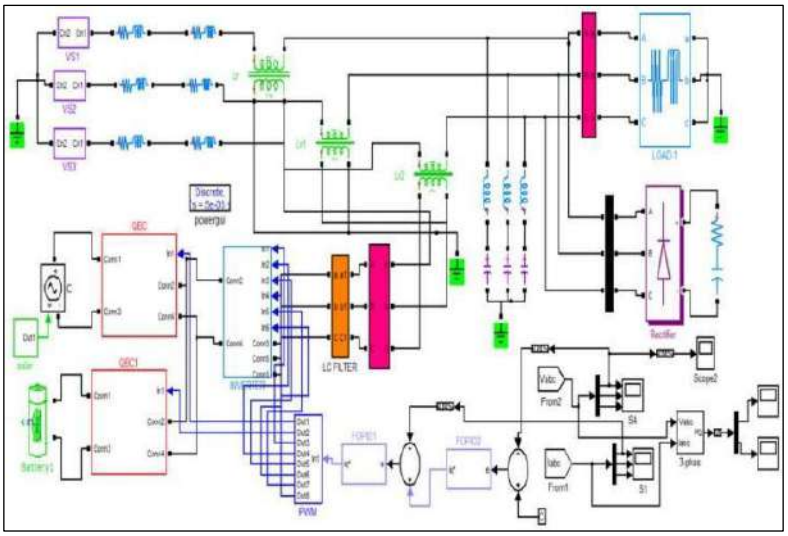

Figure 22: Circuit Diagram of QBC with hybrid active Filter FOPID Controller
Source: Authors, (2026).

Figure 22 illustrates a system of the quadratic boost converter (QBC) along with a hybrid active filter which is regulated through a closed-loop FOPID control strategy. The dynamic response time is enhanced by the fractional-order controller which improves steady state accuracy when compared to traditional PI control systems.

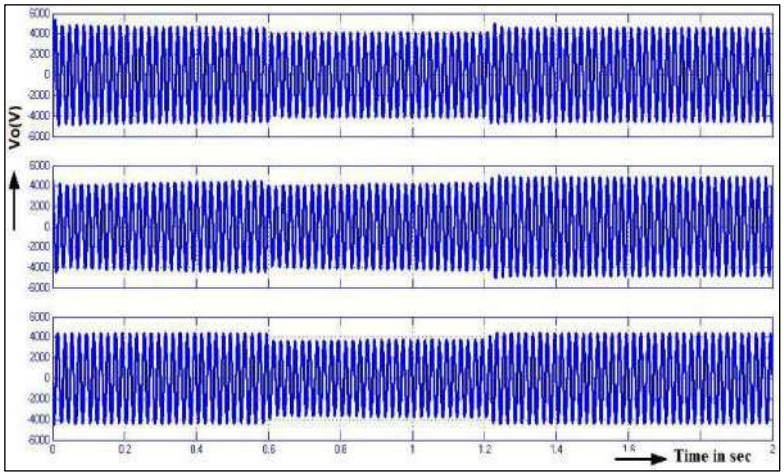

Figure 23: Output Voltage.
Source: Authors, (2026).

The instantaneous output-voltage with a peak amplitude of approximately 4600V as shown in the waveform in Figure 23. The corresponding RMS of the output voltage is shown in Figure 24 which is about 3245V witch basically shows the stable high-gain performance under FOPID based regulation.
